"International Conference on Intelligent Computing and Networking (IC-ICN 2023)"

Chief Patron

Mr. V. K. Singh, Chairman

Patron

Mrs. Karishmma V. Mangal, Secretary

Mr. Karan V. Singh, CEO

Program Chair

Dr. B.K. Mishra, Principal, TCET

Program Co-Chair

Dr. Kamal Shah, Vice-Principal

Technical Chair

Dr. R.R. Sedamkar, HOD Ph.D. & Director - IQAC (NAAC)
Dr. Rajesh Bansode, Professor (IT) & MR
Dr. Sheetal Rathi, Professor & HOD - PG (COMP)
Dr. Zahir Aalam, Professor & TPO
Dr. Rahul Khokle, Professor (IT) & ICT Incharge

Convenor

Dr. Sangeeta Vhatkar, I/c HOD- IT

Joint Convenor

Dr. Harshali Patil, HOD-COMP

Dr. Megharani Patil, I/c HOD - AI&ML

Dr. Shiwani Gupta, I/c - AI&DS

Co-Convenors

Dr. Anand Khandare, Deputy HOD-COMP

Mrs. Pranjali Kasture ,I/c Dy. HOD-IT

Conference Coordinator:

Mrs. Neha Patwari ,AP-IT
Ms. Niki Modi,AP-COMP

Advisory Committee

1 Prof. Valentina Emilia Balas, Aurel Vlaicu University of Arad, Romania
2 Mr. Preggy Ready, LMS Administrator, Durban University of Technology, South Africa.
3 Dr. Arvind Vasu Professor, Clarion University, Clarion Pennsylvania, United States.
4 Dr. Ferdinand-James D Professor, University of the West Indies, Trinidad and Tobago, West Indies.
5 Dr,Ali Safaa Sadiq, Nottingham Trent university, UK.
6 Dr. Mustaq Ahmed , Associate Professor , NIT Jaipur
7 Dr. Vivek Deshpandem Director, VIT,Pune, India.
8 Dr. Sriparna Saha, IIt,Patna, India.
9 Dr. Bhaskar Modal, NIT patha, India.
10 Dr. Vijay Bhaskar Semwal, Assistant Professor, NIT, Bhopal, MP, India.
11 Dr. Arvind Kiwelekar, DBATU, Lonere, Maharasta, India.
12 Mr. Naresh jain, Co- Founder, Snapper future Tech Pvt. Ltd., India.
13 Mr. Pratik sonawane, India Head cyber security tannings, Information security ,Mumbai, India.
14 Mr. Mitesh L. Tolia, CISO and vice president, Jio Payments Bank Ltd., India.
15 Ms. Kanchan A. Bhonde, AVP, Tech Mahindra Ltd., India

PREFACE

We are very privileged to present the proceedings of the INTERNATIONAL CONFERENCE ON INTELLIGENT COMPUTING AND NETWORKING (IC-ICN 2023) scheduled during Feb.24-25, 2023.

It is the fourteenth event in the series of international conferences organized by TCET under the auspices of MULTICON since the first event ICWET 2010.

The purpose of this event is to provide a forum for the discussion of problems, opportunities, presentation skills, knowledge and challenges while also fostering a research culture among the key participants, including students, teachers, and industry. Additionally, in order to encourage creative thinking, study in the fields of communication and intelligent systems is of critical importance because it has the potential to enhance connectivity and security while also making life simpler.

The 14th Annual International Conference, IC-ICN 2023, is affiliated with prestigious publications including the Scopus Indexed Journal for Intelligent Systems, the top publishing company Springer, the SN Springer Nature Journal, and the Conference Proceedings with an ISBN number. It provides a foremost forum for academics, researchers, and professionals in the pertinent engineering disciplines and domains to highlight their efforts to study and exchange ideas.

We are hopeful and upbeat about attending the Conference sessions. This publication will give the reader a thorough rundown of the most recent findings in the fields of Intelligent Systems and Communication Engineering, and it will serve as a useful starting point for additional investigation.

As TCET strongly believes in quality and relationship building, great care has been taken to brand the event, find resources, determine the logistical support needed for the event, compile and print conference proceedings, and create souvenirs, among other things.

We believe that without the moral support, steadfast conviction, and intermittent motivation from Thakur Educational Group management, the current endeavor would not have been feasible.

This time IC-ICN 2023 proceeding consist of four tracks as Intelligent Computing Information Security and Privacy, Network Technology, Software Technology.

The two-day event featured 478 talks from researchers and industry professionals at across the globe, as well as idea presentations with discussion by delegates and resource people.

In order to show our admiration and gratitude, we would like to thank each reviewer for their insightful advice of the submitted papers. We also want to express our gratitude to the organizing team members for all of their effort. We anticipate expanding our partnership and attending upcoming TCET activities.

Team IC-ICN 2023.

A Review on Assessing Malaria Using Machine Learning Algorithm

Mosam K. Sangole, Sanjay T. Gandhe
Department of Electronics and Telecommunication Engineering Sandip Institute of Technology and Research Center Nashik, Maharashtra, India
mosamleo@gmail.com , stgandhe@gmail.com

Abstract—**Plasmodium, the harmful parasite that causes malaria, is spread by mosquito bites (Female Anopheles). The appropriate time and speedy diagnosis of malaria pathogens are essential. In developing nations, pathologists frequently utilise conventional microscopy to identify malaria parasites by studying the slide under a light microscope. Traditional microscopy, on the other hand, needs more time and careful analysis. An approach based on computer vision has been suggested by some researchers to diagnose malaria. The purpose of the review is to use computer software to review, analyze, classify and report the latest progress in the diagnosis of malaria parasites. The malaria parasite diagnosis includes a preprocessing, segmentation, extracting descriptors and classification stage, which is discussed in detail in this article. At the end of this article, the existing problems and probable research outlooks are examined**.

Keywords: Classifier, Malaria disease, Giemsa-stained smears, Segmentation, Plasmodium, Red blood cell.

I. INTRODUCTION

Red blood cells, or erythrocytes, are the most popular type of cell present in the human body and are responsible for transporting oxygen to all of the body's tissues. Malaria can also result from abnormal erythrocytes, which might alter their physical characteristics or limit their lifespan. As per the "World Malaria Report 2021" issued by the "W.H.O.", between 2000 and 2020, an estimated 1.7 billion malaria cases and 10.6 million malaria deaths were averted globally [1]. In 2020, 241 million malaria cases were reported in 85 malaria-endemic countries (including French Guiana's territory), up from 227 million in 2019 [1]. A parasite that dwells in the liver or bloodstream is what causes malaria. Plasmodium falciparum, Plasmodium ovale, Plasmodium vivax, and Plasmodium malariae are all Plasmodium species that causes malaria in humans. Early trophozoites, adult trophozoites, gametocytes, and schizoites are all several life stages of Plasmodium species that infect erythrocytes of human. Examples of several species of Plasmodium life stages are shown in Fig.1.

In Table I, malaria parasite appearances at various stages and species, as seen under a microscope, are reported [2]. For Plasmodium falciparum, only, gametocytes and trophozoites (initial, circular) in peripheral blood vessels may appear. Adult trophozoites or schizonts in blood smears are therefore uncommon because they are normally found in body tissues.

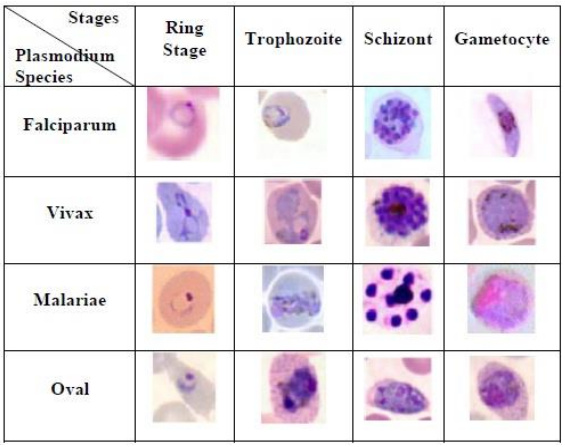

Fig. 1. Different species and stages of Plasmodium [3]

TABLE I. CHARACTERISTICS OF SPECIES AND STAGES OF PLASMODIUM [2]

Species Parameters	P.Falciparum	P.Vivax	P.Malariae	P.Oval
Red cell inflammation	No	Yes	No	Oval formed
Speckling	No	Schueffner	No	Schueffner
Circle form	Small	Large	Small	Large
Tropozoite	Not seen	Amoeboid	Band form	Oval
Schizont	Not seen	Large	Small	Small
Number of merozoites	16 to 24	14 to 20	8 to 10	6 to 12
Stain particle	Grainy grouped	Fine distributed	Grainy ample	Fine
Gametocyte	Crescent shaped	Round to oval large	Round to oval small	Round to oval small

Red blood cells that are infected typically contain multiple parasite types and do not swell. There are a number of benefits to microscopic diagnostics, including the ability to differentiate between species, determine the stage of the parasites, and calculate parasitemia [2]. Additionally, it has a high sensitivity and specificity for identifying different Plasmodium species at different stages. The classification of parasites and their types is very useful for study into the characteristics of malaria, as well as for prevention and diagnosis. However, this is a time-consuming and difficult task, and the skills and knowledge of qualified experts greatly contribute to the accuracy of the diagnosis. Designing a computerised, automatic system that enables pathologists to identify the kind of malaria parasite and its stages is therefore crucial. The development of an automated malaria diagnosis system requires the separation of the infected erythrocytes from the RBC smear and the subsequent removal of parasites (type and stage) from infected erythrocytes.

II. SIGNIFICANCE OF THIS STUDY

Computational diagnosis and malaria parasite identification have opened up a new field for rapid malaria screening, demonstrating the ability to tackle the shortcomings of traditional techniques. The objective of this review is to describe the present study of a number of experts in the field of computer-assisted malaria detection. This review article offers a good foundation for aspiring researchers to study computational methods for diagnosing malaria. This article outlines and analyzes computer vision and image analysis research, aiming to automatically diagnose malaria based on giemsa stained smear images and provide required assisting functions.

III. DIFFERENT TECHNIQUES FOR DIAGNOSIS OF MALARIA

There are many methods for diagnosing malaria. These approaches can be divided into two classes based on their effectiveness and cost. These are both expensive and cheap methods. Polymerase chain reaction (PCR) is a method depending on the detection of precise nucleic acid sequences [4] and the visualization of third harmonic generation (THG) are the cost-intensive methods. A THG imaging microscope was used to detect Plasmodium in untreated blood smears [5]. This method can provide high specificity and sensitivity for malaria detection; however, in evolving countries where the disease is more predominant, they are rarely used due to the need for specialized infrastructure and the difficulty of dealing with the disease. The rapid diagnostic test (RDT) can detect Plasmodium and some common microorganisms in the lysed blood [6]. And traditional microscopes [7] [8] is in the lower cost category. RDT can diagnose malaria relatively quickly and can be performed by less trained personnel, but the outcomes may be untrustworthy [8]. Also, RDT kits that are commercially available are specific to one species of Plasmodium parasite and different kits should be used when a patient is infected with several species of Plasmodium, which will increase the diagnostic cost of the disease. The key to effective dealing of malaria disease is a fast and precise analysis of the disease.

A. *Microscopic analysis of malaria*

Traditional microscopy is the golden rule for diagnosing malaria. During this process, blood is drawn from the diseased patient and smeared on a glass slide. The smears are then stained with chemicals called games. Staining helps distinguish the plasmodium from red blood cells. The most serious limitation of this method is that it takes a long time, the results are difficult to reproduce, and the testers must be trained. The last challenge may be that where the disease is endemic or whose skilled human capacity is limited.

B. *Diagnosis of malaria by computer*

Computers are essential in the medical sector; without them, competency and productivity would suffer significantly. Computerized diagnosis of malaria is a microscopic diagnostic technique using computer vision and machine learning techniques. This technique replaces manual microscopy examination. Machine-controlled parasite (malaria) diagnostic methods can be presented by the diagnostic information from the hematologist and demonstrating it using image processing algorithms. These techniques have been extensively studied to ensure premature and precise recognition of malaria parasites. A computerized malaria identification system must be able to differentiate between healthy and infected erythrocytes. Image acquisition, pre-processing, segmentation, feature extraction, and classification are the main phases in inspecting a microscopic image. Figure 2. shows the broad design of the automatic identification of malaria disease

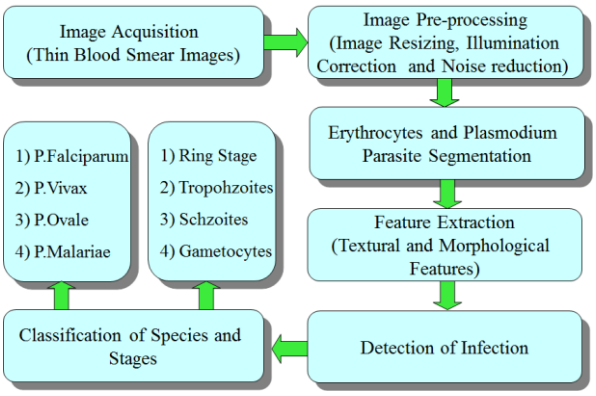

Fig. 2. Broad design of the automatic identification of malaria disease

C. *Image acquisition*

The majority of research on malaria screening focuses on thin images of blood smears, hence thick blood smear images are rarely used. To capture images of thin stained slides, Ross N. E. et al. [9] employed a light microscope at 1000 magnifications along with a charge-coupled device (CCD) camera. Camera was set at maximum resolution of 2048x1536 pixels (i.e. 3.2 megapixels camera) to captures images in JPEG format. The resolution of a photograph is measured in pixels. The width and height of a sensor in pixels are multiplied to get the photo resolution. Images in [10] were taken with a JVC 3-CCD colour video camera attached to an Olympus BX60 microscope. This microscope was having100x objective lens (oil immersion). The same approach was observed in other experiments, in which images were obtained with a charge-coupled device camera (CCD) attached to the microscope. However, images of blood smears are easily accessible on websites. Gitonga et al. [11] used the Kenya Medical Research Institute (KEMRI) and Center for Disease Control (CDC) sources to get thin blood smear images.

D. *Preprocessing*

The foremost goal of the preprocessing phase is to create blood images having low-noise as well as high-contrast, for further processing. Changing the color of the blood smear and adjusting the camera will change the brightness of the microscopic image. This problem brings difficulties to blood cell classification, because it is difficult to correctly segment objects of the same color. Different

researches have proposed several methods to solve preprocessing problems such as lighting and reduction of noise. A mixture of several filters can be utilized to decrease the lighting effects on the microscope and camera. However, the lighting problem can be overcome in some way, but human factors are still involved in the creating blood smear slides. Researchers have proposed a variety of strategies to tackle the noise issues and image enhancement in computerized malaria identification.

Devi, S. S. et. al. in [12] corrected illumination using adapted gray world normalization method for enhancing quality of the image. Sanjay Nag and S. K. Bandyopadhyay in [13] proposed an approach that eliminated impulse noise using median filter with a 3x3 kernel window. S. L. Varma and S. S. Chavan used a simple pixel replacement strategy employed to remove label artifacts [14]. Damandeep Kaur and Gurjot Kaur Walia proposed an approach to detect and classify malaria parasites [15]. To retain the edges of the malaria-infected microscopic images, spatial filtering is used initially, followed by Ant Colony Optimization. Lorenzo et al. in [16] converted images to HSI (Hue, Saturation, and Intensity) color space and then the intensity component was filtered using [3x3] median filter to remove noise. Also, a morphological top-hat operation was used to adjust illumination balance. Sadiq et al. proposed the selection of appropriate features with Z-score for the detection of malaria-infected erythrocytes using supervised learning [17]. The combination of median and Gaussian filter was used as a preprocessing step to remove noise reflected by overlapping and impulse noise. In addition to that, canny filters were used to maintain continuous edges of RBCs. Kanojia et al. identified that a 5x5 kernel of nonlinear median filter gives the best noise reduction in grayscale images [18]. Penas and P. T. Rivera used the saturation channel of HSV color space for preprocessing [19]. Image opening and closing was performed on the saturation component of image. This step confirms that impulse noise was removed. The problem of illumination was corrected by Devi et al. in [20] by using the grey world normalization method. The normalized image was then treated by an adaptive filter to remove noise. Ghosh et al. used a Laplacian filter on microscopic images [21]. This makes the cell boundaries sharp. After that, the stained regions were identified by converting the sharpened image to HSI (hue, saturation, and intensity) format. Devi et al. first obtained the normalized image by gray world normalization technique which rectifies the problem of illumination [22]. The author then used the standard median filter with a window size of 5x5 to decrease the noise from the image. Somasekar et al. suggested a method to segment infected-erythrocytes for the detection of malaria [23]. The author used an adaptive median filter followed by illumination correction. In this algorithm, the window size used was 3x3, and the maximum window size used was 7. Arco et al. proposed an approach to automatically detect malaria-infected erythrocyte using morphological operations [24]. They had used spatial filtering and adaptive histogram equalization as a pre-processing stage. To minimize the noise, Gaussian low pass filter was applied. This process makes the image brighter than the original image. Tsai et al. utilized a mean filter to eliminate image noise in [25]. Hung et al. in [26] used the mean filter to remove impulse noise in the image. Tomari et al. proposed a method to classify the red blood cell as normal and malaria-infected in blood smear images [27]. Here author used three methods as morphological operations, Connected Component Labelling (CCL), and bounding box filter to clear away the redundant items. A sequence performing twice of Erosion, twice of Dilation, and contour filling algorithm is used to decrease the small noise and holes inside the cell. Chen et al in [26] utilized mathematical morphology to remove noise and smooth the edges of the object. Gitonga et al. in [11] used median filter with kernel size of 5x5 to enhance the noisy image. Das et al. suggested a machine-based investigative method for automated malaria parasite by means of light microscopic images [28]. Here geometric mean filter was applied on the illumination corrected gray image. S.S.Savkare and S.P.Narote used a median filter of size 3x3 to eliminate unwanted pixels [29] [30]. Smoothening and edge enhancement were done by employing a Laplacian filter with second-order derivative on grayscale images. Xiong et al. in [31] first represented the image in the HSV color space. The inverse of the value channel was then applied to the median filter to remove noise. Ross et al. used a 5x5 median filter, and morphological area closing filter to reduce impulse noise in the image [9].Authors in [32] used Based-on Pixel Density Filter (BPDF). This filter first detect corrupted pixel and replace that pixel value that repeats mostly inside the window. In Progressive Switching Median Filter (PSMF), iterative method was used to detect impulse and filter it. The noise pixels treated in the current iteration are used to find new pixel value to replace other noisy pixels in the further iterations [33]. Authors in [32] used Modified Decision-Based Unsymmetric Trimmed Median Filter (MDBUTMF) to replace corrupted pixels. Corrupted pixels are eliminated from the window with the help of median filter [34]. The Noise Adaptive Fuzzy Switching Median Filter (NAFSMF) detects noise pixels using an adaptive window size. Two thresholds T1=10 and T2=30 and Fuzzy method are used to replace noisy pixel with new pixel value [35]. . Morphological operations are very useful for analyzing biological and medical images, and are a powerful tool for extracting elements from images. These elements are very useful for displaying the size, shape, and color of target elements. Table II summarizes the preprocessing strategies employed by several researchers during automated malaria diagnosis.

E. *Segmentation*

Segmentation is a crucial procedure in both computer vision and image processing. It means subdividing an image into various discrete, non-overlapping parts that come together to form the whole image. The most important and difficult stage is identifying the various cell types, such as red blood cells, white blood cells, plasmodium, etc., in a blood smear image. The two types of blood cells are distinguished from the background using image features including clusters of healthy and infected blood cells. Effective detection and classification of malaria parasites may be possible using properly segmented images.

Recent studies have suggested a number of blood cell segmentation techniques. Several factors were examined by S. S. Devi et al. [12] to identify malaria-infected erythrocytes. In this study, Otsu's segmentation technique was used to divide up the stained portions. Area thresholding and morphological filtering were then used to get rid of any remaining artefacts or stains. Finally, the overlapping blood cells are separated using a technique called marker-controlled watershed segmentation. Malaria parasites in a thin blood smear picture were identified by S. K. Nag et al. using machine intelligence [13]. A transition was made to the L*a*b* colour space here. Then, unsupervised K-means clustering was used to divide the total number of pixels in an image into three groups. While the foreground shows the cells (the region of interest), the background shows the irregular coloration. The first two groups represent the foreground of the picture, while the third group represents the background. The third cluster's colour pixels were all changed to black. In order to categorise malaria parasites, D. Kaur and G. K. Walia devised a hybrid form of ACO-SVM (Ant Colony Optimization - Support Vector Machine) [15]. In this study, author proposed using a simple ant colony optimization algorithm for malaria image segmentation. Digital image processing was utilised by J. V. Lorenzo-Ginori et al. in [16] to categorise erythrocytes infected with Plasmodium. Segmentation occurred in a two-stage procedure. As a first step, Otsu's technique was used to perform a rough segmentation on the image's intensity factor. Next, author used a marker-controlled watershed transform to identify overlapping cells and separate them. The idea of using microscopic blood pictures to diagnose malaria was introduced by G. Madhu [36]. To extract a section of the contaminated blood cell from microscopic blood smear images, the author employed an Einstein t-conorm segmentation technique and an unique fuzzy type membership function. A method for categorizing malaria parasites was proposed by Pragya et al. [37] using the Chan-Vese Method for segmentation and SVM as a classifier. The Chan-Vese algorithm is widely recommended for segmenting malaria parasite images because it is the only method that can reliably separate the parasite from its background. D. Dawale and T. Baraskar created a malaria detection method [38] using regional descriptors and the PSO-SVM (Particle Swarm Optimization - Support Vector Machine) classifier. In this study, region-based and Otsu thresholding were used to separate different types of blood cells. Separating RBCs from the background was accomplished by K. Manning et al. in [39] using a marker-based watershed segmentation technique. In [40], S. Hartati et al. automatically determined the threshold using Otsu's thresholding method. The hole in the diseased cell was then covered off and the undesirable artefacts were eliminated by performing the morphological closing and opening. Local binary pattern was employed by S. L. Varma and S. S. Chavan to identify malaria parasites in both thick and thin blood smear pictures [14]. In order to divide the data into distinct groups, the authors here employed Otsu thresholding. Sobel and Prewitt masks were employed for the purpose of edge detection. When utilising supervised learning to look for malaria-infected erythrocytes, Sadiq et al. recommended picking the best

features using the Z-score [17]. With the help of Canny edge detection, authors were able to extract the relevant data and drastically cut down on the amount of information we needed. Segmentation was carried on on images using the Otsu global thresholding and watershed approach by M. Kanojia et al. in [18]. Otsu's thresholding method was used to segment erythrocytes and artefacts by S. S. Devi et al. in [20]. Next, a morphological filter was used to remove any unwanted coloured components from the erythrocyte. The marker-controlled watershed method was then used to separate the clumped erythrocytes. A hybrid classifier was used by S. S. Devi et al. in [22] to categorise erythrocytes infected with malaria. The authors used marker-controlled watershed segmentation to separate clumps of erythrocytes into their component cells. In order to distinguish infected from healthy red blood cells in blood smear images, Hany A. Elsalamony trained neural networks [3]. The segmentation procedure made advantage of watershed and morphological functions. Parasites in stained blood smears were categorised using an MP (Malaria Parasite) detector by Y. W. Hung et al. [41]. In this study, author used Otsu's threshing technique to determine the threshold for classifying all pixels as parasites or backgrounds. Malaria-infected cells in blood smear pictures were extracted using the Fuzzy C-means (FCM) method by J. Somasekar et al. in [23]. Tsai et al. [25] suggested a strategy for identifying malaria-infected erythrocytes and then dividing them into individual parasitized cells. In this case, a threshold value was chosen using Otsu's thresholding to separate parasites from backgrounds.

Different research use various methods of segmentation, which are summarised in Table III. According to the review, Otsu's algorithm is widely used to separate erythrocytes and malaria parasites. The histogram's between-class variance is maximised to determine the threshold value in the Otsu technique. If the histogram has a bimodal or multimodal distribution, this method is useful for choosing a threshold value. Comparably, other researchers used marker-controlled watershed and watershed algorithms to segment overlapping cells during the segmentation step

F. Features extraction

This is a significant transition from graphical to numeric representation of data, a prerequisite for the processing of the vast majority of images and computer vision solutions. Other parts of a stain, such as parasites, are malleable objects of a wide range of sizes and forms. While colour information is useful, it is not alone sufficient to differentiate between, say, various species of malaria parasites. A set of features is a collection of characteristics that can be used to identify diseased cells from healthy ones. Table IV provides a summary of the many features employed by researchers.

TABLE IV. DIFFERENT FEATURES APPLIED BY DIFFERENT INVESTIGATORS IN DIFFERENT STUDIES

IV. CLASSIFICATION

Classification development is greatly facilitated by a high-quality feature extraction and segmentation technique. It is common practise in automatic malaria diagnosis to use the classification technique for two purposes: identifying the stage and species of the parasite that has infected the patient's erythrocytes.

Classifiers used in various research to categorise infected cells, phases of infection, and species are listed in Table V.

V. DISCUSSION

In this article, we systematically outline the automatic detection of malaria based from microscopic images. Malaria detection system should be able to perform imaging, preprocessing, segmentation, and classification functions. Malaria diagnostic systems need to be able to find the existence of parasites in blood samples via differentiating amongst non-parasitic substances (artifacts, lymphocytes, and erythrocytes) and malaria parasites. If the blood test is positive, it is necessary to recognize the species and the malaria parasite by distinguishing species and developmental stages. However, most imaging studies related to malaria did not meet the above necessities.

Median filter proved to be very accurate in decreasing the salt and pepper (impulse) noise from microscopic image. The local histogram method is often utilized to enhance the microscopic image of blood smears.

Segmentation is considered a vital step in automatic detection of malaria disease. Effective segmentation makes things easier in case of parasite detection and feature extraction. A review of the literature indicates that most researchers use the Otsu threshold to segment erythrocytes and malaria parasites. Otsu's threshold is based on the reduction of the criterion function to select an optimal threshold; however, the Otsu threshold cannot segment overlapped cells. To segment overlapped cells, Devi et al. [20] applied the watershed algorithm. Unless the object is flat or has at least one soft gray layer, it does not make sense to apply the watershed algorithm directly to the image. Therefore, marker-controlled watershed algorithm is usually preferred, which basically uses externally provided markers instead of regional minima [43]. The marked watershed algorithm is used to isolate overlapping cells. Similarly, some studies have used Morphological operations, K-Mean clustering, and Chanvese for segmentation.

For the classification of infected erythrocytes and the stage of malaria infection, texture, geometric shape, and color characteristics were evaluated. In most current approaches, investigators use a blend of texture and geometric features in the feature extraction phase. Several automated malaria diagnosis studies have shown that color and texture features can be utilized to classify diseased and healthy erythrocytes. Also, geometric features can be used to identify parasite species and life stages. From the review, SVM is utilized by maximum researchers. The essential benefit of SVM is that it has high-quality generalization functionality and extraordinarily influential learning rate. Numerous classifications had been suggested for the automated type of malaria parasites in existence of different marked substances in smear images. Though, those research does not often focus on classification of life phase. Finding the life phases of a parasite is beneficial and this could be answered with the aid of using a multi-class type in preference to a parasitic or non-parasitic binary type problem.

TABLE V. DIFFERENT METHODS OF CLASSIFYING THE INFECTED ERYTHROCYTES

Reference papers	**Techniques of Classification**	**Observations**
Madhu G. in [36]	Decision Tree	It predicts class membership using hierarchical relationships between input data.
Lorenzo-Ginori et al. in [16], Das D. K. in [28], Nag et al. in [13].	Naive Bayes	The naive Bayes classifier's key advantage is its quick training computation time.
Nag et al. in [13], Lorenzo-Ginori et al. in [16], Pragya et al. in [37], Kaur et al. in [15], Hartati et al. in [40], Sadiq et al. in [17], Devi et al. in [20], Das D. K. in [28].	Support Vector Machine.	SVMs are great for learning problems with a large number of features in comparison to the number of training cases.
Devi et al. in [20], Tek et al. in [42], Devi et al. in [22], Malihi et al. in [44], Lorenzo-Ginori et al. in [16].	K Nearest Neighbor	Unknown samples are classified simply by comparing them to previously recorded training data.
Sadiq et al. in [17]	Boosted Tree	There are numerous weak learners in this group, but only one strong learner emerges. In this situation, individual decision trees are poor learners. Each tree is connected to the previous one in a sequence, so that each reduces the error of the previous tree. Due to this consecutive connection, boosting algorithms are incredibly accurate but it's training process is often slow.
Lorenzo-Ginori et al. in [16], Ghosh et al. in [21]	Bagged Tree	It's the combination of several different versions of a predicted model. Each model is trained separately before being integrated through an averaging approach. Bagging's main goal is to achieve less variance than any particular model has.
Manning et al. in [39], Kanojia et al. in [18], Devi et al. in [20] [12], Tomari et al. in [27], Ross N. E. in [9], Lee et al. in [2], Gitonga et al. in [11].	Artificial Neural Network.	Employs a nonparametric strategy. The network structure and amount of inputs have an impact on classification performance and accuracy.

A. Probable guidelines for upcoming research

Automatic malaria parasite recognition and classification can support pathologists with malaria disease detection and medicine development. A lot of effort has been done on this topic, but there are still some problems that reduce the accuracy of malaria parasite detection. Therefore, improvements are needed to meet the pathologist's expectation that it may reduce the difficulty encountered in manual analysis. Literature reviews indicate that most studies are limited to detecting Plasmodium in blood smear images. Species identification and the life-cycle of the malaria parasite have proved useless in most researches.

However, investigators in [44] [11] [43] [25] have identified four malaria parasites, but they still haven't met the pathologists' expectations. Other factors, such as blood slides, microscope, noise, scale correction, and color standardization, can affect the accuracy of identifying malaria parasites. The main problem in segmenting the malaria parasite is to separate the infected erythrocyte from white blood cells and colored objects because they have the similar hue and intensity. The segmentation technology can be improved to effectively process blood smear images without removing noise or adjusting the contrast. Similarly, when measuring parasites, the exact number of non-infected erythrocytes and infected erythrocytes required to be calculated so that overlying cells give unreliable results, and appropriate algorithms can be used to correctly measure overlapping cells. This step required to be enhanced with the aim that you can further classify the infected erythrocytes and recognize the parasite and the parasite's life stage based on better features.

VI. CONCLUSION

This article offers a framework for investigators who wish to study the automatic detection of malaria from images (microscopic). The purpose of this article is to analyze, and classify the systems and methods used to detect malaria and determine existing restrictions. The problem of pathologists was also discussed. In the preprocessing, the problems of color change, illumination change, and noise in the microscopic image are discussed. Segmenting parasites form images is the next important phase in the classification of malaria parasites, which greatly affects the performance of the classifier. Color, texture and morphological features, are valuable information about features. In terms of classification, it could be advisable to add circumstantial information to the categorization of malaria parasites. This issue can be resolved by means of multi-class classification in place of the two class problems; Parasitic or non-parasitic. This review can help researchers analyze the best practices introduced in the past two decades and their restrictions. Since the automatic detection of malaria is performed not only by computer vision experts, but, it also requires the participation of pathologists.

VII. ACKNOWLEDGMENT

Sandip Institute of Technology and Research Center, Nashik, Maharashtra, India, supported this study.

Plant Disease Detection using Convolutional Neural Networks and Deep Learning based Strategies

Nidhi Kunal Jha, Kamal Shah
Thakur College of Engineering and Technology Mumbai, India
nidhijha2509@gmail.com, kamal.shah@thakureducation.org

Abstract - **The agricultural sector is considered to be as one of the major farming sectors wherein the process of automating plants on the basis of diseases can be performed upon. To monitor such an agricultural environment; it is necessary to keep a track of healthy and diseases plant leaves so that they can further be segregated to generate exponential crop yields and returns. For this purpose; various state-of-the-art technologies such as machine learning, deep learning and artificial intelligence have come together to categorise healthy plants from diseases ones using image classification techniques. On the other hand, the working theories of deep learning based models have been continuously evolving to precisely identify the presence of disease in plant leaves. This not only adds efficiency in the entire process of detection; but also adds time efficiency that increases the probability of identifying diseases at the right stage. For this purpose, we proposes the implementation of Convolutional Neural Network, ResNet-50, Efficient-B2 and VGG-16 to detect and validate the presence of plant diseases in the respective leaves. The execution of the paper occurs by gathering a dataset of 87k plant images from Kaggle repository. This repository consists of healthy and diseased plant images while executing on 38 varying categories. However, the final implementation takes place on a total of 250 images from every class. The entire dataset is trained, tested and validated for the same. The final evaluation of the proposed models occur using performance metrics such as accuracy and recall factors. On final comparison of the overall model; it was observed that Efficient-B2 generated optimized accuracy of 94 percent.**

Keywords: CNN, Efficient-B2, machine learning, deep learning, ResNet-50, VGG-16

I. INTRODUCTION

The primary resource and the origin of food has always been the agricultural sector and therefore serve the purpose of basic necessities acquired by the humans. Hence, this sector has been recognised as the survival centre of the world that is responsible for the lives of human beings [1]. This leads to a major fact; that the agricultural sector can further be declared as the most important and a centric pillar of any economy. It can be very well observed that 70 percent of the total world population depends on the agricultural sector for their livelihood. Hence, it can be concluded that the lives of individuals including their health is a major reflection of the agricultural sector [2]. Therefore, this sector must be carefully pondered upon and not neglected. An important aspect of the agricultural sector lies in the forests and the plants the trees might produce. It is important that the quality of such plants must be checked and monitored on regular intervals so as to avoid decaying of the same. This becomes one of the significant challenges in the agricultural sector to timely detect the presence of diseases in the plants so that the health of the plants and crops are maintained and not compromised upon. This occurrence of diseases in plants might occur due to various factors; such as; improper land, infertile land, amount of water and sunlight, number of pesticides etc. all such factors are in a way responsible to affect the growth of the plant and might create a hurdle in their growth; thereby leading to diseases in plant development growth and seedling growth [3]. When such a disease occurs in the plant; its growth is highly impacted and might change the morphological and biological changes in the same. The overall diseases in the plants that lead to such changes are majorly caused due to biotic stress and abiotic stress. Biotic stress includes; stress caused due to living creatures present in the soil such as bacteria and virus. Such creature tends to come in direct contact with the plant and negatively affects the overall growth of the seedling process [4]. On the other hand; abiotic stress is caused due to non-living creatures such as man-made or environmental factors [5]. Figure 1 below; represents a diagrammatic scheme of biotic and abiotic stress.

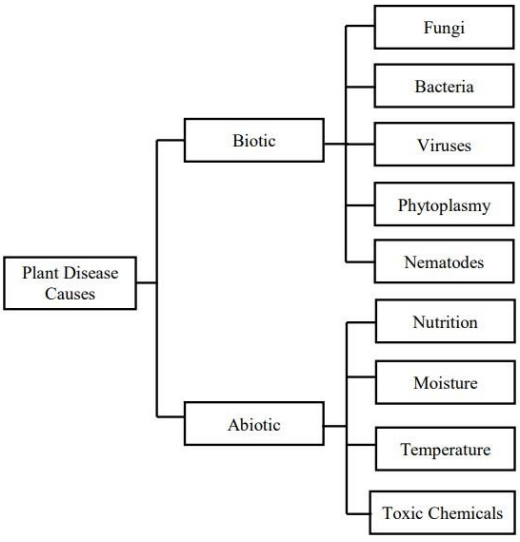

Figure 1: Schematic representation of diseases in plants [5]

However, a conventional method used by farmers is to manually inspect the presence of diseases in the plants. This manual inspection follows the process of gathering knowledge from people who have an expert

opinion on the same and can therefore contribute to identify the disease. A major disadvantage of this process; basically includes the time constraint attached to the process of manually detecting the same. Since the crops are distributed in large fields, its manual inspection and detection of the same becomes a tedious task [6]. In such a scenario, it is feasible to adapt to machine learning based techniques; in which the detection of the same can be performed through technical strategies with more precision. For this purpose, various approaches have been evolved that includes techniques of machine learning, deep learning, transfer learning and artificial intelligence. Advancement in such strategies and algorithms has proved to detect the presence of diseases in plants with highest possible accuracy in a minimal time frame. Hence, such techniques can be used on the concepts of image processing wherein; a specific part of the image is taken into consideration and algorithms are deployed on them; so as to observe a particular area of the leaf [7].

In addition to this, the depth of the plant leaf is also used which can help to detect the presence of diseases within itself. Using machine learning based algorithms of random forest, support vector machine; k-nearest-neighbour etc. this process of detection can be carried out effectively. Such algorithms tend to focus on specific features of the plant leaf such as it's; saturation colour, gradient orientation, RGB features etc. [8] hence, it can be concluded that machine learning, transfer learning and deep learning algorithms play a significant role in detecting the same and further classifying the plant leaf as healthy or diseased [9]. On the other hand, the working implementation of CNN is heavily based on the hidden layers present in the neural network. Such architecture can easily differentiate between various patterns of plants and further label them as healthy or diseased.

Hence, the primary aim of the research paper is to deploy and automate the process of disease detection amongst plant leaves using CNN and deep learning based models such as Efficient-B2, ResNet-50 and VGG-16. The added layers of deep learning models and the hidden layers of CNN tends to automate the process with less computational complexity and within a limited time frame. In addition to this, the process of fine tuning and usage of parameters for evaluation such as confusion matrix, accuracy, precision, loss graph etc. generates high levels of accuracy. For this purpose, we have collected the plant disease dataset from Kaggle repository comprising of 250 images of both health and diseased plant images from each of 38 different classes.

The contributions of the proposed study can be summarised as follows: Uploading plant disease dataset from Kaggle repository and working on images of various healthy and diseased plant leaves. Implementing CNN and deep learning based algorithms through labelling process Comparing the results thus obtained and defining the algorithm with best possible accuracy

II. RELATED WORKS

Multiple research scholars have worked upon the conceptual theory of detecting plant diseased through their leaves. An extended amount of research work has gone into detecting the same using machine learning algorithms. This section of the thesis, describes the research work performed by various authors in the same domain.

In a research work conducted by author Ashwin et al. in [10] he proposed the detection of Soybean plants wherein he incorporated the physiological features of the leaf along with its morphological features. This process helped to detect and differentiate between healthy and diseased leaves of the plants. The author used a dataset consisting of 2500 images and selected various features from it which could further be used for image classification purpose. The author implemented the model using 21 features from the acquired dataset. Such features included the evaluation of stem length, length if the root, pods present in every plant and the number of seeds sowed for the same. The entire implementation of the system occurred using six machine learning algorithms such as random forest, gradient boosting, logistic regression, SVM, KNN and naïve Bayes. In addition to this; a ten-fold cross validation as also performed on the same and the model was evaluated using confusion matrix and accuracy factors. On execution, it was observed that the gradient boosting model generated highest result of accuracy and a precision factor of 92.56 percent.

In a similar research work proposed by Bedi et al. in [11] represented a hybrid model based on the concepts of CNN and CAE (convolutional auto encoder). The model was implemented peach plant leaves and was further used to detect the presence of the disease by detecting a specific spot on the respective leaf. The author acquired the dataset from GitHub repository that consisted of 2160 diseased leaves and 2267 healthy leaves. A total of 70 percent of the acquired dataset was further used for the testing purpose and 30 percent was used for training purpose. Once the dataset was gathered; pre-processing was performed on it. On this stage; steps of labelling the data, categorising it and further splitting it was taken place. The next step; however included the process of applying respective algorithms of CNN and CAE. During the testing phase; leaf images were given as input to the algorithm and a ten-fold cross validation was performed. In the implementation phase of CNN, 14 hidden layers of the neural network were used and 17 layers of CAE were used. In addition to this; Adam was used as the optimizer and rmse values were evaluated. On execution; it was observed that the CNN generated less error loss of 0.607 and was therefore declared as the optimized model.

Jeyalakshmi et al. in [12] proposed the detection of diseases in potato leaves depending on the image thus obtained from the repository. The author worked on the Plant Village dataset that comprised of 1000

diseased leaves and 3270 healthy leaves. The dataset also had plant images of grape. In addition to this; there were different categories and sub-sets of potato plant leaves and grape plant leaves. In the initial stage; every RGB image from the dataset was acquired and its respective background was removed through the filtering process using Grab Cut algorithm. In the next stage; various features from the leaf were selected, depending upon the intensity of RGB images with respect to red, blue and green colours. Other features; such as its contrast, entropy and gradients were also determined. Three machine learning classifiers were used to evaluate the system model and thus included; the implementation of KNN, SVM and Naïve Bayes. A total of

13 features were selected from each subset as a category of grape and potato plant leaves. On execution it was observed that KNN generated an accuracy of 91 percent and was observed to be as the optimized model.

Author Xian et al. in [13] proposed the implementation of machine learning algorithm that was coined to be as an Extreme Learning Machine (ELM). The algorithm was used to detect the presence of disease in a tomato plant. The entire dataset was obtained from Kaggle repository that comprised of a Plant Village dataset. The dataset had 1000 images of healthy plants and 1245 images of diseased plants. The implementation of ELM was further combined with CNN. The neural networks present in the CNN comprised of multiple hidden layers that enabled to connect internal nodes and helped to resize the image of a tomato

plant. In addition to resizing of the image; leaf features such as its segmentation, colour, and saturation were also taken into consideration. In the later stages; a scatter plot was determined that highlighted only the relevant features of the plant image. 70 percent of the dataset was used for training purpose; whereas 30 percent of the dataset was used for testing purpose. On evaluation, it was observed that the ELM model generated better results in comparison to the CNN model and produced an accuracy of 93.65 percent.

It can be observed throughout the literature survey; that multiple authors focused on detecting the presence of disease in plant leaves. Table 1 below gives a comparison of the used literature survey of the research paper. A major disadvantage can be concluded that this detection was grouped through the classification of only one type of a disease in only one type of plant leave. Since farmers, in the agricultural sector tends to grow more than one crop; adapting to this detection becomes a tedious task. Hence, the primary aims of the proposed research work; is to build a model that can be used by multiple farmers who tend to grow and produce various crops. For this reason, we have proposed a research work; wherein various plants together and further train them for respective disease detection. In the next stage; we implement various deep learning based models along with CNN. The deep learning models includes the implementation of VGG-16, ResNet-50 and Efficent-B2.

Table1: Comparison of surveys

Research	**Year**	**Crop**	**Dataset**	**Technique**

Bedi et al. [11]	2021	Peach	Plant village	CAE, CNN
evalakshmi et al. [12]	2020	Potato and grape	Plant village	KNN, SVM and Naïve Bayes

III. METHODOLOGIES USED

This section of the research study highlights the algorithms used to implement the detection of disease in plant leaves. For this purpose; deep learning based CNN is used and deep learning based ResNet-50, VGG-16 and Efficient-B2 are used.

The primary finding of the definition of DL is that it is the addition of a multilayer network for feature extraction to the ML framework. In DL architecture, the term "deep" refers to the layer thickness. The concept's classification process is as follows: The manually labelled dataset is split into testing and training samples for the DL structure, the dataset is normalised for quality improvement using image pre-processing techniques, and the pre-processed images are then fed into the DL design for feature extraction and ultimately classification. Each layer in DL architecture operates the output of the layer below as its input, passes it to the layer above, and repeats this process. Transfer learning, on the other hand, refers to a concept in which the data gathered and put to use on one dataset can be applied to another dataset with a much smaller population to train providing that both datasets function on a similar CNN architecture objective. This technique is carried out in a traditional CNN by training the initial parameters on huge datasets. A specific model is chosen for deep learning based on a CNN's ability to extract features. This process is termed as feature extraction. The main goal of this approach is to keep both the neuron weights and the architectural framework of a CNN model. This idea is typically applied to offset the computational expense associated with creating a neural network from scratch. The second tactic entails choosing from among the several transfer learning-based variation models available, such as

Alexnet, Densenet, Mobilenet, Inception, and VGG-16, then modifying the model's parameters to get the best results. Following are the methodologies used for the purpose of implementation of the proposed thesis: CNN: The working implementation of CNN takes in input images, extracts characteristics, and then categorises them according to predetermined standards. These networks are under the category of neural networks; therefore they have all the characteristics that identify a neural network. Its execution is split into two blocks, the first of which is charged with feature extraction and the second of which uses ML techniques to classify data. CNN employs two operations—pooling and convolution—across a number of layers to carry out these blocks [14]. The first block, or feature extraction, is carried out by the first two layers of the network architecture, and the fully connected layer creates the final output by mapping the features that have been extracted from the earlier levels. Typically, this final outcome makes up the second block of execution, or classification. The convolutional layer, which is the first layer in the network, is essential to the entire implementation of the work since it performs all of the mathematical operations in the network. Additionally, the entire CNN procedure is carried out in a grid pattern. In the grid parameters of this grid pattern, which are two-dimensional arrays known as kernels, the pixels of images are stored. The real feature extractors for the model are performed by these kernels, which is what gives CNNs their high level of image processing effectiveness. All the levels in this network have a tendency to gradually raise their level of complexity since the output from one layer is supplied as the yield input to the following layer. The process of parameter optimization used in kernels to lessen the disparity between output values and input labels is known as training. Algorithms for back-propagation optimization are applied in this procedure

ResNet-50: One of the often used CNN models based on deep learning is ResNet50.

Convolutional models with 50 layers are stacked on top of one another. A crucial component of ResNet50 is how it gets around the vanishing gradient problem. Additionally, the architecture contains short links, or "skips," that frequently avoid various execution steps while iterating the model with essential and required execution stages. Efficient-B2: A version of EfficientB2 that has been enhanced and enlarged is a part of the deep learning architecture. The model usually uses a scaling technique that requires consistency for its dimensional elements, such as depth and width, at all sizes. To modify the resolution of the input dimensional image, they additionally use a compound coefficient in addition to dimensional variables. In contrast to how a standard CNN operates, which relies on scaling factors to prevent

distortion in the image's final resolution, EfficientB2's implementation employs scaling coefficients. For instance, if the computational resource to be employed is magnified to 2N times, the network's overall depth grows by N, while its width increases by N. VGG-16: The VGG-16 is a deep learning-based open-source model. The 13 levels of the VGG-16 design are separated into five groups and followed by a max-pooling layer. This feature vector is then applied to the three connected layers, all of which have the same configurations. The information is subsequently created and classified using the Softmax layer.

IV. IMPLEMENTATION OF THE MODEL

The primary aim of the research is to detect the presence of disease in plant leaves by collecting a dataset from Kaggle repository. The implementation begins by collecting a dataset and pre-processing it using labelling and resizing. After this stage, the model undergoes data visualization in which all the selected classes from the repository are used to represent the same. A total of 38 classes are chosen from the repository. After this stage; the dataset is further split into training, testing and validation phases wherein a total of 60 percent, 20 percent and 20 percent respectively is used in the subsequent stages. Once the data is split; the model undergoes the phase of testing using four algorithms including; CNN, Efficeint-B2, ResNet-50 and VGG-16. After the process of testing the dataset using four algorithms, the system undergoes the process of evaluation; wherein parameters such as accuracy, precision etc. are taken into consideration while deciding the optimized model. Once the parameters are evaluated; the models are compared on the basis of accuracy thus generated. The entire workflow of the proposed model is depicted in figure

4.1 wherein we use CNN and three deep learning based algorithms to detect features in plant leaves

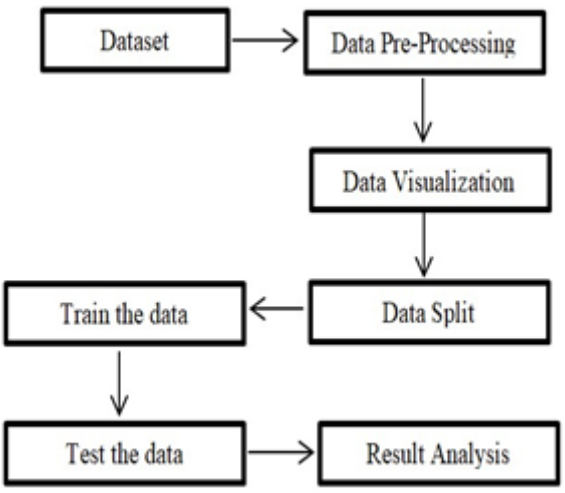

Figure 4.1: Workflow of the Proposed Methodology

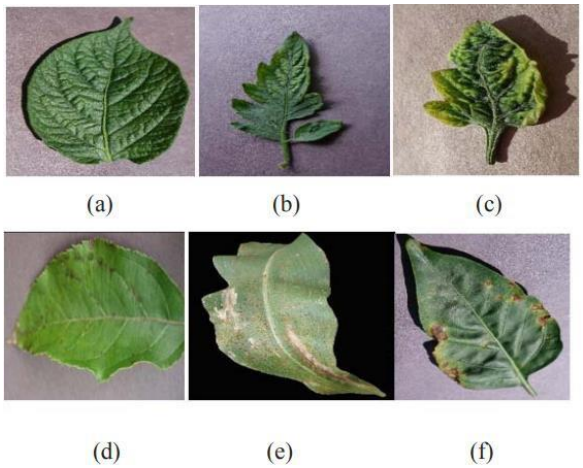
A. Dataset Used

The implementation of the system model occurs

by

gathering the dataset from Kaggle repository. This repository contains images of plant leaves from 38 different classes with each class resembling a disease and further comprises of 87k RGB based images. However, the classes and images of plant leaves do not overlap each other. These images of plant leaves contains of 250 images of various different plants having both healthy and diseased images and are further used by multiple algorithms to conduct the process of training and testing phase. Figure 4.2 below



represents a sample from the dataset that consists of 38 classes.

Figure 4.2: (a) Apple scab (b) Raspberry (c) Tomato (d) Soybean (e) Blueberry (f) Cherry

In the next stages, the system is heavily trained so that all the features of the plant images can be determined and further distinguished as either healthy or diseased.

B. Data Pre-Processing

This is an important stage of the system model; wherein the

dataset undergoes a series of process to filter redundant data so that the final implementation can be executed on relevant data. This is done so as to increase the overall efficiency of the model with less time consumption and high accuracy. The step in data pre-processing majorly includes:

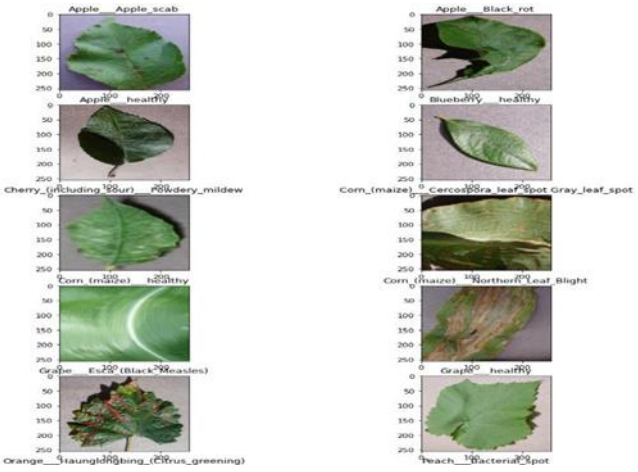
- Labelling the data
- Resizing the image

This tends to increase the resolution thus required for the process of image classification to be performed efficiently. For the purpose of implementation of the proposed thesis; the dataset images of the plant leaves are reduced to a pixel size of 128*128. This is done so as to maintain the overall resolution of all the images thus involved.

C. Data Visualization

The data visualisation method assists in the understanding

of trends by removing historical data from the dataset. Additional details about each attribute of the dataset are frequently provided through bar graphs, pie charts, and other visual representations of this data. Images of the leaves from 38 types of plants are used to visually represent the data for the suggested research. The visualisation of



plant leaves divided into all classes is shown in Figure 4.3 below.

Figure 4.3: Data Visualization of images from each class from the dataset

This process of data visualization can further be depicted using the count plot. The implementation of count plot helps to deduce all the 38 categories of classes by representing it through a bar graph. Figure 4.4 below illustrates a bar graph with 38 classes of plant leaves obtained from the dataset.

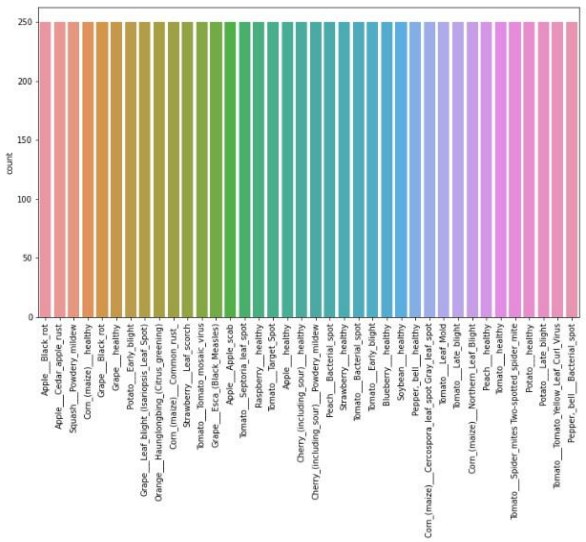


Figure 4.4: Data Visualization of 38 classes using count plot

D. Data Split

Once the process of visualizing the dataset is observed; the

system model thus undergoes the process of data split; wherein the dataset is split into ratios of training, testing and validation phases. For the purpose of implementation of the proposed thesis; the ratio is divided to be as 60 percent, 20 percent and 20 percent respectively. After this split; the system model is then sent for testing purpose onfour predetermined algorithms of CNN, Efficient-B2, ResNet-50 and VGG-16.

V. EXPERIMENTAL ANALYSIS AND RESULTS

For the purpose of evaluation; multiple parameters such as confusion matrix, classification table, sensitivity and specificity are taken into consideration and further employed on four deep learning based algorithms. The definition of the used parameters is as follows:

- Confusion matrix: it is a visual representation of the values so obtained and can further be represented by comparing the actual values with that of the predicted values. Four terms are determined while evaluating a confusion matrix.
  - TP: indicates when the actual values matches with respect to the predicted values
  - FP: indicates when the actual values predicted does not match with that of the real values
  - TN: indicates when the actual values does not matches with respect to the predicted values
  - FN: indicates when the actual values predicted matches with that of the real values
- Classification Table: a classification table consists information on the accuracy so produced; it also provides the values thus obtained from precision, recall and F1-factor. The terms associated with a classification table can be calculated as follows:

Accuracy	$Accuracy = \frac{(TP+TN)}{(TP+FP+FN+TN)}$
Precision	$Precision = \frac{TP}{TP+FP}$
Recall	$Recall = \frac{TP}{TP+FN}$
F1 Score	$\frac{2*precision*recall}{precision+recall}$

Sensitivity: Sensitivity is a ratio that informs the user of the positive values that have been obtained in relation to all instances of negative occurrence in the fraction at hand. It can be calculated using the formula below:

$$\text{Sensitivity} = \frac{TP}{TP+FN}$$

Specificity: A ratio called specificity tells us how often there are negative values compared to positive values in the fraction that is now present. It can be calculated using the formula below:

5.1 Results of algorithms using Confusion Matrix

$$\text{Specificity} = \frac{TN}{TN+FP}$$

The confusion matrix generated by all four algorithms is depicted in figure 5.1 below:

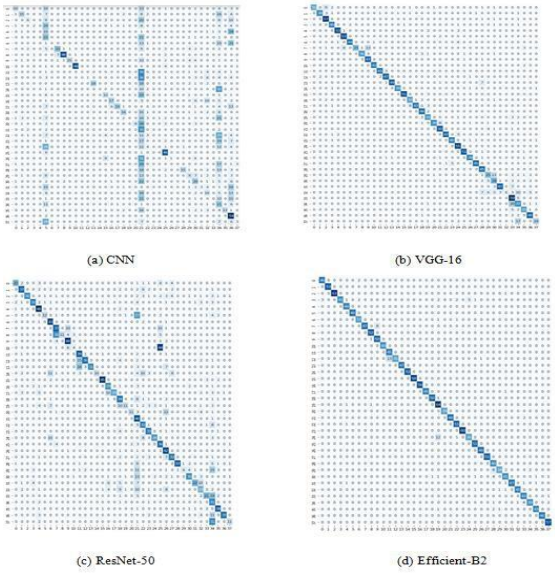

Figure 5.1: Confusion Matrix

A conventional representation of a confusion matrix is usually represented through a block diagram consisting of four blocks with four trained parameters as mentioned previously. However, for the purpose of implementation in the proposed thesis; all the 38 classes thus selected from the dataset are used to represent the same using a confusion matrix.

5.2 Results of algorithms using Accuracy and Loss graphs

A visual representation of the accuracy generated in relation to the error loss is the accuracy vs loss graph. An ideal model is one that exhibits the greatest accuracy with the least amount of error loss. Figure 5.2 below displays the accuracy and loss that were as a result attained through the implementation of various algorithms.

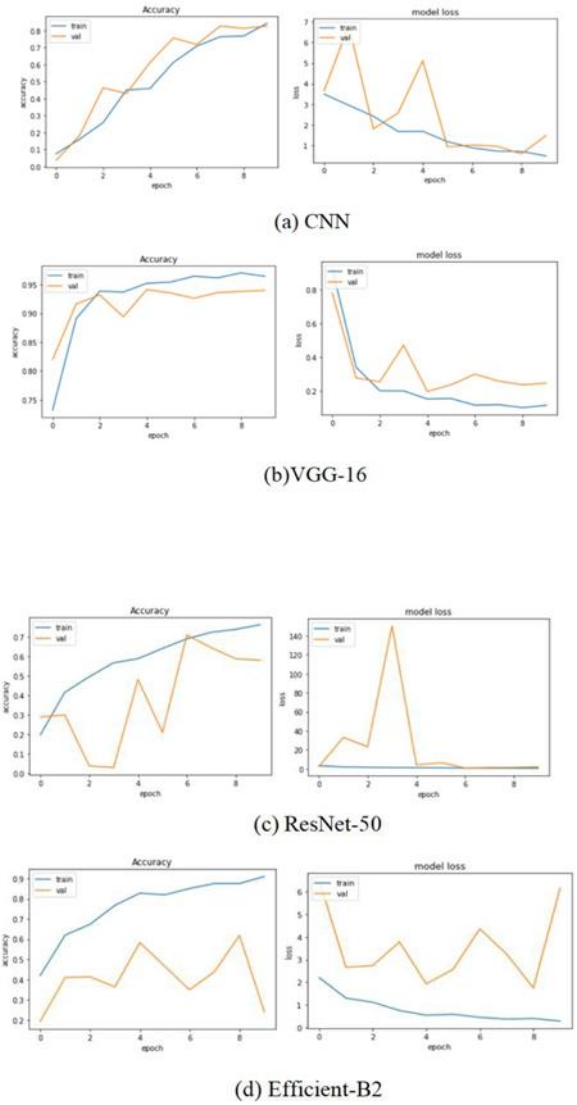

Figure 5.2: Accuracy vs Loss graphs

The graphs above were made using Adam as the optimizer, and each epoch was run ten times. A rise in validation accuracy and a corresponding decline in error loss can be seen in the graph above. However, the dataset that was utilised included images of the plant's leaves.

5.3 Results obtained using Classification Table

A classification report provides in-depth details on the precision, recall, F1 factor, and support values.

Table2: Classification Table

CNN	
Validation_Accuracy	61.78
Validation_Loss	1.7432
VGG-16	
Validation_Accuracy	82.70
Validation_Loss	1.4811
ResNet-50	
Validation_Accuracy	70.99
Validation_Loss	1.0110
Efficient-B2	
Validation_Accuracy	**94.14**
Validation_Loss	0.1954

As observed through the classification table above, it can be deduced that Efficeint-B2 generates highest accuracy of 94 percent in comparison to other algorithms thus experimented. The table above also gives information on the validation accuracy and loss error thus produced. It finally gives the values of precision through which the final accuracy of the model can be declared.

5.4 Results obtained using sensitivity and specificity

The values of sensitivity and specificity generated by all four algorithms are depicted in figure 5.4 below

	class	sensitivity	specificity
0	0	0.997849	0.550000
1	1	0.993489	0.649123

Figure 5.4: Sensitivity and Specificity

For the purpose of implementation in the proposed thesis; all the 38 classes thus selected from the dataset are used to generate values for sensitivity and specificity.

VI. CONCLUSIONS AND FUTURE SCOPE

The primary aim of the research is to detect the presence of disease in plant leaves. For this purpose, we have gathered a dataset of plant images from Kaggle repository and conducted a process of labelling and resizing the image using data pre-processing techniques. In the next stage; the dataset is expected to be split into a ratio of 60, 20 and 20 for the purpose of training, testing and validating respectively. The final implementation of the trained dataset is deployed on four deep learning based algorithm; including the implementation of CNN. The rest three algorithms include VGG-16, ResNet-50 and Efficeint-B2. However, a thorough investigation revealed that CNNs do have some shortcomings and are subject to certain restrictions. The goal of the research is to identify plant infections and further categorise them as normal or infected. This goal is accomplished by doing the research study in two parts, comparing the four models, and determining which model performs better and produces higher efficiency. To fulfil this purpose; evaluation parameters such as confusion matrix, accuracy vs loss graph, sensitivity values, specificity values, precision, f1 score and recall factors were taken into consideration. On experimentation of the proposed research; it was observed that the execution of Efficient-B2 generated an accuracy of 94 percent; which was considered to be as the highest amongst the implementation of the rest three. Hence, the model was declared to be as the optimised model.

On the other hand, a little training dataset might not yield accurate results that are satisfactory. The techniques of augmentation and the use of weak learning algorithms to obtain trained data can be used to further solve this issue. In addition to this, using a Generative Adversarial Network (GAN) for training generation enables the ML architecture to be trained with more distinctive characteristics and more robustness. Hence, this can be concluded to be as the extended study for future scope.

Abstract –**As the number of online book readers are exponentially increasing due to online teaching and growing internet-based technology, finding relevant books from a vast e-book space becomes a tremendous challenge for users. Now a days the amount of information on the internet grows very rapidly and people need some relevant tools to find and access appropriate information. One such tool is the recommendation system. Recommendation systems help to navigate quickly and receive necessary information based on the inputs given. The proposed Book Recommendation system would recommend the user books based on their interest or based on the books they have read previously. Also, a feature in the system where a user can get the summary of a page in a book without Reading the whole book.**

Recommender systems are classified according to the techniques used to make a recommendation: Content-based systems, Collaborative Filtering (CF) or Hybrid. Here we elaborate on all the techniques given above and some other machine learning techniques like KNN to make the best recommendation system. With the help of this system one can quickly search for books relevant for the user.

Key Terms - Recommendation System, Machine Learning, Collaborative-Filtering, Content-Based, Hybrid.

I. INTRODUCTION

Any system that automatically suggests information to website visitors is referred to as a recommendation system. These apps are the outcome of intelligent algorithms that may provide consumers recommendations as results. They need a powerful computer system that can conduct computations in less than half a second and a sizable database. So far today, proposals have been made for a variety of solutions. The performance of recommendation algorithms has increased thanks to machine learning, which also offers several options to do so. For the purpose of learning hierarchical representations of data, machine learning techniques employ many processing layers. A personalized recommendation system helps users find books, news, movies, music, online courses, and research articles. Recommender systems are tools that, designed for interacting with large and complex information spaces and prioritizing items that are likely to be interest to the user. An important part of many on-line e-commerce applications like Amazon.com, Netflix, and Pandora is personalized recommendations. Briefly, Recommendation Systems are based on the informational components like: information about user, purchasing or any other similar action. To implement the functions of Recommendation System, identify the items that are preferential to the user a made recommendations based on such preferences. For this, the system has to be able to predict the utility of some of them, or at least compare the utility of some items and decide what items to recommend based on this comparison.

The recommender systems are classifying according to the technique that are employed to made recommendation – collaborative, content-based, hybrid, cross-domain filtering algorithms. Firstly, collaborative filtering uses users' information and opinions to recommend products. It has narrow senses and general senses. It can make automatic predictions based on user preferences by collaborating information from many users in a narrow sense. For example, collaborative filtering could make predictions about a user that television shows a user like or dislike based on partial information of that user. In a general sense, collaborative filtering involves collaborating large volumes of multiple view-point, agents, and sources. It can be applied in mineral exploration, weather forecasting, e-commerce, and web applications where a massive volume of data needs to be processed to make the predictions. The drawback of collaborative filtering is that it needs a tremendous amount of user data, which is realistic for some applications where we do not use information. On the other hand, content-based filtering use objects information and recommendation are made based on object similarity. Generally, content-based filtering is useful when we do not have useful information. The Similarity among the products is considered while recommending. Both supervised and unsupervised machine learning algorithms are applied to measure the Similarity among products. The content can be structured, semi-structured, and unstructured, but it must be synchronized into a structured format to calculate the Similarity. A hybrid recommendation system combines two or more filtering techniques to produce the output. The performance of hybrid filtering is better comparing to collaborative and content-based filtering. Collaborative filtering does not consider domain dependencies, and content-based filtering does not consider people's preferences. A combined effort is required from both collaborative and content-based filtering techniques to make better predictions. The combined effort increases the common knowledge in collaborative filtering with content data and content-based filtering with user preferences. Cross-domain filtering algorithms can access information that belongs to different domains. Cross-domain filtering algorithms make predictions by exploring the source domain and increase the prediction in the target domain.

II. LITERATURE REVIEW

Ms. Praveena Mathew, Ms.bincy kuriakose and Mr. Vinayak hedge [1] proposed a Book Recommendation System (BRS) through the combined features of

content based filtering (CBF), collaborative filtering (CF) and association rule mining to produce efficient and effective recommendation. The existing systems lead to extraction of irrelevant information and lead to lack of user satisfaction. So, they proposing a hybrid algorithm, which combines two or more algorithms, to help the recommendation system to recommend the book based on the buyer's interest. They use association rule mining algorithm, ECLAT (Equivalence class clustering and bottom up lattice traversal). ECLAT will helps to find out the frequent item set. It uses depth first searching technique. In one scan, it will categorise. Cosine similarity is used for the similarity measuring in content and collaborative filtering. They use item-item filtering in collaborative filtering. The basic finding that achieved through this proposed work is to recommend the books based on the buyer's interest and increase the productivity and credibility. Using association rule mining algorithm to finds interesting association and relationship among large data set of books and provides an efficient recommendation for the book.

Yongen Liang and ShimingWan [2] proposed a method, which can mine products by understanding the user's preferences. It is a personalised technology with collaborative filtering. It is book recommendation system, which is for a university library. Here only provide the recommendation service to the registered users. The collaborative filtering uses both user-user filtering and item-item filtering. The important job of the collaborative filtering is to calculate the similarity of the books and users or reader then, recommend. Cosine similarity is using for the similarity measuring in collaborative filtering. Then find out or predict the rating for the particular book, which the targerted user may like or give. One of the most important problems of collaborative filtering is cold start. That is, when a new user joins then they have no data about that user. They have no previous purchase history or borrow history. Therefore, here they propose a solution that Expert and new book recommendation. Expert and new book recommendation module will recommend the books as if Best- selling, new books arrived, classical books... in short, it will recommend the books at the top rating or popular books.

Dharmendra Pathak, Sandeep Matharia and C. N. S.Murthy

[3] proposed an efficient and best unique hybrid recommendation algorithm, by providing the recommendation more satisfying the user's desire. Here the hybrid recommendation is a combination of collaborative, content and context based recommendation algorithms. The main input of collaborative filtering is rating i.e, votes of so many people, content based data that is the information about the users like their interest, date of birth, priorities... and the context based data that is the behavioural datas like date, taste, mood, weather... Cosine similarity is using for the similarity measuring. There are subject priorities according to the user's previous history. If they purchase a book then check, the purchased book is different subject priority from the subject priority has already set? If yes, then reset the subject priority3 and then subject priority 2. The subject priority1 will not change. Based on calculations and results they concluded that the proposed Hybrid book recommendation algorithm is best among the others.

Ahmed.M. Omran [4] proposed a Hybrid Recommendation system that will answer for the questions like, which book to buy? Which financial service to choose? Which website to visit next? First phase, collaborative filtering that is based on user behaviour by calculating the statistical correlation between the internet users' profiles using pearson correlation Factor by considering the number of visits to varies websites for each user to estimate the type and the strength of correlation among users. Then, Second phase applies content based filtering according to the content of websites by computing the relative similarity between each pair of websites and build, a pairwise comparison matrix to find the most nearby websites to the most visited users' websites. In collaborative filtering, from the browsing history, collect the websites, which that user visited. Then make the user profile with this data and record how many times that particular user visited in each site. Also make neighbourhood that is, find the similar users to that particular user. Spearman statistical method is the way of finding the users that have a common behaviour. Content based filtering is the second phase. Here by using the text data mining technique that commonly used in content-based technique i.e, TF–representation filter the data to predict items to users determine the similarity between websites by counting the words of the main pages and applying one of the data mining techniques to find the category to which website belongs. There are five criteria to set the similarly of each couple of websites i.e, Category, Service, Language, Rating, and Interactive. The Eucliean distance is using for similarity measuring.

Adli Ihsan Hariadi, and Dade Nurjanah [5] proposed a hybrid- based method that combines attribute based and user personality based methods for book recommender system. In this paper, they are implementing the MSV MSL (Most Similar Visited Material to the Most Similar Learner) method, and they are saying that, it is the best method among hybrid attributes based methods. The personality factor is used to find the similarity between users when creating neighbourhood relationships. The hybrid attribute will calculates the recommendation scores of rated books from neighbours using the similarity scores between a target book and its neighbours and between the active user and that user's neighbours. The score of book b from user u, denoted as score_b. This is for finding the Most Similar Visited Material to the most Similar Learner. It uses the values from both content and collaborative. Then use the result of hybrid as recommendation. That is the Most Similar Visited Material to the most Similar Learner.

Anand Shanker Tewari, Abhay Kumar and Asim Gopal Barman [6] proposed a book recommendation system based on combined features of content filtering, collaborative filtering and association rule mining. When

a buyer search for a book, then it will be store as a purchase history or a search history. When the buyer is offline the recommendation perform some filtration for recommending to buyer and the results are stored in the buyers web profile. When the buyer comes online next time, the recommendations will be generated automatically. In content based filtering, web Usage Mining (WUM) is used to provide relevant information to the buyers. web Usage Mining (WUM) typically extracts knowledge by analyzing historical data such as web server access logs, browser caches, or proxy logs. It helps to possible to model user behaviour and, therefore, to forecast their future movements. web Usage Mining stores the user's behaviour on the internet and processes that data. Item based collaborative recommendation Algorithm is using and Cosine similarity is using for the similarity measuring. Intersect the results from the association rule mining and the content, collaborative filtering.

Binge Cui and Xin Chen [7] proposed a novel book recommendation system. The readers will be redirect to the recommendation pages when they cannot find the required book through the library bibliographic retrieval system. It is an online book recommendation system for a library and it is based on web service. After login, a user search for a book with keywords like a book title, or with author name... at that time bibliographic retrieval system will search for books with the same keywords. If found any result in the recommendation system, then send these keywords to web Books Retrieval Module. In web Books Retrieval Module, it search on the online bookstore based with keywords by creating accounts on these online book stores like amazon... by the librarian or the admin of the online book recommendation system. Therefore, when the keyword comes to the web retrieval module, it searches as user on these online bookstores by login in. The result getting from these online bookstores will give to the user as recommendation results. According to the recommendation from users, the statistic and analysis module will calculate the value of that particular book. Then according to this value of book, the Auto-Order Module will produce a book order automatically based on the analysis results. When the purchased books have shelved, Book Storage System will send a report to the Short Message and Email Notification Module. Then it will notify the readers that have recommended the purchased books using Message and Email server.

Kumari Priyanka, Anand Shanker Tewari and Asim Gopal Barman [8] Personalised Book Recommendation System Based On Opinion Mining Technique. An online book recommendation; especially consider the specific features of the book that a particular user already purchased. Here, not only consider the feature but also consider the reviews given by the user for the books. So, here uses the technique that opinion mining or sentiment analysis to classify the reviews or comments from the different users for different book into positive or negative. For this, naïve bayes algorithm will perform the text classification. The classification of the review will helps to identify the user's preference and the books rating.

III. PROPOSED SYSTEM

Existing recommendation services despite their powerfulness need a strong user profile information and history. User register to such systems, browse books, rate them, write their feedbacks, recommend to others, share, read appropriate information and etc. Based on such an information a system makes its recommendations. The examples of such services are whichbook.net, whatshouldireadnext.com, lazylibrary.com and etc. Instead our recommender system focuses on simplicity and speed. A user, using an intuitive search and filtering interface updates a database by rating the books and then gets appropriate recommendations. The recommendations in turn are calculated based on collaborative filtering method.

IV. METHODOLOGIES

Collaborative Filtering Technique: Collaborative filtering[CF] technique focuses on the relationship between users and items. It is a technique that can filter out items that a user might like on the basis of ratings given by the other users and recommends the top-n similar items to the item given by the user. The similarity of items is determined by the similarity of the ratings of those items by the users who have rated both items.

Item-based Collaborative Filtering Technique: Item-based collaborative filtering was developed by Amazon. In an existing system where there are more users than items, item-based filtering is faster and more stable than user-

based. This algorithm uses a similarity measure to find

similarity between items. Steps involved in this algorithm: Step 1: Develop a user-item interaction matrix from the merged dataset as shown in the fig.1 and generate vectors from it. Here the item refers to a book.

Step 2: Now construct a cosine matrix using cosine similarity from vectors.

Step 3: From cosine matrix find the books similar to the book given by the user

Step 4: Recommend the top 'n' similar books Suppose we have n users set[7] U={user1,user2,....,usern} and m Books set B={book1,book2,...,book m}.User-item matrix is mxn matrix and values will be the ratings. Vectors will be the book1,book2,..,book m. Similarity between the books is calculated.

Cosine Vector Similarity(CVS): Cosine similarity is the cosine of the angle between two vectors and it is used as a distance evaluation metric between two points in the plane. The cosine similarity measure operates entirely on the cosine principles where with the increase in distance the similarity of data points reduces.

Cosine similarity finds its major use for character types of data wherein with respect to machine learning cosine similarity can be used for various classification data and helps us to determine the nearest neighbors when used as an evaluation metric in the KNN algorithm.Cosine similarity in the recommendation system is used with the same principle of cosine angles, where even if the

similarity of the content is less similar it would be considered as the least recommended content, and for higher similarity of contents, the recommendations generated would be at the top.

Cosine Vector Similarity is the dot product of the two data points(vectors).It measures the cosine angle between the objects i.e vectors.

Where, A=book1(vector1) B=book2(vector2) Ai=rating

given to the book 'A' by a user 'i' Bi=rating given to the book 'B' by a user 'i' Where, A=book1(vector1) B=book2(vector2) Ai=rating given to the book 'A' by a user 'i' Bi=rating given to the book 'B' by a user 'i'

$$similarity(A,B) = \frac{A \cdot B}{\|A\| \times \|B\|} = \frac{\sum_{i=1}^{n} A_i \times B_i}{\sqrt{\sum_{i=1}^{n} A_i^2} \times \sqrt{\sum_{i=1}^{n} B_i^2}}$$

Where, A=book1(vector1) B=book2(vector2)

Ai=rating given to the book 'A' by a user 'i'

Bi=rating given to the book 'B' by a user 'i'

Recommendation systems in machine learning are one such algorithm that works based on the similarity of contents. There are various ways to measure the similarity between the two contents and recommendation systems basically use the similarity matrix to recommend the similar content to the user based on his accessing characteristics.

So any recommendation data can be acquired and the required features that would be useful for recommending the contents can be taken out from the data. Once the required textual data is available the textual data has to be vectorized using the CountVectorizer to obtain the similarity matrix. So once the similarity matrix is obtained the cosine similarity metrics of scikit learn can be used to recommend the user.

Euclidean Distance Similarity(EDS):The Euclidean distance between two points is the length of the line segments connecting them.Euclidean space in this particular case is the positive portion of the plane where the axes are the ranked items and the points represent the scores that a particular person gives to both items. Two people belong to a certain preference space if and only if, they have ranked the two items that defines the preference space. So define a preference space for each pair of distinct items, and the points in this preference space, are given by the people that ranked the two items.

Euclidean Distance Similarity(EDS) is based on the distance between two vectors. EDS measure compares absolute values and determines that the best variant of similar vectors is two absolute identical vectors with zero distance between them.

$$d(p, q) = \sqrt{\sum_{i=1}^{n} (q_i - p_i)^2}$$

Weighted-Average: Weighted average is a calculation that takes into account the varying degrees of importance of the numbers in a data set. In calculating a weighted average, each number in the data set is multiplied by a predetermined weight before the final calculation is made. A weighted average can be more accurate than a simple average in which all numbers in a data set are assigned an identical weight.

$$W = \frac{Rv+Cm}{v+m}$$

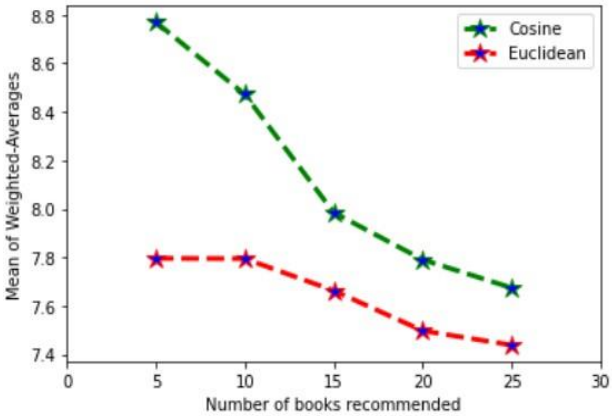
where, W=weighted-average score R=average rating for the book v=number of ratings for the book

C=the mean value of average-rating of all the books m=minimum ratings required to get recommend

V. RESULTS

Based on the information records of 278858 users, 242135 books, 1149780 ratings from the good read books Kaggle datasets, unsupervised machine learning model i.e. collaborative filtering technique .The following takes the book title "Harry Potter and the Sorcerer's Stone (Harry Potter (Paperback))" as an example input to show our proposed system recommended books as shown in the and also to compare the performance of similarity measures.

.Performance Comparison: The diagram below illustrates the performance of two similarity measures CVS and EDS in terms of weighted average of ratings with a varying number of recommendations. Same input book is given to both the measures and CVS is recommending the books with more rating than EDS and also as the size of the recommended books increases, weighted-average value for both similarity measures is decreasing. Finally, from the figure below, it is clear that the performance of collaborative filtering[CF] technique is better when CVS measure is used rather than EDS.



Evaluation Metric: Evaluation metrics are used to evaluate learning algorithms and form an important aspect of machine learning. In recommendation, we are predicting output, the error measures are fairly different here. As usual, the error metrics are obtained by comparing the predictions of the models with the real values of the target variables and calculating the average error.

Root Mean Square Error(RMSE): To compute the RMSE, we first take the square of the difference between the actual and predicted values of every record. We then take the average value of these squared errors. If the predicted value of the ith record is y(i) and the actual value is x(i), then the RMSE is:

$$\text{RMSE}=\sqrt{\frac{\sum_{i=1}^{N}(x(i)-y(i))^2}{N}}$$

Where, N=number of datapoints

The merged dataset is divided into 20% test data i.e.

206255 and 80% train data i.e. 825018, RMSE value is

7.9727.

VI. CONCLUSION

A Recommendation System is an act of trying to regulate the future work of the E-commerce industry. The prediction of user's interest of books or any other item could yield remarkable profit and change in the field of decision-making, retail business, hotel business, tourism, digital content, movie databases. From this literature survey, we found that, the most suitable algorithm for predict books for users by considering their preference and by avoiding cold start problem is, the item based collaborative filtering with opinion mining on reviews. This algorithms will be a great benefit for users as well as the owner.

As it is difficult for people to select the best books from a large set of books ,this paper provides a modern solution i.e. a book recommender system based on item-based collaborative filtering[CF] technique which provides relevant

recommendations. This paper also shows that using cosine

similarity as a similarity measure gives best results when compared to euclidean distance, as euclidean distance gives the similarity value even if there exists null values. The CSV gives the best results when the null values are not present in the dataset. RMSE score is 7.9727.

Abstract—**Anaemia is one of the common disorder based on Haematological by affecting humanity and it is usually seen in pregnant women and children. This disease has a negative impact on quality of life and sometimes in survival of patients. Mostly people don't know the nutritional food they are required what are the nutritional fruits and vegetables should have. The proposed work is a web application, intended to create awareness and predict anaemia in people and then recommending various methods and diet plans gathered from hospitals to prevent anaemia from happening ever again and as a precautionary element for other people who might get affected from anaemia in future. The prediction is done using 3 popular algorithms (Random Forest, Knn and Naïve bayes). Based on these 3 algorithms a hybrid system is created to predict most accurate prediction for anemia patients using CBC report. CBC report includes Gender, Haemoglobin, MCH, MCHC and MCV which are enough to predict anemia. This proposed work also helps in building the diet and helping in maintaining the diet.**

Keywords—Anaemia, CBC, Random Forest, Naïve Bayes Classifier, Anemia Prediction, Anaemia Disease Prediction, HealthCare website, AI based prediction, etc.

I.INTRODUCTION

Anaemia is highly prevalent in India. The third National Family Health Study (NFHS-3) conducted during 2005–6 found that amongst children aged 6 to 59 months, the prevalence of anaemia is 69.5%; in rural India, the prevalence is 71.5%. The prevalence is maximal amongst younger children (12–17 months – 84.5%, 18– 23 months 81.6%). The prevalence of anaemia in rural areas appeared to have risen since the previous NFHS (in 1998–9) [1]- [2]. Anaemia is one of the common disorder based on Haematological by affecting humanity and it is usually seen in pregnant women and children. This disease has a negative impact on quality of life and sometimes in survival of patients. Mostly people don't know the nutritional food they are required what are the nutritional fruits and vegetables should have [3]. The proposed work serves as platform where a user can get info of food which are rich in nutrition components. When a user visits the portal, they can select a particular food item categorized in different sections like protein, vitamins, carbohydrates etc. It also shows dishes related to that food like paneer dish is palak paneer which is rich in iron and protein. Proposed Work Portal also shows information related to anaemia disease through which user can gain the information needed to diagnose himself/herself.

Suggestions and nutritional tips will also be provided for better self-treatment. For an enhanced treatment at home tutorial videos for consuming nutritional food and quality talks from doctors around the world in the field of anaemia is also a part of the proposed work. Facility to book an appointment with a doctor from top hospitals around the world is being included to help user in contacting doctors researching widely in the field of anaemia. As an addon a feature called "talk to us" is being provided so that a user can express his/her thoughts or can interact directly with experts in the field of anaemia is mostly caused due to lack of iron deficiency in children 11- 14 years.

This proposed work also includes Prediction using machine learning which is most important feature of our project. The dataset is collected from Kaggle and various healthcare website to examine the performance of Naive Bayes, Random Forest, and KNN algorithms for predicting anemic disease. The dataset Includes more than 1.2 lakh records

II.LITERATURE SURVEY

Based on the survey we found some research paper [4]-[10] and found that there is no existing system for anaemia. There are some initiatives for the Anaemia projects, but the required system is not developed and there only research paper about the proposed work but no live system which helps user for guidance about anaemia and nutritional food.

Some Web apps are available for disease but the app is not specified to anaemia because it includes lots of disease. Similarly, some websites are there with old technologies which are not attractive and detailed about anaemia. So, after this survey we have taken initiative to develop an attractive and fully detailed and dynamic website for user regarding anaemia and nutritional food. Along with this we found many papers which provides algorithm for predicting anemia but they have not implemented it on any website. So, in our project we will implement these algorithms for anemia prediction. We are also making a hybrid system using various algorithm to make more accurate prediction.

III.METHODOLOGY

A. Reason to create this project

Based on research what we found that Anaemia is most common disorder but there is no website in existing system to aware the people about anaemia. So, to make people aware about anaemia and advising them about symptoms, diagnosis, prevention about anaemia and guidance about the diet we initiated an approach to solve all issue regarding anemia using our proposed work.

B. How we built this project

At first, we created a design of all the component of proposed work using figma.

After completion of design, we started implementation of proposed work using the MERN Stack. Here ReactJs

is used for frontend implementation with some extra technologies like bootstrap, Sass, CSS, html. ExpressJs and Nodes are used for backend implementation and MongoDb used for Database Management

Fig 1. Home page

The prediction part is executed using Python and

FastApi technology.

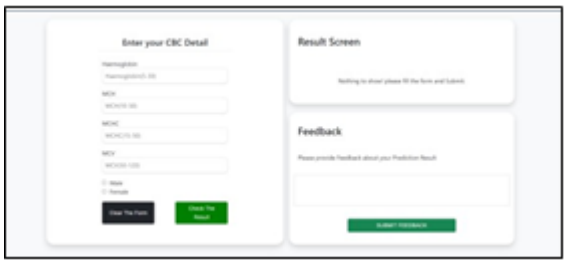

Fig 2. Input and output screen for Prediction

All propped work is divided into 4 members where

2 members are involved in fronted development and other 2 members in backend development.

Side by Side members are involved in research and documentation for proposed work.

After implementation of each component the testing conducted each time and at last after final testing of whole project, the proposed work is deployed on Heroku.

C. Features of proposed work includes

1) Anaemia details: This component includes all types of Anaemia disease along with the particular anaemia details, which includes symptoms, diagnosis, prevention, treatment etc. Along with this there is recommendation for food diet, which is recommended based on anaemia type.

2) Nutritional guide: This component includes all type of nutrients. Each nutrients contains many food items. Which contains all the details about the that food item. Which helps user to understand about nutrition diet.

3) *Hospital appointment:* This component includes list of many hospitals where a user can take appointment in nearby hospital.

4) Prediction: This component includes prediction using machine learning algorithm which helps in knowing if a particular user is suffering from anemia or not. The prediction done based on hybrid system and alterative pair average of result is taken to find most accurate prediction.

5) *Chatting system:* When user is in doubt and want to ask any query to other user then they can use chatting system to take advice from other users.

6) *Services and guidance:* Here we have shown services and also list of doctors which will be available for guidance if there is any query. A user can just call any doctor for is problems.

7) *Tutorials:* We have added some tutorial

about anaemia types with its all information and health Tips

8) *Parameters:* For prediction we have used CBC report which includes MCH, MCV MCHC, Haemoglobin and these parameters are also displayed in our proposed work with normal range.

9) *Suggestion for anemia positive patients:* When our system predicts anemia positive for entered CBC report then it also show suggestion to follow the path for treatment.

IV.DATASET

The following table contains 122k dataset for anemia patients.

G	Hb	MCH	MCHC	MCV	result
0	8.88	38.37	39.64	71.17	1
1	10.34	26.27	37.24	78.18	1
0	11.33	29.23	35.54	80.03	0
1	16.55	27.12	34.12	91.35	0
0	10.4	23.32	38.49	105.46	1
1	18.59	21.38	32.55	101.33	1
0	12.27	31.41	34.22	99.17	0
1	16.72	28.25	35.2	82.39	0
0	5.98	10.6	40.1	101.51	1

Training & Testing

Building Hybrid model

Predicting anemia Disease

more 1,22,000 records,

In the result column 1 indicates anemia positive and

0 indicates anemia negative.

V.OUTCOME

As part of eliminating anaemia, a prediction model is necessary as it would help users to know if they are suffering from anaemia or not thereby also reducing the cost of visiting a pathogen lab for specialized test of anaemia which costs around 10 times than normal blood test [11]. However, as anaemia is a disease which is caused due to decrease in the count of red blood cells (RBCs) or haemoglobin in the blood, it is required to have a blood report for the prediction model to work and predict the prevalence of this disease in a particular person [12].

When it comes to prediction model, there were three choices to choose from 1. Naïve Bayes Classifier 2. Random Forest 3. KNN Classifier, out of which, Random Forest yields the best result with the most accurate result among the three [7]. Since a prediction for anemia disease should be accurate so, we are not just using a single algorithm for prediction. In our project we are using hybrid algorithm based on above algorithms.

As far as data pre-processing is concerned, training data is collected from various pathogen labs, as a result training data is new and fresh as opposed to getting old and inaccurate data from a data repository. The dataset collected from Kaggle and various healthcare websites which contains CBC test data which gives overall data that is required for the prediction algorithm i.e., Gender, MCV, MCH, HGB, and MCHC.

These are the steps taken for the successful creation of machine learning model.

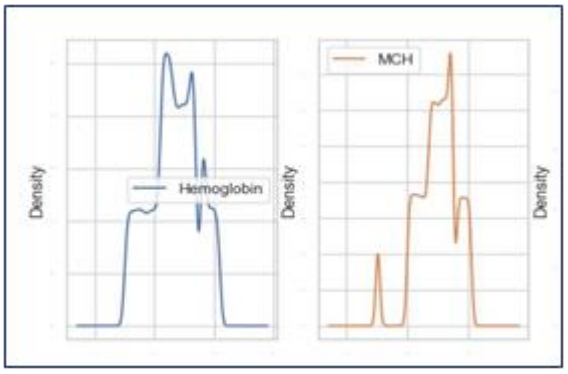

Fig 4. Data Distribution for Hb and MCH

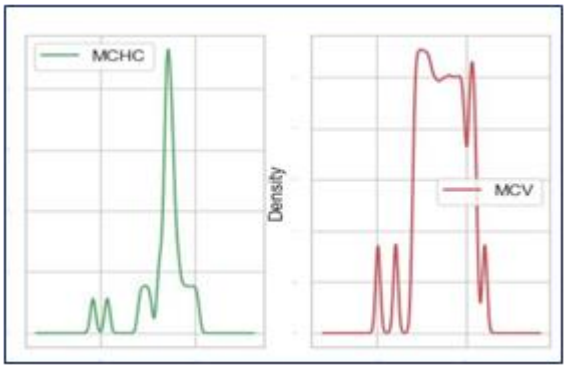

Fig 5. Data Distribution for MCHC and MCV

	Gender	Hemoglobin	MCH	MCHC	MCV	Predicted Result
0	0	6.9	28.1	32.5	94.6	1
1	1	11.8	16.3	30.9	78.7	1
2	1	11.0	26.0	32.2	98.9	1
3	1	11.0	25.2	30.9	83.2	1
4	0	10.7	21.3	29.1	78.7	1
5	1	16.2	17.2	32.2	78.4	1
6	1	15.0	30.0	34.0	90.0	0

Fig 6. Prediction of sample data

We show This result in our website Screen as seen below.

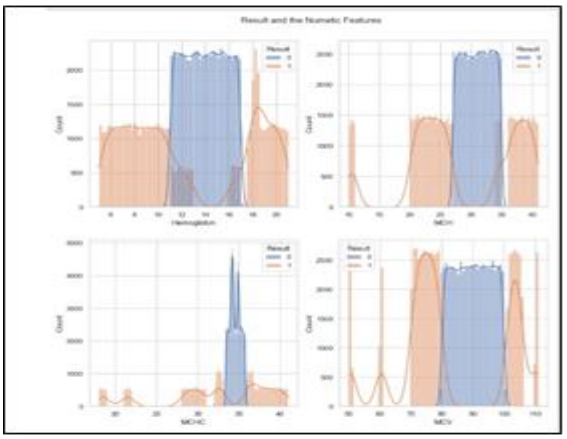

Fig 7. Finding relation between the Result and the numeric features

When user enters CBC report then we check the probability of all 3 algorithm for this input data.

Then we make pair of algorithms for prediction like (Knn, Random Forest), (Random Forest, Naive bayes) and (Knn, Naïve Bayes). After this we store prediction output separately for all pair. Along with this a combination all three algorithm is used for prediction.

```
# Loading up the all trained model
rf = pickle.load(open('../model/rf.pkl', 'rb'))
knn = pickle.load(open('../model/knn.pkl', 'rb'))
nb = pickle.load(open('../model/nb.pkl', 'rb'))

# storing prediction result for all algorithms
rfPred = rf.predict(sample).tolist()[0]
knnPred = knn.predict(sample).tolist()[0]
nbPred = nb.predict(sample).tolist()[0]

# stroing paired result of alogirthm to make hybrid alforithm
rfAndKnn=(rfPred+knnPred)/2;
rfAndNb=(rfPred+nbPred)/2;
knnAndNb=(knnPred+nbPred)/2;
rf_knn_nb=(rfAndKnn+knnAndNb+rfAndNb)/3

# taking avg of all paired output for final result
FinalPred=((rfAndNb+rfAndKnn+knnAndNb+rf_knn_nb)/4)*100;
```

Fig 8. Making Hybrid prediction

Finally, we have 4 results. We calculate the average of all result. If our result is 100% then report is anemia positive and when result is 0% then report is normal i.e., anemia negative. But as we are using hybrid algorithm with four results so percent can be in between 0-100%. So, while showing output in web screen, there is a condition, if result is greater than 50% then its anemia positive else anemia negative.

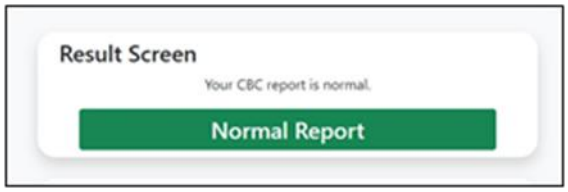

Fig 9.1 Data of patient's report

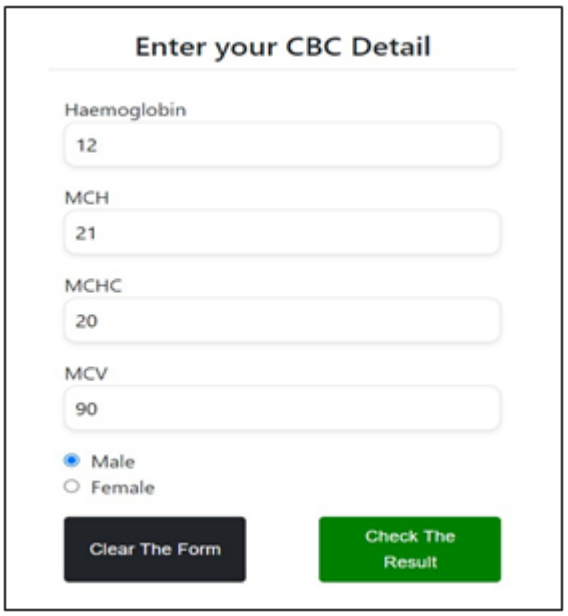

Fig 9.2 Showing Prediction for negative anemia

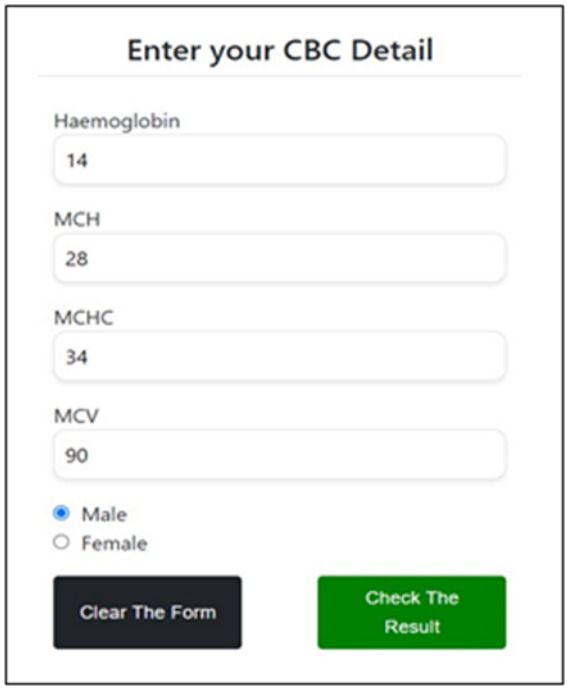

Fig 10.1 Data of new patient's report

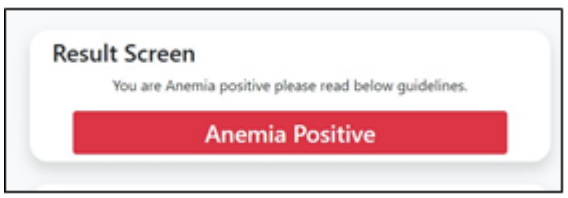

Fig 10.2 Showing Prediction for positive anemia

VI.RESULT

Our proposed work successfully predicts the accurate data for anemia disease. When CBC report is entered then combination of 3 algorithms used which are random Forest, Naïve Bayes and Knn algorithm. If one of them predicts wrong then output is 66.66% which mean anemia is positive. and if all algorithm predicts positive anemia, then output is

100%. When all predict anemia negative, then

output is 0% which mean anemia is negative. In some case when only 1 algorithm predict anemia positive and 2 algorithm predicts anemia negative then output is 33%, which means anemia is negative.

We have used combination of all algorithm which makes it Hybrid system. This hybrid System predicts more accurate result. User is allowed to provide the feedback about our hybrid system and this all feedbacks are listed on our project for making trust with users.

Along with this many features of our project helps in spreading anemia awareness. The Tutorials and Services are provided for user support and Doctor's contact are listed for 24/7 guidelines. Anemia Types and their details like symptoms, prevention, diagnosis, treatment and food item suggestion helps in getting knowledge about anemia. Nutrition food page helps user to aware about all the nutrients which exist and based on nutrients user can see food items rich in that selected specific nutrient. The Detail about each food item is also given for more clarification about food. Hospital appointment feature helps user to directly connect with hospitals and they can easily take appointments in hospitals.

The Technology used in projects successfully makes our project faster to response and quicker to load. The prediction time take only two second for showing results and recommendations.

VII.FUTURE SCOPE

Eliminating anaemia is the main motto of our project which is also the major problem in this world deficiency of nutrients in red blood cell leads to anaemia. This is because lack of awareness people doesn't know what to eat and when to eat it's really important so that people have important and also defeat this anaemia. We have learnt lots of things about anaemia and how to make an effective website which help others to grab information.

In future, proposed work will not only predict the anemia but also it will predict the type of anemia. The user will be able to store the all the result in their account. The user will also be able to take print of their report with all remarks and reasons for the prediction. Based on the type of anemia the food items will be recommended.

In future, proposed work is planned to be shaped in an android app which will be made using Android Studio. A constructive design is already in creation which is planned to take on Material UI concept with dynamic theming support as present in android 13's Material You concept. Data will be fed in using the same API created for the website. Volley API will be used to fetch data from the API and will be populated accordingly. MVC architecture will be followed for the same. For now, Android Studio is in consideration but according to

team's future decision Flutter might be used. If design of android app is not as we thought of then a switch to React Native will be required as designing is easier with React Native. An IOS app is also in consideration which will be made using X-Code. IOS app is still a decision which will require team's collective thinking and effort.

VIII.CONCLUSION

The proposed work is based on anemia awareness and anemia disease Prediction. For prediction we have compared various machine learning prediction model for predicting whether a patient has anemia or not. Out of which we found random forest, Knn and Naïve byes as fast and accurate models. We used all of three model appointment with a doctor from top hospitals around the world is being included to help user in contacting doctors researching extensively in the field of anaemia. As an add-on a feature called "talk to us" is being provided so that a user can express his/her thoughts or can interact directly with experts in the field of anaemia. Also, we are bringing the awareness among community to help understand the disease better and provide info regarding nutritional foods which plays a major role in applied field. Other additional features have been included in the proposed work to further improve the pace of eliminating this plaguing disease among the society.

Assessing the Performance of Genetic Algorithm in Solving AC-DC Optimal Power Flow Problem

Dr. Sanjay B. Warkad
P. R. Pote (Patil) College of Engineering & Management, Amravati, , India
sbwarkad@gmail.com

Abstract- **In the past decades, electricity markets have significantly restructured in both developed and developing countries. In it, Optimal Power Flow (OPF) is emerging as the main function of power generation, operation and control. OPF is an optimization problem, in which the utility strives to minimize its generation costs while satisfying all its equality and inequality constraints, while the system is operating within its security limits.**

In recent years, the incorporation of subsets of transmission High Voltage Direct Current (HVDC) in AC transmission networks brought significant techno-commercial changes in the transmission of the electric power in developing countries. This paper aims at (1) presenting Genetic Algorithm approach to solve OPF, (2) problem formulation with incorporation of HVDC link in a AC transmission system, (3) demonstrating the proposed methodology for standard power system and (4) to assess the performance of GAOPF with the traditional OPF method. The paper concludes that the proposed scheme is effective for power systems.

Index Terms – Optimal Power Flow, Genetic Algorithms, HVDC transmission

I. INTRODUCTION

In electrical power systems, Optimal Power Flow (OPF) is a nonlinear programming problem, used to determine generation outputs, bus voltages and transformer tap with an objective to minimize total generation cost [1]. Presently, application of OPF is of much importance for power system operation and analysis. In a deregulated environment of electricity industry, OPF recently been used to assess the spatial variation of electricity prices and transmission congestion study etc [2].

In most of its general formulation, the OPF is a nonlinear, non-convex, large-scale, static optimization problem with both continuous and discrete control variables [3]. It is due to the presence of nonlinear power flow equality constraints. The presence of discrete control variables, such as switchable shunt devices, transformer tap positions, and phase shifters etc., complicates the solution [2]. However, they are not assured to converge to the global optimum of the general nonconvex OPF problem, although there exists some empirical evidence on the uniqueness of the OPF solution within the domain of interest [4].

Effective OPF is limited by the high dimensionality of power systems and the incomplete domain dependent knowledge of power system engineers. Numerical optimization procedures addressed the former one based on successive linearization using the first and the second derivatives of objective functions and their constraints as the search directions or by linear programming solutions to imprecise models [5-9]. The advantages of such methods are in their mathematical underpinnings, but disadvantages exist also in the sensitivity to problem formulation, algorithm selection and usually converge to a local minimum. The lateral one precludes also the reliable use of expert systems where rule completeness is not possible.

Since OPF was introduced in 1968 [10], several methods have been employed to solve this problem, e.g. *Gradient base, Linear programming* method [11] and *Quadratic programming* [12]. However, all these methods suffer from problems. First, they may not be able to provide optimal solution and usually get stuck at a local optimal. Some methods, instead of solving the original problem, solve the problem's Karush–Kuhn–Tucker (KKT) optimality conditions. For equality-constrained optimization problems, the KKT conditions are a set of nonlinear equations, which can be solved using a Newton-type algorithm. In Newton OPF [13], the inequality constraints have been added as quadratic penalty terms in the problem objective, multiplied by appropriate penalty multipliers. Interior Point (IP) method [14-16], convert the inequality constraints to equalities by the introduction of nonnegative slack variables. A logarithmic barrier function of the slack variables is added to the objective function, multiplied by a barrier parameter, which is gradually reduced to zero during the solution process. The unlimited point algorithm [17] uses a transformation of the slack and dual variables of the inequality constraints, converts the OPF problem KKT conditions to a set of nonlinear equations, thus avoiding the heuristic rules for barrier parameter reduction required by IP method. Recent attempts to overcome the limitations of these mathematical programming approaches include the application of simulated annealing-type methods [18-19], and genetic algorithms (GAs) etc., [20-21].

GAs are essentially search algorithm based on mechanics of nature and natural genetics [22]. They combine solution evaluation with randomized, structured exchanges of information between solutions to obtain optimality. GAs are a robust method because restrictions on solution space are not made during the process. The power of GAs stem from its ability to exploit historical information structures from previous solution guesses in

an attempt to increase performance of future solutions [23]. GAs have recently found extensive applications in solving global optimization searching problem when the closed form optimization technique cannot be applied. GAs are parallel and global search techniques that emulate natural genetic operators. The GA is more likely to converge toward the global solution because it, simultaneously, evaluates many points in the parameter space. It does not need to assume that the search space is differentiable or continuous [24]. In [25], the Genetic Algorithm Optimal Power Flow (GAOPF) problem is solved based on the use of a genetic algorithm load flow, and to accelerate the concepts, it is proposed to use the gradient information by the steepest decent method. The method is not sensitive to the starting points and capable to determining the global optimum solution to the OPF for a range of constraints and objective functions. In Genetic Algorithm approach, the control variables modeled are generator active power outputs and voltages, shunt devices, and transformer taps. Branch flow, reactive generation, and voltage magnitude constraints have treated as quadratic penalty terms in the GA Fitness Function (FF). In [21], GA is used to solve the optimal power dispatch problem for a multi-node auction market. The GA maximizes the total participants' welfare, subject to network flow and transport limitation constraints. The nodal real and reactive power injections that clear the market are selected as the problem control variables.

The GAOPF approach overcomes the limitations of the conventional approaches in the modeling of non-convex cost functions, discrete control variables, and prohibited unit-operating zones. However, they do not scale easily to larger problems, since the solution deteriorates with the increase of the chromosome length, i.e., the number of control variables.

In the coming years, power consumption in developing and transition countries is expected to more than double, whereas in developed countries, it will increase only for about 35-40%. In addition, many developing, and transition countries are facing the problems of infrastructure investment especially in transmission and distribution segment due to fewer investments made in the past. To reduce the gap between transmission capacity and power demand, the trend is to adopt HVDC transmission system in the existing AC networks to gain techno-economical advantages of the investment. In such scenario, it is obvious to address this trend to design optimal power flow scheme for a real network system. In this paper full ac-dc based GAOPF is developed. This methodology also discussed the redesign of fitness function by refining penalty scheme for system constraints to get faster convergence. This avoids the necessity to perform early load flows as reported in several literatures [1-3, 9, 22].

After this introduction, section II presents the ac-dc based optimal power flow formulation. The Genetic Algorithm methodology is explained in section III. The performance of AC-DC based GAOPF is assessed and demonstrated with the IEEE 6-Bus, IEEE14-Bus, IEEE 30-Bus test systems and a complex and real network power system of India in section IV. Finally, the conclusions are presented in section V.

II. II. AC-DC OPTIMAL POWER FLOW FORMULATION

Problem Formulation:

As has been discussed, the objective function considered in this paper is to minimize the total generation cost. OPF formulation consists of three main components: objective function, equality constraints, and inequality constraints. The methodology is as follows,

AC System Equations

Let P = (p_1,…..,p_n) and Q = (q_1,…..,q_n) for a n buses system, where p_i and q_i be active and reactive power demands of bus-i, respectively. The variables in power system operation to be X = (x_1,….,x_m), such as real and imaginary parts of each bus voltage. So the operational problem of a power system for given load (P, Q) can be formulated as OPF problem [26]

Minimize f (X, P, Q) for X (1)

Subject to S (X, P, Q) = 0 (2)

T (X, P, Q) $\leq$ 0 (3)

Where S (X) = (s_1(X, P, Q),…….,s_{n1} (X, P, Q))^T and T (X) = (t_1(X, P, Q),……., t_{n2}(X, P, Q))^T have n_1 and n_2 equations respectively, and are column vectors. Here A^T represents the transpose of vector A.

f (X, P, Q) is a scalar, short term operating cost, such as fuel cost. The generator cost function $f_i(P_{Gi})$ in \$/MWh is considered to have cost characteristics represented by,

$$f = \sum_{i=1}^{NG} a_i P_{Gi}^2 + b_i P_{Gi} + c_i \quad (4)$$

Where, P_{Gi} is the real power output; a_i, b_i and c_i represents the cost coefficient of the ith generator, NG represents the generation buses,

The various constraints to be satisfied during optimization are as follows,

(1) Vector of equality constraint such as power flow balance (i.e. Kirchoff's laws) is to be represented as:

S (X, P, Q) = 0 or

$$P_G = P_D + P_{DC} + P_L \text{ and } Q_G = Q_D + Q_{DC} + Q_L \quad (5)$$

Where suffix *D* represents the demand, *G* is the generation, *DC* represents dc terminal and *L* is the transmission loss.

(2) The vector, inequality constraints including limits of all variables i.e. all variables limits and function limits, such as upper and lower bounds of transmission lines, generation outputs, stability and security limits may be represented as,

$$T(X, P, Q) \leq 0 \text{ or} \tag{6}$$

(i) The maximum and minimum real and reactive power outputs of the generating sources are given by,

$$P_{Gi}^{\min} \leq P_{Gi} \leq P_{Gi}^{\max} \quad (i \in G_B) \text{ and } Q_{Gi}^{\min} \leq Q_{Gi} \leq Q_{Gi}^{\max} \quad (i \in G_B) \tag{7}$$

Where, $P_{Gi}^{\min}, P_{Gi}^{\max}$ are the minimum and maximum real power outputs of the generating sources and $Q_{Gi}^{\min}, Q_{Gi}^{\max}$ are the minimum and maximum reactive power outputs.

(ii) Voltage limits (Min/Max) signals the system bus voltages to remain within a narrow range. These limits may be denoted by the following constraints,

$$\left|V_i^{\min}\right| \leq |V_i| \leq \left|V_i^{\max}\right| \quad (i= 1,\ldots\ldots,N_B) \tag{8}$$

Where, N_B represents number of buses.

(iii) Power flow limits refer to the transmission line's thermal or stability limits capable of transmitting maximum power represented in terms of maximum MVA flow through the lines and it is expressed by the following constraints,

$$P_f^{\min} \leq P_f \leq P_f^{\max} \quad (f= 1,\ldots, Noele) \tag{9}$$

Where, *Noele* represents number of transmission lines connected to grid.

Thus, the operating condition of a combined ac-dc electric power system is described by the vector,

$$X = [\delta, V, x_c, x_d]^t \tag{10}$$

Where, δ and V are the vectors of the phases and magnitude of the phasor bus voltages; x_c is the vector of control variables and x_d is the vector of dc variables.

DC System Equations

The following relationship is for the dc variables. Using the per unit system [27], the average value of the dc voltage of a converter connected to bus 'i' is

$$V_{di} = a_i V_i \cos\alpha_i - r_{ci} I_{di} \tag{11}$$

Where, α_i is the gating delay angle for rectifier operation or the extinction advance angle for inverter operation; r_{ci} is the commutation resistance, and a_i is the converter transformer tap setting.

By assuming a lossless converter, the equation of the dc voltage is given by,

$$V_{di} = a_i V_i \cos\varphi_i \tag{12}$$

Where, $\varphi_i = \delta_i - \xi_i$, and φ is the angle by which the fundamental line current lags the line-to-neutral source voltage.

The real power flowing in or out of the dc network at terminal 'i' can be expressed as,

$$P_{di} = V_i I_i \cos\varphi_i \quad \text{or} \quad P_{di} = V_{di} I_{di} \tag{13}$$

The reactive power flow into the dc terminal is

$$Q_{di} = V_i I_i \sin\varphi_i \quad \text{or} \quad Q_{di} = V_i a I_i \sin\varphi_i \tag{14}$$

The equations (13) - (14) can be substituted into the equation (5) to form part of the equality constraints.

Based on these relationships, the operating condition of the dc system can be described by the vector,

$$X_d = [V_d, I_d, a, \cos\alpha, \varphi]^t \tag{15}$$

The dc currents and voltages are related by the dc network equations. As in the ac case, a reference bus is specified for each separate dc system; usually the bus of the voltage controlling dc terminal operating under constant voltage (or constant angle) control is chosen as the reference bus for that dc network equation.

Here (1) – (3) are an OPF problem for the demand (P, Q). There are many efficient approaches which can be used to get an optimal solution such as linear programming, Newton method, quadratic programming, nonlinear programming, interior point method, artificial intelligence (i.e. artificial neural network, fuzzy logic, genetic algorithm, evolutionary programming, ant colony optimization and particle swarm optimization etc.)

methods [26, 28].

III. III. GENETIC ALGORITHM IN OPTIMAL POWER FLOW PROBLEM

3.1 Genetic Algorithms

GAs operates on a population of candidate solutions encoded to finite bit string called chromosome. To attain optimality, each chromosome exchanges the information using operators borrowed from natural genetics to produce the better solution. GAs differs from other optimization and search procedures in four ways [24]: firstly, it works with a coding of the parameter set, not the parameters themselves. Therefore, GAs can easily handle integer or discrete variables. Secondly, it searches within a population of points, not a single point. Therefore, GAs can provide a globally optimal solution. Thirdly, GAs use only objective function information, not derivatives or another auxiliary knowledge. Therefore, it can deal with the non-smooth, non-continuous and non-differentiable functions that exist in a practical optimization problem. Finally, GAs use probabilistic transition rules, not deterministic rules, Although GAs seem to be a good method to solve optimization problems, sometimes the solution obtained from GAs is only a near global optimum solution.

3.2 GA applied to Optimal Power Flow

A simple Genetic Algorithm is an iterative procedure, which maintains a constant size population of candidate solutions. During each iteration step, (generation) three genetic operators (reproduction, crossover, and mutation) are performing to generate new populations (offspring), and the chromosomes of the new populations have evaluated via the value of the fitness, which is related to cost function. Based on these genetic operators and the evaluations, the better new populations of candidate solution are formed. If the search goal has not been achieved, again GA creates offspring strings through above three operators and the process is continued until the search goal is achieved. This paper now describes the details in employing the simple GA to solve the optimal power flow problem.

3.2.1 Coding and Decoding of Chromosome

GAs performs with a population of binary string instead the parameters themselves. This study used binary coding. Here the active generation power set of n-bus system (PG_1, PG_2, PG_3, ….PG_n) would be coded as binary string (0 and 1) with length L_1, L_2, ……,L_n. Each parameter PGi has upper bound $b_i(p_{G_i}^{\max})$ and lower bound $a_i(p_{G_i}^{\min})$. The choice of L_1, L_2, ……, Ln for the parameters is concerned with the resolution specified by the designer in the search space. In this method, the bit length B_i and the corresponding resolution R_i is associated by,

$$R_i = \frac{b_i - a_i}{2^{Li} - 1} \tag{16}$$

This transforms the PG_i set into a binary string called *chromosome* with length ΣL_i and then the search space has to be explored. The first step of any GA is to generate the initial population. A binary string of length L is associated to each member (individual) of the population. This string usually represents a solution of the problem. A sampling of this initial population creates an intermediate population.

3.2.2 Genetic Operator: Crossover

It is the primary genetic operator, which explores new regions in the search space. Crossover is responsible for the structure recombination (information exchange between mating chromosomes) and the convergence speed of the GA and is usually applied with high probability (0.5 – 0.9). The chromosomes of the two parents selected have combined to form new chromosomes that inherit segments of information stored in parent chromosomes. The strings to be crossed have been selected according to their scores using the roulette wheel [24]. Thus, the strings with larger scores have more chances to be mixed with other strings because all the copies in the roulette have the same probability to select. Many crossover schemes, such as single point, multipoint, or uniform crossover have been proposed in the literature. A single point crossover [1] has been used in our study.

3.2.3 Genetic Operator: Mutation

Mutation is used both to avoid premature convergence of the population (which may cause convergence to a local, rather than global, optimum) and to fine-tune the solutions. The mutation operator has defined by a random bit value change in a chosen string with a low probability of such change. In this study, the mutation operator has been applied with a relatively small probability (0.0001-0.001) to every bit of the chromosome. A sample mutation process has shown as below.

$$\underbrace{0110}_{P_{G1}}\ \underbrace{0101}_{P_{G2}}\ \underbrace{0110}_{P_{G3}}\ \underbrace{0100}_{P_{G4}}\ \underbrace{1100}_{P_{G5}}\ \underbrace{0011}_{P_{G6}}\ \underbrace{1110}_{P_{G7}} \quad \overrightarrow{After\ mutation}$$

$$\underbrace{0110}_{P_{G1}}\ \underbrace{0101}_{P_{G2}}\ \underbrace{0110}_{P_{G3}}\ \underbrace{0100}_{P_{G4}}\ \underbrace{1110}_{P_{G5}}\ \underbrace{0011}_{P_{G6}}\ \underbrace{1110}_{P_{G7}}$$

3.2.4 Genetic Operator: Reproduction

Reproduction is based on the principle of survival of the fittest. It is an operator that obtains a fixed number of copies of solutions according to their fitness value. If the score increases, then the number of copies increases too. A score value is associated with a given solution according to its distance from the optimal solution (closer distances to the optimal solution mean higher scores).

3.2.5 Fitness of Candidate Solutions and Cost Function

The cost function has defined as:

$$f = \sum_{i=1}^{NG} a_i P_{Gi}^2 + b_i P_{Gi} + c_i ; \quad P_{Gi}^{\min} \le P_{Gi} \le P_{Gi}^{\max} \tag{18}$$

To minimize F(x) is equivalent to getting a maximum fitness value in the searching process. A chromosome that has lower cost function should be assigned a larger fitness value. The objective of OPF has to be changed to the maximization of fitness to be used in the simulated roulette wheel. The fitness function is used [3] as follows:

$$FitnessFunction(FF) = \frac{C}{\sum_{i=1}^{NG} F_i(P_{Gi}) + \sum_{i=1}^{Nc} w_j * Penalty_j} \tag{19}$$

$$Penalty_j = h_j(x,t)|.H(h_j(x,t)) \tag{20}$$

Where C is the constant; $F_i(P_{Gi})$ is cost characteristics of the generator i; w_j is weighting factor of equality and inequality constraints j; $Penalty_j$ is the penalty function for equality and inequality constraints j; $h_j(x,t)$ is the violation of the equality and inequality constraints if positive; H (.) is the Heaviside (step) function; N_c is the number of equality and inequality constraints.

The fitness function has been programmed in Matlab in such a way that it should firstly satisfy all inequality constraints by heavily penalizing if they have been violated. Then the equality constraints are satisfied by less heavily penalizing for any violation. Here this penalty weight is not the price of power. Instead, the weight is a coefficient set large enough to prevent the algorithm from converging to an illegal solution. Then the GA tries to generate better offspring to improve the fitness. Using these components, a standard GA procedure for solving the OPF problem is shown in Fig.1.

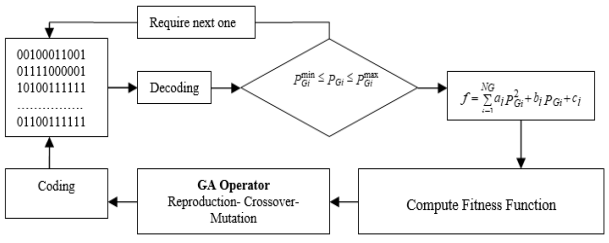

Fig.1: Flowchart of a Simple Genetic Algorithm for OPF

IV. IV. EXAMPLE, SIMULATION AND RESULTS

4.1 IEEE-6 Bus System

The performance of the proposed methodology has been assessed through the results obtained for IEEE-6 Bus system (Fig. 2) with 7 circuits and 2 generators. A dc link has been connected between bus 1 and bus 5. The ratings of the converter at buses 1 and 5 were 1.0 p.u. The voltage values for all buses are bounded between 0.95 and 1.05. The fuel cost function for generators is expressed as ($f_i = a_i P_{Gi}^2 + b_i P_{Gi} + c_i$) in ($/MWh) and demand at various buses are as shown in table A2. All the values have indicated in Per Unit (PU). The results obtained for best and worst GAOPF solution and that for traditional OPF have been shown in Table 1.

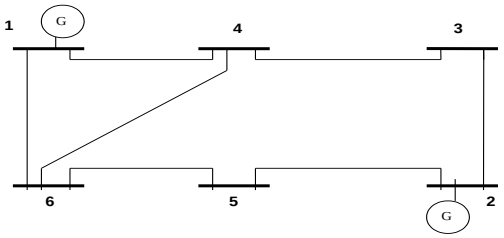

Fig.2: One line diagram of IEEE-6Bus System

Table 1: GAOPF results and Comparison with Traditional OPF Method

Bus No.	GAOPF						Newton Method		
	Best Solution			Worst Solution					
	Voltage (PU)	P (PU)	Cost ($/MWh)	Voltage (PU)	P (PU)	Cost ($/MWh)	Voltage (PU)	P (PU)	Cost ($/MWh)
1	0.99	0.14	26.67	0.97	0.7	138.09	1.00	0.16	25.73
2	1.02	0.03	5.64	0.97	0.3	47.70	0.95	0.04	6.58
3	1.00			1.04			0.96		

4	1.01			0.96			1.05		
5	0.97			1.03			1.02		
6	0.99			1.03			1.04		
Total		**0.17**	**32.31**		**1.0**	**185.79**		**0.20**	**33.83**

The best GAOPF solution gives the improved bus voltage profile and lower total cost of generation as compared to traditional i.e Newton's OPF method.

4.2 IEEE-14 Bus System

The performance of the proposed methodology has been assessed through the results obtained with the well-known IEEE-14 Bus (Fig.3) with 18 circuits and 4 generators. The generator and circuit data have been given in Appendix-B. A dc link is connected between bus 1 and bus 14. The ratings of the converter at buses 1 and 14 were 1.0 p.u. The voltage values for all buses have been bounded between 0.95 and 1.05. All the values have been indicated by p.u. The results obtained with given methodology are shown in Table 2.

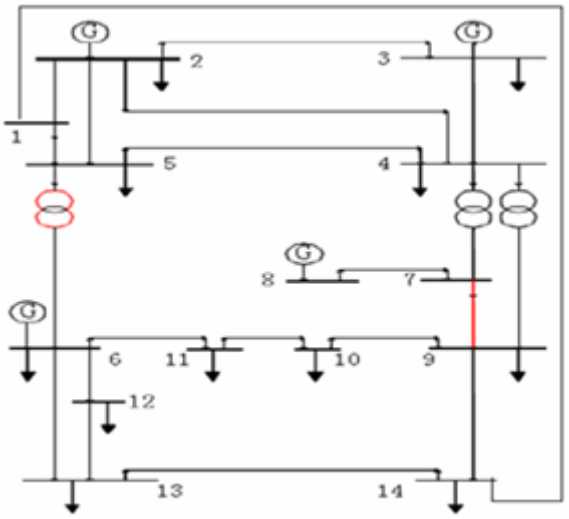

Fig. 3: One Line diagram of IEEE-14 Bus System

Table 2: GAOPF results and Comparison with Traditional OPF Method

Bus No.	**GAOPF**						**Newton Method**		
	Best Solution			**Worst Solution**					
	Voltage (PU)	**P (PU)**	**Cost ($/MWh)**	**Voltage (PU)**	**P (PU)**	**Cost ($/MWh)**	**Voltage (PU)**	**P (PU)**	**Cost ($/MWh)**
1	0.98			1.02			0.99		
2	0.99	0.70	68.47	1.00	0.92	120.01	0.98	0.86	90.94
3	1.01	0.75	60.34	0.97	0.92	180.20	0.97	0.72	90.46
4	0.96			0.96			0.96		
5	0.97			0.99			0.96		
6	0.99	0.55	102.6	0.99	0.87	85.51	1.02	0.66	89.87
7	1.02			0.98			0.97		
8	0.99	0.70	118.6	1.01	0.75	120.91	1.02	0.64	88.40
9	0.98			0.98			0.95		
10	0.97			0.95			0.96		
11	1.01			1.01			0.99		

12	0.98			0.95			1.00		
13	1.03			0.99			0.99		
14	0.97			1.02			0.95		
Total		**2.70**	**350.01**		**3.46**	**506.63**		**2.88**	**359.67**

The voltage at several buses obtained by GAOPF best solution has shown improvement as compared to the Newton method. In addition, total cost of generation obtained by GAOPF best solution is low.

4.3 IEEE-30 Bus System

This system consists of 6 generators and 43 transmission lines as shown in Fig. 4. A dc link connected between bus 1 and bus 28. The ratings of the converter at buses 1 and 28 were 1.0 p.u. The upper and lower bounds (reactive power) for all generators are $-0.4 \le Q_{Gi} \le 0.4$. The voltage values for all buses have bounded between 0.95 and 1.05. The fuel cost function for generators is expressed as $(f_i = a_i P_{Gi}^2 + b_i P_{Gi} + c_i)$ in ($/MWh). For this system there are 2 × 24 equality constraints of S corresponding with their respective real and reactive power balances of the buses without a generator, and about 72 inequality constraints of T corresponding to 30 pairs of voltage, 2 × 6 pairs of generation output and one pair of line flow upper and lower bounds respectively. Table 3 indicates the results for GAOPF best and worst solutions and for Newton method.

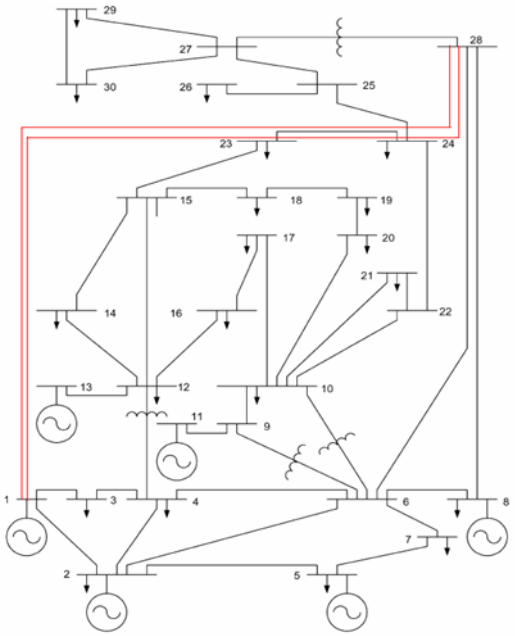

Fig. 4: One line diagram of modified IEEE-30 Bus system.

Table 3: GAOPF results and Comparison with Traditional OPF Method

Bus No.	GAOPF						Newton Method		
	Best Solution			Worst Solution					
	Voltage (PU)	P (PU)	Cost ($/MWh)	Voltage (PU)	P (PU)	Cost ($/MWh)	Voltage (PU)	P (PU)	Cost ($/MWh)
1	1.00	0.35	9.77	0.99	1.67	30.40	1.00	0.37	10.55

16	0.98			0.97			1.00		
17	0.99			0.96			1.00		
18	0.99			1.01			0.99		

19	1.01			0.98			0.99		
20	0.97			1.01			1.03		
21	0.98			0.97			0.99		
22	0.99			0.99			0.98		
23	0.99			1.01			0.99		
24	1.01			1.01			1.02		
25	0.98			0.97			1.03		
26	0.99			1.01			1.02		
27	0.98			0.97			1.05		
28	0.99			0.95			0.99		
29	1.01			0.98			1.05		
30	0.99			0.98.			1.05		
Total		**1.23**	**48.54**		**5.8**	**122.88**		**1.23**	**49.30**

Results indicates that the voltage profile at few buses have improved for best GAOPF solution as compared to Newton's OPF method. In addition, total cost of generation by best GAOPF is marginally low as compared to Newton's OPF method.

V. V. PERFORMANCE EVALUATION

The performance evaluation of AC-DC based GAOPF and traditional OPF method has been tested with reference to parameters given in Table 4 and in Table 5. Newton's method takes less iterations to perform the OPF for the test system and real network mentioned in Table 4. The program execution time depends on the equality and inequality constraints handled by the methodology. The advantage of Newton's method is that the OPF results are obtained in one run only. The performance parameters for GA based AC-DC OPF for various test system and real networks are shown in Table 5. However, program execution time varies from smaller system to larger system and it depends on the number of iterations assigned initially to obtain the best OPF results.

Table 4: Newton's Parameters/performance for Best Optimal Power Flow

SN	Parameters	IEEE-6 Bus System	IEEE-14 Bus System	IEEE-30 Bus System
1	No. of iterations	9	43	58
2	Execution Time (sec.)	8 sec.	20 sec.	40 sec.
3	No. of Runs	1	1	1

Table 5: GA Parameters/performance for Best Optimal Power Flow

SN	Parameters	IEEE-6 Bus System	IEEE-14 Bus System	IEEE-30 Bus System
1	Initial Population	210	210	520
2	No. of iterations	80	120	150
3	Probability of crossover	0.5	0.5	0.5-0.9
4	Probability of mutation	0.001	0.001	0.0001-0.001
5	Execution Time (Sec.)	90	120	825
6	No. of Runs (for best Soln.)	4	15	19

VI. VI. CONCLUSION

Recently, many developing and transition countries are facing the problems of transmission and distribution infrastructure due to inadequate investments incurred in the past. To reduce the gap between transmission capacity and power demand, trend is to adopt HVDC transmission system in the existing AC networks to gain techno-economical advantages of the investment.

This study proposes an AC-DC based GA optimal power flow solution which may be applied to different size power systems. This method also employs its techno-commercial advantage over the traditional method of optimal power flow. The GAOPF method avoids early load flow as reported in other published literatures. Finally, the result obtained by this scheme is quite comparable with the traditional OPF methodology.

rishikeshnaware7@gmail.com, manassingh300@gmail.com, amaan.faruk@gmail.com, kasturepranjali@gmail.com

Abstract – **The stock market is seeing elevated activities and is progressively acquiring significance over the population. In the ongoing setting of globalization and the ensuing coordination of the worldwide markets, this paper catches similarities, patterns in the activities and the impact of US stock markets on the Indian Stock Market. Five years of data from 2015 to 2019 of National Association of Securities Dealers Automated Quotations (NASDAQ), National stock exchange FIFTY (NIFTY) was taken into consideration for analysis. In this work, an attempt is made to predict the development of the stock market. Different algorithms were used to check which one gives the most accurate prediction results. Machine Learning algorithms such as Decision tree and Random Forest are used and the results of both were compared.**

Keywords: Stock Market, Comparative Analysis, Statistical analysis, Efficiency Test.

I. INTRODUCTION

Stock market price data is generated in huge volume, and it changes every second. Stock market is a complex and challenging system where people will either gain money or lose their entire life savings. In this work, an attempt is made for prediction of stock market trends. Supervised machine learning algorithms are used to build the models. Financial decisions to buy or sell an instrument may be made by the traders by choosing the effective predictive model. Successful prediction of Stock Market Index movements may be beneficial for investors. As part of the daily prediction model, historical prices are combined with sentiments. Up to 70% of accuracy is observed using supervised machine learning algorithms on daily prediction models. Monthly prediction model tries to evaluate whether there is any similarity between any two months' trend. Evaluation proves that the trend of one month is least correlated with the trend of another month. Various factors affect stock market prices, here, an effort is made to analyze how US stock markets and their changes can and possibly do affect the Indian Stock Market. Different Machine Learning algorithms are used to get an idea about not only the factors affecting the stock market, but also which algorithm gives better and more accurate results.

daily data from the Dow Jones from 1 October 1928 to

31 January 2009, and daily data from the SENSEX during 1st July 1997 to 31st January 2009 to investigate the relationship between USA and Indian stock markets. To determine the relevant Hurst exponents, the Finite Variance Scaling Method, a type of scaling, is used to

II. II.LITERATURE SURVEY

AVINASH POKHRIYAL et al [1] proposed a method wherein the Multiple Linear Regression and neural networks is carried out to the investor's economic choice making to make investments all type of stocks no matter the high / low index of the scripts, in a continuous time framework. The proposed framework has been examined with stock information received from the Asian Stock Market Database. Finally, the design, implementation and overall performance of the proposed multiple regression and neural network model are described. technique offers two key explanatory variables for bank performance and clearly and simply illustrates the impact of the contributing components. The approach has several drawbacks because its fundamental assumptions are always broken when real data is involved. Biased results are also produced by outliers. Data transformation, robust regression and ridge regression is one of the corrective actions to be implemented. This calls for the necessity of comprehending more statistical methods, which was outside the purview of this work. An artificial neural network uses inputs to produce results that are extremely accurate. The method increases its performance with many examples.

K.J SANDEEP et al [2] made a correlation analysis which focused on for very short term period that is from

10th November to 20th November of 2014, the variables of Asian and European countries were extracted by Indian opening time 9:15 from Asian countries previous day closing prices, European countries were opening

12:30 to 12:40. Estimates indicated that Japan, Singapore, European markets were impacting nifty, partial correlation indicated that all the countries that were selected had slightly to strong correlation. This investigation showed that the Singapore and Nifty are significantly influencing the Nifty opening. European

markets were having an impact on nifty movement

during the afternoon hours period. The volatility of the Indian market is also influenced by openings of selected Asian European markets on nifty.

K. MOFAZZAL HOSSAIN et al [3] presented a study which wherein they examined daily data from the NASDAQ from 5 February 1971 to 31 January 2009 process these three-time series. According to the study, all three series display anti-persistent behavior (short-memory process). It is interesting to note that the related Hurst exponent values do not considerably differ from one another.

RAJIV KUMAR et al [4] suggest that India's financial area isn't profoundly coordinated with the worldwide financial framework, which saved it from the main round not favorable impacts of the worldwide financial crisis

and left Indian banks generally unaffected. In any case, as the financial crisis transformed into an all-out worldwide economic slump, India couldn't get away from the subsequent round impacts. The worldwide crisis has impacted India through three channels: financial markets, exchange streams, and trade rates. The inversion in capital inflows, which made a credit smash in homegrown markets alongside a serious disintegration in trade interest, added to the downfall of GDP by multiple rates in the fiscal year 2008-2009. In accordance with endeavors taken by governments and national banks from one side of the planet to the other, the public authority and the Reserve Bank of India went to forceful countercyclical lengths, strongly loosening up financial strategy and acquainting a fiscal improvement with support homegrown interest.

JANAK RAJ et al [5] provides and acknowledges the national stock markets have arisen as the significant channel for financial integration of developing business sector economies during globalization, liberation, and advances in information technology. Among the elements adding to developing financial integration are a fast expansion in the crossline versatility of private capital inflows because of investors looking for portfolio enhancement and improved yields, a developing dependence of countries on the reserve funds of different countries, and a change in the influence of organizations from debt-to-equity finance. It is by and large apparent that financial integration can be related with a few advantages, including improvement of markets and organizations and powerful cost disclosure, prompting higher reserve funds, speculation, and economic advancement.

CHARLES K. AYO et al [6] stock price prediction is an important topic in finance and economics which has spurred the interest of researchers over the years to develop better predictive models. The autoregressive integrated moving average (ARIMA) models have been explored in literature for time series prediction. This paper presents an extensive process of building stock price predictive models using the ARIMA model.

YAZEED ALSUBAIE et al [7] study shows that stock market forecasting using technical pointers (TIs) is universally applied by investors and researchers. Utilizing an insignificant number of info highlights is essential for fruitful prediction. Be that as it may, there is no agreement about what comprises a reasonable assortment of TIs. The selection of TIs reasonable for a given forecasting model remains part of an area of dynamic research. This study presents a point-by-point examination of the choice of a negligible number of pertinent TIs determined to increment precision, diminishing misclassification cost, and further developing venture return. Fifty universally used TIs were positioned utilizing five different element determination methods. Tests were led utilizing nine classifiers, with a few element choice methods and different options for the quantity of TIs. A proposed cost-touchy calibrated naïve Bayes classifier figured out how to accomplish preferable in general venture execution over different classifiers. Tests were directed on datasets consisting of everyday time series of 99 stocks and the TASI market record.

TROY J. STRADER et al [8] proposed a systematic literature review methodology to identify applicable peer-reviewed journal articles from the past twenty years and bundle studies containing similar methods and contexts. Four categories that emerged were: artificial neural network studies, support vector machine studies, studies using genetic algorithms combined with other techniques, and studies using hybrid or other artificial intelligence approaches. Results showed that Artificial neural networks are best suited for predicting numerical stock market index values. Support vector machines are more suited for predicting whether the forecast is to rise or fall. Financial funding concept desires to be a stronger driving force underlying the ML structures' inputs, algorithms, and performance measures.

POLAMURI SUBBA RAO et al [9] studies different prediction techniques and their advantages when it comes to the stock market. The two general methods for stock prediction: Fundamental Analysis and Technical Analysis are studied, and technical analysis is preferred over fundamental analysis. Different prediction techniques included: Holt-Winters, Artificial Neural Network, Hidden Markov

Model, ARIMA Model, Time Series Linear Model, Recurrent Neural Networks. They concluded that to improve the prediction of the results of stock, combining two or more methods to construct a novel approach method would be efficient

ERNEST KWAME AMPOMAH et al [10] proposes the ability of Gaussian Naïve Bayes ML algorithm to predict stock price movement. It has not been explored properly in the existing literature, Thus, the performance of GNB algorithm when combined with different feature scaling and feature extraction techniques, evaluated using F1-Score, specificity and AUC evaluation metrics showed that using scaling techniques alongside GNB provided much better results than the ones produced on combining either feature scaling technique or GNB algorithm and feature extraction technique except for GNB_LDA.

MEHTABHORN OBTHONG et al [11] illustrates that while many stocks are traded on a stock exchange, different factors influence the decision-making. Moreover, the behavior of stock prices is very difficult and challenging to predict. In addition to historical prices, other factors could also affect stock prices such as politics, economic growth, finance-related news, and social media.

SAMPAT PATIL et al [12] in this study used data from global financial markets with machine learning algorithms to predict stock movements. SVM is used primarily in this study as it does not have the problem of overfitting and works well with large data. Correlation analysis proves strong relations between the Market index and global markets that close before or at the very beginning of the trading cycle. The model also had high profits on some benchmarks.

ARGYRIOS KETSETIS et at [13] states the SLR made obvious that the research community clearly preferred

LSTMs over alternative DL techniques, following the lead of studies in other markets. As just two of the publications used text mining for data extraction, it is also crucial to note that the European stock market- related papers have not widely used text mining techniques from diverse sources to apply sentiment analysis to the forecasts. In these papers, the training and testing times range from 3 months to 26 years. The difference in data frequency employed in those articles can be used to explain the discrepancy in the duration of time.

III. PROPOSED WORK

The Indian stock market holds a crucial value in the world's economy. Integration and influence of global markets on Indian markets need to be studied for investors to get a better understanding and for their benefits.

In Order to analyze the variation in the Indian markets, the goal of this paper is to identify the trends of the global markets and how it affects the Indian economy.

A. Objective

1. To identify impact of US economy on Indian Market
2. To compare different models under Machine Learning.

The historical data of Nasdaq and Nifty Index was downloaded from the website "yahoofianance.com" which is openly accessible, in CSV (Comma Separated Value) format. The available attributes in the historical data were S.No, Open, High, Low, Close and Date. S.No and Date attributes were skipped as these attributes are not important for prediction. As shown in the Open, High, and Low attributes are selected as features and Close attribute is selected as target because it is to be predicted.

To detect outliers in the dataset, box plots for both the datasets were visualized and are shown in 'Fig 1.' and 'Fig 2.' respectively.

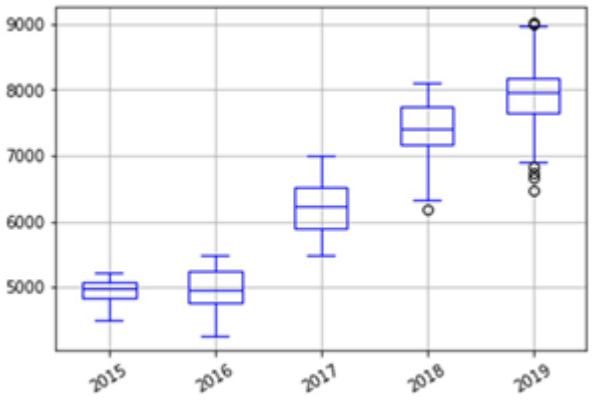

Fig. 1. Box plot for NASDAQ

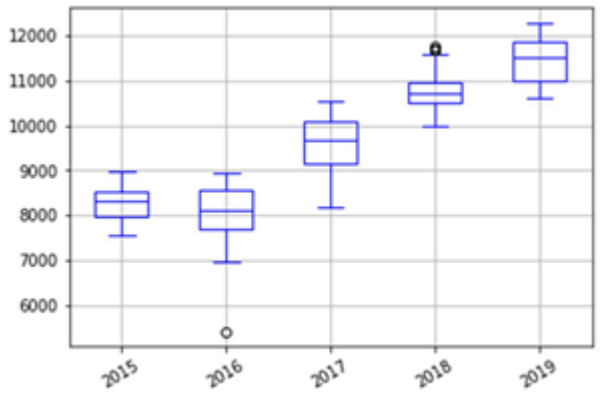

Fig. 2. Box plot for NIFTY

The research data used in this study is the direction of daily closing price movement in the Nifty and NASDAQ Index. The entire data set covers the period from January 1, 2015, to December 30, 2019.

Feature extraction is very important as wrong selection of features can result in wrong predictions.

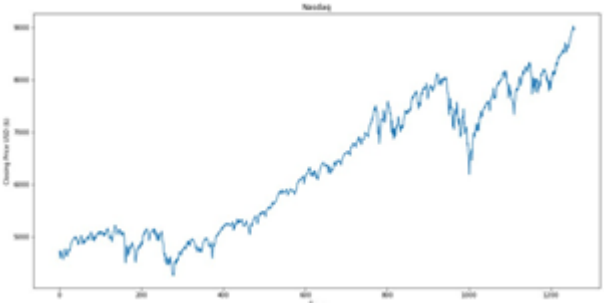

Fig. 3. Graph of Closing Price of Nasdaq

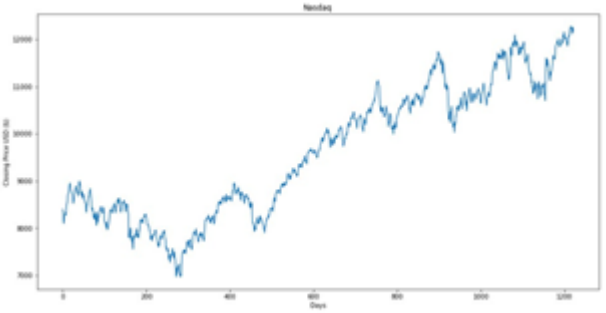

Fig. 4. Graph of Closing Price of Nifty

The above figure shows the graph of the Closing column of Nifty and Nasdaq's data . The closing price is also plotted to get an overview about how the trend is throughout the years.

Table 1. NIFTY and NASDAQ Error validation.

Stock	Error Validation

Nasdaq	Training R-squared: 1.0 Training Explained Variation: 1.0 Training MAPE: 0.72 Training Mean Squared Error: 3979.81 Training RMSE: 63.09 Training MAE: 43.53 Validation R-squared: 0.89 Validation Explained Variation: 0.89 Validation MAPE: 0.77 Validation Mean Squared Error: 3979.81
Nifty	Training R-squared: 1.0 Training Explained Variation: 1.0 Training MAPE: 0.63 Training Mean Squared Error: 5981.98 Training RMSE: 77.34 Training MAE: 58.38 Validation R-squared: 0.92 Validation Explained Variation: 0.92 Validation MAPE: 0.72 Validation Mean Squared Error: 5981.98

B. Methodology

Under machine learning, two models were implemented i.e., Decision tree and Linear Regression.

The Linear Regression model was used for the dataset in the early phase as it is a useful measure for technical and quantitative analysis in global markets. It analyzes two separate variables in order to define a single relationship. Plotting stock prices along a normal distribution—bell curve—can allow traders to see when a stock is overbought or oversold. For this model, 88% of data was selected for training,10% of data for validation and the remaining 2% for testing.

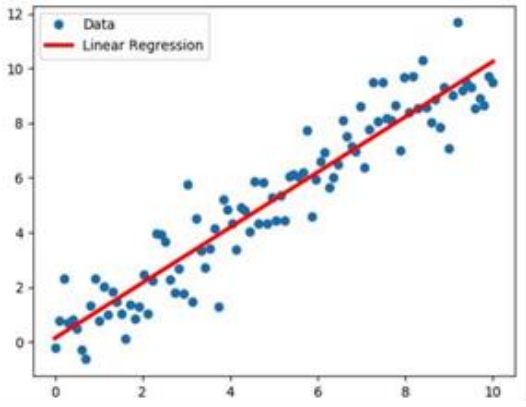

Fig. 5. Diagram of Linear Regression

Decision trees are important tools that work based on flowchart-like structures that are mostly used. Each interior node of the decision tree specifies a condition or "test". Attributes and branches are based on test conditions and results

Finally, a leaf knot has a class label which is obtained after calculating all attributes. distance from root to leaf represents a classification rule. The amazing thing is that it can work with categories and subordinate's variables. They are excellent at identifying the most important variables and show the relationships between variables very well. It is important for creating new variables and functions. It is useful for data exploration and predicts target variables efficiently.

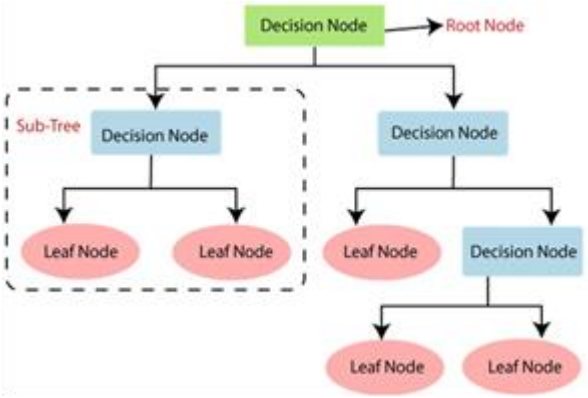

Fig. 6. Diagram of Decision Tree

IV. RESULTS

The below figure represents the difference and variation in stocks between Nifty and Nasdaq for the time period of 2015 to 2019. The trends and fluctuation can be seen from the graph and helps get a better understanding of how Nifty's stock rises and falls in comparison to Nasdaq's. Prediction done below is done using Linear Regression.

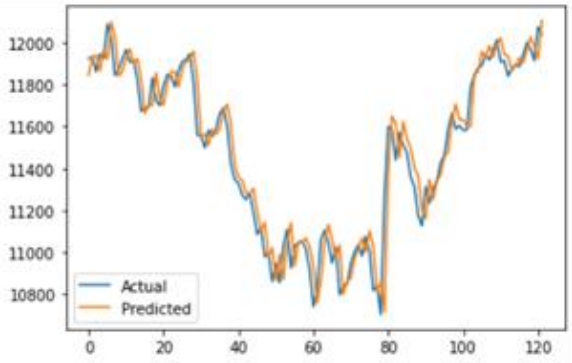

Fig. 7. LR for NIFTY

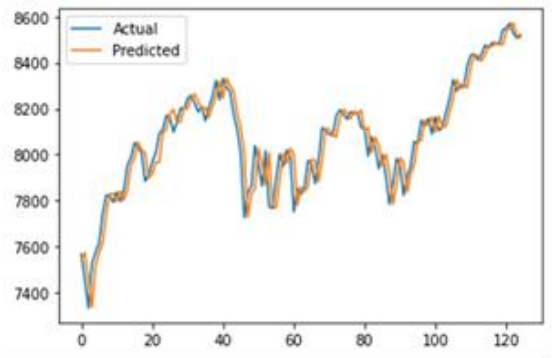

Fig. 8. LR for NASDAQ

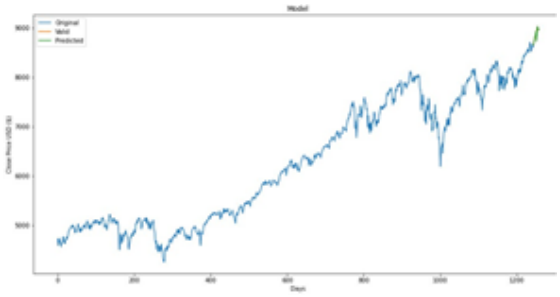

Fig. 9. Prediction Graph for Nasdaq (Decision Tree)

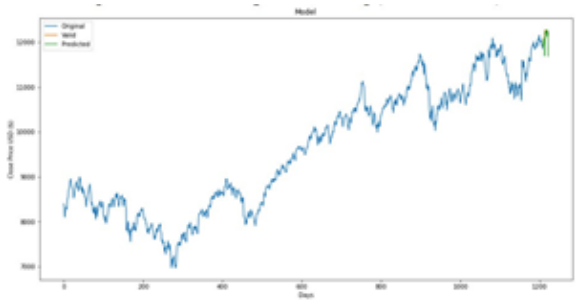

Fig. 10. Prediction Graph for Nifty (Decision Tree)

The above figure represents the predicted value of stocks for a month. The predicted trend is represented in green while the original data set is represented in blue. Prediction is done using Decision tree algorithm.

Table 1. NASDAQ predicted values (May-June 2019).

Index	Actual	Predicted LR	Predicted DT
0	7567.72	7545.31	7520.84
1	7453.14	7572.68	7439.65
2	7333.02	7454.75	7395.71
3	7527.12	7337.67	7512.63
4	7575.47	7515.42	7480.72
5	7615.54	7574.34	7609.19
6	7742.10	7614.47	7666.80
7	7823.16	7739.76	7808.75
8	7822.56	7828.70	7849.27
9	7792.72	7831.60	7707.50
10	7837.12	7796.64	7795.81

Table 2. NIFTY predicted values (May -June 2019).

Index	Actual	Predicted	Predicted DT
0	11924.75	11845.33	11898.67
1	11928.75	11934.65	11921.07
2	11861.09	11939.06	11870.71
3	11945.90	11864.65	11909.07
4	11922.79	11966.46	11939.41
5	12088.54	11920.13	11971.06
6	12021.65	12098.29	12084.84
7	11843.75	12028.47	11913.95
8	11870.65	11839.14	11845.03
9	11922.70	11863.44	11955.89
10	11965.59	11924.97	11970.16

V. CONCLUSION

Prediction of the movements of the stock market index is very important for developing effective market trading strategies. This empirical study attempted to predict the direction of the various stocks and identify the trends and patterns associated with them. The task of predicting the movements of the Stock Market Index is highly complicated and very difficult. This empirical study attempted to predict the direction of the Nasdaq stock. This empirical study used around 5 years of historical data, which is good for machine learning because in such a long period many bull and bear phases of stock market were included.

After all the inclusions of results, applied Machine Learning algorithms. We conclude that Decision Tree and Random Forest Regressor are the best regression algorithms after comparing the results. It is concluded that the Global market affects the Indian markets in a huge way. The algorithms and systems which are traditional systems may not efficiently solve problems associated with this huge amount of data and may lead to the systems running very slowly and cannot yield the best and accurate result of prediction. But with the help of the Python environment, we can handle large data very efficiently without alternating the methods in the existing procedures.

VI. FUTURE WORK

Future work can be proceeded using deep learning algorithms like RNN, LSTM as further implementation of this work to check with comparative analysis of machine learning vs deep learning techniques.

bkrutish@gmail.com, praveerdwivedi@gmail.com, rahul.khokale@thakureducation.org, sourabhjamdar1@gmail.com

Abstract—**In this coming age of Artificial Intelligence and Machine Learning (AI & ML), automation along with safety is the top priority and a major concern to the people. We need accurate signs and symbols for maximum safety on roads which can be achieved with the power of machine learning and computational intelligence. Sometimes these symbols or signals are broken and unrecognizable. These signs need to be maintained for the safety of the mass. We have compared two approaches and tested two models that classify signs and detect broken signs that need maintenance. The model is trained on a dataset which consists of cropped images of the traffic signs for model training and testing. A Convolutional Neural Network (CNN) is used for classification and it is successful in determining whether traffic signs need maintenance or not. Between the compared approaches, the approach of only two classes of damaged and undamaged signs displayed worse results compared to the approach of having one broken sign class among multiple classes of different unbroken signs. Any car with a dashcam and this system can pick up on a broken**

system automates the recognition of broken traffic signs for maintenance. This eliminates the need for an additional manual workforce and minimizes sign breakdown time for safer roads.

Keywords—Traffic, sign, recognition, maintenance, broken, dash-cam.

I. INTRODUCTION

A. Motivation

In today's day and age where vehicles on the road are increasing tremendously in number and are getting faster and more dangerous, road safety has become a genuine issue. Even though traffic rules are made strict and people are taking traffic signals more seriously than ever, traffic signs are a different case. Many times these traffic signs are not followed because of several reasons, one of which is that they are not visible to the vehicle driver itself. These traffic signs are not properly maintained or are vandalized by the local people by sticking advertisements or are made unrecognizable through other means such as paint sprays or spit. Traffic signs themselves also get old or rusted with time or their paint fades away which makes them unreadable. In some rare cases, the traffic sign is completely or partially broken. All these traffic signs require maintenance and we must make the concerned authorities aware of such issues.

To address this issue we have proposed and tested a Machine Learning (ML) model using Convolutional Neural Network (CNN) to recognize and identify broken traffic signs. Our proposed system captures live video from the dashcam of the vehicle and classifies the detected signs if they need maintenance/broken or not. If such a sign is identified, an email with the location and image of the sign will be sent to the concerned authorities so that they can take the appropriate actions at the earliest. The main objective of this research is to automate the maintenance of traffic signs which are many times not taken seriously and ignored, even though they are very essential for the safety of people on the road, drivers and vehicles.

B. Difficulties

- No Dataset is available for damaged signs: One of the biggest difficulties was finding a proper database for the research and model creation. Even after several hours of browsing the internet in search of a database, it was not found. This proved that there was no database or a dataset available of

this research. The absence of an online database meant that we had to create our database for broken signs. This included going out in the world in search of such signs which is a time-consuming and thus an infeasible process. The other option was gathering images from the World Wide Web (WWW). The main problem with gathering images from the internet was that the internet was confusing traffic signs with traffic lights. It also mostly displayed fallen traffic signs where the pole of the sign is broken rather than the actual sign itself.

- Simulate damaged signs: Since no data were available on the internet and finding images on the internet as well as out in the real world was infeasible, we had to create our database by simulating damaged traffic signs. We achieved this with the help of image editing software and some smart editing to simulate broken traffic signs without them looking fake and inconsistent with real-world situations. Even though this was a tedious and time-consuming task, it was the only way to obtain the data which we were looking for to conduct this research. It is possible to improve this study further in future when a proper database is available with multiple classes and various other real-world scenarios and parameters.

- Limited data to work with: As the database was created by editing images by us, the data itself in each class was limited in number. Normally Machine Learning model datasets have thousands of items in each class. This was not possible in this study as editing so many images while maintaining their size within a limit was impossible keeping time constraints in mind. A low volume of data causes a loss of accuracy in Machine Learning models. Having a proper database is a critical part of conducting such studies.

II. EXISTING SYSTEMS

III. PROPOSED SYSTEM

The proposed system takes advantage of CNN to classify damaged signs from undamaged signs on roads for their maintenance. We have tested two approaches to compare which model performs better at distinguishing

faulty traffic signs from operational ones. To compare both approaches, parameters were kept constant to analyze which model performed better. The dataset consists of simulated images of damaged traffic signs.

Approach 1: Two-class approach

This approach is based on Binary classification in Machine Learning. Binary classification is a supervised learning technique which works on tasks that have exactly two class labels. It is mainly used in the determination of things based on a 'YES' or a 'NO' which is very useful in our first approach for determining if the traffic sign is

'broken' or 'not broken'. To achieve this, the dataset was divided into two classes. These were based on whether the traffic signs were damaged or not. A dataset of about 65 images per class was used for training and additional images were used as the testing data.

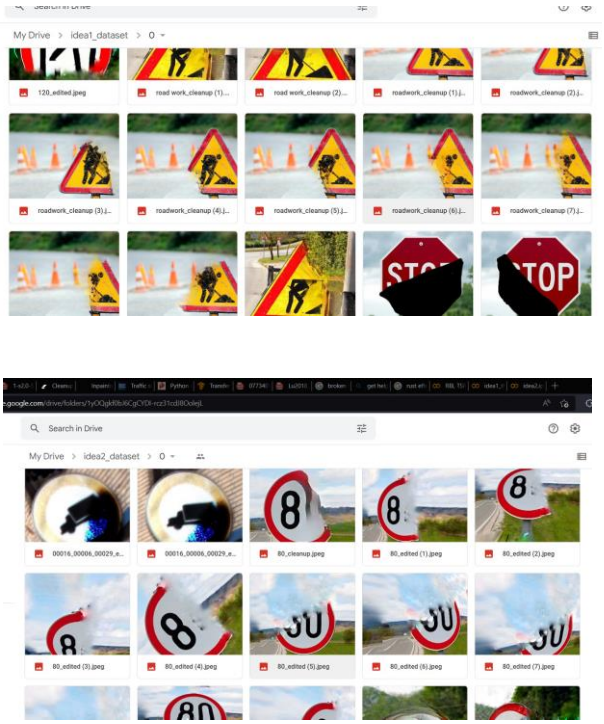

Fig. 1. Damaged Signs dataset

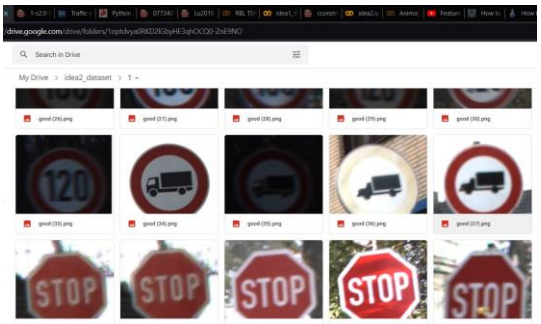

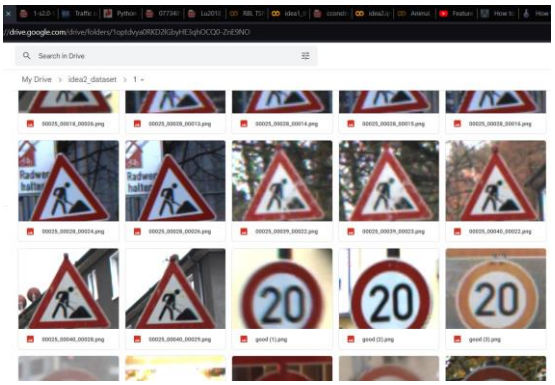

Fig. 2. Undamaged Signs dataset

Only a few sign types were chosen to be represented in both classes for the experimentation. This includes the road work sign, speed limit signs, and stop signs. All of the above-mentioned signs were present in each of the two classes in a damaged as well as an undamaged form to allow the model to learn and discern their difference with maximum accuracy.

Approach 2: Multiclass approach

The second approach is based on the multiclass classification in Machine Learning. Multiclass classification is a supervised learning technique which works on tasks that have more than two class labels. The dataset was divided into different classes based on the sign type including a

'damaged signs' class. For the purpose of this research, three types of signs were chosen: stop signs, A dataset of about 60 images per class was used for training and additional images were used as the testing data.

For the comparison of the approaches the model specifications were kept constant.

TABLE I. MODEL SUMMARY

dense_7 (Dense) (None, 43) 11051

Layer (type)	Output Shape	Param #
conv2d_12 (Conv2D)	(None, 26, 26, 32)	2432
conv2d_13 (Conv2D)	(None, 22, 22, 32)	25632
max_pooling2d_6 (MaxPooling 2D)	(None, 11, 11, 32)	0
conv2d_14 (Conv2D)	(None, 9, 9, 64)	18496
conv2d_15 (Conv2D)	(None, 7, 7, 64)	36928
max_pooling2d_7 (MaxPooling 2D)	(None, 3, 3, 64)	0
flatten_3 (Flatten)	(None, 576)	0
dense_6 (Dense)	(None, 256)	147712

We have created a model with a series of conv2d layers and max_pooling2d layer. After that, we used a flatten layer to convert the matrix into a vector. Finally, we have attached that with dense layers. At the end of the output layer, we have only one neuron responsible for

identifying whether the given image contains a broken sign or not. If not broken then its class label is displayed.

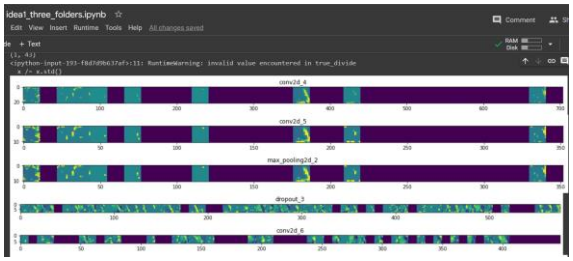

Fig. 3. Feature Maps

IV. PERFORMANCE EVALUATION AND VISUALIZATION

Approach 1: Two-class approach

This model displayed an accuracy of 66.67% on unseen data. Although this method is easy to implement and understand, it produces underwhelming results when working with real-world data. This model also required twice as much time to train when compared to the second model. This difference in train time can be significant when dealing with a huge amount of data.

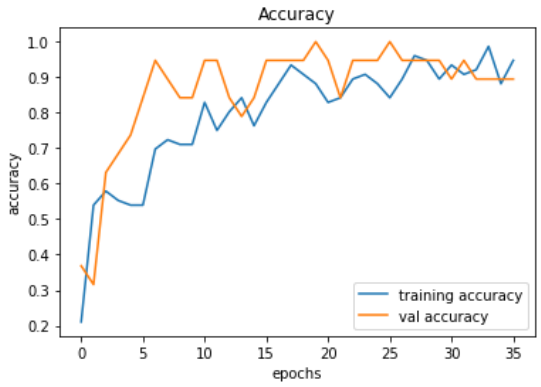

Fig. 4. Training accuracy for Approach 1 (Two class)

Approach 2: Multiclass approach

This method yielded an accuracy of 83.33% on unseen data. Although this approach performs better than the first approach, it was difficult to create an appropriate database to maximally squeeze out the model's accuracy.

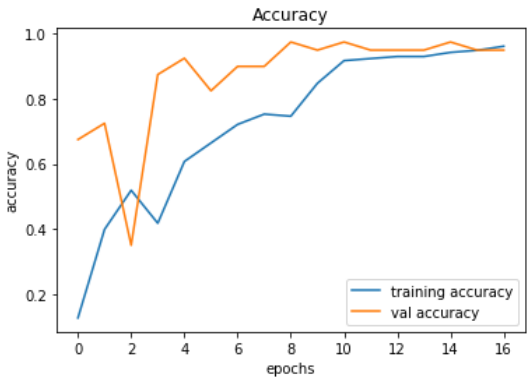

Fig. 5. Training accuracy for Approach 2 (Multiclass)

V. RESULT

The Two-class approach was considered due to the sheer simplicity of its execution with respect to dataset creation. All of the 'good' signs were dumped in the undamaged signs folder whereas all of the 'bad' or faulty signs were put in the damaged signs folder. But model testing proved that the Multi-class approach outperformed the Two-class approach. It also recognizes signs while simultaneously classifying them into damaged and undamaged signs. Hence, this approach eliminates the need of requiring a separate step of recognition as opposed to the two-class approach in which the undamaged signs would require further classification.

VI. CONCLUSION

Through rigorous testing it was concluded that the accuracy difference between the two-class and multiclass approaches was significant enough to consider using one approach over another. Even though both of the approaches have their respective pros and cons, the Multiclass approach turned out to be superior to the Two-class approach. The success of the Multiclass approach and its accuracy proves that the maintenance of traffic signs is plausible and feasible using CNN and can be implemented by the government to automate the task of maintenance of road signs cutting off the costs of manual labour to do so further improving general safety on the road.

VII. FUTURE SCOPE ACKNOWLEDGMENT

The authors would like to extend their sincere gratitude to Mr. Rahul Khokale for their invaluable support and guidance throughout the research process. This work would not have been possible without their contributions. The authors would also like to acknowledge Dr. B.K. Mishra and Thakur College of Engineering and Technology for their support.

Abstract—**This research paper presents a novel approach for scaling entity resolution (ER) frameworks using enhanced blocking techniques and machine learning. It proposes an unsupervised model for the entity resolution problem, whi ch is a common task in natural language processing and information retrieval. Entity resolution is the process of identifying entities that describe the same real -world object across many databases and merging duplicate records in large datasets. However, traditional ER methods are often slow and inefficient when dealing with big data. Our proposed approach addresses this issue by incorporating advanced blocking techniques, such as indexing and hashing, to reduce the search space for duplicate records. Instead of considering all possible pairings of items, it restricts the computing cost to those that are equivalent. This is accomplished successfully by classifying entities with similar or identical signatures and giving each entity one or more signatures. Extensive experimental assessments have demonstrated that the schema-agnostic signatures outperform the schema-based ones without the need for domain or schema expertise. The result is that any entity's characteristics or subsets of its values can be used as signatures. Additionally, we utilize machine learning algorithms to improve the accuracy of the ER process. Through extensive experimentation, we demonstrate that our approach significantly improves the scalability and performance of ER frameworks. The proposed method can be applied to a variety of domains and has the potential to greatly enhance the efficiency of data cleaning and integration tasks.**

Keywords— Entity Resolution, Redundancy-positive Blocking, Metablocking.

I. INTRODUCTION

Entity resolution, often referred to as de-duplication, is a current research issue of interest. The process of determining whether two references to the same real-world things are equal is known as entity resolution (ER). This process can seem straightforward, but it gets quite difficult when dealing with Big Data issues. Deep Learning, which makes use of neural networks with numerous layers, is the foundation of many current research projects aimed at developing models for emergency room issues. These techniques need substantial time and computing resources to train and eventually be ready to operate. Take DeepER, one of the deep learning frameworks created for ER, as an example.

In this work, we aim to build an unsupervised

Machine Learning (ML) model that is very effective, remarkably simple, and depends on basic principles of Pattern Recognition. The majority of research is conducted on supervised learning since it is a safer method to get reliable results. However, the majority of demonstrate that it competes with and surpasses other state-of-the-art models.

II. EXISTING SYSTEM

1. Conventional data matching:

Conventional record linking devices have been around for quite a long time and are an essential way to deal with entity resolution. In any case, the accuracy accomplished by these items is essentially lower than genuine entity resolution tools, and they battle to deal with the bad quality data.

2. Custom tool development:

A few organizations attempt to take care of the issue in-house, entrusting their development department to construct data matching tools from scratch. Much of the time, these drives convey some early accomplishment with 'straightforward' matches, however they miss a ton. They regularly battle to operationalize their underlying evidence of ideas into a creation grade framework that can adapt to complex difficulties, bringing about long lead times prior to seeing worth and building high improvement costs. Organizations have billions of data records spread across numerous frameworks yet don't have the right solution to utilize it and create meaningful value out of it. No association can fabricate a 360-degree perspective on clients, possibilities, accomplices and associations without a solid data record establishment and it's basically impossible to transform this information into bits of knowledge.

For most associations, more data means more issues.

From duplicate client records to endless information, there are unlimited difficulties. Also attempting to conquer these difficulties is troublesome: associating dissimilar data records into an extensive single chunk of information is time-consuming and relentless, with a labyrinth of security issues.

III. LITERATURE REVIEW

Collaborative filtering is one of the prominent techniques used in recommender systems. Collaborative filtering as the name itself suggests that it is a method of filtering the interests of a particular user based on collaboration among the various users, various thoughts, etc. Collaborative filtering involves a large amount of user data and his/her preferences. Collaborative filtering is of two types namely model-based and memory-based.

Memory-based approach requires us to find the similarity measure i.e. we need to find the correlation between two users or a group of users while in Model-based approach a model has to be created using various data mining and machine learning algorithms.

IV. OBJECT IVES

We plan to build a tool for Entity resolution to MDM, which will consist of Features such as:

• Ability to handle any entity like customer, organization, supplier, product etc.

• Ability to scale to large volumes of data

• Ability to handle inputs in multiple formats like csv, json ,etc.

V. PROPOSED SYST EM

The model's first component is this part, The input string data must now be transformed into an object space. There are several methods available for prototype selection, but many of them are sensitive to data variability, making it impossible for them to perform equally well across different data sets.

A Dissimilarity Space Of Objects will be constructed in order to get around this circumstance.

We investigate and contrast well-known string metrics, such as the Edit and Jaccard distance, and from this work, we provide a unique distance in articles.

These investigations show that a metric may have both euclidean and dissimilarity properties simultaneously. Nevertheless, a Euclidean distance that produces a dissimilarity score offers a lot of promise from a more theoretical and in-depth standpoint. Since the string distance selection is at the core of our model's prototype selection phase, it is important to stress at this point that we will perform an extensive analysis of it. We shall explain how this hybrid string distance, which we refer to as Euclidean-Jaccard, operates both theoretically and empirically.

Additionally, we provide a short explanation of the "tokenization" strategy that is necessary for this measure to function correctly as a member of the Jaccard family. Since sets are necessary for the Euclidean-Jaccard distance, the strings must first be transformed into sets of letters or words. There are other ways to carry out this transformation, but we'll focus on the n-grams approach. Next, we provide the framework's prototype selection section. For this, we use the method outlined in the original study, which was created using the Vantage Objects schema from the paper. In addition to discussing the theoretical foundations for this schema, we will also go into the clustering and prototype selection procedures we use. We will also discuss how we modified and enhanced this algorithm to make it more compatible with our framework. Last but not least, we use the Maximum Mean Discrepancy (MMD), a statistic measure between two data distributions, to assess the effectiveness of the prototype selection strategy. One way to carry out the assessment is to calculate the MMD between the two distributions that were constructed, one using the prototypes and the other using the original data set. Algorithm 1 String Clustering and Prototype Selection Algorithm

The second component of our model is this. Currently, we have a schema in place that produces a number of prototypes from a given data collection. The original strings must now be converted into numerical arrays. This process is known as vectorization in pattern recognition, and the vectors themselves are known as embeddings. A number of vectors, one for each string, that each uniquely describe it are called embeddings. For each string in our scenario, we want to create a vector (think of it as a list of integers). We will use an embedding method based on Vantage Objects in this model. The work Efficient picture retrieval with vantage objects by J. Vleugels and R. C. Veltkamp contains the fundamental concept behind the Vantage Objects. To construct an effective object indexing, they first described and used a technique known as Vantage Objects. The Vantage Objects in our research will be the prototypes created in the previous model process.

The third and arguably most crucial component of the paradigm is hashing. Entity resolution issues are difficult in terms of time and memory complexity. This is because it takes a lot of comparisons to figure out which items are similar and which ones are not. Consider an issue with a 1,000 string data collection, which is regarded as being quite little in modern times. In a brute force approach, we would compare each string to all the others in order to identify the strings that are identical to real-world things. This indicates that to do this work, we would need to make 1,000,000 comparisons. The processing time and computer power needed for this strategy would be considerable.

Therefore, a hashing approach is used in this study, which may often reduce the number of comparisons to 10%. In line with the preceding illustration, this model can provide predictions with 100,000 comparisons and respectable results.

This tactic, also known as blocking, divides sets of data into smaller subsets using a criterion function (i.e., a hashing method), with records only being examined for matches inside the same block. Standard blocking places all records with the same blocking key into the same block, where they are compared pairwise.

Blocking is a typical tactic in Entity Resolution issues. It may be used to connect records from many sets or to resolve ER problems in a single set. Furthermore, as shown by the studies, blocking is a technique utilized in cutting-edge frameworks with a performance gain.

This research embeds a blocking architecture using Jay Yagnik's Locality Sensitive Hashing (LSH) Approach, often known as Winner-Take-All (WTA) Hashing. Yagnik first introduced a very effective hashing technique in his article The Power of Comparative

Reasoning, which may quickly group items from the original data set that have similar characteristics. WTA schema is one of the quickest hashing methods accessible, while having a pretty simple purpose. This method creates a hash for each input vecto r that is rank-ordered. This hash is used as an indication in our model to create collections or buckets of embedding that seem to be comparable.

Because it dramatically reduces the amount of time needed to operate correctly, this step is crucial in our methodology.

The last component of our model is this. Many buckets have been created through WTA hashing. It is now time to thoroughly compare all of the string embedding inside of each bucket.

The process of comparing two items to each other is known as similarity checking. To do this, a similarity measure may be used. In general, this metric produces a forecast using two vectors (in our case, embedding) as input. This forecast is a number that falls between a range of values, most often between zero and one.

The similarity between two predictions increases as one approaches. We first define a similarity threshold and then execute. If the similarity measure returns a value larger than this cutoff, we shall rely on the assumption that these

VI. SYSTEM ARCHIT ECTURE

We will provide the model scores to the CORA data set in detail in this part and demonstrate how it outperforms other applications in the same data set. The four scores Recall, Precision, F1 and Accuracy as well as the time required to create these predictions comprise our criterion. To begin, assess this model using the CORA data set. Along with presenting the findings from this data set, we will also quickly assess each model element independently. We'll look at the choice of prototypes, show the embeddings, watch WTA acceleration, and then comment on the outcomes and evaluate how the similarity metrics we recommended performed. Remember that our model has to be adjusted for it to function. With the aid of the cutting-edge framework Optuna, the fine-tuning will be carried out. We will briefly discuss how we utilised it and why it was so important to our work. Finally, we will evaluate the effectiveness of several ER models and contrast them with our own. Another cutting -edge framework, JedAI, will be used to build these models.

IX. CONCLUSION

We provide a unique approach in this paper for solving ER issues with string data sets. To start, we offered a Prototype Selection strategy that, as the findings demonstrate, may lead to a collection of prototypes that have undergone careful selection in addition to a rich Euclidean and Dissimilarity, Embedding Space. After then, a rank-ordered approach was presented in order to escape the effects of dimensionality and take use of rank-ordered embedding' benefits.

The Winner-Take-All hashing strategy, which extends the

life of our model over time while retaining excellent Recall scores, was then presented as the most crucial part of the study.

We were able to cut the number of comparisons by around 80% and restrict the similarity checking phase to just the most similar pairings by using our blocking method. In the last segment, we went into great depth about the performance of our models and used and presented two cutting-edge frameworks, Optuna and JedAI. We demonstrated how our model generates a high recall score and an F-Measure that competes with other effective ER frameworks using these two frameworks. To sum up, we created an end-to-end model that can be applied to string ER issues and provide high-performance and reliable ratings in a short amount of time.

X. CONCLUSION

Route Optimisation using Particle Swarm Optimization and Genetic algorithm- A detailed comparison

Shruti Mathur, Purvi Sankhe
Thakur College of Engineering and Technology, Kandivali East, Mumbai
Shruti.mathur@thakureducation.org, purvi.sankhe@thakureducation.org

Abstract— **This paper puts light on various routing problems faced in the transportation system. The Vehicle Routing Problem (VRP) and movement of goods that need to be transported from one destination to another should be planned in a way they are cost and energy efficient, It highlights various optimization techniques which can yield a powerful client and driven-centric outcome. Strengths and weaknesses of these methods are described. Soft computing techniques are proposed and these methodologies are compared to the real-world example. We compare different techniques used for VRP.**

Keywords – Soft computing, Optimisation, Particle Swarm, Vehicle Routing Problem, Road Transportation, Vehicle Utilization.

I.INTRODUCTION

Route is a particular road used for travel or transporting goods. There are various routes between a source and a destination. The user has the liberty of selecting a specific route but the problems faced are cost and point in time at the destination. The standard event is to travel between two points using the shortest path known, within a given specific time and value. But usually, what happens when the shortest path or route becomes the longest because of an occasion leading to deadlock on the route[5]. Then ,the user is probably going to spend more time and cost on the route which is meant to be shorter than other routes available, thus making it not an optimal or the feasible route at that point of time.

Most optimization problems are often solved by using any evolutionary algorithm. One of the most important classes of Evolutionary algorithms is Genetic algorithm (GA). GA uses various biological techniques such as inheritance, selection, crossover or recombination, mutation and reproduction[1]. Since GA is ready to handle both discrete and continuous variables, it can be used to solve complex optimization problems.GA has been very efficient in various problems like optimization, design and scheduling ,data handling, etc.

Particle Swarm Optimization (PSO) was developed by

Kennedy and Eberhart in the 1990s. The fundamentalidea in PSO is that each particle represents an optimal solution which it updates according to two important kinds of information available within the decision process. The primary one (cognitive behaviour) is gained by its own experience, and also the second one (social behaviour) is the experience gained from the neighbours, that is, they tried the choices themselves and have the knowledge which choices their neighbours have outstand to this point the way positive the most effective pattern of choices was [1],[2].

II. OBJECTIVE

The objective is to deliver goods to all kinds of customers, at the same time minimizing the cost required to deliver those goods. It allows the user to specify a number of business-specific constraints like time capacity windows, multiple capacity dimensions etc., and it can even be used to solve large scale problems.

III. VEHICLE ROUTING PROBLEM

The Vehicle Routing Problem (VRP) occurs when there is movement of goods from a certain point to serve the customers in various places. It is widely applied to various areas such as transport delivery routing, mail delivery, public bus routing planning, trucks that deliver products across the country [4]. This VRP is a mixture of the well-known routing problem called Capacitated Vehicle Routing Problem (CVRP). This problem helps to identify routes which start and end at an available centre. It has been designed such that a vehicle visits a customer once. The goal is to minimize the distribution cost for the assigned routes.

VRP can handle large volume problems quite efficiently. It offers a solution that is more scalable, cheaper to execute in real-life problems. Customisable algorithms and iteration logic can give us the mathematical result.

IV.PARTICLE SWARM OPTIMIZATION

The PSO model is designed to obtain optimal distance, and the transport objective is designed to minimize the transport cost in main logistics considering the Capacitated Vehicle Routing Problem[2]. To find the maximised output, there are several ways one can look into.

One optimization problem which can be suitable for a certain problem may not necessarily be optimal for another problem.

This algorithm is based on the swarm intelligence concept which solves complex mathematical problems in engineering. PSO is frequently implemented in VRP field. An advanced PSO is also designed to solve demands of customers that are uncertain and the demand distribution is undetermined. The goal of this optimization is to determine a variable represented by a vector X that minimises or maximises depending on the proposed optimisation of the function f(X) [1].

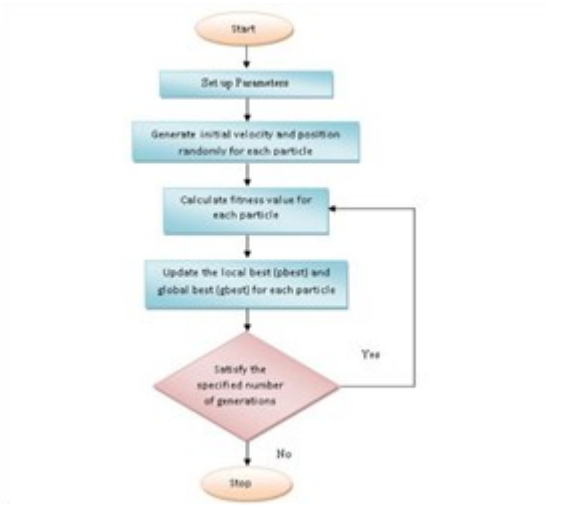

Fig 1. PSO Flowchart

The various steps used in the PSO algorithm are mentioned below:

1. Initialize the particles with some arbitrary velocities and positions within the search space.

2. Start calculating the corresponding value of fitness function of the swarm particles.

3. Equate the fitness value evaluation with the present value of the particle's pbest. If current value is best than pbest, set it as new pbest value and set the pbest location to this location in n- dimensional space;

4. Next equate the fitness value with the previous overall best. If current value is healthier than gbest, then reset gbest to the current particle's array index and value;

5. Finally assign these values to the corresponding position and velocity of the swarm particle.

PSO Variants:

Various versions of the PSO algorithm may be obtained by combining it with other evolutionary algorithms. There is a trend in research to create hybrid PSO algorithms to boost the general optimization of the algorithm. Some commonly used variants of PSO algorithm are:

- Discrete PSO
- Constriction Coefficient
- Bare-bones PSO
- Fully informed PSO.

Applications:

PSO found its first application within the field of neural network training. Since then, it's been used in various kinds of fields including telecommunications, design, power systems, control and lots of others. PSO algorithms have been majorly used in dynamic tracking, MinMax problems and various optimization problems [2].

V. GENETIC ALGORITHM

Genetic algorithms are a category of numerical and combinational optimizers which are especially useful for solving complex nonlinear and nonconvex problems. Genetic algorithms are randomized search algorithms that are developed in a shot to imitate the mechanics of natural selection and natural genetics. Genetic algorithms operate on string structures, like biological structures, which are evolving in time in keeping with the rule of survival of the fittest by employing a randomized yet structured information exchange. In a genetic algorithm, a population of candidates to an optimization problem is evolved toward better solutions. Each candidate solution encompasses a set of properties which may be mutated and altered; traditionally, solutions are represented in binary as strings of 0s and 1s, but other encodings are also possible [2].

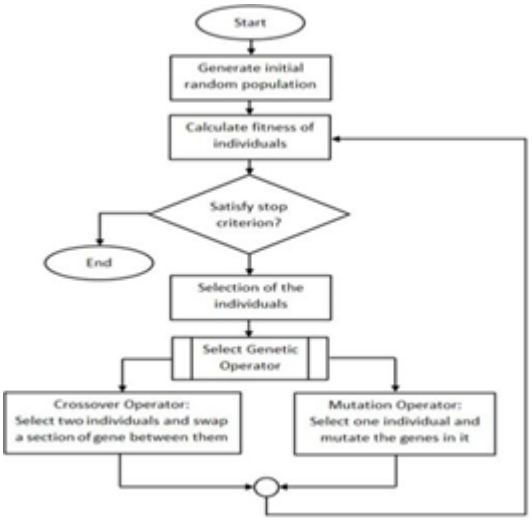

Fig 2. GA Flowchart

Hybrid discrete particle swarm optimization algorithm for clustered vehicle routing problem (2019) - Anisul Islam,Yuvraj Gajpal,Tarek Y

Key Findings: A new hybrid approximation algorithm is developed in this work to solve the problem. In the hybrid algorithm, discrete particle swarm optimization (DPSO) combines global search and local search to search for the optimal results using a certain probability to avoid being trapped in a local optimum.

Research Gap: Future research should focus on improving the DPSO-SA algorithm for solving larger vehicle routing problems. The proposed approach is also

suitable for other problems. It is especially suitable for discrete optimization problems.

Genetic algorithms can be used in a wide variety of fields. It is mainly used to solve optimization problems. Some of the fields where GA is used are: bioinformatics, computational science, electrical engineering, manufacturing, and phylo-genetics, etc

VI. LITERATURE SURVEY Performance Comparison between Particle Swarm

Optimization and Differential Evolution Algorithms for Postman Delivery Routing Problem (2021) - Warisa Wisittipanich, Khamphe Phoungthong, Chanin

Srisuwannapa , Adirek Baisukhan and Nuttachat

Wisittipanit.

Key Findings: In this study, two methods—particle swarm optimisation (PSO) and differential evolution (DE)— were applied with particular solution representation to find delivery routings with minimum travel distances. The performances of PSO and DE were compared along with those from current practices. Research Gap: It is important to note that the results

obtained from this study were based on the delivery constraints of the Chiang Rai post office. However, for the operations of other post offices, other constraints such as vehicle capacity, a customer's time window and the delivery time horizon could be taken into consideration. In such cases, the problem must be remodelled, and new solutions will be obtained.

Route Optimization in logistics distribution based on Particle Swarm Optimization (2019) - Appiah Martinson Yeboah Xiong Qiang.

Key Findings: Optimisation algorithm. A

computational experiment is carried by the proposed model to obtain optimal distance and imputed into the cost function to obtain the optimal cost. We found that an increase in population size and the number of iterations gives better minimisation results.

Research Gap: Only mathematical formulae and a flowchart were provided to demonstrate the particle swarm optimization. Also, cumulative results were obtained on the basis of problem assumptions. Real time constraint should also be checked.

Hybrid discrete particle swarm optimization algorithm for clustered vehicle routing problem (2019) - Anisul Islam,Yuvraj Gajpal,Tarek Y

Key Findings: A new hybrid approximation algorithm is developed in this work to solve the problem. In the hybrid algorithm, discrete particle swarm optimization (DPSO) combines global search and local search to search for the optimal results using a certain probability to avoid being trapped in a local optimum.

Research Gap: Future research should focus on improving the DPSO-SA algorithm for solving larger vehicle routing problems. The proposed approach is also

suitable for other problems. It is especially suitable for discrete optimization problems

A Stochastic Approach Towards Travel Route Optimization and Recommendation Based on Users Constraints Using Markov Chain

(2019) - Shabir Ahmad, Israr Ullah, Faisal Mehmood , Muhammad Fayaz, and Dohyeun Kim

Key Findings: The results indicate the difference between the short- and long-term popularities to prove the

effectiveness of the Markov chains in forecasting long-term behaviour. The accuracy of the system is computed based on the historical data and the recommendation system, and it is ascertained to fall between 95% and

100% all the time.

Research Gap: The long-term steady states predictions alongside user preferences and constraints helped in finding optimal routes within user constraints. A

recommendation system is developed to take user constraints such as current location, number of locations to visit, maximum time and maximum distance from users and return optimal routes on Google Maps having maximum index within input constraints.

Research on Logistics Scheduling Based on PSO (2017)

- Huifang Bao, Linli Zhou and Lei Liu

Key Findings: The study of the logistics distribution vehicle routing optimization problem is not only of great

theoretical significance, but also of considerable value.

Particle swarm optimization algorithm is a kind of evolutionary algorithm.

Research Gap: Solutions were derived by experimenting under standard conditions and avoiding real life conditions and variables.

Route Optimization Techniques: an overview (2016) - Bale, D. L. T. Ugwu, C Nwachukwu, E. O

Key Findings: This paper discusses the various routing problems in the road transportation system and focuses

on route optimisation and its techniques. The techniques

were categorised as hard and soft computing; presenting their general strengths and weaknesses

Research Gap: With different techniques mentioned, the swarm based technique is not discussed. Fuzzy logic, artificial neural networks are a part of soft computing but other than that no other algorithms have been provided.

Performance Evaluation between GA versus PSO (2016)

- Ajay kaushik, Hiesh Kumar

Key Findings: When sensor nodes are in operation, performing their task most of their energy is depleted in

improper routing, uneven distribution of traffic load. So in this paper we are proposing two metaheuristic based

load balancing techniques GA and PSO and have a comparative result analysis in between them.

Research Gap: In the Upcoming future scope we can work on an agent-based burden balancing positioning algorithm for wireless sensor networks.

Hybrid discrete particle swarm optimization algorithm for capacitated vehicle routing problem (2015) - CHEN Ai-ling† , YANG Gen-ke, WU Chi-ming

Key Findings: A new hybrid approximation algorithm is developed in this work to solve the problem. In the hybrid

algorithm, discrete particle swarm optimization (DPSO)

combines global search and local search to search for the optimal results using a certain probability to avoid being trapped in a local optimum.

Research Gap: Future research should focus on improving the DPSO-SA algorithm for solving larger vehicle routing problems. The proposed approach is also suitable for

other problems. It is especially suitable for discrete optimization problems.

VII. GENETIC ALGORITHM VS PARTICLE SWARM OPTIMIZATION

PSO has been used increasingly because of its several advantages like robustness, efficiency and ease to use, compared with other stochastic algorithms it has been found that PSO requires less computational effort. Although PSO has shown its potential on various aspects for solving different kinds of optimization problems, it still takes considerable execution time to find out the optimal solutions for large-scale engineering problems.

GA is discrete in nature, i.e., it changes the variables into binary 0's and 1's, and so it can easily handle discrete problems, and PSO is continuous and hence must be modified in order to handle discrete problems.

Unlike GA, the variables in PSO can take any values supporting their current position within the particle space and therefore the velocity vector [5]. Genetic algorithms do not handle complexity in an efficient way, because in such cases the number of elements undergoing mutation is extremely large which causes a considerable increase in the search space. So, during this case PSO is the best alternative because it requires a smaller number of parameters and correspondingly lower number of iterations [7].

The performance of Particle Swarm Optimization is found to be better than the Genetic Algorithm, because the PSO carries out global search and the native searches simultaneously, whereas the Genetic Algorithm concentrates mainly on the world search. Hence, the findings show that the proposed PSO optimization algorithm is easy to develop and apply , producing competitive designs compared to the GA algorithm.

VIII. SWARM INTELLIGENCE ALGORITHMS

Types of Swarm Intelligence Algorithms include

- Genetic Algorithms (GA)
- Ant Colony Optimization (ACO)
- Particle Swarm Optimization (PSO)
- Differential Evolution (DE)
- Artificial Bee Colony (ABC)
- Glow worm Swarm Optimization (GSO)
- Cuckoo Search Algorithm (CSA).

1. ANT COLONY OPTIMIZATION

Ant Colony Optimization (ACO) is a systematic approach inspired by the Ant System, proposed in the year 1992 . It is inspired by the foraging behaviour of the real ants. This algorithm consists of 4 main components

; Ant, Pheromone, Daemon action, and Decentralized control, which contributes to the general system. Ants are agents that are employed in order to mimic the exploration and exploitation of the search space [3]. In reality, pheromone is a chemical material spread by ants over the path they travel and its intensity changes over time thanks to evaporation.

In ACO, the ants drop pheromones when traveling within the search space and also the quantities of those pheromones indicate the intensity of the trail. The ants choose the direction based on the path marked by the high intensity of the trail. The intensity of the trail can be considered as a worldwide memory of the system. Daemon actions are used to gather global information which cannot be done by a single ant and uses the information to determine whether it is necessary to add extra pheromone in order to help the convergence [2],[3].

Step 1:Edge selection

Step 2:Pheromone update

ADVANTAGES :

1.Provides Feedback accounts for rapid discovery of optimal solutions

2. Efficient for Representative Traveling Salesman

Problem and similar problems

3.Can be utilized in various dynamic applications

:Adapts to changes such as new distances. [4]

2. Artificial Bee Colony

Artificial Bee Colony (ABC) is one of the most recent swarm intelligence algorithms. It was proposed by Drevis Karaboga in 2005 . During one of the years, the performance of ABC was analyzed and it was concluded that ABC performs efficiently well compared to the various other approaches. This algorithm is inspired by the intelligent behavior of real honey bees in finding food sources, known as nectar, and then indulging in sharing information about that food source among other bees within the nest. During this approach, the artificial agents are defined and categorized into three types: the employed bee, the onlooker bee, and therefore the scout bee [3],[6].

Each of those bees have different tasks assigned to them so as to complete the algorithm's process. The employed bees target a food source and retain the locality of that food source in their memories. The number of employed bees is equal to the number of food sources since each employed bee is related to one and only 1 food source [9]. The onlooker bee receives the knowledge of the food source from the employed bee within the hive. After that, one of the food sources is chosen to assemble the nectar.

Step 1. Initialization Phase Step 2. Employed Bees Phase Step 3. Onlooker Bees Phase Step 4. Scout Bees Phase

Step 5. Termination Checking Phase

ADVANTAGES:

- Easy to implement, robust, and highly flexible.
- Only requires 2 parameters of maximum cycle number and colony size.
- It is often employed in many optimization problems with none modification.
- ABC has been implemented in various fields including engineering design problems, networking

, electronics , scheduling and image processing [3].

3. Differential Evolution

Differential evolution (DE) is a population-based search algorithm that optimizes an issue by iteratively improving a candidate solution supporting an evolutionary process. Such algorithms make few assumptions about the underlying optimization problem and can quickly explore very large design spaces. DE is arguably one among the foremost versatile and stable population-based search algorithms that exhibits robustness to multi-modal problems. Within the field of structural engineering, most practical optimization problems are associated with several behavioral constraints [8].

In the present study, we investigate the performance of 4 DE variants in dealing with structural optimization problems.

• The standard differential evolution (DE)

• The composite differential evolution (CODE)

• The self-adaptive differential evolution (SADE)

IX. CONCLUSION

Particle Swarm Optimization (PSO) is a relative algorithm where its behavior is based on swarming characteristics of the living organisms. PSO is kind of like Genetic Algorithm as both of those are evolutionarily search methods, which implies that they change from a set of points to another set of points within an iteration.GA is well-established and a popular algorithm with many applications and different versions.

Even though they have been a fundamental part of this research paper, there are certain disadvantages which limit their usage to only certain problems. They are still not an optimal solution for real-world problems. In order to overcome these disadvantages, a mixture of both GA and PSO will be accustomed to improve the performance. So, a hybrid algorithm of GA and PSO could be a good topic for future research too.

Crop Yield Prediction using a Wavelet based Fusion of Landsat and Sentinel Data with Meteorological Parameters

Monisha Linkesh, Dr. Vaishali Jadhav, Afreenzehra Sayed
TCET, Mumbai
monishajames15@gmail.com, vaishalijadhav@sfit.ac.in, afreenzehra.sayed@tcetmumbai.in

Abstract- **Crop yield prediction before harvest will help the formers to maximize their crop production. Thisproposed research, works on satellite data. The goal of this proposed paper is to enhance the precision ofthe yield forecasting model by considering various growing stages of wheat and using the fusion of Landsat and Sentinel images with meteorological parameters for improving the prediction accuracy compared to using the single satellite image. The collected images were fed into the atmospheric correction process to remove the atmospheric effect from the satellite images and to get the surface properties. This process is significantly necessary when calculating the vegetation indices. Then fusion technique was applied to combine the Landsat and Sentinel images. NDVI was calculated from the fused images then this value was combined with meteorological data and find the final yield of the crop using ensemble learning. This work also compares the production accuracy of wheat and jowar and predicts which crop will give maximum production in rabi season**

Keywords —Satellite imagery, Machine learning, Normalized Difference Vegetation Index, Fusion,Ensemble learning.

I. INTRODUCTION

Wheat is the most used cereal in the world. In the production ranking of wheat, India is the second place across the world. It occupies approximately 29 million acres of cultivation land. The growing season varies according to the type of wheat. In India, it is mainly sowed in the winter season. it's also called rabi season. The important factors which mostly affect the growth of wheat are radiation, rainfall, temperature,humidity, wind speed, and fertilizers. The wheat has almost seven developmental stages: it starts from March to June. The Green-up (beginning of March) is the first stage, followed by the Jointing Stage (end of march), Elongation Stage (beginning of april), Booting (middle of april), Heading Stage (end of april), Anthesis Stage (beginning to middle may), and finally maturity stage (beginning of June).

The previous study of this paper used sentinel data with meteorological parameters like sunshine hours,minimum and maximum temperature and NDVI. This proposed work used the combination of Landsat andSentinel data with meteorological parameters. This paper aims to predict the yield of wheat crops. The satellite images of Maharashtra state were collected for this proposed work. The various growing stages areconsidered for the yield prediction model. The same dates of Landsat and Sentinel images for various growing months are collected. Then these images were preprocessed and combined to find the Vegetationindex of the crop (NDVI). This vegetation portion was mainly used to find the yield of the crop. Then NDVI value is combined with meteorological parameters such as rainfall, temperature, humidity and find the yieldusing the ensemble learning technique. This is the combination of Random forest and Ada-boost algorithm. This technique is mainly used to enhance the accuracy of the yield prediction model. Ensemble learning is mostly used in complex real time problems to reduce the variance and minimize bias.

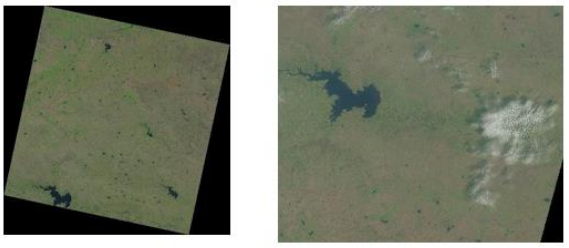

Fig. 1. Example Landsat and Sentinel image

II. RELATED WORK

Asha et al [1] used Landsat data with meteorological parameters to develop the yield prediction model.
U.S Nagar data was collected for the experiment. This paper developed four models using four meteorological parameters such as Bright sunshine hours, Maximum temperature, minimum temperature, and NDVI. The model with all four parameters has higher accuracy than the other three models.

Chang Xu et al [2] developed a soybean yield prediction model by using the remote sensing satellite images incorporating NDVI. This proposed work analyzes the relation between vegetation portion and production by utilizing the Flexible Fourier Transform model (FFT). This paper proves that the Flexible Fourier Transform model performs better than the ordinary least square regression model.

Shakarika Sharma et al [3] proposed a yield forecasting model using Deep LSTM. This paper used MODIS satellite images. It considers 7 states in India for their experimental zone. It has not used any preprocessing steps; they directly work on collected satellite images. This proposed work proves that the addition of information like farmlands, water bodies, and urban areas helps in enhancing prediction accuracy.

Pengfei Chen et al [4] considered the Landsat8 images for winter wheat yield prediction. It consideredYucheng city in china as their research zone. It covers 990km2. This paper compared the two multivariatemethods such as Partial Least Square Regression Model and Artificial

Neural Network. The result of this study showed that ANN outperforms the PLSR model.

Gang Pan et al [5] used digital camera images to estimate the crop cover area. The vegetation and soil background were classified using an Object-based image analysis technique. Images were classified into shadow and non-shadow classes by using a membership function. The non-shadow class is further grouped into soil or vegetation area. Then to determine the vegetation area, the no. of green pixels was divided by the image's absolute count.

III. DATASET DETAILS

The data set was obtained from USGS (United State Geographic System) website. This study focused on the state of Maharashtra. Landsat 8 OLI/TIRS c2 L1 and sentinel images were collected for Maharashtra state. The Path and row of this dataset are (146, 046). The latitude and longitude of this study area are 19 45'05" North latitude, 075 42'50" East longitude respectively. The Cloud cover range is below 5%. The dataset years were collected from 2013 to 2021

IV. METHODOLOGY

The basic process followed in this paper is explained below. It has 5 steps. Each step is explained in detail below

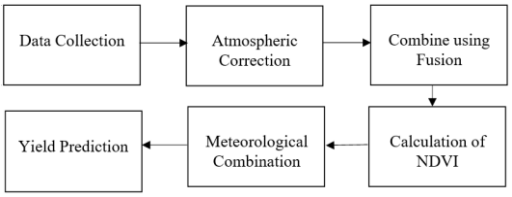

Fig 2. The Workflow of Yield Prediction Model

A. Data Collection

The Dataset used in this research work is taken from the USGS website. It consists of various satellite images. This proposed work uses Landsat 8 and Sentinel images dataset.

B. Atmospheric Correction

The main objective of doing atmospheric correction is to extract the surface properties from the satellite images. This method improves the accuracy of classification. The atmospheric corrected images significantly will give better accuracy when using multiple date images. It is a significantly necessary process when calculating the vegetation indices.

This process can be calculated using two phases

1.DN to Radiance conversion L= G* DN+ B

where DN: Digital number G and B are gain and bias values for a particular band

2.Radiance to TOA conversion P=Π * L* D 2 / ESUN * Cosɵ

All the values used in the formula are available in the metadata file of the image file.

B. Fusion

Image fusion is a technique for combining images. It combines two images and the resulted images is the fused one. The fused image contains more information than a single image. This fusion technique is not only needed for reducing the amount of data but it also helps to restore an image from more than one degraded image and for mixing images. There are various fusion techniques are available for combining images. Some of the examples are; feature-based, pixel-based and decision-based fusion. The fusion technique is of two types: spatial and frequency domain. The spatial domain consists of High Pass Filter, Intensity Hue Saturation, Brovey algorithm and Principal component substitution method. The frequency domain consists of pyramid-based algorithms, discrete cosine transforms, curvelet based and discrete wavelet transforms. This proposed work uses a wavelet based fusion technique. It is a mathematical tool for decomposing the images and it provides efficient localization in both spatial and frequency domain. It the extension idea of high pass filtering and it produce enhanced accuracy than other fusion methods. These wavelets are generated using High and low pass filters. The signal S is passed through these filters and down sampled by two. It produces low and high-frequency signals called an approximation and detailed coefficient respectively. The atmospherically corrected images were fed into the image registration step. This method converts the two different sets of images into one format. It is used in the remote sensing field to align different satellite images. Then resampling was done. It is same as resizing but it changes the physical number of pixels. This proposed work uses the down sampling method rather than up sampling because it preserves most pixels information and enhances the quality of the image. The 30m resolution band was reduced to 10 m as same as in the sentinel band.

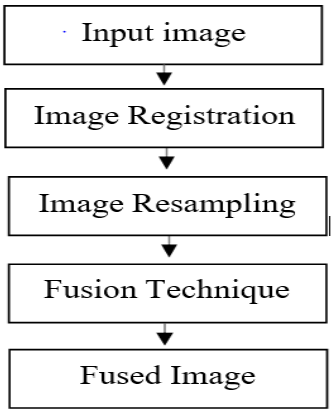

Fig 3. Fusion Steps

The Wavelet transformation based fusion technique was used in this proposed work. It has two forms discrete and continuous wavelet transforms. This research work uses the discrete wavelet transform technique.

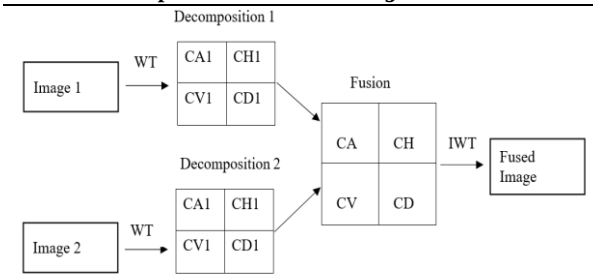

Fig 4. Working of wavelets in fusion process

Steps followed in wavelet transform technique

1. Gets the input images

2. Apply wavelet transformation on two images to get the decomposition of two images. This function decomposes the two images into 4 coefficients.

NDVI = NIR- R / NIR+ R

3. Find the detail and approximation coefficient of two input images. CA is the approximation coefficient of image, CH, CV, and CD are the detailed coefficient of input images.

Here CA1 is the approximation coefficient of image1. CH1is the detailed horizontal coefficient of image1

CV1is the detailed vertical coefficient of image1. CD1 is the detailed dimensional coefficient of image1

4. Merge the coefficient of two images by using the rule CA=fusion1(CA1,CA2)

CH=fusion2(CH1,CH2) CV=fusion2(CV1,CV2) CD=fusion2(CD1,CD2)

Fusion 1 and 2 are two mathematical operations. Fusion 1 is for approximation coefficient and fusion 2 is for detailed coefficient. These operations can be mean, max or min. so nine combinations of operations are possible.

5. Apply inverse transform on the merged coefficient

6. Get the final fused image as output.

Table 1: Final fused output

Fusion 1	**Fusion 2**
Mean	**Mean**
Mean	**Max**
Mean	**Min**
Max	**Mean**
Max	**Max**
Max	**Min**
Min	**Mean**
Min	**Max**
Min	**Min**

D. Calculation of NDVI

Normalized Difference vegetation Index (NDVI) estimates the green portion by calculating the ratio between the discrepancy between the near-infrared (NIR) and red bands (R) and the summation between the near-infrared and red band.

This NDVI value fluctuates between minus one to plus one at all times. water bodies are represented by a negative attribute. The value near to zero indicates, there is no vegetation portion, and the value near to positive one indicates dense leaves portion.

In Landsat8 image, NIR is the 5th band and RED is the 4th band as shown in Table no.2. In sentinel 2 image, 8 and 8a bands are NIR and RED is the 4th band as shown in Table no .3

E. Meteorological combination

Meteorological parameters such as temperature, precipitation, dew point, humidity, pressure and production factors are combined with NDVI value and find the final yield of the crop using ensemble learning. This ensemble learning is a combination of Random Forest and Ada-Boost algorithm.

Working of Random Forest:

Step1: N number of the decision tree was built for the various subset of the given dataset

Step 2: Then take the average of all decision trees to improve the accuracy of the prediction model. Advantages of using Random Forest Model:

1. It's Fast, Accurate and doesn't overfit

2. It can be used to solve both classification and regression problems

3. Work better with the high dimensional data point

4. It handles well missing values

5. Versatile in nature

Working of Ada-boost:

Step 1: First decision tree model is made from the dataset.

Step 2: The misclassified items from the first model only given as input to the second modelStep 3: These steps will continue up to the specified number of base learners

Advantages of using Ada-boost model:

1. It can be used with any model to improve its efficiency

2. Can be used to solve a decision tree problem

3. It learns from the model's prior error.

Table 2: Landsat8 resolution band

Bands	**Name of the band**	**Resolution in m**
I	Ultra-blue	30m
II	Blue	30m

III	Green	30m
IV	Red	30m
V	Near infrared	30m
VI	Cirrus	30m
VII	Short waveinfrared	30m
VIII	Short waveinfrared	30m
IX	panchromatic	15m
X	Thermal infrared	100m
XI	Thermal infrared	100m

Table 3**:** Sentinel resolution band

Bands	**Name of the band**	**Resolution**
I	Coastal	60m
II	Blue	10m
III	Green	10m
IV	Red	10m
V	Vegetation rededge	20m
VI	Vegetation rededge	20m
VII	Vegetation red edge	20m
VIII	Near infrared	10m
VIII a	Near infrared	20m
IX	Water vapor	60m
X	cirrus	60m
XI	Shortwaveinfrared	20m
XII	Shortwaveinfrared	20m

F. Performance Evaluation

The performance of the yield prediction model was estimated using Mean Absolute Error, Mean squared Error, and Root Mean Squared Error metrics.

$$Mean\ Square\ Error = \sum_{i=1}^{N} \frac{(predicted\ value - actual\ value)^2}{N}$$

Table 4 shows that ensemble algorithm shows better MAE results. Hence the ensemble algorithm of random forest and Ada boost with ensemble of SVM and Linear Regression was compared and former showed better results as shown in Table 5.

Table 6 shows wheat has less values in all three metrics which indicates the higher accuracy of production. Compared to jowar, wheat will give maximum production and jowar will give less production in rabi season as it needs different weather conditions for growing.

Table 4: Comparison of ML algorithms for predicting wheat yield

Metrics / Methods	MAE	MSE	RMSE
Random Forest	0.1772	0.0865	0.2941
Ada-Boost	0.1493	0.0648	0.2547
Ensemble Learning	0.0737	0.0276	0.1661

Table 5: Comparison of ML ensemble algorithms for predicting wheat yield

Metrics / Methods	MAE	MSE	RMSE
Random forest and Ada-boost	0.0737	0.0276	0.1661
SVM and Linear Regression	0.1794	0.0562	0.2372

Table 6: Comparison of wheat and jowar yield prediction using ensemble of Random Forest and Ada Boost

MetricsCrops	MAE	MSE	RMSE
Wheat	0.0737	0.0276	0.1661
Jowar	0.2222	0.1029	0.3209

V. Experimental Results

The satellite data in the day of 29/12/15 was collected and then atmospheric correction was done to get the surface properties of the land As shown in Fig 5.

The performance was estimated using the R2 score, Mean Squared score, and Root Mean Squared Value. The accuracy was increased when fusing two images. This proposed work increases the precision of the yield forecasting model compared to utilizing the single satellite image.

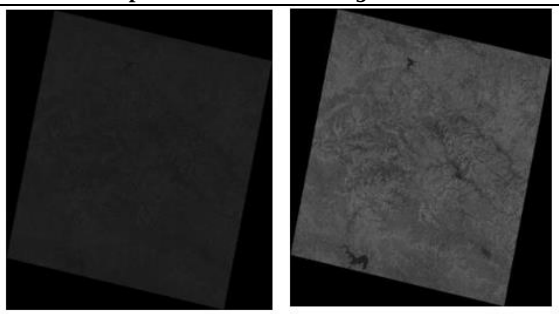

Fig.5. 29/12/15 atmospheric correction of Landsat data

NDVI calculation

The NDVI value was calculated from the atmospheric corrected image to get the value of vegetation and other parameters as shown in Fig 6.

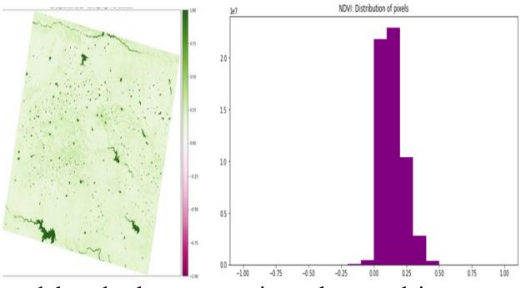

Fig 6. Distribution of NDVI value

It was observed that compared to the single satellite image the fusion of images increased the accuracy of the estimation model and when comparing wheat and jowar crop in rabi season, the wheatcrop will give maximum yield than jowar crop as shown in Fig 7.

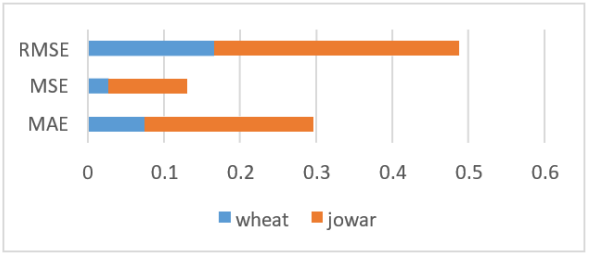

Fig. 7. Accuracy comparison of Landsat, Sentinel and Fused image

VI. CONCLUSION AND FUTURE WORK

Various works are done in the agriculture sector to predict the yield of the crops. The proposed work uses the combination of Landsat and Sentinel data with meteorological parameters to enhance the precision of the yield estimation model. The performance was estimated using the R2 score, Mean Squared score, and Root Mean Squared Value. It was inferred that the accuracy of predicting the wheat yield is more compared to jowar yield predicting. This proposed work increases the precision of the yield forecasting model compared to utilizing the single satellite image.

This proposed work will extend in the future by considering more input parameters. And also, will extend for other combination of satellite images like MODIS, sentinel 2B, etc.

Sarcasm Detection for Code-Mix Language using Machine Learning Khushbu Ravaria,

Dhruti Seksaria, Sanyuktha Udyavar, Shruti Mathur
Thakur College of Engineering and Technology Kandivali (East), Mumbai-400101, India
khushburavaria777@gmail.com, 29dhruti@gmail.com, usanyuktha@gmail.com, shruti.mathur@thakureducation.org

Abstract – **Sarcasm is a way of communication that creates gap between the intended meaning and the actual meaning comprehended from the conversation. Communication and human relations over social media sites like Facebook, Twitter circles around a lot of sarcasm and debates. Sarcasm detection is an important processing problem which is needed to understand the human and machine communication better. This paper aims to understand the gap between the emotion and the contextual meaning by using different machine learning approaches for Sarcasm Detection of code-mixed Hi-En dataset. The algorithms that we have used are Bernoulli Naïve Bayes, Logistic Regression and Support Vector Machine. SVM outperforms all the used algorithms giving an accuracy of 87.36%.**

Keywords --- machine learning, natural language processing, human interpersonal communication, support vector machines

I. INTRODUCTION

A code-mix dataset consists of phrases and words from two are more languages in a single sentence. It is generally used by people who understand and use more than one language to communicate in their daily life. Today, the world over, people communicate using not just one language, but rather with a mixture of more than one language.[1] Code-Mix language is widely seen on social media and with so many social media applications available the amount of code-mix data available is tremendous. So code-mixed text data analysis in multilingual societies like India has become a vital linguistic research area more specifically for social media content.[2] However, this data has various combinations of languages especially in India where 22 different languages exist.

Sarcasm detection is a relatively specialised area of NLP

research, a particular application of sentiment analysis where the emphasis is on sarcasm rather than detecting a sentiment throughout the entire spectrum. Consequently, the goal of this sector is to determine whether a particular text is satirical or not. Sarcasm detection is an important processing problem in natural language processing (NLP), which is needed for better understanding to serve as an interface for mutual communication between machines and humans. To understand this is to underline the basic problem behind it - being able to detect the contradiction. [3]

The sarcasm over social media can be of various types. Social media is an open platform to let people express their thoughts and feelings over something or someone. An individual may like-dislike, agree or disagree with another person's tweets, posts, or opinions. It is however easier for humans to understand the gap between the underlying sarcastic nature of the comment, but the machine brain cannot easily differentiate. This is an addition to the numerous machine learning as well as natural language processing approaches that have been used to address the problem. The paper focuses on code-mix data for the Hindi-English dataset abbreviated as the Hi-En dataset

TABLE I: EXAMPLE OF HI-EN CODE-MIX DATASET

Tweet: "Ha ha ha, really great job, yaar. Tune dikha diya that even a clock that doesn't work is right twice a day."	Sarcasm
Tweet:	Non- Sarcasm
Tweet:	Sarcastic
"Very well done, shayad apne aapko Einstein	
Translation:	
"Very well done, perhaps you have thought	
Tweet:	Sarcastic
" Bahut hi unique kaam kiya hai, koi bhi nahi kar	
Translation:	
"Very unique work done, no one else can do it."	
Tweet:	Non-Sarcastic
"In dino economy achi chal rahi h."	
Translation:	
"These days the economy is doing well."	

The messages in Twitter or tweets are generally labelled with hash tags like #angry, #driving, #joy etc. These hash tags have been used to construct a marked set of naturally transpiring negative, sarcastic and positive tweets.[4]

II. LITERARY SURVEY

The paper "Sentiment Analysis of Mixed Code for the Transliterated Hindi and Marathi Texts" [1] throws light on using plain machine learning algorithms for sentiment analysis of texts English-Hindi and English-Marathi. The dataset used in this paper contains 1200 Hindi and 300 Marathi samples collected from social media including YouTube comments, tweets and chats. The proposed methodology includes 6 steps which are Language Identification, Word Transliteration, Sentiment Scores Tagging, Feature Extraction, Supervised Learning Methods and lastly the Output as sentiments. Among all the algorithms applied direct linear SVM has the maximum F1 score.

"A Corpus of English-Hindi Code-Mixed Tweets for Sarcasm Detection" [5] sarcasm detection have been provides a resource of English-Hindi code-mixed tweets

which contain both sarcastic and non-sarcastic tweets. It provides tweet level annotation for presence of sarcasm and token level language annotation. For training the algorithms, developing them and evaluating the performance of language identification and sarcasm detection on code-mixed data, this corpus can be used.

The paper "Detection on sarcasm using machine learning classifiers and rule-based approach" [6] shows comparative study on various algorithms to identify which of these algorithms give the best results. Machine Learning algorithms used to detect the sarcasm here are Support Vector Machine, Naïve Bayes and Decision Tree for the SemEval 2018-T3-train- taskA.txt dataset and found Support vector machine algorithm to be the best suited for the particular dataset. Algorithms like Random Forest and SVM are used for the dataset Sarcasm Detection.txt and found Random Forest algorithm to give best results with the accuracy of 76%.

The paper "Sentimental analysis from imbalanced code-mixed data using machine learning approaches" [7] throws light on class imbalance distribution in code-mixed Tamil-English data for sentiment analysis. Oversampling techniques namely Synthetic Minority Over-Sampling (SMOTE) and Adaptive Synthetic (ADASYN) is used to solve the class imbalance problem. An enhanced spell-checking algorithm is used for sentence classification. Levenshtein distance metric is used to normalize the words with spelling variations. TF-IDF is used for feature extraction. Different machine learning algorithms that were experimented includes Random Forest Classifier, Logistic Regression, XGBoost classifier, SVM and Naive Bayes. For evaluation of the algorithms macro average F1 score is used. According to this paper the performance of Logistic Regression is superior to other algorithms.

"A Dataset of Hindi-English Code-Mixed Social Media Text for Hate Speech Detection" [8] paper addresses hate speech detection in code-mixed text. Using Twitter Python API tweets were mined by selecting certain hashtags and key words from politics, public protests, riots, etc. A total of 1,12,718 tweets were retrieved in JSON format. After pre-processing, a dataset of 4574 code-mixed Hindi-English tweets was created. Different feature vectors were used to train supervised machine learning model. These vectors included Character N-Grams, Word N-Grams, Punctuations, Negation Words and Lexicon. Support Vector Machine algorithms performs the best with an accuracy of 71.7%.

Sarcasm Detection in Hindi-English Code-Mixed Data using Bilingual Word Embeddings" [9] has five different deep learning models. The corpus was scraped from twitter. The dataset included 100k Hindi-English code-mixed tweets with 49% of it being sarcastic and rest 51% non-sarcastic tweets. Data pre- processing was performed in order to remove any sort of extra URLs, hashtags, mentions and other punctuations. Two types of word embeddings were used that is Word2Vec and FastText. The paper also presented a comparison of traditional Machine Learning algorithms for sarcasm detection. From which RBF Kernel SVM had the maximum accuracy of 71.23%. The paper concludes with attention based Bi-directional LSTM being the best performer with an accuracy of 78.49%.

In the paper "SA-SVG@Dravidian-CodeMix-FIRE2020: Deep Learning Based Sentiment Analysis in Code-mixed Tamil- English Text" [10] Bi-LSTM algorithm is used for classification of text which processes the data both in forward and backward direction. Along with this transformers-based models can be used to achieve more accurate results then LSTM and traditional machine learning algorithms such as SVM, random forest, etc.

The paper "Multi-modal sarcasm detection and humor classification in code-mixed conversations" [11] uses Attention based multi-modal classification model. This paper presents a unique dataset named MaSac that is extracted from the hindi series Sarabhai vs Sarabhai. MaSac is a qualitative multi-modal dataset for sarcasm detection and humor classification in code mixed conversations. To extract speech signals Google Speech API-based automatic speech recognition tool is used.

In the paper "Multilingual and code-switching ASR challenges

for low resource Indian languages" [12] approximately 600 hrs of speech dataset was created for the research from different sources and different domains. The variabilities in each language was preserved. Robust Multilingual ASR was built by considering graphemes and phonemes in six different languages. Code-switching ASR designed for 2 major pairs Hindi-English and Bengali-English. The dataset generated is huge as compared to existing publicly available dataset in this category and can be further used for future research.

The paper "Sentiment Analysis of Code-Mixed Text: A survey" [13] talks about how sentiment analysis has wide range of applications in e-commerce, recommendation systems, review analysis, etc. Sarcasm detection, multipolarity, word ambiguity are the major issues in sentiment analysis. The two major ways of sentiment analysis discussed in this paper includes machine-learning based and lexicon-based techniques.

III. OUR RESEARCH

Topics like sentiment analysis and sarcasm detection with machine learning and neural networks have gained attention in the past few years. Research has been done for monolingual dataset and certain code-mix dataset like Tamil-English, Bengali English and mainly the English dataset.

However, very few research has been done for sarcasm detection for Hi-En dataset. Our approach is to research on various algorithms, compare accuracy metrics and thus

provide insight on the most suitable algorithm that can be implemented. We are aiming to do sarcasm detection on code-mix dataset of Hindi-English by using machine learning algorithms as well as convolutional neural networks and we then compare the results.

The machine learning algorithms that will be implemented are Bernoulli Naïve Bayes, Logistic Regression and Support Vector Machines. The accuracy metrics that will be measured for analysis are F1 Score, Precision and Recall. Deep learning techniques like Long-Short Term Memory and Recurrent Neural Networks will also be will be implemented in the future.

IV. DESIGN & IMPLEMENTATION

A. Dataset

The dataset consists of tweets and comments from Twitter with over 115000 samples. The dataset is in JSON format. It has 3 parameters which are article_link, headline and is_sarcastic. In the is_sarcastic parameter, 0 means that the statement is non-sarcastic and 1 means sarcastic.

```
{
  "article_link": 5,
  "is_sarcastic": 1,
  "headline": "koi toh hamko bhi follow karlo bhai"
},
{
  "article_link": 6,
  "is_sarcastic": 1,
  "headline": "idhar toh alag level ka offer chal raha hai toh aap
  bhi aao aur ek pizza pe dusra pizza free leke jao"
},

{
  "article_link": 7,
  "is_sarcastic": 0,
  "headline": "for a sec i thought this was a rally in rawalpi
},
{
  "article_link": 8,
  "is_sarcastic": 1,
  "headline": "bhaai ko sab pata hain"
},
{
  "article_link": 9,
  "is_sarcastic": 0,
  "headline": "kiya dhoni k liye as a captan e tne safal rahe
  uska ek bahot bada karan rahe hain"
},
{
  "article_link": 10,
  "is_sarcastic": 0,
  "headline": "ab yeh kaam bhi karne laga hain hamara kuldee
},
{
  "article_link": 11,
  "is_sarcastic": 0,
  "headline": "jeeta hu bhai aise comment karke"
},
```

Fig 1: Dataset

Table II gives the overview of total number of tweets and count of sarcastic and non-sarcastic tweets in our training dataset.

Further the model assigns 'Sarcastic' class to 1 and 'Not sarcastic to 0. When an input is provided from the testing dataset features of the input text are compared with the training dataset and accordingly output is produced.

TABLE II: TRAINING DATASET

Category	Tweet Count
Total Tweets	115000
Sarcastic	57633
Non-Sarcastic	57367

B. System Architecture

The overview of our project has been shown in Fig 2 which includes the key algorithms we have used for implementation. The accuracy yielded by each will enable us to make decision on the effectiveness of the algorithm for sarcasm detection.

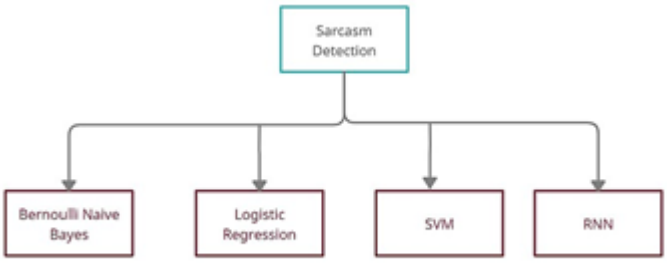

Fig 2: Block Diagram

The diagram in Fig 2 defines the hierarchy of the algorithms with respect to implementation and defines the various components and sub-components. We have used 80% of the data for training and the remaining for testing in each of the algorithm applied

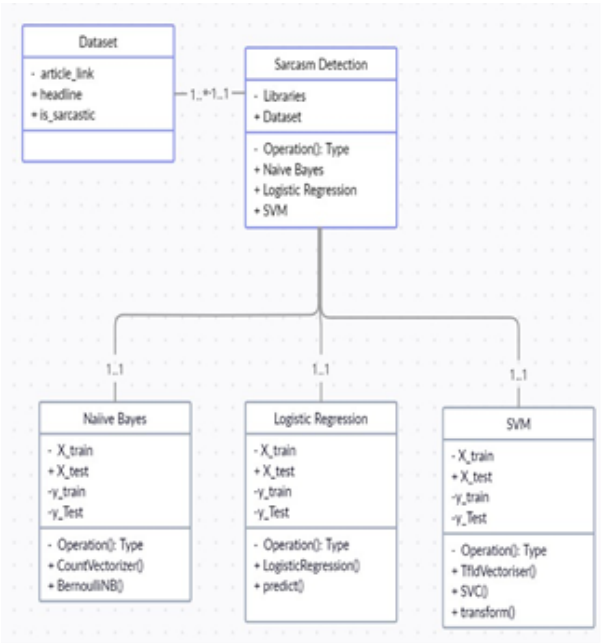

Fig 3: UML Diagram

The step-by-step process in the development of the machine learning model has been outlined in Fig 3.

The key component of any machine learning algorithm is the dataset. Hence the process starts with collecting suitable dataset and data analysis. Further the algorithms have been implemented in sequence to follow.

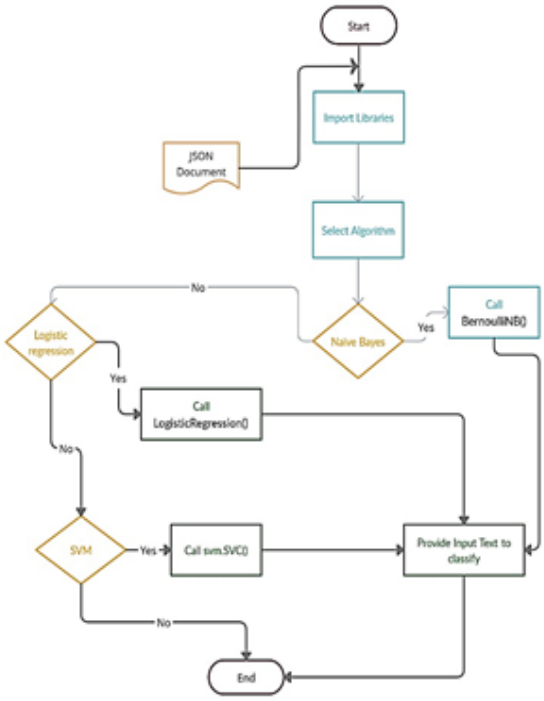

Fig 4: Flowchart for Mode

C. Algorithms

Machine Learning allows computers to seek new tasks without being explicitly programmed to perform them.[2] In Sentiment analysis, machine learning can be used to analyse text for polarity. The three models that we have used in our project are discussed below.

1) Bernoulli Naïve Bayes

Bernoulli Naive Bayes is a part of the Naïve Bayes family. Naïve Bayes classifier is a probabilistic classifier and has been derived from the concept of Bayes Theorem which assumes that all features are independent or unrelated.

The concept of Bernoulli Naïve Bayes follows the concept of probability called the Bernoulli Distribution as shown below.

$$p(x) = P[X = x] = \begin{cases} q = 1 - p & x = 0 \\ p & x = 1 \end{cases} \quad (1)$$

One of the reasons for using Bernoulli Naïve Bayes is that it based on Bernoulli Distribution and accepts only binary values such as true or false, yes or no, 0 or 1 and so on. In our model we have used sklearn and calculated the accuracy and f1 score of the model.

2) Logistic Regression

Logistic Regression is a type of statistical model which is used for classification and predictive analysis which comes under the Supervised Learning technique. It is mainly used when the dependent(target) variable is categorical.

As a result, the result must be a discrete or categorical value. Rather than providing the exact values of 0 and 1, it provides the probabilistic values that fall between 0 and 1. The Logistic regression equation can be obtained from the Linear Regression equation

1−*y* 0 1 1 2 2 3 3 n n (2

In logistic regression, we fit a "S" shaped logistic function, which predicts two maximum values, rather than a regression line (0 or 1). The logistic function's curve represents the likelihood of something.

Since it can classify new data using both continuous and discrete datasets, logistic regression is a key machine learning approach. The Fig 5 shows the logistic function:

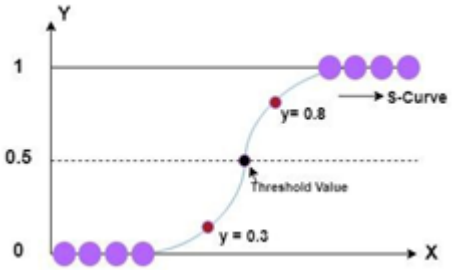

Fig 5: Logistic Regression

3) Support Vector Machine

SVM was introduced by Vladimir N. Vapnik and Alexey Ya. Chervonenkis in 1964. The SVM algorithm's objective is to establish the optimum decision boundary which is chosen in a way that maximizes the margin, which is the distance between the boundary and the closest data point from each class.

The new data points are then classified based on which side of the boundary they fall on.

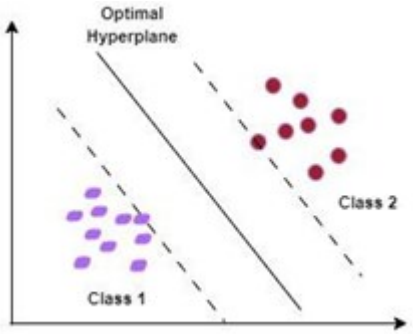

Fig 6: Support Vector Machine

In the case of sarcasm detection, SVM can be used to classify a given text as sarcastic or not by training the model on a labelled dataset of text examples. In our project we have used sklearn linear SVM library for implementing our SVM based models.

V. RESULT AND ANALYSIS

A. Result

We have used 3 different approaches to split the data into training and testing sets. The first approach includes 80-20 split with 80% of data used for training and 20% used for testing. The reason for splitting the dataset into 80:20 ratio is that it provides a good balance between having enough data for the model to learn from, while still reserving enough data for evaluating the model's performance.

The other two splitting approaches have been summarized in Table 3 below. The accuracy of a model is defined as the ratio of the number of correct predictions to the total number of predictions.

We can infer from the Table III that all the three algorithms have very close performance results. The performance decreases when the train-test split is made 50-50. Support Vector Machine gives the best result at a 80-20 split.

We have used F1 Score to evaluate the performance of different algorithms from which we have seen that SVM performs the best out of the three models.

Train-Test Split	**Accuracy Obtained**		
	Bernoulli Naïve Bayes	**Logistic Regressi**	**Support Vector Machi**
Training Set: 80% Testing Set: 20%	0.7918717122	0.7918717122	0.873652173
Training Set: 60% Testing Set: 40%	0.7911845730	0.7918717122	0.870413043
Training Set: 50% Testing Set: 50%	0.7785357468	0.7785357468	0.868643478

B. Error Analysis

We found that the model showed bias in the result depending on the length of the test input. A comparatively shorter sentence would have higher probability to be classified as being "Sarcastic" whereas a longer sentence would be classified as "Not Sarcastic".

To rectify these errors, we have planned to use POS tagging on the dataset and further implement deep learning techniques.

VI. CONCLUSION

With the increase in number of people using social media to express their views, tasks like opinion mining and sentiment analysis have gained a lot of importance. And using sarcasm in these social media texts make these tasks much more challenging. In our project, we have presented an English-Hindi code-mixed dataset for sarcasm detection. We also presented a baseline supervised classification that is developed using the same dataset which uses three different machine learning techniques.

VII. FUTURE SCOPE

In the future, we intend to implement a deep learning algorithm

for detecting sarcastic texts. We will compare the two approaches that we have implemented to understand which algorithm or approach gives the best results

ACKNOWLEDGMENTS

We acknowledge Thakur College of Engineering and Technology for giving this wonderful opportunity to think innovative and express our ideas. We would also like to express our gratitude to our mentor Mrs. Shruti Mathur for her guidance throughout. It is our privilege to be able to do such work

Disease Prediction System

Shubh Patel, Ashutosh Yadav, Mrs. Mary Margaret, Nishant Upadhyay
Thakur college of engineering & technology Mumbai, India
pshubh291@gmail.com, ashutoshy115@gmail.com, mary.margarat@thakureducation.org, nishantu876@gmail.com

Abstract-Predire is a web-based application that will help to predict diseases and provide an educational environment for students and patients. This project will provide an effective platform for the medical students and patients. There's been an increase in soul disease prediction models but there has never been models which predicts more than one variety of disease in a wider spectrum. This project focuses and tackles this research problem by using classification algorithm of data science on meticulously curated medical dataset. Random Forest Classifier is used for the classification of the dataset, where the users predict their disease based on 5 input symptoms. The met conclusion of this project is to predict user's diseases accurate, however the research is labelled to be in progress as with more medical data, more accurate, descriptive and intricate prediction models can be made.

Keywords— Healthcare Prediction, Recommendation, Machine Learning.

I. INTRODUCTION

Predire is a website that uses Machine Learning algorithms to predict diseases with the help of symptoms provided by our users/patients. It also provides Healthcare related news and research papers for doctors and medical students.

This website caters not only to the public but also to hospitals and private corporations.

With the integration of powerful machine learning techniques and accurate medical data, we have developed a website that can predict 41 diseases. It predicts diseases that range from common diseases such as common cold, fever, etc. to severe diseases such as hepatitis, tuberculosis, diabetes, etc.

The already existing applications for disease prediction do not predict a wide variety of diseases, instead, they are focused on predicting a single disease. Additionally, they do not provide an environment where the user can learn or gain knowledge about topics related to their application.

Predire tackles all the above constraints and provides an intricate and accurate prediction using a different approach than the pre-existing systems on the internet. Predire's prediction model is weight-based. It predicts the highest weighted disease based on 5 symptoms provided by the user. Here, weights are values ranging from 1-5 assigned to each disease based on their severity, where the higher value indicates a higher severity.

II. THEORY

The main objective of making this project (Predire) is to create an environment where the user can browse through various Health-related news, site curated research papers and get an accurate synopsis of the disease they might have while using our Prediction page. As this is a Web Application, it is easily accessible from anywhere in this world as long as there is a stable internet and hardware, and software requirements are met. The User Interface of the website is meticulously designed for a user-friendly experience wherein the user can easily navigate through the website using our well-designed Home page and Navigation bar. The main highlight of the website is our Prediction model. It is an easy-to-

understand model which consists of 5 symptom inputs and a predict button. We have also provided detailed instructions on how to use the model for the user's convenience. There is also a Blog/News section where we provide news feeds from around the world related to the field of medicine. This project is also trying to create an environment that caters to medical students

by providing latest research papers in the field of medicine.

III. LITERATURE SURVEY

We read a variety of research articles as our project was being developed, and they helped us comprehend our alternatives and potential solutions. They also assisted us in comprehending the technical and mathematical knowledge that will be useful.

One of the papers that we studied was the "Disease Prediction in Data Mining Technique" by the Authors S. Vijyaranhi and S. Sudha and it talked about how data mining techniques are used to predict various types of diseases. This paper reviewed research papers that focused on predicting heart disease, diabetes, and breast cancer. The prediction of heart disease was discussed using machine learning algorithms such as naive bayes, K-NN, and Decision List. When compared to other algorithms, the nave bayes algorithm has the highest classification accuracy. The author concluded that naive bayes correctly classifies

74% of the input instances. Following that, we will talk about breast cancer prediction. It is carried out using a variety of data mining techniques, including C4.5, ANN, and fuzzy decision trees. Using C4.5, the author discussed and resolved the problem's issues and algorithms. Using ANN, the author concluded that the network is trained to have consistent accuracy over time and good performance. Finally, we discuss diabetes prediction, where the author discovers overfitting and over generalization behavior of classification using a homogeneity-based algorithm. The author predicts class accuracy using a genetic algorithm.

The second article was titled "The Use and Role of

Predictive Systems in Disease Management" published by the authors David H. Gent,, Walter F. Mahaffee, Neil McRoberts, and William F. Pfenderdid a study about the Disease predictive systems are intended to be management aids. With a few exceptions, these systems typically do not have direct sustained use by growers. Rather, their impact is mostly pedagogic and indirect, improving recommendations from farm advisers and shaping management concepts. The degree to which a system is consulted depends on the amount of perceived new, actionable information that is consistent with the objectives of the user. Often this involves avoiding risks associated with costly disease outbreaks. Adoption is sensitive to the correspondence between the information a system delivers, and the information needed to manage a particular pathosystem at an acceptable financial risk; details of the approach used to predict disease risk are less important. The continuing challenge for researchers is to construct tools relevant to farmers and their advisers that improve upon their current management skill.

And the third paper published by the authors Mangesh Limbitote and Kedar Damkondwar named "Prediction Techniques of Heart Disease using Machine Learning" talks about Heart is one of the most important parts of the body. It helps to purify and circulate blood to all parts of the body. Most number of deaths in the world are due to heart diseases. Some symptoms like chest pain, faster heartbeat, discomfort in breathing are recorded. This data is analyzed on regular basis. In this review, an overview of the heart disease and its current procedures is firstly introduced. Furthermore, an in- depth analysis of the most relevant machine learning techniques available on the literature for heart disease prediction is briefly elaborated. The discussed machine learning algorithms are Decision Tree, SVM, ANN, Naive Bayes, Random Forest, KNN. The algorithms are compared on the basis of features. We are working on the algorithm with best accuracy. This will help the doctors to assist the heart problem easily.

Furthermore, in the fourth paper named "Data-driven Automatic Treatment Regimen Development and Recommendation" by authors Leilei Sun, Chuanren Liu, Chonghui Guo, Hui Xiong, Yanming Xie discussed about the analysis of EMR records to detect typical treatment regiments and measuring (quantitatively) the effectiveness of those regimens for specific patient cohorts. The authors compare the similarity of treatment records in the EMR, use Map Reduce Enhanced Density Peaks based Clustering to group similar ones to treatment regimens, extract semantically meaningful information for the doctor, and estimate the treatment outcome for a patient cohort for a typical treatment regimen. The results of an empirical study using this approach show that the patient's effective rate and cure rate both increases.

In summary, recommendation systems are used to suggest various measures to patients or users based on their history or symptoms. Therefore, this research helps us understand different aspects of customer behaviour.

IV. METHODOLOGY AND PROPOSED MODEL

When creating a project or piece of software, it is essential to comprehend the process or kind of software development lifecycle model that will be used. We need to select the SDLC model that will work best for our project from a variety of models, which is why we use the agile methodology.

Additionally, the actions taken up until this point have been previously discussed. After deciding on a project title, we first began studying about and establishing the project's requirements. During this, we also decided on the approaches to be applied. After that, we made the decision to research already-in-use systems to gain a deeper knowledge before implementing them. We devised a schedule for when this implementation should take place, along with considerations for any revisions that could be necessary and the errors that should be investigated. Therefore, we selected Agile methodology

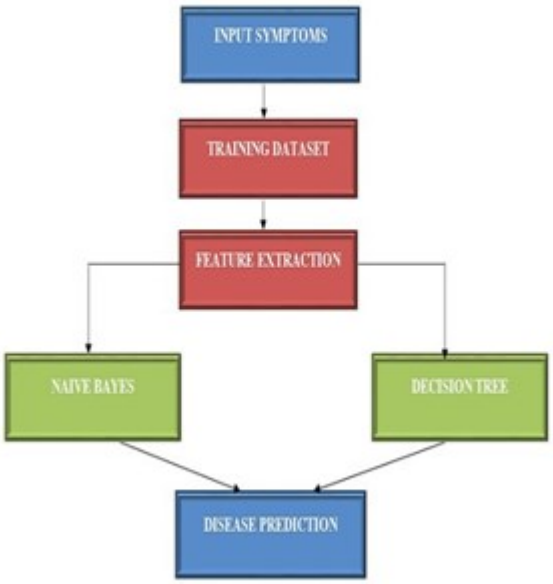

Fig. 4.1 Data flow diagram

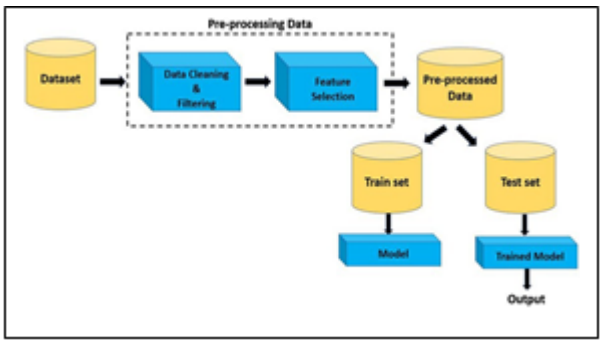

Fig. 4.2 Block diagram

Above attached diagrams are a couple of the ones that we made during our project planning phase using tools available online to achieve our goal.

V. IMPLEMENTATION

This system's primary goal is to diagnose illnesses using user-provided symptoms as input. Additionally, if

it is feasible, we might test a few additional machine learning models so that we can compare how they perform to the ones we are currently using

Fig 5.1 Random Forest Classifier

We decided on Logistic Regression algorithm along with feature selection to yield high accuracy using training and testing dataset which was freely available for us to use. The model was trained and tested using the dataset which contains the columns of different symptoms and based on these symptoms the prediction of diseases.

Fig. 5.2 Libraries Used

Fig. 5.3 Reading and training the dataset

Figures 5.1 and 5.2 are a few code examples that we used and put into practise when categorising the dataset during training and testing and when using feature engineering, respectively

Fig 5.4 Data Exploration and Optimisation

VI. RESULTS AND DISCUSSION

The model predicts the diseases and makes a confusion matrix and based on the predictions results are provided. Based on the results of confusion matrix using different algorithms results are displayed. Below is the output that we managed to achieve.

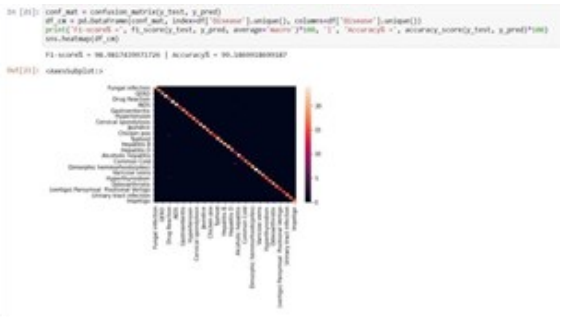

Fig 6.1 Heat Map

Fig. 6.2 Confusion Matrix

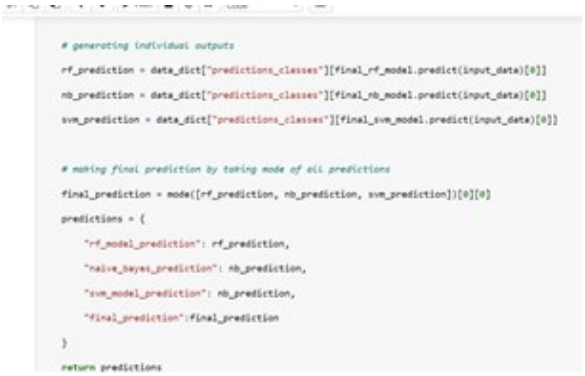

Fig. 6.3 Results

All the above-mentioned actions were taken after consulting the manual and receiving advice from professionals in the field. What is anticipated of the system is predicted by its output. One anomaly, which is that the values that are to be submitted for prediction right now are being given and taken in normalized form, is something we would like to fix in the following phase. So, that's one significant feature that we anticipate changing later in the ensuing period.

The Website will be based on prediction model where users can embed their symptoms and get the possible prediction based on the symptoms. The best possible accuracy level of prediction model. Nearby hospital will be suggested based on the predicted disease. Users will have all the medical data stored in one place with all the prescribed data uploading facilities. The simple Gui will help user in easy navigation. Many other side features such as recommendation of nutritional foods, tracking of one's data hence acting as a data storage as well, appointment booking system, chatting system and

many more minor features which are aimed to healthify one's life

The scope of the project is clear to give a simple and attractive application to simplify the work as well as to reduce the efforts while doing it offline or we can say by doing it with old methods. In this application we are able to save database of all patients present on the site.

Prediction Module: As part of healthcare, a prediction

model is necessary as it would help users to know if they are suffering from disease or not thereby also reducing the cost of visiting a doctor which costs a lot.

Throughout this research paper, logistic regression, naive Bayes, support vector machines, decision trees, random forests, XGBoost classifiers, CatBoost classifiers, AdaBoost classifiers, and extra-tree classifiers. Experimental results show that there are his two ensemble learning methods, Adaboost classifier and XGBoost classifier. It is very difficult to predict the actual customer society. With the upcoming concepts and frameworks of reinforcement learning and deep learning, machine learning is proving to be one of the most efficient ways to tackle problems such as churn prediction with more accuracy and precision in the future. increase.

VII. CONCLUSION

The mechanism proposed aims at the continuous data and establishes the prediction model based on the regression analysis method, which is not only applicable to the analysis and prediction of the guidance data in the smart medical industry. In the future, new features can be added to improve the accuracy of the prediction model. For example, new disease data have an impact on the number of systems seeking medical treatment and the hospital. In addition, in the face of a larger amount of data, we can use the cloud architecture in this paper to carry out distributed computing. It has all necessary features for one's need. So, this project will help consumers for improving their health and know more about digital healthcare. In the near future, smart medical healthcare can be improved in some aspect, for example, this way can help patients and doctors identify the right information and deal with this information effectively. The first step of literature survey and research was completed till now for more knowledge of the domain.

Abstract— **For intelligent vehicles, the detection of traffic lights is an essential duty. Due of the variety of backgrounds and lighting situations, it is not trivial. Consequently, a traffic light detection system that may be used in various settings is required. Human drivers can typically recognise the relevant traffic lights with ease, but autonomous vehicles must incorporate their recognition. For the detection and recognition of the traffic light, however, an extra solution is needed. Deep learning algorithms have demonstrated excellent performance and a strong capacity for generalisation, which includes issues with traffic.**

Keywords— Blob analysis, color thresholding, waterwashed.

I. INTRODUCTION

In the modern world, real-time traffic light recognition via a camera stream has a variety of uses. The majority of trains in Indian Railways now rely on manually detecting train signals, which raises the risk of accidents. In this case, a system that instantly recognises the traffic light from the video feed and warns the driver can increase the safety of the roads and railways. When there is low vision due to fog or other environmental circumstances, this device might help the driver recognise traffic lights. Different colours, sizes, and shapes can be found in traffic lights. We concentrate on the detection of circular red and green lights in this work. Later, the same strategy can be expanded with a few minor adjustments for traffic signals with different colours and forms.

II. THEORY

The structure for image recognition problems generally looks like the following –

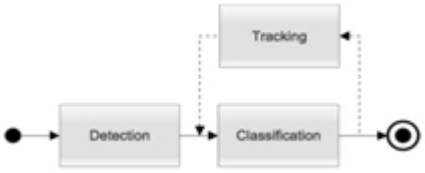

Fig. 2.1 Data flow diagram

The process breaks down in a similar three part fashion- Identifying Regions of Interest, Training a Classifier, Tracking and Optimization. Images from urban scenes have

a lot going on. There are cars, pedestrians, traffic signs, and a whole slew of information that needs to be processed at a quick rate. Detection limits the amount of information that needs to be analysed to much smaller regions of interest (ROI). In our case, the ROI represent a list of potential traffic light candidates. If handled properly, detection should improve the system's speed and performance.

III. LITERATURE SURVEY

We read a variety of articles as our project was being developed, and they helped us comprehend our alternatives and potential solutions. They also assisted us in comprehending the technical and mathematical knowledge that will be useful.

One of the papers that we studied was the "Literature Review on Traffic Control Systems Used Worldwide" by the Authors Vaishali Mahavar and Dr-Jayesh Juremalani and it talked about over the past few years, the condition of the road infrastructure has steadily improved. Road transportation has become a focus of rapid development as connectivity has grown. Better access to services, simpler transportation, and greater freedom of movement are all made possible by roads. However, when traffic congestion in major cities worsens, it creates a recurring problem in the crowded downtown regions. The system of urban transportation is significantly enhanced by traffic signals. By selecting the proper signal timing settings, they manage the flow of traffic on metropolitan roadways. Intelligent transportation systems' primary component, adaptive traffic signal controllers, play a key role in efficiently reducing traffic congestion by making real-time adjustments in response to shifting traffic network dynamics.

The second article was titled "Traffic Lights Detection Based on Deep Learning Feature" published by the authors Changhao Wang, GuanWen Zhang, Wei Zhou, Yukun Rao

& Yu Lv. In this study, they investigated the recognition of traffic lights using deep learning, which can automatically extract features with representation and resilience from input images and prevent the need of artificial features. The

method for detecting traffic lights that is suggested in this paper consists of two stages: (1) A proposed region; and (2) An organization of traffic signals. They suggest a method for determining regions based on the geometrical, colour, and intensity information of traffic lights. Second, convolutional neural network (CNN) was used to classify traffic lights,

with an average accuracy of 99.6%. On 6804 photos of various scenarios, they tested their system for detection, and the recall and accuracy of detection were 99.2% and 98.5%, respectively.

And the third paper published by the authors Karsten Behrendt; Libor Novak; Rami Botros named "A deep learning approach to traffic lights: Detection, tracking, and classification" talks about how the classification and recognition of traffic lights is essential for automated driving in urban settings. There are currently no systems that can accurately detect traffic lights in real-time, without using a map, and at adequate distances for comfortable city driving. They suggested a comprehensive system that combines a real-time traffic light detector, tracker, and classifier based on deep learning, stereo vision, and vehicle odometry.

Furthermore, in the fourth paper named "Traffic Light Detection with Convolutional Neural Networks and 2D Camera Data" by Dennis Hein discussed about the popular datasets BSTLD and DTLD that were used to train a variety of traffic light detection models utilizing the TensorFlow Research repository. The analysis showed that there is typically little performance loss when transferring predictive power from one dataset to another that is similar. This conclusion does not appear to be impacted by either architectural decisions or geographic differences between datasets (such as traffic signals at the beginning or end of an intersection). Additionally, it demonstrates how crucial it is for self-driving autos to obtain predictions promptly in addition to accurately. On realistic hardware, the architectures and resulting models should be tested for computational performance. Both topologies deliver (near) real-time performance on strong, contemporary hardware (RTX 2070), with SSD Mobile net reaching about 50FPS and Faster RCNN Inception reaching about 22 FPS. An RTX 2070 will be too expensive for car manufacturers though.

IV. METHODOLOGY AND PROPOSED MODEL

When creating a project or piece of software, it is essential to comprehend the process or kind of software development lifecycle model that will be used. We need to select the SDLC model that will work best for our project from a variety of models, which is why we use the agile methodology.

Additionally, the actions taken up until this point have been previously discussed. After deciding on a project title, we first began studying about and establishing the project's requirements. During this, we also decided on the approaches to be applied. After that, we made the decision to research already-in-use systems to gain a deeper knowledge before implementing them. We devised a schedule for when this implementation should take place, along with considerations for any revisions that could be necessary and the errors that should be investigated. Therefore, we selected Agile methodology.

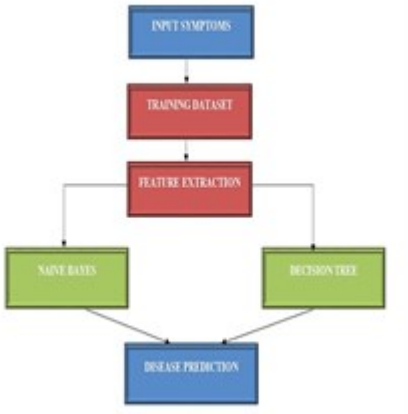

Fig. 4.1 Data flow diagram

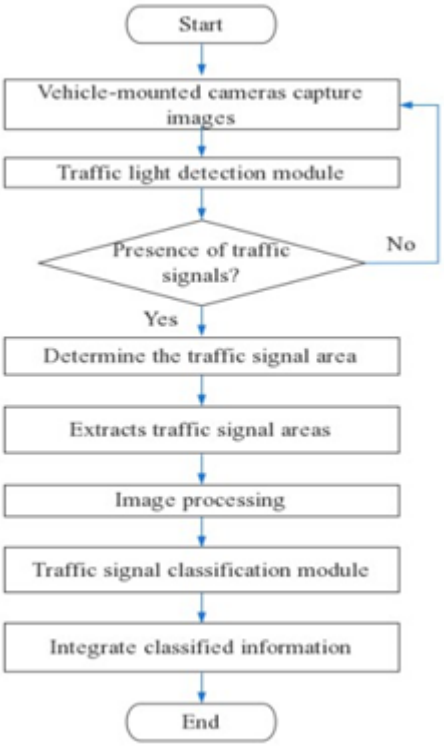

Fig. 4.2 Block diagram

Above attached diagrams are a couple of the ones that we made during our project planning phase using tools available online to achieve our goal.

V. IMPLEMENTATION

To precisely identify the regions of interest in photographs, numerous, varied strategies have been presented. Color thresholding, BLOB analysis, and spotlight identification are three of the most used methods for finding traffic signal candidates. Although obviously not all possible combinations, it is fairly frequent to see at least one of these three used. Given that we know the traffic lights will always appear in the top-half of the image, we can begin by removing the bottom portion of the image.

Fig. 5.2 Getting rid of the lower part of the image for removing unwanted part.

The application of colour thresholding is the subsequent step. Red, yellow, or green are the three hues that are emitted by traffic lights. Limiting the image to areas where certain colours are present is the core notion behind colour thresholding. The image's non-red, non-yellow, and non- green areas are all set to zero (black). The colour space, the threshold cutoff, and fluctuations in light are three crucial factors to take into account in order to successfully isolate the colours we're interested in. Images are often represented in the RGB colour space. However, RGB combines information about colour and intensity across all of its channels. The RGB format is hence sensitive to variations in illumination. We cannot allow differences in lighting (such as sunny, rainy, cloudy, etc.) to prevent our threshold from identifying the proper colors if our objective is to detect traffic signals. Many choose to switch to color spaces that separate the chroma, or color information, from the luma, or image intensity, in order to combat this.

After this, we have to get the image information refined. The information in the scene is often refined using morphological filters by colour and BLOB-based approaches. The term "BLOB" (Binary Large Object) refers to collections of linked pixels in an image. Blobs are the black, linked areas in the illustration below.

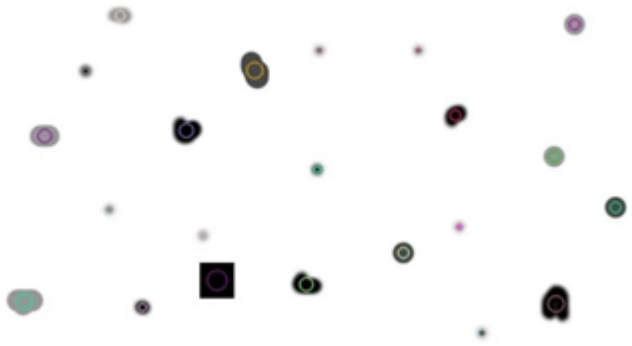

Fig. 5.3 Example of blob analysis from OpenCV

The red threshold image from above is another illustration. It is possible to think of each red object in the image as a BLOB with significant characteristics like size and form.

A wide range of image processing techniques known as morphology process images based on forms. The two main morphological processes are erosion and dilation. Dilation enlarges the foreground object, whereas erosion removes the foreground object's boundaries.

Fig. 5.4 Left the original image. Center the dilated object. Right the eroded object. Graphic by OpenCV

Dilation is excellent for fusing together damaged pieces of an object, while erosion is useful for removing noise later on. This will enable us to fill in any gaps left by the color threshold and provide a more comprehensive image. Spotlight detection is the third technique. A bright area in an image surrounded by a darker area is what is meant by this technique. With this detecting technique, it is anticipated that the intersection's traffic lights will appear to be brighter than the area around them. A grayscale conversion and a white top-hat filter are applied to the image. The top-hat filter emphasizes regions that stand out from their surroundings in brightness.

VI. RESULTS AND DISCUSSION

In order to find a group of bright spots in the image, we first use the spot light detection method described above

Fig. 6.1 Applying a top-hat filter to a grayscale image

Fig. 6.2 Applying colour thresholding to the processed image

Take note of the fact that many of the spot lights come from the sky or nearby structures. We could drastically cut down on false positives if we could disregard the spot lights that emanate from such locations. We must carry out some type of image segmentation to distinguish items from the foreground and from one another. Watershed is what we employ to do this.

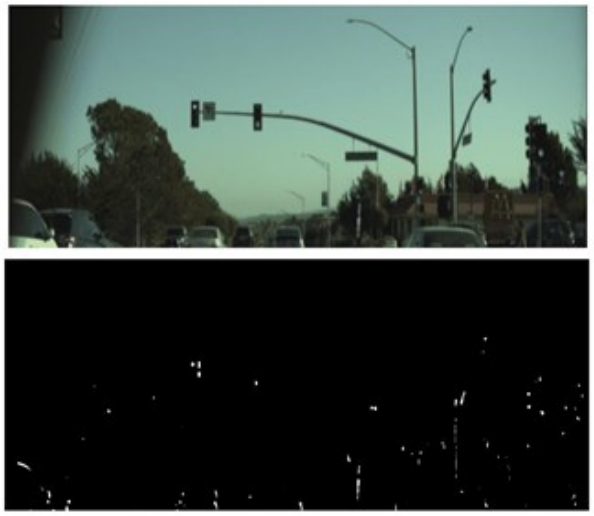

Fig. 6.3 Example of the top-hat morphology and threshold

The watershed algorithm is a well-known segmentation algorithm that is particularly helpful when removing touching or overlapping items from photos. The spot lights we discovered serve as the starting indicators in our situation. The background elements in the image will expand into larger sections as the markers begin to flood, while the lights emanating from the traffic lights will maintain roughly the same size.

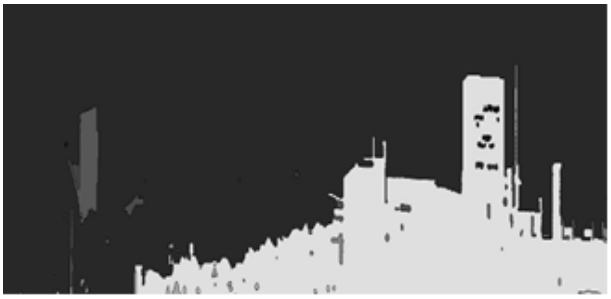

Fig. 6.4 Watershed Segmentation

Fig. 6.5 Extracting windows around spot lights that do not grow too large

We may contrast the size of our original bright spots with those of their newly segmented equivalents when the watershed change is finished. It is safe to presume that a bright spot is not a traffic signal if it became significantly larger. The penultimate stage is to remove windows from the vicinity of the light areas that have maintained relatively the same size. The end result is a set of windows that are small enough to send to the classifier.

VII. CONCLUSION

The approach we suggest in this paper can identify circular red and green traffic signals. To recognize the traffic signals, blob detection and color extraction are performed. The percentage of successfully collected traffic lights is the focus when it comes to detecting. Even though it compromises accuracy, it is critical that we do not overlook traffic lights during the detection phase. The point is that while we can always afterwards filter out false positives, we can never make up for a light that was initially overlooked. If done correctly, detection is an excellent approach to expedite the process and minimize false positives.

The management of the transportation system is a significant problem for the next generation due to the global population's ongoing growth. Future developments will be very positive. We should consider the intelligent and autonomous manner of managing the traditional transportation system. The number of automobiles likewise rises along with the population. The use of clever solutions is required to manage the enormous number of automobiles. The usage of an image sensor or imager is possible in the future. It does its task by creating an image of the roads. It does this by turning the light's fluctuating attenuation into a

signal that communicates the image. Imagers employed both analogue and digital technology.

Online Exam Proctoring System

Parikshit Acharekar , Shivani Yadav , Sejal Yadav
Information Technology TCET, Mumbai, India
1032210011@tcetmumbai.in, *1032200434@tcetmumbai.in,1032200378@tcetmumbai.in*

Abstract—**In the present world, the need for Online education is growing very rapidly and is playing a vital role in changing the world's pace of learning. The result of COVID-19 pandemic has directed many students to switch to virtual way of learning. Education through online mode is very feasible, convinient and cheap and therefore many students around the globe find it user friendly. It not only helps us to enhance our understanding of a particular concept but also it inspires us for meticulously researching of any technology which can proove a career option for us in the future. But like every other object in this world has some flaws, online education too generates and contain some disadvantages and weaknesses respectively. In this abstract we deeply articulate the problem of online learning and the technological solution for it. As conduction of examination through online mode is becoming a very tough challenge than learning. The present system used by various schools and colleges is very vulnerable and can fail to provide discipline during examination.Students appearing can try to dismantle the rules of examinations by cheating, copying or by implementing any kind of malpractices undetected by the system. This questions the integrity and confedentiality of the system. Supervision through virtual mode is not as compatible as it is in physical mode, since supervisors have to monitor each and every student present at one time which can lead to breaking of the discipline. The need of Machine learning was very essential to resolve and to extract a permanent solution for this problem. By introducing and implementing technologies of Artificial Intelligence, it will boost the organisations efforts for conducting the examinations and also will help to smoothly conduct any examination. Designing appropriate algorithms, can strategically help the machine to achieve the targets of unsupervised and reinforced learning. Artificial Intelligence can address many problems and itself contains various technologies which can provide better results in limited time. The use of Convolutional Neural Networks in the proctoring system of online learning can simplify many tasks which the developer wants to achieve. CNN (Convolutional Neural Networks) is a network of interconnected data neurons which transfers information each other, analyse with the help of input data and will train the machine itself to generate the expected output accurately. Online proctoring system can engender CNN becuase of its various vulnerabilities. It will calculate the data of the students face typically connected through webcam and can process the data by applying the appropriate algorithm like geez detection, face detection, eyeball movement, person detection etc and will provide the programmed output for each one respectively hence improving the accuracy and decreasing the malpractices of students. The CNN algorithm will divide the data into various pixels and will store them across various nodes publicly accessible by anyone which will help to initiate the learning of the machine by mapping them appropriately for expected outcomes through algorithmic calculations and deep learning mechanism. The system can also be upgraded by introducing more security improvements like secure browser detection, audio processing and analysing, deploying secured database for storage etc thus limiting the misconduction threat of a particular student and also help proctors to smoothly conduct examinations by monitoring student through the system artificially. By developing this system we will also try to discover many alternate technologies like cloud computing, data science and uncover the concept of neural networks in a deeper way.**

Keywords— Convolutional Neural Networks, Machine LEARNING, ARTIFICIAL INTELLIGENCE.

Exams are a very important component in education. In any exam, there is a risk of cheating from the students and therefore, its detection and prevention are important. Educational Trusts are offering various programs on courses that can be done online from anywhere to upgrade the skills. Besides due to COVID – 19 institutions have to switch rapidly from offline to online mode thereby changing their entire educational model. Instead of taking the lectures in classroom, students can now attend the lecture from anywhere in the world. During examinations, authentication and detection of misconduction becomes very crucial. Some institutions only authenticate the identity, some may take effort to monitor but most of the work is done by the proctors to identify malpractices and to detect them. But it is not feasible for a large scale of attendees. While some research is being done to make the systems totally human based solutions (non-scalable) or fully automatic ones (non-reliable). Authentication becomes a very important step for the next activites or functionalities in the system. However, there is no comprehensive solution which will combine multi-biometric continuous authentication with continuous visual

and audio monitoring to provide 100% accurate results. During the examinations, the web camera is used to capture the photos of the candidate after certain intervals of time (approximately 30 to 60 seconds). These photos are compared with the one which is already scanned and stored in the system during validation. This helps to keep a check on the candidate who attempt for cheating with disguise. If the system finds any deviation, then it is flagged as an error and notified to the administrator. These photos are analysed by the proctor to ensure the security of the online exam. This mechanism is especially useful in the areas where internet stability is relatively low. These were the key features of the system. Besides conduction of examinations, result displayer, paper uploading section, scanner etc will be present in the current system. This paper describes about the specifications and features explained thoroughly in this section and will also additionally upgrade as per the custom needs. It is based on applications which offer a rigid authentication service of students through a biometric recognition system, as well as an artificial continuous proctoring through automatic image which will constantly check the behavior of the student through his posture, gaze estimation, eyeball movement and detecting the presence of another person as well as switching of one browser to another during the examinations, allowing the institute to mainatin the

discipline and not harm the integrity of the examination courses to gain value of which will benefit both institutions and students. Neural Networks algorithm use will constantly help to change, monitor and specify the movement of the student at every point of time through passing the data to different neurons.

LITERATURE SURVEY—

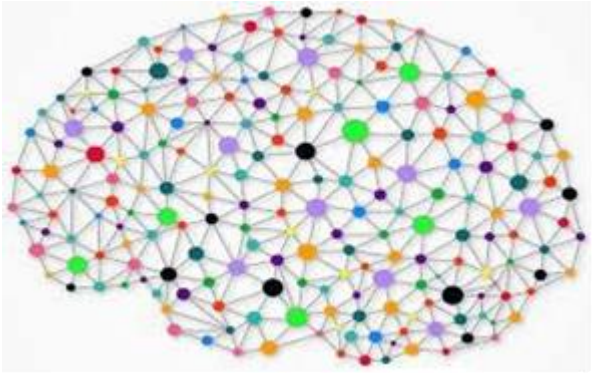
Prior to this proposed system, some researchers and technologists have carved some intelligent techniques which can prove very beneficial to monitor and analyse human behavior and to predict the outcomes based on the input data and many digital ways like semi automated machine processing and by using IOT devices. Previously there was an attempt to do semi-automated machine proctoring, through building desktop robot. This desktop robot contains a 360◦ camera and motion sensors. The robot will then capture the data through web camera and then will transmit the data to a monitoring center and will predict if there is any suspicious motion inside the captured video. The most important flaw in this system was that a single camera cannot rotate and see what the subject sees, and as a result it may inspire the user to provide a breakthrough from the algorithm and he/she can try to cheat via vaiorus non integral ways which were not significantly programmed in the system like rotation of the camera and the time taken for the system to send the data from the motion sensors which are not fully capable of acquiring every single piece of reactions of the user.

In 2016, Jin, Jian, Feng, Huihui, Gu, Liubao developed an intelligent exam management system based on the Browser/Server structure for Hebei University. This system was integrated with three levels: user interface, business logical, and data access. These levels were able to manage the data, behavior analysing of the student and performance of students through intelligent data processing. Three function modules based on ADO.NET, C#, and ASP.NET

technology were developed. Many sub-function modules, including the exam arrangement module and the score registration module, were also insalled. The results showed that the established intelligent exam management system can efficiently achieve education informatization and plays a significant role in eadministration and managing the system.

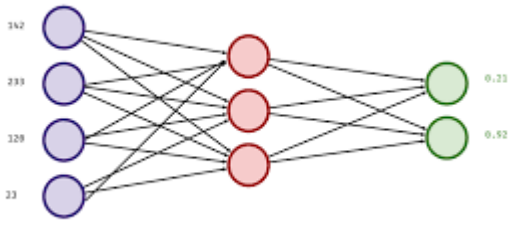
Proposed Methodology—

The paper demonstrates some features of this system which are used by the technique convolutional neural networks. CNN is the main important sub type and the most powerful type of neural networks than RNN(Recurrent nerual network), ANN(Artificial Neural Network). This system will be using a combination of both CNN and RNN. Neural networks are basically are collection of neurons interconnected with each other which are used for passing the data from one node to another. Likewise in biological term, our brain carries a millions of neurons which are interconnected with each other which helps us to recieve and store the input data from our sensory organs and then process the data by using past experiences and making it applicable to our real life.



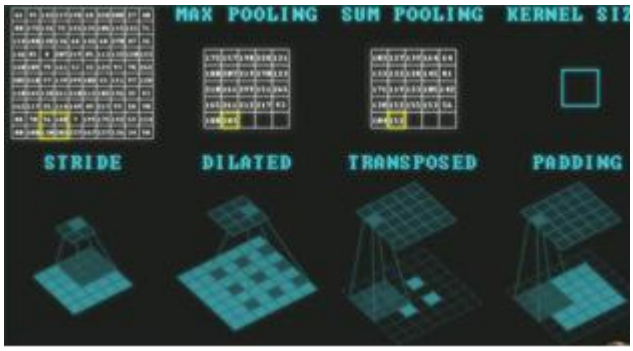
Similarly the machine stores data which it recieves from the input devices or motion sensors into the neurons. These neurons are inteconnected with each other and are capable of storing and passing the information from one neuron to another thereby helping the machine to process the data and analyse it in an effective way thereby helping the machine to generate the user expected outcome from the given input. Various types of algorithms are applied like the backpanel algorithm used in RNN which is used for finding the data stored in the nodes previously thereby making it efficient for reusing the same node which carries, saves and extracts data of the node all time. The machine carrying NN technology is capable of learning itself from the data and this proves very beneficial for the machine to process any type of input, learning it and then producing the expected outcome. Various machines running on deep learning concept carries Neural networks technology for executing machine learning. ANN(Artificial Neural Networks) works mainly on the input data which is text or string format and it is a linear network going in only one direction therefore not efficient and reliable for the machine to learn from the data. CNN(Convolutional Neural Network) works mainly

onimage processing and RNN(Recurrent Neural Network) consists of sequential data which includes backtracking of the node data.



In this paper we have briefly discussed about CNN(Convolutional Neural Networks) as it is used for processing the image input. In CNN firstly, the input data in image format is divided into multiple pixels or array of numbers and then the data is stored in a matrix format. In the beginnning the input data stored in neurons is very large in size (in kilobytes) as it is very necessary to shorten the data. The data is then represented as a matrix

and then the feature detector matrix is applied to each and every portion of the input data. Feature detectors or filters help identify different features present in an image like edges, vertical lines, horizontal lines, bends, etc. After applying the feature detector matrix then the final convolutional matrix is generated which is very shorter in size as compared to CNN. This matrix which contains every part of the regular image is used to compare with any type of input images which the machine recieves in the future to predict and analyse the data. For example: The human brain can recognize any of his known person regardless of any look he/she may come in front of you. Bur the machine programmed with a certain images will not be able to identify the person. Feature extractor is a very important model in CNN technology as it determines the structure of the image divided into pixels connected through neurons altogether and then applying the feature extractor, max pooling, sum pooling for dilating and shortening the input image which will contain the exact version of the input image which can identify further images of similar kind.



Our system will mainly focus on delievering the expected outcome to the user by using convolutional neural networks as using the base technology for identifying the user and his positions through video which is a combination of images. The system will mainly include 5 base modules which will

help the user and the institute for a smooth conduction of examination.

Authentication Module – This proposed module will authenticate the user with the input image which will be already stored in the system to check the authenticity of the user and to identify the disguise appearing for the test.

Pose and Geez estimation – The proposed module will observe the head movement and the physical movement of the user and will check their changing behavioural pattern. A new method, called as M3L (Multi- level, Multi-modal, Multi-task Learning), is used to improve efficiency in face points and other facial attributes detection (gestures of the face and eyes).

Active Window detection – The proposed model will check whether the system from which the user is giving the examination is having any alternate browser or window opened, by detecting it and getting a screenshot.

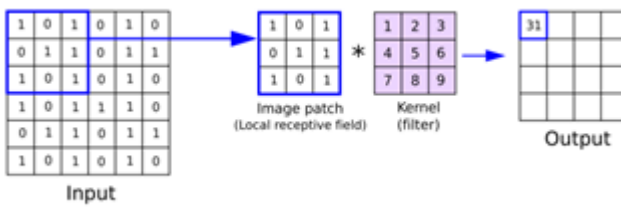
Facial Recognisation – This proposed model will check the facial expression changes recieved by the user through the webcamera and will identify and ensure the change in patterns of the structure of the image, eye movement, lips movement, analyse the changes and and will provide the estimated output to the user as programmed.

Person detection – This proposed model will ensure that there is no one in the surroundings of the user and also will ensure that the user does not leave the original place. It will detect the presence of another person and will formulate the data and will send the expected output to the user accordingly. Besides this, the system will also contain a Non relational database eg:- Mongo DB to store the exam information and subject score unknown to the user seperatley in each users database. While monitoring the test, the captured images are processed with different techniques in order to detect and identify inappropriate behaviour of students during examination. For instance if , the system is able to detect if the student is receiving or is checking forbidden documentation (books, other electronic devices) by facial and pose detection. All these actions can be strictly forbidden in some face-to-face learning activities according. This system will include a facial detection and recognition module through a biometric model which will capture images and compare the student appearing for the exams with the input user image stored at server side. Besides This system includes a facial detection and recognition module through a biometric model created using registration time face pictures. The output results are clustered in five groups a) Detect another person b) How many people are present in front besides user c) who should be the legitimate person allowed to enter the screen d) If the person is helping the user inappropriately by using false means. This totally will provide integrity and will maintain the decorum, values, and trust between institution and the student and will help the student and institution to progress efficiently.

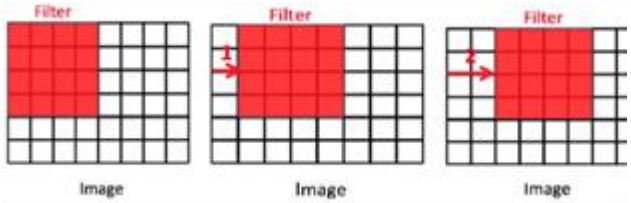
Mathematical Modelling— Mathematical modelling is the process of depiction and conversion of real life problems and solving then using mathematical solutions and

which is a type of mathematical modelling which represents the processing of the objects in a continuous manner. Video data taken through the input devices like webcamera will pass this information to the CNN neurons, where in the processing of the data will take place. However this data will not be in a discrete state, it will constantly change its patterns and create a new structure every single time. Also this system will be using quantitative model where matrix representation of the input data are executed by applying various equations like max pooling, sum pooling equations of the feature extractor. This section decsribes about the stages of the input data when passed to the CNN network feature extractor and the steps carried by it to generate a convolutional network matrix by applying mathematical modelling. It goes through convolutional modelling first before passing the new dataset of the input image to the neural networks. The input video is the result of multiple images, these images will be divided into pixels and then passed to the first stage of the feature extraction which is filtering. In this stage the pixel matrix which is of fixed height and width will be multiplied with the kernel matrix of fixed rows and columns. Every block of the matrix will

be multiplied with the kernel matrix and lastly forming the feature map or convolutional matrix. The equation used in this process is O=[ƨ-K]+1 where ƨ is the input matrix style and K is the kernel size.

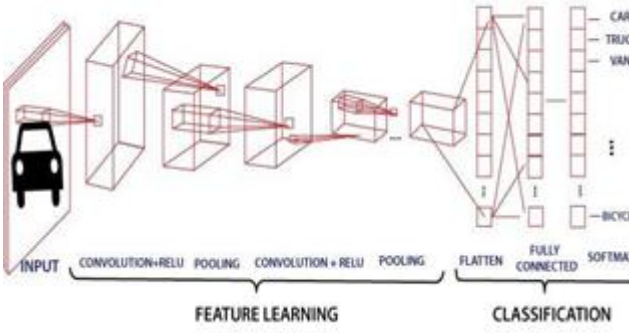


After filtering of the data the the next step is striding. Stride is the process where the filter is moved from left to right, top to bottom with one pixel column changeon the horizontal movements, then one pixel row change on vertical movements. The equation for striding can be derived as O=[(ƨ-K)/S]+1 where ƨ is the input matrix style and K is the kernel size and S is the number of strides. The matrix size decreases in this step. Then the input matrix goes for padding



Padding is the best approach needed for convolutional kernelto process the edge pixels are added onto the outside copying the pixels from the edge of the image. Here the edges of the input matrix are surounded by 0 values and then multiplied by the kernel matrix to find the output. Here the size of the output remains same as the original matrix. The equation for striding can be derived as O=[(ƨ- K)+2ϕ/S]+1.

After padding Pooling comes into picture where is required to down the sample detection of the features in feature maps. Pooling layers provide an approach to down smapling feature maps by summarizing the presence of features in patches of the feature maps. Finally Flattening of the data takes place where the feature matrix is then fed to neural network or neurons for processing.



Expected Results— This section mainly describes about the outcomes the system will have after the project is implemented. With the use of convolutional neural networks the result generation becomes very accurate and expected to the customer. The basic flow of algorithm of this project will be as follow:

Start □ login □ examination authentication □ enter exam session □ if caught then warning issued (maximum3) □ else continue session until meeting ends □ logout □ end.

Still some more findings are yet to be performed on the technology used for constructing the system and also the platform on which the system should be deployed. The expected system will detect any type of malpractices happening and will issue an alert to the user. If the user recieves the alert 3 times then the users exam session will automatically be terminated and marks will be counted. Physical movement, hand and facial gesture recognizer will recognize the changing gestures of the user and will issue gesture warnings to the user if detected. It will also identify the unknown person coming in the users screen while the examination. Besides authentication by comparing the data with the live facial data of the user is very much important for security reasons. Also the system will help the proctors to constantly take a follow up of all the students and will recieve the count of warnings each student gets with their respective screenshots. The data of every student will be managed by the Non relational database which will store the information of every user independently. Lastly, the system will also detect the active window and will ensure that no other window is opened during the examination.

Future Scope—

Delievering the product basic functionality and with the expected outcome will be the primary aim of this system. Planning and upgrading the project to a large scale as per the customer needs, making the prototype version of the modules before the final project is very crucial for testing and analysing purposes. Therefore we can determine what

exactly the customerr expect from the system and also will make a greater change for the system to excel in the education+technology sector. Audio voice analysing will be the key factor for the system which we will be focusing on mainly after the successful execution of the system with the required modules. Analysing the voice of the student through VoIP Since the data used in VoIP which will normalize the voice data collected from students microphone and will analyse the input by encoding it into digital format. Signal pre-processing will be applied to discard that acoustic segments that do not contain speech in silence, music or noise. Also system monitoring will be another aim to be achieved which will constantly track and check the systems actions and behavior, through keystroke management technique by implementing the combined CNN and RNN model. Shortcuts like copy pasting from different browsers, active window detection, splitting window on screen and mouse movement will be tracked during the exam session therby providing a complete secured access to user for its system.

Conclusion—

The effect of proctoring the video is large enough that can have an actual impact on the results of the students, with the likelihood that when non proctored, students may resort to academic dishonesty or malpractices by using techniques that were disallowed during the exam and may score more marks. The potential effect of conducting examinations in a fixed time constraint which will redundantly reduce the extra time students take to complete the examinations. Besides, Lockdown software without video monitoring, did not have a similar impact as proctoring software. Online test conduction is the new way of adopting and delievering transparency during tests with the use of latest technological algorithms. This system will not assure full proof online security and conducting exams 100% accurately but it will significantly decrease the amount of false practices conducted during exams. Furthermore with the use of neural networks passing the data and determining the possibility of breakthrough of misconducts through actions, voices, facial expressions by training it with the data passed by the input devices will gradually benefit in the quality of the output delievery and will help for increasing the accuracy of the outcome. With the advent of Online Proctoring system, security issues associated with it will play a vital role and is increasing significantly and detecting it will be the priority concern of this system. Biometric data collected through the by the input deives from camera and passing and analysing the data through it by algorithms supported by various features will constantly help to identify and keep a check on students activites internally and externally.Hence, personal data collected during OPS operations need to be carefully identified, classified, and labeled accordingly. Non relational databases will help us a lot for storing and accessing the data of each and every student and will provide real time data to the proctors without any tampering happening in between. Furthermore, we have to accept the fact that it is vital to maintain academic integrity to protect both students and institutions future life.

Adaptive Authentication Based Security Enhancement of Banking Application Using Facial Recognition

Harshi Vageria, Aakash Natani, Shrihari Poojari, Dr. Rajesh Bansode
Thakur college of Engineering and Technology
harshivageria85@gmail.com, aakash.natani25@gmail.com, shriharipoojary@gmail.com, rajesh.bansode@thakureducation.org

Abstract-**The increasing prevalence of online banking has made security a major concern for financial institutions and their customers. To address this issue, many banks are turning to biometric authentication methods viz. facial recognition technology to improve the security of their applications. This research aims to evaluate the effectiveness of facial recognition technology in enhancing the security of a banking application. The research methodology includes surveys, user testing, and performance metrics to assess improvements in security, user experience, and overall effectiveness of the technology. The results of the research indicate that facial recognition technology can provide significant benefits in terms of improved accuracy and reduced risk of fraud. However, the technology also has some limitations such as privacy concerns and potential for errors. These results have important implications for the use of facial recognition technology in banking applications, and provide guidance for future work in this area.**

Keywords python library, facial recognition, scalability, availability.

I. INTRODUCTION

The project is all about digital banking system and how we can enhanced the features of the existing websites for the banks and improve the security of the website with facial recognition(deep learning), adding advanced features such as stock analysis, chat system, Making the entire bank work for the customers online. Easy and handy to use. In today's world security has become a big concern which is being possible by providing various security systems with the use of passwords

and user ID/pin available to the user for it access. These systems were facing the drawback like misplace of passwords, pin code hacking, forgetting passwords etc. Due to these reasons a new technology emerged which is known as biometric technology which uses the feature parameter of the user as the password like finger print [1], palm, voice, heartbeat etc. This technique is safe since we don't have to fear about ID card misplacement, stolen or password hacking.[1]

If we consider one of the situations where recognition of face and detecting it is done. In a simple way, facial recognition means identifying and confirming whether a person in a digital image or in a video frame is the same in the Database or not. Face detections are the first and foremost step for face recognition. Previously, people used nonliving things such as plastic cards, tokens, smart cards, Pins and authentication keys to get access grants in a confined area such as DRDO, ISRO, SpaceX, NASA, and in Industries. Eyes, Nose, Forehead, and mouth which leads to facial extraction. In a system with recognition of face and detection is cheaper, simpler, more precise, and non-interrupting process contrast with biometrics. Commonly most members used OpenSource Computer Vision Library, in short, it is called OpenCV which is used for execution or operation related to pictures. In other words, we have to install a library called OpenCV to do Image processing. Regularly used facial detection algorithms by OpenCV are Haar Cascade Classifier, LBP Cascade Classifier but here in this work I used Harr Cascade Classifier and face recognition algorithms are Haar-like features, Fisher face, and Eigen's face. Several face recognition techniques provide analyzing the geometric features of facial images, such as location and distance amongst, nose, eyes, and mouth. After this Ojala etal in produced one of the extraction feature methods called a local binary pattern (LBP) [2]

Online transaction has end up a common place fashion now- a-days and security related to the identical is turning into an difficulty. Authentication using passwords is liable to assaults like hacking; therefore by making use of biometric traits we are able to authenticate the person‘s identification. Face is a included internal organ whose random texture is complex, particular, and very stable at some stage in lifestyles, it can serve as a kind of living passport or password that one want no longer to be remembered however can usually be gift. So face popularity is on efficient manner of securing online transactions. Iris popularity machine affords correct, strong, speedy, secure and user-pleasant authentication solution. It protects personal identity of users by using the acquisition, processing, evaluation and contrast off ace patterns from their iris image. The intention of this undertaking is to enhance the safety of Internet Banking using face biometrics, as comfy authentication can't be judged most effective on the basis of username and password as they may be guessed easily. Face is an inner organ of an eye fixed this is rather blanketed. It has random texture with excessive complexity. They are recognised for their forte and balance throughout lifestyles. This undertaking aims to put in force an application so as to ask for the username, password as well as an iris photograph of the consumer, which the person must provide through his respective tool digicam. The software will pre-technique the iris photo and experiment through the database for authentication. If the username, password and iris image suits with database that in database then the consumer is authenticated [3]

II. BACKGROUND

In recent years, there has been a growing concern for

security in banking applications, as more sensitive information is being stored and accessed online. This has led to a need for stronger authentication methods to ensure the safety of user data. One such method is the use of biometric authentication, which uses unique physiological or behavioral characteristics to identify a user. Facial recognition technology, in particular, has become increasingly popular as a secure and convenient form of biometric authentication. This technology works by analyzing and comparing the unique features of a user's face, such as the shape, size, and position of their eyes, nose, and mouth, to confirm their identity.[4]

The use of facial recognition technology in banking applications has the potential to greatly improve security and user experience. By providing a secure and efficient means of authentication, it can reduce the risk of fraud and protect sensitive financial information. However, there are also concerns about privacy and the potential for errors in the technology, making it important to carefully evaluate its effectiveness in real-world applications.

Banks in India as a whole were very reluctant to adopt the changes brought about by technological advancement. A number of factors brought about the mechanization and digitization in banking industry in India. The putting in place standard cheque encoders was the first step forward in digital transformation in banking. Magnetic Ink Character Recognition (MICR) helps in the sorting and processing of cheques with each bank branch having an MICR code. The next step was more of a necessity than an innovation. Banking is a repetitive job, and therefore a labor intensive one where the worker is prone to making mistakes. In order to minimize errors and speed up the process, banks began using computer technology with standalone personal computers and then set up their own local area networks (LAN).

A. Importance of the Project

The importance of Adaptive Authentication Based Security Enhancement of Banking Application Using Facial Recognition is driven by the growing need for more secure and efficient authentication methods in the digital age. With sensitive information increasingly being stored and accessed online, the risk of fraud and data breaches is also increasing. Facial recognition technology offers a convenient and secure method of authentication, by using biometric features unique to each individual. By incorporating this technology into banking applications, security can be greatly improved and user experience enhanced. As such, the study of Adaptive Authentication Based Security Enhancement of Banking Application Using Facial Recognition is a significant contribution to the field of digital security and technology.

The current work carried out in the project is useful in terms of digital marketing and also the customers don't have to visit the banks for the small papers work or authentication everything will be there in the website and is very useful in terms of security and features provided to the customers.[5]

B. Perspective of stakeholders and customers

The perspective of stakeholders and customers regarding security enhancement of banking applications using facial recognition technology may vary. Stakeholders, such as banks and financial institutions, may view it as a valuable investment to improve security and reduce the risk of fraud. Customers may appreciate the convenience and efficiency of the technology, but may also have privacy concerns. To ensure widespread adoption and acceptance of the technology, it is important to address these privacy concerns and educate customers on the benefits and secure implementation of facial recognition technology.

C. Objectives and Scope of the project

Face recognition systems are becoming more prevalent than ever. From face recognition on your iPhone/smartphone, to face recognition for mass surveillance. However, face recognition systems are easily fooled by "spoofing" and "non-real" faces. Face recognition systems can be circumvented simply by holding up a photo of a person (whether printed, on a smartphone, etc.) to the face recognition camera. In order to make face recognition systems more secure, we need to be able to detect such fake/non-real faces — face detection is the term used to refer to such algorithm More in the project development can happen in terms of biometrics and online atm system and more security with high accuracy and cryptography part with complex algorithms can be added. Also in the designing part more of user interactivity and automation can happen for the users. More deep learning algorithms could be added for the enhancement of security [6]

III. II. LITERATURE SURVEY & PROPOSED WORK

Facial recognition technology has been the subject of numerous studies and research in recent years, with a focus on its use in security enhancement, particularly in the financial sector. Previous research has shown that facial recognition technology can provide improved accuracy in authentication compared to traditional methods, such as passwords or security tokens. This technology can also reduce the risk of fraud, as it is much more difficult to forge or steal someone's facial features compared to a password or security token. However, the use of facial recognition technology in security enhancement has not been without its challenges and limitations. Privacy concerns have been raised, as the technology requires access to personal information and the storage of facial images. There have also been instances of errors in facial recognition systems, particularly with regards to accuracy and bias.

Despite these challenges, facial recognition technology has proven to be an effective solution for enhancing security in banking applications. Further research is needed to address the limitations of the technology and to ensure that it is used in a manner that protects privacy and ensures accuracy.

The use of facial recognition technology in security enhancement has several benefits, including improved accuracy and reduced risk of fraud.[2],[7]

Benefits:

- Improved accuracy: Facial recognition technology can provide improved accuracy compared to

traditional methods, such as passwords or security tokens. By using unique facial features, the system can accurately identify users, reducing the risk of false rejections or fraud.

• Reduced risk of fraud: Facial recognition technology can reduce the risk of fraud, as it is much more difficult to forge or steal someone's facial features compared to a password or security token.

However, the use of facial recognition technology in security enhancement also has some limitations, including privacy concerns and potential for errors.[6]

Limitations:

• Privacy concerns: The use of facial recognition technology requires access to personal information and the storage of facial images, which can raise privacy concerns.

• Potential for errors: There have been instances of errors in facial recognition systems, particularly with regards to accuracy and bias. These errors can result in false rejections or incorrect identifications, reducing the reliability of the system.

Despite these limitations, facial recognition technology has proven to be an effective solution for enhancing security in banking applications, with its benefits outweighing its

limitations in many cases. Further research is needed to address the limitations of the technology and to ensure that it is used in a manner that protects privacy and ensures accuracy

2.1 Introduction

In the literature survey part there were various surveys conducted for the software of the bank website that is digital banking , enhancing the features of the website and also the security part of the website using facial recognition(Deep learning). So the various years papers were studied under this and gaps were identified accordingly using research methodology(Applied research & Fundamental research) of just enhancing the feature of the website and adding some new feature to it.[1]

2.2 Problem definition (Phase wise)

1.In the first part as mentioned in the table the first gap identified is Yet lot of paper works is done in banks not 100% the banks are digitalized. The form that has to be filled is not online available totally. And for submission of the documents with it.[8]

2. In the second gap as mentioned in the table it is related to Improvement of the Face recognition using specific characters in the face (distance between eyes) and also analyze the face in 3-D .

The software for the system was coded in MATLAB and was based on face detection and

recognition. Although its accuracy is above 90%, this system may be improved by utilization of additional features(increasing the accuracy of the system and using appropriate software and algorithm for the security).[9]

3. The backend which is used is MYSQL instead we can use No-SQL for the faster accessibility, scalability, and many more features like analyzing the data (for the stock market analysis)

2.4 Feasibility Study

There were two types of study involved in it Applied and fundamental where in the features are updated to the existing system and many more unique and advanced features like facial recognition. The project is study based.[10]

2.5 Methodology used

2.5.1 Agile methodology is used for the making of the project with code, testing and review and adjust. Role: Scrum master which comes under agile and 2W1hmodel.

They enable the close co-operation between all the roles and functions.

They remove all the blocks which occur.

They safeguard the team from any disturbances

They work with the organization to track the progress and processes of the company.

They ensure that Agile Inspect & Adapt processes are leveraged correctly which includes

A. Planned meetings

B. Daily stand-ups

C. Demo

D. Review

E. Retrospective meetings.

2.5.2 Customer interaction details

A kind of questioners conducted in family and grp for the requirement means what features should be enhanced and what are the drawbacks you fill for the digital bank website and also what should to be improved in the website and should be there in the new website.

IV. III.ANALYSIS AND PLANNING

• Understand – Understand the entire project and also break them down into steps to allow the team to visualize and complete the task in an orderly manner. Discuss with the customer about your understanding before communicating the same to the team.

• Prioritize – Prioritise each item and list them in the order. Sit with the team and SM while prioritizing that will be making it more effective. Include the advantages of the story point, efforts involved in creating, the complexity and the customer need in mind while prioritizing the items.

• Estimate – Estimate the stories based on the definition that is mutually agreed upon. Keep the stories at a high level and never elaborate on the details at the time of estimation. The team will do this task of breaking it down and the PO can leave it at a high level. Do not interfere too much with the team and give them free hands to take

a call on their time estimation.

• Keep it dynamic – Keep the backlog dynamic giving rooms for revisiting based on the suggestions given by the customer and the possibility agreed by the team. Keep the list open for the addition or deletion of backlogs at any time during the project.

Asana(calendar) is a popular tool for managing projects of various sizes, and while the free version comes with limited features, it seems to be perfectly suitable for smaller projects.[4]

V. DESIGN AND IMPLEMENTATION

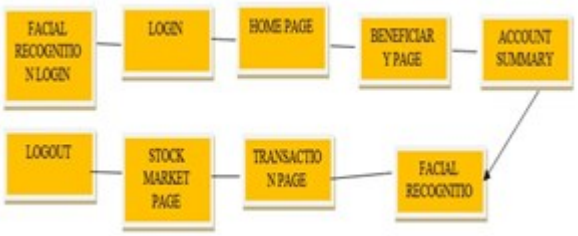

Fig.1 Flow Chart of Facial Recognition

VI. V. RESULTS AND DISCUSSION

5.1 Outcomes

A. In this paper has been developed with authentication with facial recognition and enhanced security features.Firstly the user will be verified with face detection and then the user have to enter the credentials then the user can login into the system.

Fig.2 Image Uploading as shown in UI

B. The website is being developed with front end technologies like Html, CSS, Bootstrap and backend technology NOSQL. The beneficiary page is also added where the user can add, delete and update the account

Fig.3 Model Detecting the face

C. Improved User Convenience: Facial recognition can provide a quick and convenient authentication method, reducing the need for users to remember passwords or use security tokens.

Fig.4 Request send by the user saved in postman

D. Enhanced User Trust: Implementing a secure and user-friendly authentication process can increase user trust in the banking application and improve customer satisfaction.

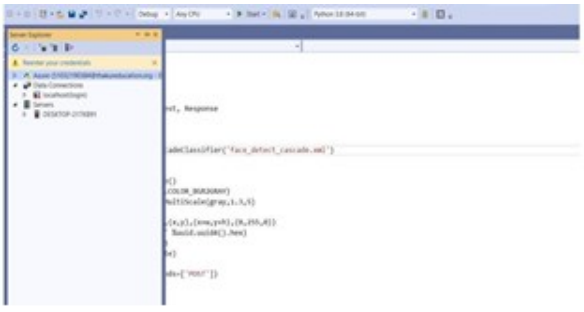

Fig.5 Apllication Code

The outcomes of implementing an adaptive authentication- based security enhancement of a banking application using facial recognition technology could be:

a) Increased Security: Facial recognition can provide an additional layer of security and reduce the risk of fraud and unauthorized access to sensitive information

b) Improved User Convenience: Facial recognition can provide a quick and convenient authentication method, reducing the need for users to remember passwords or use

security tokens.

c) Enhanced User Trust: Implementing a secure and user- friendly authentication process can increase user trust in the banking application and improve customer satisfaction.

d) Reduced Cost and Increased Efficiency: By reducing the need for manual authentication processes, the solution can lower costs and increase operational efficiency for the bank.

e) Data Privacy and Compliance: The solution should adhere to data privacy laws and regulations and provide robust security for sensitive user information.

f) Improved User Onboarding: Facial recognition can provide a smooth and fast onboarding process for new users, improving their overall experience with the banking application.

Overall, the implementation of facial recognition technology for adaptive authentication in a banking application can provide a range of benefits in terms of security, convenience, and efficiency.

5.2 Future Scope

The future scope of research on the adaptive authentication- based security enhancement of banking applications using facial recognition technology could include:

a) Improved Accuracy: Continuously improve the accuracy of facial recognition algorithms to reduce false positives and negatives.

b) Integration with other biometric methods: Research ways to integrate facial recognition with other biometric methods, such as fingerprint or iris recognition, to provide multiple layers of security.

c) User Experience: Study the user experience of the solution to identify areas for improvement and ensure the technology is easy to use and convenient.

d) Security and Privacy: Investigate ways to further enhance the security and privacy of the solution, such as implementing encryption and data anonymization techniques.

e) Cross-platform compatibility: Explore the feasibility of making the solution compatible with various platforms, such as desktop, mobile, and web, to increase accessibility for users.

f) Large-scale implementation: Study the scalability and feasibility of implementing the solution in large-scale banking systems, potentially in multiple countries.

g) Advancements in Facial recognition: Stay updated with the latest advancements in facial recognition technology and explore new techniques, such as deep learning and 3D facial recognition, to further improve the solution.

Machine Learning-Based Career Guidance System for Engineering Students (CS/IT)

Amit Singh, Shreyash Suthar, Mukesh Yadav, Mr. Vijaykumar Yele
Thakur college of engineering & technology Mumbai, India
amits3115@gmail.com, shreyash.91suthar@gmail.com, mukeshyadav78605@gmail.com, vijaykumar.yele@thakureducation.org

Abstract - In today's world, choosing the right career is the most difficult decision. Many students today are confused about their future. They have some abilities, but they are unable to identify their abilities and appropriate areas. Different people offer different career options, but ultimately students have to choose their own career. This project focused on this issue for students using machine learning. We use machine learning to help students determine the best career options and disciplines for them using a variety of machine learning techniques. Career is determined based on the personal and academic information provided by the student. This project helps students focus on specific areas according to their abilities.

Key Words: Machine Learning, Naive Bayes, Random Forest, Web Development.

I. INTRODUCTION

The Career Guidance System using Machine Learning is very helpful for Engineering Graduates who've finished their very last year (Computer Science), who're stressed concerning which field/route to select for his or her career. As there are already many alternatives to be had to select Careers, nevertheless taking the ideal choice is a challenge. So we've taken into consideration all of the factors that are crucial to select a Career. The factors taken into consideration in our mission are marks scored in individual subjects which covers the academic side of student, personality based questions which covers the non- academic/psychological side of student[2]. These two factors are crucial for making any choice on Career.

We have created a user friendly internet site for our users. The user has to give a test on our internet site[3]. The solutions given by user on Front-End will be saved

withinside the backend. The Backend is used to keep a classifier version for prediction. Already advanced code for classifier prediction is appended with the input given through the user.

Classifier (Gaussian Naïve bayes) offers us 3 career choices primarily based on probability. The output is saved in Backend and once more exhibited to the user in Front-End. The user can test the encouraged Career and may select the high-quality amongst 3 choices. The Career with the best possibility is displayed first then 2nd and at remaining third. Accuracy metrics are used to calculate the accuracy of our Prediction System.

A feedback mechanism is also a part of our system, which helps us improve accuracy and obtain user input on how well it works. They can write to us and rate us on our portal. They can get in touch with us via our system's email address.

II. SYSTEM ANALYSIS

A. Existing System

In the current scenario, the career prediction system works to get job recommendations. Some platforms, such as AMCAT and CoCubes, provide work recommendations. There is no system that takes input and recommends the appropriate job profile[1].

B. Proposed System

Learn about career guidance systems for students in the CS

/ IT industry who are confused by their career path. The contribution of this system is to help such students reach their hidden and important abilities, guided by the standard system. We want to keep students from getting confused in many areas. Based on the student's opinion, we want to make it easy for the student to use by recommending the three areas that are best for the student. The system we propose takes input from the GUI and processes it to provide three task fields. We also need feedback on student satisfaction with the output to know where we can improve the system. You can also send an email report on your career selection and after graduation to see if you are happy with your career path. This feedback system helps to make the system more and more robust.

III. DIAGRAMS

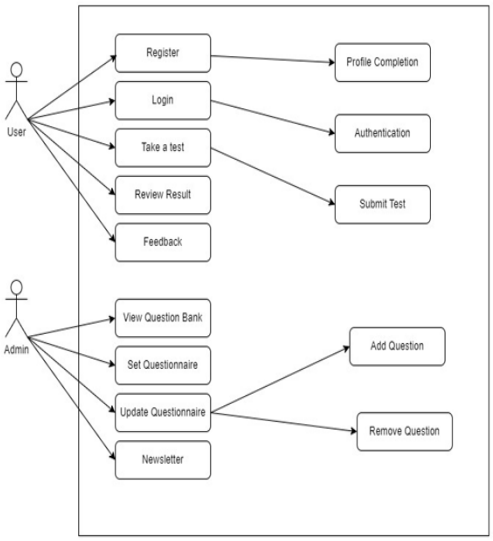

Fig-1: Use case Diagram

IV. COMPARISON TABLE

	Existing system	Proposed System
Main Function	Job Recommendation	Career Path Recommendation
Test	Based on Aptitude and Logical Reasoning	Based on Performance in academics and personal traits
Feedback System	Consist of job Recommendation interest feedback	Consist of Career path recommendation feedback

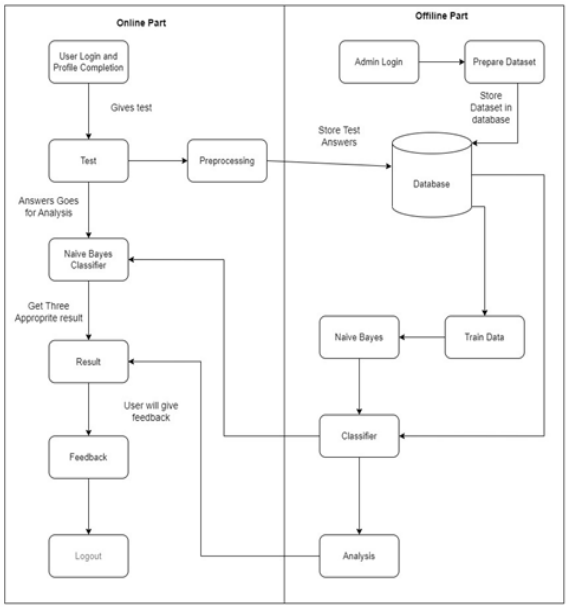

Fig -2: System architecture

V. SYSTEM IMPLEMENTATION

A. Collection of Data:

C. Label-encoding:

Data collection is an important part, but another

[5]

Data collection is one of the largest and most important tasks of a machine learning project to provide the correct data for an algorithm. Therefore, the efficiency and accuracy of the algorithm depends on the accuracy and quality of the collected data. Predicting a student's career requires many parameters, including various subjects, personality traits such as interests, academic performance of students in hackathons, hobbies, workshops, etc. All of these factors are taken into account as they all play an important role in determining student progress in the field of career. Data is collected in a variety of ways. A total of 20,000 records will be collected, including 21 columns of data.

B. Feature Scaling:

Initially, the dataset had 38 features, but to reduce the features, we used the Select best and chi2 (chi-square) methods to scale the features. The number of functions has been reduced from 38 to 20. This has improved accuracy. algorithm with raw data. This data must be preprocessed

before it can be sent to the algorithm. Label encoding is part of the preprocessing. Since the dataset consists of both categorical and numeric data, we need to convert the categorical data to numeric format. You also need to track the conversion because you need to reverse the conversion of the categorical data. You can use scalar's Label Encoder library to convert categorical data to numeric format and vice versa.

D. Training and Testing:

In training and testing, the model is divided into kfolds (2 folds) and most of the data is used to train the model. Later, we will use the test parts to calculate the accuracy of the model. The higher the accuracy, the more efficient the model.

E. Algorithm Implementation:

We have used several algorithms to implement the

project. Based on f1 score we have finalized with using Gaussian naïve bayes algorithm because in the final step it calculates the class probabilities for each class and displays the class with the highest probability. I modified this algorithm so that I could finally get three outputs for each input.

F. Machine learning Algorithm

The algorithm we have finalized is Gaussian naive Bayes algorithm[6]. This is a classification algorithm used to predict the probability of each class specification. It is based on Bayes' theorem, which presupposes naive (strong) independence between functions. This is a very scalable model that requires parameters in vector form. Naive Bayes is an easy way to create a classifier and model that assigns a class label. It is represented as a vector of feature values. These classes are extracted from a finite set of class labels. There is no single algorithm for training such a classifier, but there is a group of algorithms based on a common principle.

G. Accuracy

It shows the performance of the algorithm, the quality of the data, and the required output. We calculated the accuracy of the model based on the expected number of outputs and the actual expected outputs.

H. Result

The data provided by the user is evaluated on the backend using a naive Bayes algorithm with 75% accuracy. So we built a website that takes input from the user, calculates the output using the Naive Bayes algorithm, and returns the result to the user. In the future, more e-learning blogs will be added about the latest technologies on the market, linked to websites that teach these technologies, which could be the best platform for e-commerce and career prediction.

VI. CONCLUSION

This paper proposes a career guidance system that uses machine learning for prediction. It is the most effective and efficient method used by CS / IT engineering students (currently in their final year or graduate) to assess the talents, skills, and specific career paths available to choose from. System. This system is designed according to the needs of the user and provides an excellent user interface.

VII. FUTURE SCOPE

The field of education is evolving day by day with the advent of the Internet and the availability of learning materials, videos, and numerous tutorials. This website is also used to provide these learning materials and tutorials on the website. If you wish to continue investigating the guidance provided by our website, we will use the research materials available on our website. With the revolutionary changes in the technology field, many technology fields have become available. Expand the scope by adding guidance to other areas such as mechanicals, Electrical, Civil etc. including CS/IT. Chatbot will be used for interaction with human beings.

VIII. ACKNOWLEDGEMENT

We would like to take this opportunity to thank Mr.Vijaykumar Yele, mentor of the team and friends for providing the most effective and valuable guidance. They have always motivated and encouraged us to make this project a success and showed great insight during the development of the project.

A Coupon Exchange System Using Blockchain Technology

Alisha Gupta, Pratibha Dwivedi, Bhushan Chaudhary, Dr. Sangeeta Vhatkar
Thakur College of Engineering & Technology, Mumbai, India
alishacamb@gmail.com, pratibha23dwivedi@gmail.com, bhushanchaudhary3333@gmail.com, sangeeta.vhatkar@thakureducation.org

Abstract - **Blockchain technology is experiencing a transformation similar to the advent of the internet. This type of distributed ledger technology (DLT) not only encompasses economic areas such as cryptocurrencies, but is also proving useful for commercial purposes. It has a great potential to bring about significant changes in international enterprises. The evolution of blockchain began with the creation of Bitcoin and other cryptocurrencies, then expanded to include the development of blockchain applications through platforms like Ethereum [1]. Subsequently, other blockchain derivatives such as Hyperledger and Corda have emerged. With the growth of blockchain technology, many issues faced in everyday life can be addressed, such as the problem of unused discount coupons when making online purchases. In today's society, both shoppers and store owners view coupons as being quite important. Both sides of the market suffer an indirect or direct loss when this discount voucher is lost.**

Keywords – Blockchain, Centralization, Technology, Ethereum, Coupons

I. INTRODUCTION

There are several problems in the world, many of which go unnoticed. One such issue is that we now pay for things online, where we may obtain a lot of discount coupons which goes in waste if we don't use that particular object. For example, suppose a user received a Domino's coupon and his friend received a Pizza Hut coupon. If his friend uses only Dominos and if the original user uses only Pizza Hut then both their coupons get waste. In order to resolve the issue in the above-mentioned problem, we have elaborated the idea of token exchange where the user will be allowed to put up coupon/coupons for exchange on the platform and describe the specifications (validity or expiration date, type of coupon like money off, percentage off, etc.) of the coupon and also the details regarding what they expect in return. Depending on the demand-supply chain the user can demand a varying number of coupons. A search filter option be available for users who wish to check for any existing desirable offers, where they can add a filter and search based on any particular brand, coupon type, discount amount, etc.

An online exchange system for coupons using blockchain technology could potentially solve this problem by allowing users to trade their coupons with others. By leveraging the decentralized and immutable nature of blockchain, the system can provide a secure and transparent platform for coupon trading [2]. This would enable users to trade coupons for brands and stores that they do not regularly use, allowing them to make use of coupons that would otherwise go to waste. Additionally, the use of smart contracts could automate the trading process, making it more efficient and convenient for users. Overall, this system has the potential to reduce waste and increase the value of coupons for both consumers and businesses.

The two major problems with the coupons exchange system is Lack of Trust and Centralization. Coupons can easily be duplicated or manipulated, leading to fraud and a lack of trust between coupon issuers and users. This can also result in difficulties in verifying the authenticity of a coupon and ensuring that it can be redeemed as intended. Traditional coupon exchange systems are usually centralized, with a single entity controlling the issuance and exchange of coupons. This creates a single point of failure and can result in security breaches and data loss. In addition, the centralized entity often has complete control over the coupon exchange process, which can lead to inefficiencies and longer wait times for coupon transactions to be processed. Blockchain technology can eliminate these problems by creating a decentralized and secure platform for coupon exchange.

With blockchain, coupon transactions are recorded on a distributed ledger, which is transparent and immutable. This ensures that coupon transactions are secure and tamper-proof, eliminating the possibility of fraud and ensuring the authenticity of each coupon. In addition, the decentralized nature of blockchain eliminates the need for a central authority, creating a more efficient and user-friendly coupon exchange system[13]. With blockchain, coupon transactions can be processed in real-time, without the need for intermediaries. This results in faster and more secure coupon transactions, and provides users with greater control and transparency over their coupon holdings.

II. OVERVIEW OF BLOCKCHAIN

A blockchain is a decentralized and distributed digital ledger that is used to record transactions across multiple computers. It allows for secure and transparent record keeping without the need for a central authority. In the context of an online coupon exchange system, a blockchain could be used to track the issuance, ownership, and redemption of coupons in a secure and transparent manner. Each coupon could be represented as a digital asset on the blockchain, with ownership and transfer of the asset being recorded on the blockchain. This would provide a tamper-proof record of all coupon transactions, ensuring that coupons can be easily tracked and verified by all parties involved. Additionally, smart contracts could be used to automate the redemption process, making it more efficient and secure. Overall, using blockchain technology in an online coupon exchange system can provide increased security and transparency, as well as the ability to automate certain processes. Blockchain works by maintaining a chain of blocks, each containing a list of recent transactions.

Blockchain technology has evolved significantly over the past few years, making it increasingly suitable for widespread use in projects like the online coupon exchange system. Some of the key developments in the evolution of blockchain technology include Scalability. Earlier blockchain systems struggled with scalability, making it difficult to handle large volumes of transactions. However, with the development of new technologies such as sharding, blockchain systems have become more scalable, making them suitable for use in large-scale projects like the online coupon exchange system [1]. Next is Interoperability. In the past, different blockchain systems were not able to interact with each other, limiting their usefulness. However, with the development of cross-chain communication protocols, blockchain systems can now interact with each other, allowing for a more seamless exchange of information and assets. Blockchain has evolved in terms of User Experience as well. Early blockchain systems were difficult to use and had a steep learning curve. However, with the development of new user interfaces and user experience design, blockchain systems have become more user-friendly and accessible, making them easier to use for a wider range of users. It has also evolved in terms of Regulation. In the past, there was a lack of clear regulation around blockchain technology, making it difficult to know how it should be used[3]. However, with the development of new regulations, blockchain technology has become more regulated, providing users with greater clarity around how it can be used in various industries.

The evolution of blockchain technology has made it increasingly suitable for widespread use in projects like the online coupon exchange system. With increased scalability, interoperability, user experience and regulation, blockchain technology is well positioned to support the development of a more efficient and secure coupon economy[4].

III. WORKING OF THE SYSTEM

A blockchain-based online coupon exchange system could work as users receive coupons in the form of digital tokens and store them on a blockchain platform. Users can trade or exchange their coupons with others using the platform. The platform operates on a decentralized ledger, ensuring that all transactions are transparent, secure, and tamper-proof. The coupon tokens are unique and can only be used once, so they cannot be duplicated or counterfeit[5]. The platform uses smart contracts to automate the coupon exchange process and to enforce the rules of the coupon exchange system. The platform can be integrated with existing e-commerce platforms and digital wallets for easy access and use. To ensure security, the platform can use cryptographic techniques such as public-key encryption and digital signatures[2]. This system can help eliminate the issue of coupon wastage and increase the utility of coupons by making it possible to exchange them with others. By implementing a blockchain-based solution, the online coupon exchange system can provide a secure, transparent, and efficient way to exchange coupons and reduce waste.

Here are the basic steps on how blockchain works:

- A transaction is initiated on the network by one user, such as the transfer of digital currency or the recording of an asset ownership.
- The transaction is broadcasted to the network and verified by nodes, which are computers participating in the network.
- Once verified, the transaction is grouped together with other transactions that have occurred in the last few minutes, forming a new block[6].
- The block is then added to the chain of blocks, creating a permanent and unchangeable record of the transaction.• Each copy of the blockchain contains the same information, so no single copy can be altered without the consensus of the network.
- This creates a secure and transparent way to record transactions, as each block in the chain contains a unique code, called a "hash", that is generated based on the information in the block, and the hash of the previous block[7].
- This creates a chain of blocks that are linked together, each one containing the hash of the previous block and making it extremely difficult to tamper with the data stored in the blockchain.

Overall, the technology behind blockchain is complex and relies on complex mathematical algorithms and cryptography to ensure the integrity and security of the network. This is essentially how blockchain technology operates. The flowchart that follows outlines the fundamental steps involved in using blockchain technology to an online coupon exchange system.

- Coupon Generation: Coupons are generated and added to the blockchain as digital assets. The coupon details, such as value, expiration date, and terms and conditions, are recorded on the blockchain.
- Coupon Issuance: The coupons are then issued to users and recorded on the blockchain, providing a transparent and immutable record of who holds each coupon.
- Coupon Trade: Users can trade coupons with each other using a smart contract on the blockchain. The smart contract automatically verifies the validity of the coupons and executes the trade.
- Coupon Redemption: When a user wants to redeem a coupon, they present the coupon to the merchant. The merchant verifies the coupon on the blockchain to confirm its validity and redeem the coupon[8].
- Coupon Update: As coupons are traded or redeemed, the details of each coupon are updated on the blockchain, providing a real- time record of the status of each coupon.

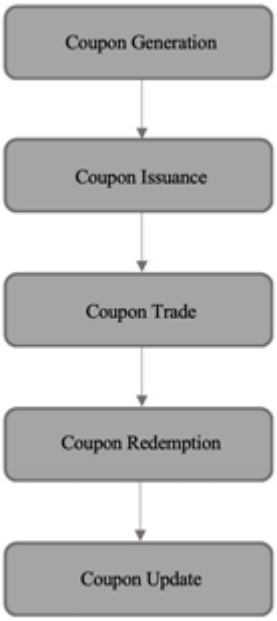

Fig 1. Flow of the system

IV. TECHNICAL ARCHITECTURE OF THE SYSTEM

The technical architecture of a blockchain system for the online coupon exchange would typically consist of the following components:

• Blockchain Platform: A blockchain platform, such as Ethereum, is used as the underlying technology for the coupon exchange system. Ethereum provides a secure, decentralized, and immutable ledger for recording transactions.

• Smart Contracts: The coupon exchange system would be implemented using smart contracts on the Ethereum blockchain. Smart contracts are self-executing code that enforce the rules of the coupon exchange system, such as coupon issuance, coupon trade, coupon redemption, and coupon update[9].

• Tokenization: Coupons are represented as tokens on the Ethereum blockchain. Each token represents a unique coupon with specific terms and conditions, such as value, expiration date, and redemption requirements.

• Consensus Mechanism: Ethereum uses a proof-of-work (PoW) consensus mechanism, where miners compete to validate transactions and add them to the next block in the chain[6].

• Security Measures: To ensure the security of the coupon exchange system, the Ethereum blockchain implements several security measures, including private key management, encryption, and secure key storage.• API Layer: An API layer is provided to enable integration with existing systems, such as merchants, coupon providers, and users. The API layer allows for seamless interaction with the blockchain and smart contract system.

• User Interface: A user-friendly interface is provided for users to interact with the coupon exchange system, such as viewing available coupons, trading coupons with other users, and redeeming coupons at merchants[10].

V. NEED FOR THE SYSTEM

The implementation of a blockchain-based online coupon exchange system is important for several reasons:

• Security: Blockchain technology provides a secure and tamper-proof platform for the exchange of coupons. Transactions are recorded on a decentralized ledger, reducing the risk of fraud and data manipulation[11].

• Transparency: With a decentralized platform, all transactions are recorded in real-time, providing users with a transparent view of the coupon exchange process.

• Efficiency: By using smart contracts, the coupon exchange process can be automated, reducing the need for intermediaries and speeding up the exchange process.

• Reduced Waste: The platform can provide a solution to the problem of coupon waste by allowing users to trade their unused coupons with others.[12]

• Support for Sustainable and Efficient Economy: By reducing coupon waste and providing an efficient platform for coupon exchange, the blockchain-based online coupon exchange system supports the development of a more sustainable and efficient economy.

The implementation of a blockchain-based online coupon exchange system has the potential to bring numerous benefits, such as increased security, transparency, efficiency and reduced coupon waste, thereby supporting the development of a more sustainable and efficient economy.

VI. IMPLEMENTATION

The system would contain a number of webpages where buyers and sellers may trade coupons. Below are a handful of the pages the system comprises of.

• Homepage: The homepage will have an introduction to the website and its purpose, along with a brief explanation of how the blockchain-based coupon exchange system

works. There will also be a login/sign-up button for users to access their accounts.

• Login/Sign-Up: The login/sign-up page will allow users to create an account or log in to an existing one. They will need to provide personal information, such as their name, email, and password, to create an account.

• Dashboard: The dashboard is the main interface for users to interact with the coupon exchange system. It will display their current balance, the number of coupons they own, and the coupons they are interested in purchasing.

• Coupon Listings: The coupon listings page will show all the available coupons, along with their details, such as the coupon's face value, expiry date, and the number of units available for purchase. Users can select the coupons they want to buy and proceed to checkout.

• Checkout: The checkout page will show the total amount the user needs to pay for the coupons they have selected, and will allow them to complete the transaction by making a payment.

• Transaction History: The transaction history page will display a list of all the transactions the user has made, including the date and amount of each transaction, along with the coupons they have bought and sold[14].

• Contact Us: The contact us page will provide a form for users to send their queries and feedback to the website's support team.

• These webpages will provide a user-friendly interface for users to interact with the blockchain system for online coupon exchange, and will allow them to buy and sell coupons securely and efficiently.

VII. RESULT & DISCUSSIONS

A blockchain system for online coupon exchange can offer several key benefits that can enhance the overall experience for users. Firstly, it provides a high level of security by using decentralized ledger technology, which prevents the potential for fraud or counterfeiting. This means that users can be confident that their coupons are legitimate and will be accepted as valid by merchants. Secondly, the transparency provided by the blockchain ensures that all transactions are recorded and easily traceable, which enhances the accountability and reliability of the system. This can also help to prevent any disputes between users or merchants. Additionally, blockchain technology enables the use of smart contracts, which can automate new and untested technology. These limitations and challenges must be carefully considered and addressed in order to ensure the success and widespread adoption of the blockchain system for online coupon exchange. Overall, a blockchain system for online coupon exchange can offer significant benefits, but it is important to the coupon redemption process, making it faster and more efficient. This can help to reduce the administrative burden for merchants, freeing up their time and resources to focus on other areas of their business. The decentralized nature of the blockchain system also means that users have more control over their coupons, as they can buy, sell, or exchange them with other users without the need for a central authority.

There are several potential limitations and challenges that must be addressed for a successful implementation of a blockchain system for online coupon exchange. These include scalability issues, a lack of technical knowledge among users, and the potential for network congestion[15]. Additionally, the decentralized nature of blockchain technology can make it more difficult for authorities to regulate and monitor the system, which may raise concerns about money laundering or other illegal activities. Furthermore, there may be a slow adoption rate due to the perception of blockchain being a

VIII. FUTURE SCOPE

Blockchain technology has the potential to revolutionize the way coupons are exchanged online by providing a secure and transparent platform for tracking and verifying coupon ownership and usage. Some possible future applications of blockchain in the coupon industry include:

• Digital Coupons: Blockchain technology can be used to create digital coupons that are tamper- proof and can be easily tracked and exchanged between parties.

• Supply Chain Management: Blockchain can be used to track the origin and movement of coupons through the supply chain, providing a transparent and auditable record of all transactions.

• Loyalty Programs: Blockchain can be used to create and manage loyalty programs, allowing customers to earn and redeem points or tokens for discounts and other rewards.

• Fraud Detection: Blockchain can help detect and prevent fraud by providing a secure and tamper-proof record of all coupon transactions, making it difficult for bad actors to forge or counterfeit coupons.

• Decentralized Coupon Platforms: Blockchain technology can also enable the creation of decentralized coupon platforms, where users can buy, sell and trade coupons directly with each other, without the need for intermediaries.

Security of Blockchain Systems. Journal of Information Processing Systems, 13(3), 579-593.

Face Detection and Recognition from Video using Deep Learning

Hemant Yadav, aurabh Yadav, Sejal Singh, Rahul Neve
TCET-Mumbai.
thisishemantyadav@gmail.com, saurabhyadav0613@gmail.com, sejalsingh0607@gmail.com, rahul.neve@thakureducation.org

Abstract- **Facial recognition (FR) and verification are currently the most effective techniques for detecting illegal activity. It can be used in a wide range of applications from criminal identity, security and surveillance to entertainment websites. For verifying consumers, this method (facial recognition) is very useful in banks, airports and other organizations. Convolutional neural networks (CNNs) have sparked interest in deep learning for face recognition, but training CNNs requires more data and applications such as criminal activity (robbery, murder, etc.). It's a big problem when it comes to relationships. Therefore, this study provided a facial recognition system that effectively supports law enforcement and administration by making criminal investigations easier, faster, and more time-consuming.**

In this study, face recognitionfrom videos is performed using a pre-trained model called FaceNet (FN). Face images are transformed by FN into a compactEuclidean space with extended inter-face distances.

We are attempting to create a medisale app utilising this concept, in which we register medical store owners by doing KYC verification on them. The KYC procedure uses real-time video and still images of the user to perform face landmark detection. This entire procedure takes ten seconds, but we can make it faster.

Keywords - FaceNet, security, convolutional neural networks.

I. INTRODUCTION

Faces are important to human identity. It is the most easily recognized human trait. FR impacts key applications in a variety of areas such as security access, personalized identities, law enforcement her identities, and financial authentication. It's both fascinating and complicated. Face recognition is very easy for humans, but more difficult for machines. How images become autonomous and how the brain encodes them is still largely unknown. Are inner (nose, mouth, eyes) or outer (face shape, structure, hairline) highlights used for efficient face recognition?showed that our thoughts respond to specific neurons such as boundaries, curves, movements, and angles under the conditions. No one sees it as scattered pieces, so our visual brains have to supplement amultitude of data sources with helpful examples in many ways. Auto FR removes, inserts, and applies specific categories of desired characters from an image. FR based on facial geometric highlights is probably the easiest way to identify humans. Thewhole process he can divide into three main parts. Thefirst part is finding a good database of human faces, each containing multiple photographs. The photos in the database are used to identify and prepare faces forthe FR in the second stage, and in the final stage they are checked to confirm the faces on which the FR wastrained. Facial Recognition (FD) is now used by various websites such as Facebook, Picasa, Photo Bucket, etc. Images shared among people in photographs are given a new perspective by natural day characters. The FR method is reviewed and applied in this study. This was simple but very effective. This article uses a system of FR (this is the person), verification (this is the same person), and FN. Our system uses a deep coevolutionary network to learn Euclidean embeddings for each individualimage. The framework is trained to connect surface similarity directly to the second-order L2 distance of the embedding space.Faces of similar people are slightly apart, but faces ofdissimilar people are far apart. Police and investigative departments can use this method to identify criminals.The FR method used is fast, easy to learn, reliable and accurate using very simple algorithms and methods. Fixed the initial issue with face recognition difficulty. Tools have been developed to detect not just a single human face in a photo or video, but many faces and return the user's face.

II. RELATED WORKS

FR became a major academic movement in the 1970s. For input images containing multiple faces, FR first performs face separation FD. After preprocessing the individual surfaces, a final low-dimensionalembedding is created. Low-dimensional integration is essential for professional taxonomy. Facial descriptions must be effective for different images within individuals, such as style, appearance, and age,while taking into account image differences between individuals.

Validation and FR are significant challenges. It is widely used in image processing and computer vision research. With the neuronal frameworks at our disposal for the purpose, the issue has grown broader.In general, more time is needed for neural network development, training data, and computercapacity. As a result, several research have been conducted to lessen these variables.

For more than 20 years, there has been discussion about FR. Model-based and phenomenon-based approaches can be used to categorize the techniquesthat have been suggested so far in the text[1].

The authors create a deep 'warp' network to the canonical front before learning from the CNN how to classify each face as part of a pre-existing identity. PCA is used with his group of SVMs for face verification [2].

Introduction of a multi-step process corresponding to

the basic 3D structural model. A multiclass network of over 4,000 characters is created to perform the FR

task. The Siamese network is also used by the designer to investigate her L1 distance between her two surfaces. Three systems with different layouts and shading channels perform best in LFW (97.35%). A nonlinear SVM prediction of the predicted distances from these networks is combined with a two-core nonlinear SVM.

They offer a small and inexpensive measurement network. Each of these 25 systems works using a specific facial patch. In his final LFW run, the developer combined 50 responses (normal and reversed) (99.47%) [4],[5].

This is done using Joint Bayesian and PCA [6], which accurately represent linear embedding-space transformations. Their strategy is not specifically designed for 2D/3D. The system is created by a combination of classification and loss of validation. Validation loss is the same as TL [7],[8] because it limits the L2 gap between faces with the same features and establishes a buffer between distances between faces with different personalities. Semantic and visual closeness to the evaluation images assessed lossescomparable to those used here [9].

Separation vector approach between facial features, Eye and ear sizes were first used in FR [6]. Thevector contains 21 subjective characters, each emphasizing arecognizable face. They took a similar approach in his 1973, globally adjusting facial features using his matching template [7]. The authors developed a fully automated FR (1973) on a computer system containinggeometric parameters to extract 16 emoticons [8]. The average positive detection was over 50%. In the 1980s, several blueprints were improved by computing algorithms developed based on improved subjective facial highlights and ANNs. In 1986, the author provided his own face based on his

PCA [9]. The core concept was to replicate low-dimensional images without loss of information. Finally, in 1922,a new algorithm was implemented to correctly classify the heads of faces [10].

Here, the authors perform criminal identification procedures using FR and documentary evidence. In this article, we use the Quick Data Boost training approach. They use a combined identification and verification approach for facial expression documents.

III. METHODOLOGIES

FaceNet is Google's facial recognition and clustering feature with 99.63% accuracy. The goal of this proposed paper is to achieve FR with high accuracy. FN uses a deep neural network architecture. The architecture of the FN model is shown in Figure 1.

It maps face images from Euclidean space where distances correspond directly to face similarity approximations. Once the space is available, you can easily perform various tasks. For face verification, identification,

and clustering, we use regular FN embedding methods as feature vectors. Triplets are used for training frameworks. A triplet is a set of his one image of an anchor, a positive image of an anchor,and a negative image of an anchor.

Let's follow the steps of the pre-trained model. A.To create a model, collect images of people who are one step ahead.

B. Place faces using a multitasking cascaded convolutional neural network and Open CV (MTCNN). It can identify, align and recognize faces.

C. Represent or embed each person's face in 128-dimensional Euclidean space using a pre-trained FN model.

D. Accumulate the embeddings on a disc with the names of the respective user.

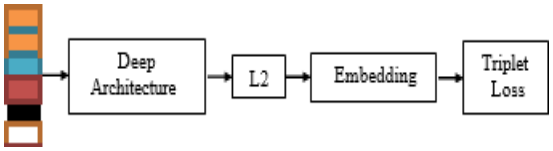

Fig. 1. Illustrating FaceNet Model architecture

Our approach involves deep CNN and batch input layers, followed by normalized L2 and face embedding. TL will follow this during preparation.

The L2 or Euclidean distance between two points p and q is the length of the line segment connecting them. If wehave two points p = (p1, p2, , pn) and q

= (q1, q2, , qn) in Euclidean n-space, we get "(1)" increase. Distance (S) from p to q or q to p.

$$S(p,q) = S(p,q) = \sqrt{(p_1 - q_1)^2 + (p_2 - q_2)^2 + \dots + (p_n - q_n)^2} \sqrt{\sum_{i=1}^{n} (p_i - q_i)^2}$$

(1)

In Euclidean n-space are Euclidean vectors. The Euclidean length of a vector estimates the length of the vector Represented by $||S||$. facial treatment system Recognition is now complete.128-dimensionalembeddings containing people's namesare available.Whenever a face is visible, the image is passed througha previously trained network to create a 128- dimensional embedding and compared to the saved embedding using Euclidean (L2) distance. To this end, we use triplet loss to demonstrate andachieve ourgoals in FR and verification. In other words, the images are integrated into the feature space such that the squared distance between each face of differentidentities is small and the squared distance between a small number of face images is large, regardless of theimaging conditions.

The main goal is to create a complete facialrecognition system that works on all kinds of images and continuously improve it. To better recognize and engage citizens, this transformation must be self-sufficient. Moreover, this identification must be done

as timely as possible, so it is a matter of time. Facial recognition is a very difficult problem, especially outside of controlled environments. Indeed,throughout history, some approaches have fallen short.

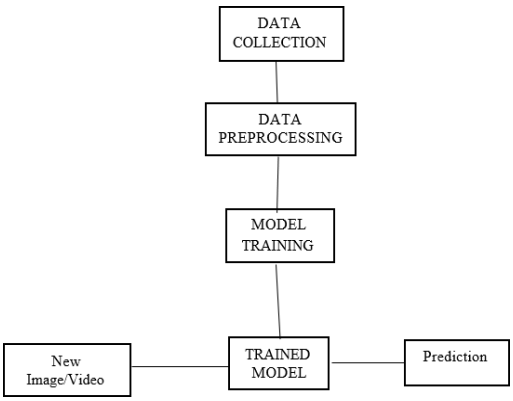

Fig. 2. Work Flow of the proposed methodology

Aside from differences between images of similar faces, such as hair, lighting conditions, and expressions, it is difficult to determine what makes a face visible. Therefore, when starting this project, you should use certain existing work instead of starting from scratch. These speeds up the process and makes iteasier to get quality results. To this end, a literature search was performed. Many effective methods have been discovered and encouraged to deal with the problem. Finally, it was decided to focus on the FN modeling approach. The main reasons are good results (very close to the state of the art) and quality of explanation. The FN model offers an excellentaccuracy of 99.63%. Figure 2 shows the workflow of the proposed methodology, including various phases of face recognition.

A. DATA COLLECTION

Proposed database created. Images of Indianactorsare pulled from Google to prepare the data. In the database, there are 8 photographs of the subject (person) of him. There are 100 photos for each participant, of which 680 are for training and120 are for testing. A key component of ongoing development in automated face and appearance recognition is the creation of a face database for benchmarking. Newtechniques for automated FR were developed in the 1990s as a result oftremendous advances in computing and sensortechnology. Many databasesare currently used to recognize faces based on factors such as size, joints, position, lighting, obstacles, and image quality. The differences in posture, illumination, imaging locations, ethnicity, sexual orientation, and outerlooks from the year 2000 and beyond were noted in the facial databases. The most recent databases, which are built from various sources like the web and social media, capture variations in picture sizes, pressure, and obstructions. Below are some of themost recent face databases:

Labeled Wikipedia Faces (LWF) compiled pictures from over 500,000 biographical passages from Wikipedia Living People, featuring 8,500 of 1,500 people.

The YouTube Faces Database (YFD) consists of 3425 recordings of him from 1595 different people,with 2.15 recordings for each subject, with videos cut at edges between 48 and 670. I'm here. A collection of records and names of subjects for which records were created.

Images from 151 participants (Caucasian females) of a YouTube makeup tutorial exercise are included in the YouTube Makeup Dataset (YMD), with cosmetics mentioned ranging from subtle to overwhelming. It has been. 2 injections before applying cosmetics and 2 injections after application, 4 injections per person. This database is growing steadily, but presents FR problems due to aesthetic changes. The Indian Film Faces Database (IMFD) is a collection of 34512 images of him of 100 Indian actors, including various typesof poses, moods, lighting, lenses, obstacles and cosmetics. edited to Images were edited from approximately 100 exposures.

B. FaceNet

Google scientists announced FN in 2015. 128DModify faces like words embedded in Euclidean space. FN is a one-shot model that allows direct mapping of facial photographs into a compact Euclidean environment, with distance corrected directly by facial proximity measurements. Tasks such as face control and recognition can be effectively performed using standard methods using FN integration as feature vectors once this space is developed. For training, we loosely matched identical/non-identical face patches three times. Manufactured using approximately spaced triplets of identical/non-identical area patches. A representation of the FN model shown in Fig. 3. In particular, f(z) from image z is integrated into

the feature space, and the separation of small squares between all faces without image conditions is similar, but between several face images with different features The separation of the squares is larger. Triple loss is considered to be the best for face checks, but has not been specifically compared to other losses such as: B. Containing affirmative and negative sentences, as used in.

IV. RESULTS & DISCUSSION

The necessary individuals for the system to recognise are stored in a database. Data pre-processing is a process that clarifies unprocessed data. Real data frequently contain several flaws and are inadequate, incompatible, or missing from other patterns or habits. Each face will be cropped, and the folder name will be written on each face. Immediately following the pre-processing of the data, the model should be trained using a pre-defined model. Finally, the step is prepared, and it may test this step using our video and picture data. This method is carried out using the Python language. The model works well and can identify faces in still photographs, video, side views, dark faces, and paintings. The outcome is seen below for several photos.

Figure 4(a) shows that our system can detect human faces from images. When the image is processed, a square box for the face is drawn and the person's name is composited underneath it. Figure 4(b) shows a handwritten image of an Indian actor. The system recognizes faces from hand-drawn images. Figures4(c) and 4(d) show a profile image of a person and a dark face image of a person. This model can be recognized in the picture above. Figure 4(e) shows the resulting video image. Given a video with a person in it, it was able to track and recognize that person. After each video is edited, a square box for the face is drawn and the name of the person inside is pasted at the bottom. This system can detect multiple faces from a video.

According to a literature review, the FaceNet model showed the highest accuracy among all these models after training on a specific dataset. With this in mind, a dataset was collected, FaceNet was applied to it, andthe resulting 90% accuracy was taken into account.

V. CONCLUSION

The recommended solution is to be able to accurately identify faces in both photos and videos. It can be used with any kind of image and is relatively robustto

changes in face orientation and appearance, lighting, and other factors. The advantage of thismodel is that it can distinguish blurry images and sides, unlike other traditional models. Using the resulting framework, we explored many other parameter combinations. When viewing a video with aperson in it, it was able to track and identify the person. Each video is processed, a square box of the face is drawn, and the person's name is constructed below. Several faces can be seen in the video.

A collection of 800 headshots is compiled for preparation and testing. The facial recognition component has been tested with consistent results at around 90% accuracy. These results are better than expected and consider several real-world use cases. In any case, there is still room for improvement. This could in the future be used to identify a person via video recording to identify a person from a surveillance camera and allow the police to identify a person in a matter of seconds. It can also be used for visitor analytics systems and home security systems. Face detection and timing of faces in video will be integrated in the future.

VI. Future Scope

The biometric information of a person is not presently specifically covered by any laws in the United States. More than half of Americans have reportedly created their faceprint by this point, and facial recognition technology is already being tested or used for airport security. A face recognition algorithm may gather and process data without the subject even realizing it. The knowledge of a person would then spread without their awareness as a hacker may access the information. This information may also be used to keep an eye on people by marketers or government agencies. Even worse, a false positive might involve someone for a crime they did not commit.

Numerous businesses now use facial recognition. Although integrating and installing it is not very difficult, consumers now feel as though they are usinga system that is more advanced and secure than passwords or PINs, which improves user experience. Nevertheless, much is frequently unclear on the path to putting into practice what many consider to be the best biometric method, leading to a number of rather serious errors along the route.

Abstract— **Detecting financial misstatements presumed anomalous in general ledger (GL) data is a long-standing problem in accounting. This insinuates that highly skilled audit teams try to distinguish needles in a haystack; in such cases, review risk may emerge. When tackling this issue, supervised learning techniques are often taken into account by the majority of machine learning systems. This approach has been utilized in external audits to distinguish between fraudulent and non-fraudulent financial statements. Labeling becomes feasible for general ledger (GL) since financial statements are structured across multiple reporting regulations in external audits. On the other hand, internal audits usually lack procedure labeling due to the risk-based methodology used to choose which areas, departments, or processes to examine. Therefore, when used in internal audits, unsupervised learning is frequently the only viable solution. For the clustering of financial statement ratios, an unsupervised learning method can be used. Data vectorization is used in this program to handle the fluctuation in journal entry size, and a real-world GL dataset was used to train and assess the models. The evaluation's results demonstrate that the best-trained supervised and unsupervised models had a high potential for identifying specific categories of anomalies as well as efficiently sampling data to identify journal entries with a higher likelihood of being false positives. In order to give an optimal auditing solution made up of multiple audit components, this system uses a variety of supervised and unsupervised learning methods, offering a one-stop solution to the auditing challenges.**

Keyword—Finance statements, auditing, data-mining, risk management, supervised and unsupervised learning.

I. INTRODUCTION:

The trend of increased activity in the securities market persists. With approximately 227 million annual transactions, 2021 was a record year for Nordic securities trading in terms of activity, and since the year 2000, the number of executed orders has increased elevenfold. Unfortunately, as market activity and interest in the securities market increase, so does the frequency of financial market crimes. This covers transgressions under the headings of insider trading and market manipulation. Insider trading refers to the act of a participant trading securities using insider information, such as confidential information regarding a publicly traded corporation. Trading and activities that provide false or misleading supply, demand, or price signals are examples of market manipulation. Market manipulation will be the main topic of this study.

There are many ways to manipulate the market, including through the spread of false information; pump and dump is one such strategy. One or more players work together to increase the sentiment surrounding a security using supportive comments on social media or similar in order to raise the price of the security. when consumers are influenced to purchase as the price of the securities increases, the scheme's operators can sell them for a profit. Another sort of manipulation involves actual trading and order placement, and the typical techniques used include momentum igniting and spoofing (layering). The methods' actual implementation varies. However, the fundamental idea remains the same: to artificially increase the price of a security by using a variety of ordering mechanisms. Monitoring orders and closing lists can help identify market manipulation, particularly the varieties that depend on actual trading and order placement.

The EU-regulated Market Abuse Regulation now applies to all Swedish stock exchanges, trading platforms, and individuals that do business professionally (MAR). Monitoring is a requirement, and market participants are required to notify Finansinspektionen (FI) if they come across orders or transactions that they perceive to be of the sort of financial market violations. Most monitoring is rule- based, which means that if particular "thresholds" are met, pre-programmed alarms based on knowledge and past data are triggered. Although these systems have shown to be highly effective, they still have flaws, such as the possibility that manipulators discover how to work them. Since rule- based alarms only use some of the customers' accessible data rather than all of it, they also run the danger of missing behavior.

Using a different approach to objectively monitor trade data and perform outlier detection using machine learning is one way to address this. Differentiating between what a dataset considers normal and what it considers abnormal is the fundamental tenet of outlier detection. The threshold is used in rule-based monitoring to categorize an activity as normal or abnormal, applying the same logic. The method used to determine the classification itself differs. Rule-based systems look for deviations from participant expectations,which are what market manipulation is. Rule-based algorithms search for these deviations by combining static thresholds, whereas machine learning categorizes data as normal based on the dataset's real structure. Instead, because the classification is based on all available data and not only on select portions of the data where rule-based thresholds exist, it is dynamic and may discover new market manipulation strategies. The interpretability of the approaches is a general issue for machine learning solutions, which is not present in rule-based systems. The rule-based system explains the criteria used to determine whether a transaction qualifies as market manipulation by identifying the thresholds that have been crossed. However, machine learning solutions frequently merely produce a result without making it clear to the user why a data point is classified in the way that it is. A common issue with machine learning and artificial intelligence

(AI) is the lack of interpretability, which makes consumers lose confidence (faith) in the processes since they cannot understand why certain outputs are produced.

Machine learning solutions are not employed as much as

they may be as a result of this problem. explainable Artificial Intelligence, a new branch of machine learning and AI, has emerged in response to this hot topic (XAI). Making so-called "black-box" machine learning models intelligible to people is the aim of this field.

Billions of dollars of loss are caused per annum thanks to fraudulent mastercard transactions. The planning of efficient fraud detection algorithms is vital to reducing these losses, and more algorithms believe advanced machine learning techniques to help fraud investigators. The planning of fraud detection algorithms is however particularly challenging thanks to non-stationary distribution of the info, highly imbalanced class distributions and continuous streams of transactions. At an equivalent time, public data is scarcely available for confidentiality issues, leaving unanswered many questions on which is the best strategy to affect them.

III. METHODOLOGY:

Operations in the field of data science, whether it be in research or industry, typically include some standard data mining principles made up of a variety of techniques and procedures. Several data mining approaches were formally established in order to standardize the operations. While these techniques generally use the same steps, there are variances in the granularity of those steps as well as how and when they are implemented. Based on extensive research, SEMMA, KDD, and CRISP-DM are the three most well- liked and widely accepted techniques. We also looked at the TDSP technique, which is very adaptable and supports projects that started out using different methodologies. Some of them have been modified numerous times; however, we have listed their basic procedures and guiding ideas below.

SEMMA: The abbreviation SEMMA refers for a closed cycle that iterates from the start until the goal is reached and consists of the phases Sample, Explore, Modify, Model, and Assess. Because there aren't as many steps as possible in this method, it's straightforward and simple to understand. A representative sample of data from the entire population is used to start the cycle. The necessary data transformations, such as feature selection, data cleansing, and engineering, are done after data exploration. The algorithms and models that will be put to the test in the final Assess stage are kept in the modelling section.

KDD: The acronym KDD refers to Knowledge Discovery in Databases. Executing the five stages acknowledges the Pre-KDD and Post-KDD phases in order to understand the user's goals and, ultimately, to incorporate a created solution into already-existing user operations. Data cleaning, transformation, and evaluation of the analytical component comes after the selection, pre-processing, transformation (data mining), and interpretation (evaluation) of a target analytical dataset. In KDD, procedures are carried out iteratively and collaboratively.

CRISP-DM: Business insight is the first phase of the Cross- Industry Standard Process for Data Mining (CRISP-DM), which consists of six more steps that are deployed after production is complete. The phases of Data interpretation, Data preparation, and Modeling evaluation all involve handling data-related responsibilities. Iterations are possible all the way through business knowledge and the evaluation procedures.

The major goal of employing an unsupervised machine learning approach was to identify outliers or abnormalities in a dataset. There are many reasons to choose this method, but the lack of labels in the data was by far the most important. The ability to detect recent, undiscovered fraud activities is another benefit of adopting unsupervised approaches. This contrasts with manually created rules, which are still primarily employed in fraud detection and do not apply to newer scam tries. Another justification for adopting detection algorithms to begin with is that the internal auditor may have more time for extra checks and a thorough analysis of those anomalies if there are a few irregularities originally discovered.

Methods used: Isolation forest

The Isolation Forest is an extension of decision trees and

random forests that was created to find abnormalities in records. It performs outlier detection differently from the majority of anomaly detection algorithms. It never analyzes the regular points, instead identifying observations that do not fit the profile of a normal point and then determining what is normal in the data. Instead, it focuses only on the outliers, resulting in a substantially

lower total computing complexity than the majority of alternative approaches. This strategy is based on the idea that anomalies are rare, unique, and so more easily isolated than a typical set of features. Isolation Forest, also known as isolation trees, works on the basis of the notion of recursively splitting the data by randomly choosing a feature and a split value between the minimum and maximum value of the observations in the selected feature. The data is then tested using the trees with the intention of separating each observation.

The observations will require a varied number of splits to be isolated depending on the different splits in the trees, and the path length will change. Because they needed fewer splits and hence indicated more extreme values than those requiring numerous splits, observations isolated near to the root node and with a short path length are therefore more likely to be an outlier.

Clustering

The goal of clustering algorithms is to find groups of data

points in a dataset that are more similar compared to those in other clusters. There are several varieties of the clustering process, principally three basic ones. The first technique makes the assumption that outliers belong to tiny, sparse clusters whereas typical data points in a dataset belong to big, dense clusters. The second strategy is predicated on the notion that outliers are points that do not fit into any cluster. The centroids, or geometric midpoints of each cluster, are used in the third method to categorize points. Outliers are defined as points farthest from the centroids of each cluster, whereas normal points are those closest to the centroids. This category includes the most used cluster algorithm, k- means. The clustering algorithm adopted determines the general difficulty of clustering approaches. However, the distance between distinct sites must be computed for clustering-based approaches, including distance-based and density-based ones. However, for cluster algorithms, it is typically sufficient to calculate simply the distance to the centroids for each data point, rather than the complete dataset. As a result, the complexity is modest and is constrained to O (n).

K-Nearest neighbor classifiers work by allocating data instances to classes while taking into consideration the nearest class data points.

Boosting

One common approach for boosting is gradient boosting.

Each predictor in gradient boosting corrects the mistake of its predecessor. Unlike Adaboost, each classifier is trained

using the residual errors of the predecessor as labels rather than adjusting the weights of the training examples.

The Gradient Boosted Trees approach uses CART as its basic learner (Classification and Regression Trees).

Decision Tree

In order to develop a decision assistance tool, a decision tree

is a combination of iterative and incremental stages that connects logical sequences based on straightforward tests, with each test comparing a numerical property to a threshold value. By posing queries regarding the characteristic pertaining to the node and the data point, a decision tree characterizes these data points. Every node has a single query, and every internal node links to a child node that represents each potential response. As a result, the queries take on a hierarchical structure that may be represented graphically as a tree. In order to attempt to appropriately identify the classes in the training set, the query nodes are gradually added while building a decision tree based on the learning data. As a result, queries are recursively chosen to divide training materials into smaller groups and merge them into a single tree. By increasing information gained or reducing impurity, the optimum query for each node is selected. In order to produce homogenous class labels, it is ideal to accomplish the fewest number of splits feasible. Entropy and Gini index are typically employed in decision trees to quantify impurity in objects. Decision trees are categorized as a supervised approach since they need labelled data to operate. A data point that has to be classified travels along a path that starts at the root node and continues via internal nodes that contain "yes" and "no" children until it reaches a leaf node. The class linked to the leaf node where the data point ends up will then be assigned to it. As a result, it is simple to comprehend why a point is classified in the way that it is, which places decision tree in the category of intrinsically explainable algorithms. This is a characteristic shared by many supervised algorithms. Decision trees have the drawback of being prone to overfitting since the model is dependent on training data. Applying methods like random forest, which makes use of an aggregation of decision trees, helps prevent overfitting.

Random Forest

A popular advancement of decision trees, random forests

construct each tree using bootstrap samples. Multiple decision trees are included in a random forest, and bagging is the process of replacing the original data in each tree with replacements drawn from the random sampled data in that tree. An ensemble of decision trees includes a sample with substitution from the training set that was bagged. A class label for an unlabeled data point is determined by each and every tree in the ensemble. Each classifier votes for its own anticipated class label during the majority voting process used for labelling. The data point is then classified using the class label that received the highest support from the several classifiers. The idea behind random forests is to use the rule of large numbers to solve the overfitting problem. By integrating a lot of weak learners into one strong learner, the random forests qualified majority structure prevents overfitting and produces a strong learner.

Neural network autoencoder

An artificial neural network may automatically learn a

compressed logical representation of the information using the autoencoder, which then reconstructs it so that the input and output are identical. The neural network learns on the entire set of data in the "encoder" portion through a series of progressively smaller layers until the compressed data representation is achieved. The second component, the "decoder," frequently mirrors the compressed representation's inclining layers to reconstitute the original input. Since the last compressed layer of an encoder is the bottleneck of a model with non-linearly learnt semantics, it does not only recall the original data. For this kind of learning, there is no need to separate the train and test data; instead, the entire dataset is used to fit the model twice, once for training and once for testing.

Data Understanding

Understanding the data's purpose, collection methods, and

mapping to business knowledge are all necessary for data- centric operations. This stage involves describing the gathered dataset(s) and doing data exploration and analysis. Data quality has to be evaluated and reported. Additional data transformations shouldn't be added to this stage.

Data Pre-Processing

Data selection (sampling), data cleaning, feature selection,

feature engineering, and algorithm-required transformations including reformatting, encoding, scaling, class balancing, and dimensionality reduction must all be completed before data can be utilized in the modelling stage.

Data preprocessing is a data mining technique used to turn

the raw data into a format that is both practical and effective. The data is pre-processed to reduce non-uniformity before applying the model. The dataset was cleaned up by removing any rows from it that had attributes with empty values. Only those qualities that were pertinent to the instances created after data processing were used. We then continue with the modelling process after calculating the correlation between the characteristics.

Modelling

This phase involves actual implementation of the

algorithmic component. The ability to train machine learning algorithms or use other statistical techniques to accomplish previously stated goals is made feasible by having prepared input data. The selection of algorithms and hyperparameters, composition of the models, and fitting the models are carried out in the case of machine learning modelling. Following model training, chosen metrics values are obtained and the models' performance is evaluated. The optimal model hyperparameters are found through a model tuning method, if necessary, to enhance model performance.

Data Understanding

Journal entries gathered from various businesses with

registered financial accounts over various time periods make up the general ledger data that is offered. To create a system to find abnormalities in the accounting data, supervised machine learning was used. Six different classifiers were trained and evaluated using data from a single firm that was taken from the ERP system. The task

was defined as a multi-class classification, and the dataset for journal entries had 11 categorical variables. The authors emphasized that there aren't many machine-learning applications and that most investigations employ conventional data analytics and statistical methods. Based on several assessment criteria and comparisons to the traditional rule-based method, they came to some encouraging conclusions and claimed excellent performance of the chosen models. The journal entry unique identification JE_NO is a categorical value that designates a unique entry within a fiscal year FY for the particular firm COMPANY and registered on the effective date EFF_DATE. The ACCOUNT field for a single transaction contains a four-digit account number together with the AMOUNT field's embedded debit-credit amount. A source system category value may be found in the SOURCE field.

	JE_NO	EFF_DATE	ACCOUNT	AMOUNT	SOURCE	COMPANY	FY	Fabricated_JE	TYPE
0	A-111	2019-07-07	1930	10512.00	C	44	2018-09-01 - 2019-08-31	0	0
1	A-111	2019-07-07	1510	-10512.00	C	44	2018-09-01 - 2019-08-31	0	0
2	B-222	2019-06-10	2330	-2374.00	E	55	2018-07-01 - 2019-06-30	0	0
3	B-222	2019-06-10	2440	2374.00	E	55	2018-07-01 - 2019-06-30	0	0
4	C-333	2017-07-05	1930	-23334.20	D	66	2016-09-01 - 2017-08-31	0	0

We have labels in addition to the attributes of the provided dataset. A binary tag for a journal entry is included in the Fabricated_JE field, where 1 corresponds to a synthetic anomaly and 0 to the original data value. We have a TYPE along with a binary-value label.

N	Column name	Column type
0	JE_NO	string
1	EFF_DATE	datetime
2	ACCOUNT	string
3	AMOUNT	float
4	SOURCE	string
5	COMPANY	string
6	FY	string
7	Fabricated_JE	string
8	TYPE	string

Data Cleaning

We examined the dataset to see whether any records had missing values, but none were found. Dropping duplicates was done to make sure there were no records

that repeated themselves in a data. The column data types were aligned, with the effective date column becoming a datetime type and category values becoming string data types. There is only one continuous column of numbers here: AMOUNT. The data doesn't contain any values that curiously don't match the columns they belong to.

Models Used:

I. Logistic Regression

Logistic regression is basically a supervised classification

algorithm. For a certain collection of characteristics (or inputs), X, the target variable (or output), y, can only take discrete values in a classification issue. In order to determine the likelihood that a certain data input falls into the category designated by the number "1," the model creates a regression model. Logistic regression models the data using the sigmoid function, much like linear regression assumes that the data follows a linear distribution.

II. Decision Tree Algorithm

A supervised learning algorithm is the decision tree

algorithm. By learning straightforward decision rules derived from previous data, a Decision Tree is used to generate a training model that may be used to predict the class or value of the target variable (training data).

In decision trees, the process begins at the tree's root when anticipating a record's class label. It contrast the root attribute's values with that of the attribute on the record. It takes a branch that corresponds to that value and go on to the next node based on the comparison.

III. Random Forest Algorithm

Random forest is a supervised learning algorithm. The

"forest" it builds is an ensemble of decision trees, usually trained with the “bagging” method. The general idea of the bagging method is that a combination of learning models increases the overall result. Hence, random forests build multiple decision trees and merges them together to get a more accurate and stable prediction.

IV. XGBoost Algorithm

XGBoost is a decision-tree-based ensemble Machine

Learning algorithm that uses a gradient boosting framework. In prediction problems involving unstructured data (images, text, etc.) artificial neural networks tend to outperform all other algorithms or frameworks. However, when it comes to small-to-medium structured/tabular data, decision tree-based algorithms are considered best-in-class right now.

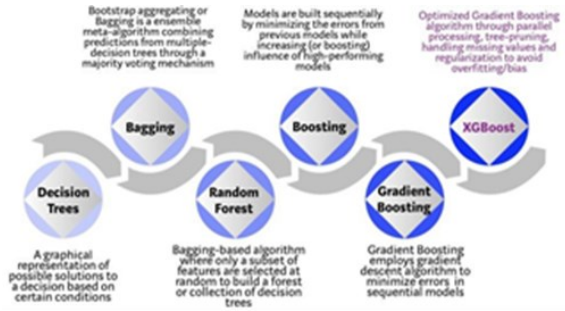

Fig. 06: Evolution of XGBoost from decision trees

V. IMPLEMENTING MODELS:

To find outliers in the preprocessed dataset, we trained 7 supervised and 2 unsupervised machine learning models using various algorithms. A dichotomous class will be predicted by supervised models, turning the problem into a binary classification one. We discussed the methods and outcomes of empirical modelling in this section.

For machine learning models to operate at their best,

tweaking algorithm-specific hyperparameters is necessary. This is typically an iterative procedure that calls for careful parameter selection to be modified as well as the use of a more intelligent automated method to quickly iterate over large hyperparameter spaces. In this study, Bayesian optimization was applied to fine-tune the hyperparameters over intricate input spaces using the Hyper opt Python module. In contrast to random or conventional grid search, Hyper opt uses adaptive learning to focus on the most effective combinations of hyperparameters that speed up the search process. The algorithm is very adaptable and minimizes a loss function. A set of hyperparameters from the defined space must be passed to an objective function in Hyper opt in order to establish an optimize function that runs trials and generate an evaluation measure. Given that Hyper opt reduces the loss, we applied a negative value of this measure to the loss in order to increase the value of the evaluation metric.

We must divide the data into train and test datasets or train, test, and validation datasets in order to perform supervised learning. The amount of data and other data features, including a distribution of classes, heavily influence how the data should be split. Compared to the entire number of anomaly classes in our dataset, only few anomaly classes have been labelled. Despite the fact that we have a binary classification problem, we still want our model to develop and be evaluated on all of the different sorts of anomalies. In this case, we divided our data into two datasets: train and test data, each comprising 70% and 30% of the total data. To ensure that the proportions of each anomaly type in the train and test data were identical, we needed to stratify the data while separating it. We set a random state value while splitting in order to ensure reproducibility and accurate model comparison. Cross validation resampling is frequently used to obtain better generalization loss estimates. The K-fold cross-validation approach, which randomly divides data into train and test datasets k times with a holdout (test) dataset accounting for 1/k, is one

example of that. The training procedure will take k times longer using this strategy. To optimize the models in our setup, we use Hyper opt with 100 iterations. The objective function of Hyper opt optimization advises against employing cross-validation since the search for the correct hyperparameter value predominates. However, in our situation, 100 iterations would result in 300 with 3-fold cross-validation for each trained supervised model. The necessity to get the classification report and confusion matrix that would be for the cross-validation of the unspecific random split when comparing different tuned models is another reason to only use cross-validation for the model that performs better. In light of this, we came to the conclusion that the use of cross-validation within Hyper opt will only be advantageous for the model productionazation,when the best technique across examined is picked to refine the model and retrain it on the whole dataset using best parameters.

Positive (0) and negative (0) classes are predicted by binary classification models (1). We view anomalous class positively in our work. Accuracy, Precision, Recall, and F1- Score are the most often used classification metrics for evaluating binary classification models. A confusion matrix, which is a consequence of a model's anticipated classes representation, can be used to determine these metrics. Explained in terms of true/false positive and negative classes utilising the actual class y-axis and predicted class x-axis position is the confusion matrix structure. When a trained ML model predicts a class, we may determine the value of the corresponding T N, T P, F N, and F P counts. The weighted average, macro average, and micro average levels can all be used to produce the aforementioned metrics. Selecting the appropriate metrics for a model's evaluation depends on the task at hand and the class balance property. For a dataset with imbalanced classes, such as the one in our scenario, Accuracy would not be a reasonable metric to grade a model on.

V. RESULT INTERPRETATION

We developed Logistic Regression, Support Vector Machines, Decision Tree, Random Forest, K-Nearest Mean, Nave Bayes, and Artificial Neural Network models for supervised modelling. The Hyper opt Bayesian optimizer was used to find the optimum model hyperparameters across

100 iterations for all models with the exception of the K-

Nearest Mean model. In order to effectively search for the optimal values, each machine learning technique was built with Hyper opt optimization to train 100 distinct models. To ensure an unbiased train and evaluation process, we used a stratified split by anomaly types. In this scenario, an equal percentage of each anomaly type instances ended up in each of the splits. In the Hyper opt optimization trials object, we stored the model hyperparameters and corresponding classification report metrics.

No.	Algorithm	TN	FN	FP	TP	Recall avg macro
1	Logistic Regression	3747	2	70	19	0.9432
2	Support Vector Machines	3732	1	85	20	0.9650
3	Decision Tree	3710	0	107	21	0.9859

5	K-Nearest Neighbour	3814	6	3	15	0.8567
6	Naïve Bayes	3817	17	0	4	0.5952
7	Deep Neural Network	3811	3	6	18	0.9277

We used unsupervised learning strategies, such as Isolation Forest and Autoencoder neural networks, to identify abnormalities in the general ledger data. The primary distinction between unsupervised and supervised learning is that unsupervised learning does not require labelled data. However, to determine assessment metrics based on the created categorization report, we employ the class labels. For each instance of the dataset, the isolation forest and autoencoder models provide an anomaly score.

Based on the chosen performance metric and an overview of the confusion matrices, we evaluated and compared the performance of the models. The criteria listed in include comprehensibility, operating efficiency, economical cost, and regulatory compliance in addition to correct the trained models how statistically are. Operational efficiency considers a model's technical time-performance while interpretability addresses the issues of whether and how we are able to comprehend the outcomes that are generated by the models. Economic cost is a practical factor that determines how expensive it is to train, implement, and use the model in the system environment that is currently in place. The final significant point is a legal one.

The accuracy is been calculated of these different algorithms with their respective AUCs and get the correct number of predictions in each of the algorithms. As shown, the rate of correct predictions increases with every algorithm performed.

LOGISTIC REGRESSION: Acc = 0.9992

AUC = 0.8207 Correct Predictions: 68/106

DECISION TREE ALGORITHM: Acc = 0.9992

AUC = 0.8867 Correct Predictions: 82/106

RANDOM FOREST ALGORITHM: Acc = 0.9995

AUC = 0.9009 Correct Predictions: 85/106

XGBOOST ALGORITHM: Acc = 0.9996 AUC =

0.9104 Correct Predictions: 87/10

VI. FUTURE SCOPE:

While this project couldn't reach the goal of 100% accuracy in fraud detection, it did end up creating a system that can, with enough time and data, get very close to that goal. As with any such project, there is some room for improvement here. The very nature of this project allows for multiple algorithms to be integrated together as modules and their results can be combined to increase the accuracy of the final result.

This model can further be improved with the addition of more algorithms into it. However, the output of these algorithms needs to be in the same format as the others. Once that condition is satisfied, the modules are easy to add as done in the code. This provides a great degree of modularity and versatility to the project.

More room for improvement can be found in the dataset. As demonstrated before, the precision of the algorithms increases when the size of the dataset is increased. Hence, more data will surely make the model more accurate in detecting frauds and reduce the number of false positives. However, this requires official support from the banks themselves.

VII. CONCLUSION AND RESULTS:

This study covered the use of data science in the context of financial auditing, where we employed machine learning strategies to find irregularities in general ledger data.

Smart analytics solutions are more necessary than ever to update the outdated manual methods of performing audit-related chores. The amount of accounting data that must be examined during a financial audit process is growing, and audit professionals must regularly review it despite their limited human capacity to understand the extent of financial misstatements. Automating and increasing the effectiveness of these jobs has long been an aim.

Through a survey of the literature and the use of empirical

techniques for developing and accessing machine learning models, we added to the body of knowledge in the topics under discussion in this work.

In this project we have tried to show different methods of dealing with unbalanced datasets like the fraud transaction dataset where the instances of fraudulent cases are few compared to the instances of normal transactions. We have argued why accuracy is not an appropriate measure of model performance here and used the metric AREA UNDER ROC CURVE to evaluate how different algorithms like Logistic regression, Decision tree, Random Forest algorithm and the XGboost algorithm the response variable can lead to better model training. We concluded that the XGboost algorithm technique works best on the dataset and achieved significant improvement in model performance over the imbalanced data. The best score of 0.9104 was achieved using an XGBOOST model though both random forest and logistic regression models performed well too. It is likely that by further tuning the XGBOOST model parameters we can achieve even better performance. However, this exercise has demonstrated the importance of sampling ineffectively modelling and predicting data with an imbalanced dataset. We discussed the costs and hidden fraud consequences of undiscovered financial misstatements and enhanced labor operations. We were able to provide cutting-edge machine learning methods for identifying abnormalities in the accounting data with the aid of a study of similar work in the appropriate chapter.

The articles that have been studied indicate that using machine learning approaches to solve the issue at hand has a high potential. Despite this, we found a research gap that prevents existing private industrial solutions from being explained and prevents relevant in-depth studies from being conducted in academia or industry. We used the CRISP-DM technique to construct a data science application as part of the research effort for this thesis that included an empirical component.

VIII. ACKNOWLEDGMENT

We thank Thakur college of engineering and technology for providing such an incredible platform where students can express their ideas and research related to the technical or non-technical subject and also can develop their skills. And we also acknowledge our mentor Mrs. Neha Patwari for her guidance and support.

Abstract—**Semantic segmentation classifies each pixel of an image into one of several predefined classes. In the context of road scenes, it is used for self-driving cars, traffic monitoring, and map generation. Recent advances have beendriven by the development of large, publicly available road scene datasets, such as Cityscapes and SYNTHIA. The current SOTA is dominated by FCNs and encoder-decoder architectures that directly produce a dense, per-pixel prediction. Encoder decoder architectures, such as the U- Net, use a combination of convolutional and transposed convolutional layers to upsample a lower-resolution feature map to output a dense, per-pixel prediction. One area of particular interest is the development of models that handle variations in lighting and weather conditions. We use DAFormer for semantic segmentation, which is trained end- to-end using the cross-entropy loss function and the stochastic gradient descent optimizer. The use of data augmentation techniques such as random flipping, scaling, and cropping is also performed during training to improve the robustness of the model to different image variations. The performance is evaluated using several standard metricswith mean IoU scores of over 95.7% on the Cityscapes and 84.5% on the SYNTHIA dataset.**

Keywords—semantic, segmentation, DAFormer, SegFormer, transformers, self-driving, cityscapes, GTA5

I. INTRODUCTION

Semantic segmentation is a task in computer vision that involves classifying each pixel in an image into one of several predefined categories. This technology can be used in a wide range of applications, including self-driving cars, traffic monitoring and surveillance, and urban planning. In the context of Indian road scenes, semantic segmentation can be used to identify different types of vehicles, pedestrians, buildings, and road markings, which can be used to improve traffic safety and efficiency [1].

However, training semantic segmentation models on Indian road scenes can be challenging due to the wide variability in lighting, weather, and other factors that can affect the appearance of the scene. Additionally, the availability of labeled data for Indian road scenes is often limited, which can make it difficult to train high-performing models.

Unsupervised domain adaptation is a method that can be used to improve the performance of semantic segmentation models on Indian road scenes. This approach involves training a model on one set of data, and then fine-tuning it toperform well on a different, but related, set of data. This can be done by using a technique called adversarial training, which involves training two models simultaneously: one that generates images that are similar to the target domain, and another that tries to distinguish between the generated images and the real images.

II. RELATED WORKS

A. Semantic Segmentation

Semantic segmentation is a computer vision task that involves classifying each pixel in an image into one of several predefined categories. The goal of semantic segmentation is to assign a semantic label, such as "car" or "person," to each pixel in an image. This technique is used to identify and locate various objects and features in an image, such as vehicles, pedestrians, traffic signs, and lane markings.

Semantic segmentation is typically performed using deep learning techniques, such as convolutional neural networks (CNNs) and fully convolutional networks (FCNs). These models are trained on large amounts of labelled data and are able to learn to recognize patterns and features in images that are relevant for semantic segmentation. One of the key advantages of semantic segmentation is its ability to provide a detailed understanding of the scene.

By assigning a label to each pixel, semantic segmentation can be used to identify and locate specific objects and features in an image, such as vehicles, pedestrians, traffic signs, and lane markings. This information can be used for a variety of applications, including self-driving cars, robotics, and surveillance systems.

Semantic segmentation is also used in the field of computer graphics, where it can be used to create high-quality images and animations. The technique can also be used in medical imaging and satellite imaging, where it can be used to identify and locate specific structures or regionsin images.

B. Unsupervised Domain Adaptation

Unsupervised Domain Adaptation (UDA) is training a statistical model on labelled data to a target domain's data from a source domain more efficiently, having access toonly unlabeled data in the target domain. It is a framework for learning that allows information to be transferred from source domains with lots of annotated training examples to target domains with just unlabeled data [2]. It aims to adapt a model trained on synthetic data to real-world data without requiring expensive annotations of real-world images.

In principle, UDA mainly focuses on the global distribution alignment between domains while not includingthe local distribution properties. Its objective is to leverage features from a labelled source domain and use them on an unlabeled target domain, with a similar

but different data distribution. The majority of deep learning methods for domain adaptation involve two phases:

i. learn features that preserve a low risk on labelled samples (source domain) and,

ii. make the features from both domains to be as indistinguishable as possible, so that a classifier trained on the source can also be applied on the target domain.

Most approaches only work with downscaled pictures since UDA methods for semantic segmentation are often GPU memory heavy.

C. Indian Road Scenes

Semantic segmentation of Indian road scenes is the process of classifying each pixel in an image of an Indian road scene into one of several predefined categories. This technique is used to identify and locate various objects and features such as vehicles, pedestrians, traffic signs, and lane markings. One of the key challenges in the semantic segmentation of Indian road scenes is the variability in the appearance of objects and features. Indian road scenes often contain a large number of pedestrians and other non- vehicular objects, which can further complicate the task of semantic segmentation.

To address these challenges, researchers have developed several approaches that leverage deep learning techniques such as convolutional neural networks (CNNs) and fully convolutional networks (FCNs) to improve the performance of semantic segmentation models. The application of semantic segmentation of Indian road scenes is mainly used in the development of advanced driver assistance systems (ADAS) for self-driving cars, road safety, traffic management, surveillance, and robotics [3].

ADAS systems use cameras and other sensors to perceive the environment and make decisions about how to control the vehicle. Semantic segmentation can be used to identify and locate objects and features such as vehicles, pedestrians, and traffic signs, which can be used to improve the performance of self-driving cars. Semantic segmentation can also be used to improve road safety by identifying and locating potential hazards such as pedestrians, bicycles, and motorcycles on the road. This information can be used to alert drivers or to control the speed and trajectory of self- driving cars [4].

III. DATASETS COMPARATIVE STUDY

A. CityScapes

Cityscapes is a comprehensive database that concentrates on comprehending urban street scenes semantically. It offers detailed annotations for 30 different classes, which are divided into 8 categories (such as flat surfaces, humans, vehicles, constructions, objects, nature, sky, and void), and includes both instance-wise and dense pixel annotations. The dataset encompasses around 5000 images with fine annotations and 20000 with coarse annotations. The data was captured in 50 cities over a period of several months and only during daylight hours and good weather conditions.

The footage was initially recorded as video, and specific frames were selected for inclusion based on the presence of a high number of dynamic objects, diverse scene layouts, and changing backgrounds. The dataset is comprised of a diverse set of stereo video sequences from 50 cities and boasts high-quality pixel-level annotations. This makes it significantly larger in scale compared to similar previous efforts. It is designed for evaluating the performance of vision algorithms in crucial tasks of semantic urban scene understanding, such as pixel-level, instance-level, and panoptic semantic labelling, and to support research that utilizes large amounts of (weakly) annotated data, like for training deep neural networks.

B. GTA5

The GTA5 dataset comprises 24966 synthetic images with pixel-level semantic labelling. The images were created through the open-world video game Grand Theft Auto 5 and feature a car's view of American-style virtual cities. There are 19 semantic categories, similar to those in the Cityscapes dataset. The dataset encompasses an extensive range of road scenes, from urban to rural, and provides comprehensive annotations for objects such as buildings, roads, vehicles, and pedestrians. Its diversity and large number of images make it a valuable resource for training models to handle diverse input and generalize effectively to new images.

C. SYNTHIA

The SYNTHIA dataset is a synthetic collection of images and annotations designed to support research in semantic segmentation and other scene-understanding tasks related to driving scenarios. It features a large volume of data with precise pixel-level semantic annotations, including over 200,000 high-definition images from video streams and 20,000 images from separate snapshots.

The dataset offers a diverse range of scenes, including a European-style town, modern city, highway, and green areas, as well as a variety of dynamic objects such as cars, pedestrians, and cyclists. Additionally, the dataset includes different seasons, lighting conditions, weather patterns, and a simulation of multiple sensors, including 8 RGB cameras and 8 depth sensors.

D. National Dataset for Indian Roads

The National dataset for Indian Roads is a dataset created for research and development of autonomous

systems, specifically for Indian roads in partnership by

IISc and Wipro.

It was created to address the lack of publicly available datasets for Indian road scenes, having unique characteristics of such as crowded roads, diverse traffic, and a wide range of vehicle types. It includes 1000 images captured from various locations in India, with a resolution of 1920x1080 pixels. Each picture is annotated with 29 classes, including roads, buildings, vehicles, pedestrians, and traffic signs.

The dataset is composed of images and annotations useful for semantic segmentation of road scenes and Indian Road traffic scene analysis. The dataset was created using real-world data captured in Bengaluru and includes a wide variety of different types of road scenes, from urban to rural, which makes it unique and valuable for researchers working on autonomous systems in India.

One of its key features is that it includes detailed annotations and labels for different types of roads (such as highways, residential streets, and dirt roads), as well as for different types of vehicles (such as cars, trucks, and buses) and different types of buildings (such as houses and factories). These annotations can be used to train models to accurately identify and segment different objects in the images, which is an important step in developing models for autonomous vehicles and other applications that rely on understanding the environment. This dataset also includes annotations for unique and specific Indian road conditions such as, traffic signals, traffic signs, potholes, and road markings. This allows for the development of models that are specifically tailored to Indian road conditions and regulations.

IV. METHODOLOGY

In this paper, we implement two models for semantic segmentation, namely SegFormer [5] and DAFormer [11], and discuss their results and performance.

A. SegFormer

SegFormer [5] includes a new hierarchically structured transformer encoder structure that outputs multi-scale features. SegFormer does not require positional encoding, thereby preventing the interpolation of positional codes leading to a lower performance while the resolution during testing differs from that while training. It also has the tendency to disprove complex decoders. The MLP decoder combines local and global attention by merging information from various layers, resulting in effective representations.

The SegFormer framework has 2 modules: A hierarchical transformer encoder to extract the coarse and fine features, and a decoder to directly fuse these multi-level features and predict the segmentation mask. There are two core ideas to SegFormer: the encoder in the model outputs multi-scale features, and the MLP-based decoder aggregates this information from different layers to output a segmentation map.

1. Encoder

An input image is first divided into 4 x 4 patches (similar to vision transformers), but in vision transformers, it generally uses a patch size of 16 x 16. A smaller patch size used to make better dense prediction tasks. The transformer block is composed of three sub-modules:

1. An efficient self-attention,
2. A mixed feed-forward network, and
3. An overlapping patch merging module.

The first efficient self-attention module works like the original multi-head self-attention transformer, but it uses a sequence reduction technique in order to lower the computational costs. The next block, which is a mixed feed- forward network, is used to solve the fixed resolution problem. Instead of using fixed sized positional encoding, layers of convolution and multi-layer perceptron (MLP) are used to implement data-driven positional encoding. The last module, which is the overlapping patch merging block, is used to reduce the size of the feature map. The size of the feature is reduced as it goes to the higher part of the network.

2. Decoder

The decoder is quite simple compared to the modules in the encoder, because there are different features of different sizes in each layer of the encoder. • The full MLP layer in the decoder takes the features from the encoder and fuses them together. This all MLP decoder is composed of four main steps:

1. Firstly, multi-level features from the encoder are fed into the multi-layer perceptron layer to unify in the channel dimension.
2. Next, the features are up-sampled to ¼ of its size and are concatenated together.
3. Thirdly, a MLP layer is adapted to fuse the concatenated features.
4. Finally, another MLP layer takes these fused features to predict the segmentation mask.

B. DAFormer

Training a neural network for semantic segmentation usually requires expensive pixel-wise annotations of real- world images. Therefore, it is more desirable to exploit other domains that are easier to annotate, such as synthetic data. However, a model trained on the source domain typically experiences a performance drop when applied to the target domain. The goal of Unsupervised Domain Adaptation (UDA) is to increase the

performance over the target domain by using unlabeled target images.

Many state-of-the-art UDA methods are based on self-training. The network is trained using ground truth labels for source images and pseudo-labels for target images. The pseudo-labels are generated by taking confident predictions of a teacher. The teacher network is an exponential moving average of the student for temporally stable predictions. In that way, the networks are iteratively adapted to the target domain. Previous UDA methods mostly use a DeepLabV2 network architecture. However, DeepLabV2 is significantly outperformed by more recent networks in supervised semantic segmentation.

DAFormer [11] studies the influence of the network architecture on UDA and compiles a more sophisticated architecture, representing a major advance in UDA.

Image **Ground Truth** **SegFormer [5]** **DAFormer [11]**

Fig. 1. Qualitative results for semantic segmentation on the National Dataset for Indian Roads. Example predictions

showing a better recognition of most classes by DAFormer as opposed to SegFormer. Compared to SegFormer, the DAFormer model predicts the Ground Truth masks with substantially finer details near object boundaries. It also reduces long-range errors as highlighted in white in images 1, 4, and 6.

It improves the state-of-the-art performance by a significant margin of 10.8 mIoU on GTA→Cityscapes. A hierarchical transformer is utilized for the encoder, which is revealed to be more domain-robust than the predominant CNNs.

For the decoder, a context-aware feature fusion is used, which utilizes domain-robust context clues from different encoder levels. Compared to the DeepLabV2 architecture, DAFormer significantly reduces the performance gap between UDA and the supervised oracle. In many cases, the source dataset is imbalanced as some rare classes appear only in a few images. Therefore, the performance of these rare classes heavily depends on the random seed of the data sampling. By frequently sampling images with rare classes, the network can learn them more stably, which improves the quality of pseudo-labels and reduces confirmation bias.

During UDA, the network overfits the source domain, and difficult classes of the target domain are not distinguished clearly. Therefore, a Thing-Class ImageNetFeature Distance is introduced to regularize the source training. DAFormer shows significant successive improvements of the proposed components over a strong UDA baseline. In particular, it learns even difficult classes that previous methods struggled with.

V. RESULTS

The observations made while applying the DAFormer model are as follows:

The DAFormer struggles to deal with shadows, particularly if they cover the part of the road right in front of the vehicle. It is not effective at dividing the road into proper segments if the sidewalks or walkways are not well- defined. The model is vulnerable to creating inaccurate segmentation maps in situations where there is too much light exposure, particularly on roads that are overexposed to sunlight. The DAFormer also fails to recognize or segment road signs incorrectly.

The observations made while using the SegFormer model are:

It frequently makes incorrect identifications and classifications for objects that are far away in the frame, particularly for vehicles and humans. The model struggles torecognize the road surface or sky if the image is not clear enough, as seen in an example where the ground is partially segmented. Shadows or bright patches of light present in the image can cause the model to leave the affected area unclassified. In some cases, a single vehicle may be divided into multiple classes due to sharp boundaries or margins in the image.

The results of the benchmark of previous models on various classes and shown in Table 1 and Table 2. Fig. 1 shows the inference results for some images from the National Dataset for Indian Roads.

VI. CONCLUSION

The task of semantic segmentation of Indian road scenesis difficult due to the complexity and variety of these scenes,as well as the lack of sufficient labeled data. Unsupervised domain adaptation has proven to be a promising solution by fine-tuning pre-trained models on the target domain using limited labeled data. This approach has shown positive results for different types of Indian road scenes, including urban, suburban, and rural areas, with the ability toaccurately segment road surfaces and objects like vehicles, pedestrians, and buildings. The unsupervised domain adaptation also increases the generalization of the models tonew scenes, which is crucial for practical applications.However, there are still some challenges to be overcome, such as the models' incapacity to fully capture variations like lighting and weather conditions, which may affect theirperformance.

Furthermore, further research is necessary to assess the robustness and scalability of unsupervised domain adaptation for semantic segmentation of Indian road scenes. In conclusion, unsupervised domain adaptation is a hopeful method for semantic segmentation of Indian road scenes. It

effectively uses pre-trained models and limited labeled data to enhance the performance and generalization of the models. Despite the existing limitations, this field continues to evolve with advancements in computer vision, deep learning, and the availability of large labeled datasets, which could result in even better and more reliable models for applications like self-driving cars, traffic monitoring, and smart city planning.

Abstract—**In various critical applications such as video surveil- lance, self-driving cars, robotics, and scene understanding, deep learning-based object identification surpasses traditional object detection techniques due to its exceptional abilities in feature representation and feature learning. In order to solve the issues with traditional architectures, more potent tools that can learn semantic, high-level, deeper features are being offered as a result of the rapid progress in deep learning. In terms of network architecture, training methodology, and optimization function, these models behave differently.This object detection classifies various objects in live video as well as in images and video files.In this research , we have not use coco dataset but instead we have train a custom object detection model using our own dataset. We have use different animals,birds,different food items and many different objects so that our model can classifies more and more objects in live videos as well as in different images and video files. Various objects can be detected easily with our model,inlive video as well as in images.The classical approaches for object detection are introduced in this work, along with comparisons and contrasts between them and deep learning methods for object recogni- tion. Additionally, it describes the emergence of object detection based on deep learning in detail.**

Index Terms—Object detection, deep learning, framework design, model per- formance.

I. INTRODUCTION

The main objective of object detection is to identify one or more valuable targets within images or videos by utilizing vari- ous essential techniques such as artificial intelligence, machine learning, image processing, and pattern recognition.It has sev-eral potential applications, including enhanced human-com- puter interaction, monitoring militarily restricted areas, alerts of unsafe commodities in manufacturing, and preventing traffic accidents [1, 2]. While multi-target detection application set- tings in the real world are frequently complicated and varied,

it can be challenging to strike a balance between accuracy andcomputational costs.

The prominent study area and focus in computer vision that may be used in automated driving, robotics, video surveillance, and pedestrian identification is object detection from video frames. The use of deep learning technology has altered how objects are recognised and detected in the past.Through deep learning objects are detected easily.

The vital feature representation capacity in video frames pro- cessing and is usually used as the feature extraction module in object detection. The deep learning models don't require special hand engineering features and can be designed as the classifiers. Therefore, the deep learning is of significant prospect in object detection as well. The problem statement of object detection is to determine where objects are normally located in a given video frame (object localization in image) and hence detecting it. Therefore, the traditional object detec- tion models mainly divided into three stages: 1) informative region selection; 2) feature ex- traction; and 3) detection.

A. Informative Region selection

Various items with various aspect ratios or sizes appear in all locations in the video frame. Scanning the entire frame using a multi-scale sliding window is a required task. Although this thorough approach can determine every conceivable position for the items, it also has clear flaws. It is computationally in- tensive and results in several duplicated windows due to the enormous number of candidate windows. However, if there is merely a chance that the supplied current video frame containspoor areas (image).

B. Feature Extraction

To categorise various things, we must extract visual character- istics that might offer a strong and meaningful representation. This is because complex cells in the human brain have charac- teristics that may generate representations. However, it is chal- lenging to construct a universal feature descriptor for manually defining all types of objects due to the diversity of looks, light- ing, and backdrops.

C. Detection

A detector distinguishes a target object from all other categories, presenting it for visual identification in a more informative and hi- erarchical manner. In general, Support Vector Machine (SVM) and Deformable Part-based Model(DPM) are viable alternatives for it. Among these classifiers, the DPM is a flexible model since it man- ages severe defor- mations by combining object parts with defor- mation cost. In DPM, kinematics-inspired component decomposi- tions and meticulously created low-level features are combined with the help of a graphical model. Additionally, discriminative learning of graphical models enables the generation of high- precision part- based models for a variety of object classes.

II. OBJECT DETECTION

Computer vision research employs object identification and tracking in various applications, including traffic detection, vehicle navigation, and interpersonal connections. Object de- tection is a computer hardware-

based task that recognizes examples of semantic objects belonging to a particular class, such as buildings, people, or automobiles, in both digital still photographs and moving pictures. Object detection has wide- ranging applications, including face detection, face recognition, and video object detection, and is useful in areas like image retrieval and video surveillance. The system can detect the presence or absence of objects in a scene or camera's field of view. Object detection can be classified into specific and conceptual categories based on various domains and different objectives, with explicit or implicit models and varying com- ponents. The selection of objects is based on matching and hypothesis, making it suitable for processing and searching objects found in real-world applications. Additionally, it is useful for tracking the motion of objects like balls and people in videos.

A. Features of the Object Detection

The computer's work accessibility may be decreased by the ob- ject identification, tracking, and selection of various distinctive attributes. The combination of the various charac- teristics is cal- culated in multiple processes [5] below when tracking is carried out using various algorithms.

a Color: This aspect of the computer system is utilised to portray the look of histograms. The characteristics of the colour representations for tracking have the broadest range of attributes. The characteristics of colour track significant issuesthat can detect changes in light.

b) Histogram of gradients: It is the most often utilised char- acteristic for human body detection. The histogram's ac-tions are based on the image's local grid unit. Therefore, the optical deformations are affected by geometric differ- ences. Additionally, the upright posture and bodily mo- tions are maintained by the sample orientation and local optimization. The key benefit of the HOG feature in de- tecting humans is that these movements have no impact on the detection phase [6].

c) Edges: When an item is being detected or identified, the picture intensity boundaries may shift. The object detect- ing feature differs from the colour characteristics method [7].

d) Optical Flow: The function relies on the applications of tracking and motion segmentation. Every pixel in the area is recognised by the displacement vector. The displace- ment vector is what defines how each pixel in each picture will change over time. Applications for motion-based seg-mentation and tracking frequently make use of optical flow as a feature. Each pixel's translation inside an area is defined by a dense field of displacement vectors. It is cal-culated using the bright-ness constraint, which makes the assumption that the brightness of consistent pixels over consecutive frameswould remain constant. With the ad- vancement of technology,several well-liked methods for calculating dense optical flow have emerged, including the Horn-Schunck Algorithm [8].

B. Challenges of object detection

a) Position of the image may be modified whenever desired.The system will handle the photos uniformly in the tem- plate matching process [9].

b) Lighting Conditions might alter while the system is run- ning. The illumination of a photograph could be impacted by weather variations. In this situation, the lighting situa- tion may change over time. The lighting system for the image is impacted by the image's shadow. Any lighting situation may be used for object recognition from a pic- ture. [10]

c) Rotation Images might be able to handle this kind of chal- lenge. For instance, a character may appear in any shape, but the character's detection has no bearing on the orienta- tionsof an image.

d) Occlusion is the term used to describe a situation in which items are obscured from view.

e) Scaling method is a method of object detection that takes into account picture scaling [11]. The item's size change has no impact on the object detection systems. The diffi- culties might be brought on by object detection.

III. LITERATURE REVIEW

This section discusses the literature on the many subjects in- cluded in this proposal. CeLi et. al [12] presented a deep learning-based object detec- tion using tiny data. The suggested nodel enhances the accuracy of weak feature ob- jects in complicated circumstances by utilis- ing the semantic relevance of items.

a) Cong Tang et. al [13]Discussing the framework's archi- tecture, the models' underlying principles, and evaluating real- time model performance and detection accuracy. Christian Szegedy et.al [14] shows how to formulate object identification as a regression issue to object bounding box masks in a straightforward yet effective way. It describes a multi-scale inference method that enables a small number of network applications to recognise objects with high resolution and cheap cost.

b) XiaogangWang et.al [15] gives a general introduction to deep learning with an emphasis on applications in object identifica- tion, detection, and segmentation, which are the main difficul- ties in computer vision and have many usesin both still and moving pictures.

c) ShuaiZhang et.al [16] provides a framework for carrying out activities in a network of several nonoverlapping cameras. With the introduction of a new object detection technique that uses mean shift (MS) segmentation, objects are further divided.There is vision with the aid of depth data from stereo fixed number of sliding window templates. Additionally, utilising Decision Trees or, more likely, SVM in deep learning, super- vised learning may be used to implement the issue.

d) XinyiZhou et. al [17]primarily works in the area of computer vision for the purpose of object detection. The datasets and deep learning methods utilised in computer visionare briefly summarised.

e) Girshick et al. [18] suggested a multi-stage pipeline known as Regions with Convolutional Neural Networks (R- CNN) for deep CNN training to identify region suggestions for object identification. The detection problem is broken downinto a number of steps, including bounding-box proposal, CNN pre- training, CNN fine-tuning, SVM training, and bounding- box regression. A similar framework was used by other approaches because of its successful performance.

f) QiuZhao et.al [19] Discuss a thorough analysis of deep learning-based object detection frameworks that address vari- ous sub-issues including clutter and low resolution with vary- ing degrees of R-CNN changes. Sandeep Kumar et.al [20] is- cusses the Easynet model, which enables detection predictions with a single network..

IV. FUNDAMENTAL OF DEEP LEARNING

The term ”deep learning” has gained popularity. Deep’s suc- cess may be attributed to two factors: first, the abundance of datasets, and second, the strength of the graphics processing unit. Deep learning is a type of artificial intelligence that simu- lates how the human brain processes data and develops patterns for making decisions.It is

a branch of artificial intelligence’s machine learning where networks may learn from data unsupervised. Our goal is to gain access to Convolutional Neural Network (CNN)-based deep learning methods for object detection. Convo- lutional neural networks are beautiful since they don’t rely on man- ually constructed feature extractors or filters. Instead, they learn independently from the initial pixel level to the final object cate- gory.

A. Convolution Neural Network

It has several hidden layers as well as input, output, and output layers. A set of convolutional layers in a CNN’s hidden

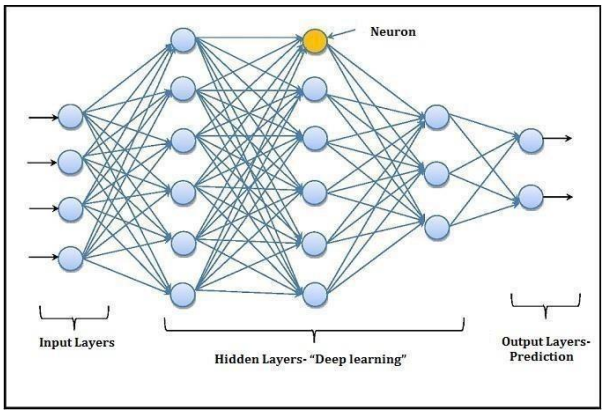

Fig. 1. Architecture of Deep Learning Source :

Source :- ”https://srnghn.medium.com/deep-learning-overview-of-neurons- and-activation-functions-1d98286cf1e4”

layers convolve with a multiplication or other dot product. Typically, a RELU layer serves as the activation function, and further con- volutions come afterwards such as pooling layers, fully linked layers, and normalisation lay- ers, which are referred to as hidden layers since the activation function and final convolution hide their inputs and outputs. A sliding dot product or cross-correlation is typically used. These CNN layers combine the input before sending the outcome to the following.

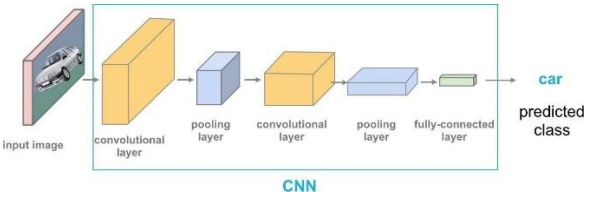

Fig. 2. Working process of Convolution Neural NetworkSource:-”https://viso.ai/deep-learning/mask-r-cnn/”

B. The YOLO (You Only Look Once)

Convolutional neural networks (CNN) and deep learningare used for object detection. Each images just has to seen.It makes YOLO one of the quickest detection algorithms possi- ble. It has a real-time object detection speed of up to 30 FPS. The pic- ture is partitioned into a S*S grid for detection (left image). N po- tential bounding boxes will be predicted for each cell, and the likelihood that each of them will occur This means S*S*N boxes are calculated.

C. R-CNN- Region based CNNs

The R-CNN model initially chooses a number of suggested ar- eas from an image, then labels the regions’ categories and bounding boxes. It performs forward computation using a CNN to extract characteristics from each suggested location.

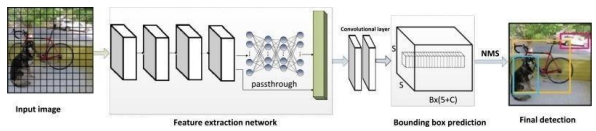

Fig. 3. Yolo Technique
Source:"https://www.sciencedirect.com/science/article/abs/pii/S105120042030 1019"

Then, we forecast each suggested region's categories andbounding boxes based on its features.

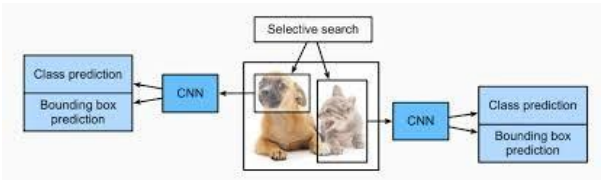

Fig. 4. R-CNN Technique

Source:-"https://neptune.ai/blog/object-detection-algorithms-and-libraries"

D. Methodology

Basic architecture of CNN model consists of a) Input Image

b) Convolution Layer c) Pooling Layer d) Fully ConnectedLayer e) Output Layer

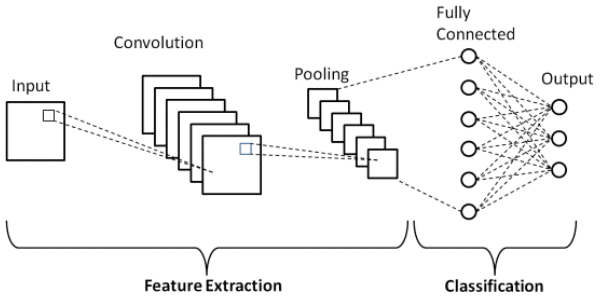

Fig. 5. Methodology

Source :- "https://www.researchgate.net/figure/Schematic-diagram-of-a-basic- convolutional-neural-network-CNN-architecture-26*ig*1$_3$36805909"

a) Input Image: The model receives an image as input to ex- ecute various operations on it in order to validate the re- sult. The block known as the convolution layer receives it.

b) Convolution Layer:The initial layer of this technique is convolution. The specified input picture will be used to extract features from this layer. Convolution repairs the link between pixels by employing tiny input data squares to learn picture characteristics. It is a mathematical pro- cess that requires a filter and two inputs, such as an image matrix.

c) Pooling Layer: When the photos are too huge, the pool- ing layers lower the number of parameters. Spatial pool- ing, also known as down sampling or subsampling, low- ers the dimensionality of each map without affecting the crucial data. Different forms of spatial pooling exist, in- cluding

maximum pooling, average pooling, and sum pooling. The biggest element from the corrected feature map is selected via max pooling. The average pooling might be taken instead of only the biggest element. Sum pooling refers to the total ofall feature map elements.

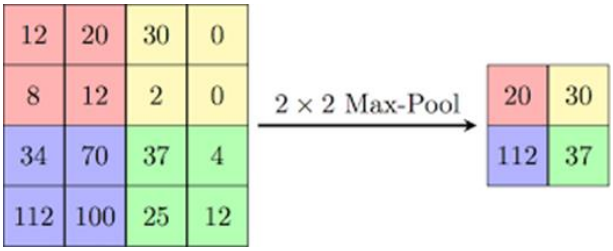

Fig. 6. Pooling Layer

Source :- "https://paperswithcode.com/method/max-pooling"

d) Fully Connected Layer: The provided matrix is converted to a vector and fed into a fully connected layer in this layer, much like a neural network. All are combined in the completely linked layer,combining the features to produce a model. The outputs are then classified as cat, dog, automobile, truck, etc. using an activation function like softmax or sigmoid.

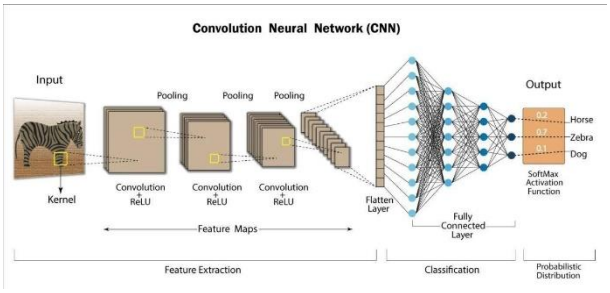

Fig. 7. Fully Connected Layer

Source :- "https://www.analyticsvidhya.com/blog/2022/03/basics-of-cnn-in-deep-learning/"

e) Output layer: The model's output picture, which is the outcome. The output is acknowledged based on the com- pletely connected layer.

V. TECHNIQUE USED :-

The YOLO (You Only Look Once) team has created YOLOv5 (You Only Look Once version 5), which is a real- time object detection model. It is the latest version of the YOLO model and is known for its high speed and accuracy in detecting objects in images and videos.

YOLOv5 is imple- mented in the PyTorch deep learning framework and is trainedon the dataset.in this project we have not used coco dataset , but instead we have used our own dataset and have train the model.It is often used in applications such as self-driving cars, surveillance systems, and robotics.

A. Why YOLOv5 ?

a) Real-time performance: YOLOv5 is designed to detect objects in real-time, which makes it suitable for use in ap- plications such as self-driving cars and surveillance systems where fast detection is crucial.

b) High accuracy: YOLOv5 is trained on the COCO (Com- mon Objects in Context) dataset and can detect and classify up to 80 different object categories, which makes it one of the most accurate object detection models currently available.

c) Easy to use: YOLOv5 is implemented in the PyTorch deep learning framework, which makes it easy to train and fine-tune the model on custom datasets.

d) Smaller model size: YOLOv5 has smaller model size compared to YOLOv4, which makes it more efficient to deploy on edge devices with limited resources.

e) Multi-scale training: YOLOv5 uses multi-scale training which means the model is trained on different image sizes to improve the accuracy and generalization of the model

f) Faster inference: YOLOv5 uses a new architecture and several other optimization techniques which makes it faster than YOLOv4.

g) Incremental training: YOLOv5 has an incremental train- ing feature which allows you to fine-tune the model on new datasets without having to re-train the entire model.

VI. IMPLEMENTATION

A website is created using HTML, CSS, and JavaScriptfor the frontend, and the Flask Framework of Python for the backend. The website allows users to upload video files for object detection, and also provides the capability to detect objects in live video.

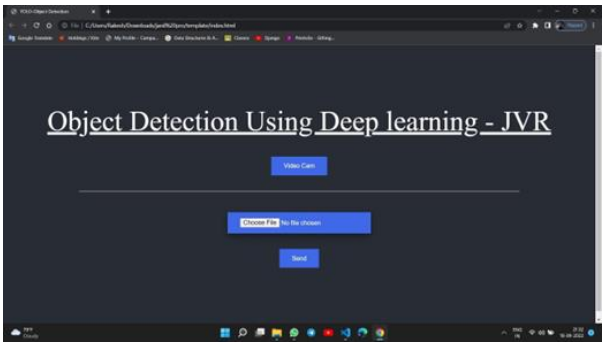

Fig. 8. Website

VII. EXPERIMENTAL RESULTS

An approach for object detection using deep learning that utilizes a fully convolutional architecture, in which almost all of the layers are used. The approach is tested on boththe PASCAL VOC dataset, a widely used dataset for object detection, and a custom dataset that the authors have trained. The test speed of the approach is 170ms per picture, which is relatively fast. The performance of the object detection model is evaluated using precision and recall for the best matched bounding boxes for known objects in the image. This means that the model's ability to accurately detect and identify the objects in the image is being measured.

A. Detection in Live Video :-

B. Detection using video files :-

Fig. 10. Object Detection in Video Files

VIII. CONCLUSION

It begins by introducing the traditional deep learning object de- tection approaches. Deep learning-based object detection has become a popular topic in recent years because to its potent learning capabilities and advantages in handling occlusion, scale transformation, and background shifts. We elaborate on a typical deep learning-based object identification model that uses CNN to tackle a variety of sub-problems, including occlu- sion, clutter, and low resolution. The popular object detection approach based on deep learning is then discussed in more de- tail. Finally, this work conducts a thorough investigation of the difficulties in deep learning-based object recognition and offers insightful recommendations for future development.

Automated KYC

Aakanksha Maurya, Janhavi Mishra, Mr Vijaykumar Yele, Unnati Mistry
Thakur college of engineering & technology Mumbai, India

Abstract— **A series of procedures for confirming a customer's identification before or while conducting business with banks and other financial organisations is known as KYC, sometimes known as "Know Your Customer" or "Know Your Client.". KYC entails several steps, including establishing customer identity, comprehending the nature of customers' activities, and ensuring the legitimacy of the source of funds. We have a portal in this project where clients can upload a video of themselves saying all of their information, and it then verifies the identity of clients from the database while also automating the KYC process this is done with the help of HOG (Histogram of Oriented Gradients) and for SVM(Supervised algorithm). This is done to reduce the possibility of financial fraud and identity theft. It also ensures the veracity and authenticity of the information presented. This Project will help the Financial institutions to precisely identify suspicious actions by first confirming a customer's identity and intentions at the time of account opening, then understanding their transaction patterns**

Keyword– Automated KYC, liveness, audio extraction, detection

I. INTRODUCTION

Financial organizations always struggle to identify their customers and implement policies to stop financial crime. A significant set of requirements known as KYC for customer identity verification must be followed by financial institutions (including banks, credit unions, and Fortune 50 financial businesses) to ensure security. A series of procedures for confirming a customer's identification before or while conducting business with banks and other financial organizations is known as KYC, sometimes known as "Know Your Customer" or "Know Your Client." Following KYC regulations can assist prevent the funding of terrorism, money laundering, and other common fraud schemes. Financial institutions can more precisely identify suspicious actions by first confirming a customer's identity and intentions at the time of account opening, then understanding their transaction patterns.

When it comes to KYC laws, financial institutions must adhere to ever-higher criteria. To comply with KYC, they must spend more money, or face heavy penalties. Due to these restrictions, practically any company, platform, or group that interacts with a financial institution to open an account or conduct transactions is required to adhere to these requirements.

Know Your Customer (KYC) is used for customers Administration and Identity Verification. This document was sent to your organization by a customer Build trust between the two. At first there was no way to verify the customer's identity. KYC was proposed in the US in 1990 and back then, the purpose of KYC was to stop terrorists Bank financing and money laundering. the most important KYC stakeholders are banks. Banks ask customers to fill out the KYC document so they can verify your Identity. The bank will verify the information submitted. Clients are involved in money laundering, terrorist financing, and financial fraud.

Therefore, banks currently do not allow account holders without KYC documentation. KYC documents include customer information, proof of identity, proof of address, and photo. Originally, a pen-and-paper approach was used to submit KYC documents, but problems with record keeping were evident. Banks were busy verifying identities each time through customer-filled forms. In such cases, documents are more likely to be misplaced. Therefore, a digital KYC system called eKYC has been proposed. In this approach, the customer fills out the KYC document via her organization's web application. The transmitted data was stored in a central database. Organizations can access customer information at any time through the customer ID. Overall costs were reduced because the system is paperless, but since data is stored in a centralized database, there are no single points of failure, data redundancy, and third-party involvement in validation. There are still loopholes in centralized systems. Also, data stored in centralized servers can be compromised/attacked by hackers, so the existing centralized system architecture increases the chances of leaking sensitive customer data.

II. IMPORTANCE

KYC stands for knowing your customer. The standards of KYC are designed to protect financial institutions against fraud, corruption, money laundering and terrorist financing. KYC involves several steps. Understand the nature of customer activity and ensure that funding sources are legitimate. KYC policy was introduced by the Reserve Bank of India. Financial Action Task Force (FATF) Recommendations on Anti- Money Laundering (AML)Standards and Counter- Terrorism Financing (CFT). anti-money laundering law Banks, financial institutions and intermediaries must ensure that they meet certain minimum requirements KYC and AML standards. comply with KYC and anti-money laundering regulations to limit fraud. The process of KYC is the collection of information about the customer. They must complete an online KYC registration form on the portal they wish to conduct financial transactions with.

Whether the information provided is accurate and upto-date depends on the applicant's duty of care. Stage two is uploading of evidence which includes After the information is collected, the applicant must verify the information entered in the form with relevant documents. These documents certify that the prior information entered by the user is genuine and not forged. The third step is verification in which After a document is uploaded, the document's template is identified and checked using various checks.

This ensures that the document has not been tampered with. Once the documents are verified data is extracted from the documents. This was the process of online KYC. For offline the offline KYC process is like the online

process. However, the key difference is that a physical copy of all documents and applications is required.

III. OBJECTIVE

The primary purpose of automated KYC is to reduce the use of physical documentation, storage space for such records, and to reduce costs and time required. E-KYC allows submission to take place in real-time. This makes the process streamlined and less prone to corruption in industries such as banking, finance, etc.

With online verification, customers can open new accounts, apply for loans, take out new life insurance policies, invest in new mutual fund companies, and trade with cryptocurrencies through electronic devices, especially smartphones, in an era when customers prefer to communicate through online channels.

Our system provides software that makes automation of the Know Your Customer processes easy. It reduces the time required for onboarding of a new customer and eliminates the possibility for human error. Therefore, your company is on the safe side, when visited by the regulator. Moreover, the onboarding speed of the customer provides your company with business advantage among the competition. Faster onboarding means more customers.

IV. LITERATURE SURVEY

1. Decentralize KYC system

Independent third-party KYC systems can be used in several places to verify the identity of Individuals are the order of the day. Distributed immutability Ledger is a key concept to ensure that the data stored in it is stored. The system is tamper-proof. Data stored in distributed databases is encrypted Provides an extra layer of security. even if there is one Data stored in distributed databases is at risk. The data is encrypted so no harm is done.

2. Optimized and dynamic KYC system based on blockchain technology

adoption via means of monetary establishments (FIs) is very difficult. device that reduces and stocks out several the monetary establishments that paintings with a patron the fees of the KYC method and additionally makes it feasible for FIs to dynamically replace statistics associated with clients and disseminates these statistics amongst taking part FIs. Additionally, our device addresses several the attributes that avoid the adoption of formerly proposed answers via way of means of FIs

3. Know Your Customer (KYC) Implementation withSmart Contracts on a Privacy-Oriented Decentralized Architecture

As part of Know Your Customer (KYC) standardized, decentralized scheme to enable user privacy protection within the enterprise, Blockchain has been proposed by developing two types of smart contracts. This system introduces simplicity of its scheme and efficiency and time efficiency of operation. Intelligent integration of various technology modules and components.

4. Hassle - Free and Secure e-KYC System Using Distributed Ledger Technology

The blockchain technology is a prominent, reliable and secure technology which is getting into almost every The fundamental essence of blockchain technology offers features like transparency, decentralization, how the present banking industry, especially the KYC document verification process, can be impacted after using The current day banking KYC processes are highly reliable on paper a reliable and trustable technology like blockchain, that could withstand frauds, and resolve the scalability and In the proposed system, the use of blockchain in KYC process restricts the presence of middlemen. efficiency, reduction in costs, enhanced customer rendezvous and end-to-end transparency during the process of integrating the customer documents into the bank database.

5. KYC Optimization using Blockchain Smart Contract Technology

organization for better understanding of customers and their financial operations. The current KYC mechanism is serious. Every institution has its own KYC process and sometimes involves third parties, which can cause problems. Increased maintenance costs, time, and redundancy. Starting at about $27, including opportunity costs, maintenance costs, and know-your-customer costs The current KYC process is very time consuming and proposed an improved KYC system utilizing blockchain Technology to improve existing KYC systems. Blockchain mechanism, proposed model of KYC process, can be stored, updated, Maintenance costs and many other costs that can affect your organization's performance.

6. KYC Optimization by Blockchain Based Hyperledger Fabric Network

financial institution with a long history and the future of financial institutions. Hyperledger Fabric network for KYC optimization. The proposed system can speed up KYC payment transfers. Challenge the inefficiencies that result from duplicative actions

V. PROBLEM STATEMENT

Know Your Customer is the process of crosschecking a customer's identity. KYC policies aim to prevent criminals from using banks for money laundering activities. It also helps banks better understand their customers and their financial operations, and manage risk prudently. The offline method requires a lot of documentation and on the other hand KYC online is not automated. The details must be entered manually, which is time consuming as it involves many people and requires someone who can work and collect the information.

Online systems tend to consume both time and effort. The goal is to automate the system to reduce the time and effort involved. This can be done by recording a video that provides all the important details of a person which is required for KYC.

1. Contact with too many people within Organization: The customer needs to contact corporate clients at least 4 times during the KYC compliance, while corporates on an average of eighth times.

2. Security concerns

The documents required for KYC include the personal documents (such as passports) of company directors.

3. Compliance is taking longer

The survey of more than 1,100 organization executives earlier this year highlighted several problems with the KYC process globally. KYC regulations take 26 days .Corporate customers claim that they spend 32 days on KYC compliance.

VI. SOLUTION

KYC is a standard which is used globally by many sectors like banking, finance, business, Institutes, etc. KYC helps these organizations verify their client and protect the client's data from malicious attacks. Basically, KYC protects both the client and the organization and helps more clients to trust in them.

As the whole world is going Digital, so has these organizations. Unlike before KYC verification is now usually done online but still the process is very time consuming as it involves long video call, long waiting time, verification time, etc.

The primary purpose of automated KYC is to reduce the use of physical documentation, storage space for such records, and to reduce costs and time required. E-KYC allows submission to take place in real-time. This makes the process streamlined and less prone to corruption in industries such as banking, finance, etc.

With online verification, customers can open new accounts, apply for loans, take out new life insurance policies, invest in new mutual fund companies, and trade with cryptocurrencies through electronic devices, especially smartphones, in an era when customers prefer to communicate through online channels.

Our system provides software that makes automation of the Know Your Customer processes easy. It reduces the time required for onboarding of a new customer and eliminates the possibility for human error. Therefore, your company is on the safe side, when visited by the regulator. Moreover, the onboarding speed of the customer provides your company with business advantage among the competition. Faster onboarding means more customers.

The solution we propose is removing the human part from this process. The client needs to upload a video then the verification happens within minutes through the portal. This not only solves the timeconsuming issue but also does not need long waiting, or booking appointments. For a global Standard like KYC which is used almost in all sectors, the proposed solution is best for organizations.

VII. TECH STACK

Tech Stack:

1. Language:

Python

SQL

2. Software:

Jupyter Notebook

Phpmyadmin server

Xampp

3. Libraries:

Face_recognition

Speech_recognition

Pyaudio

Moviepy.editor

VIII. WORKING

This project is a platform for implementing a digitalized KYC process that includes liveness and audio detection. To expedite the KYC process, users must upload a video containing identity proof such as a PAN card/ AADHAR. After you upload the video to the website, These organizations verify their client and protect the clients data from malicious attacks. Basically KYC protects both the client and the organization and helps more clients to trust in them.

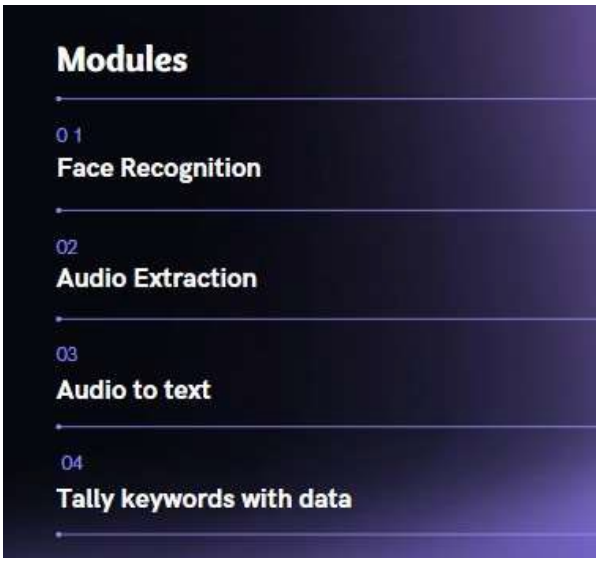

Fig 1

As the whole world is going Digital , So has these organizations. Unlike before KYC verification is now usually done online but still the process is very time consuming as it involves long video calls, long waiting time, verification time, etc.

It does so by comparing the user's live video with the uploaded national identity document and making the KYC Procedure Complete. Our solutions use liveness detection technology to determine and validate customer's identity in real-time. In this way by uploading video, KYC helps in mitigating the risks of identity thefts and financial frauds

For a global Standard like KYC which is used almost in all sectors, the proposed solution is best for organizations. it will follow the following steps:

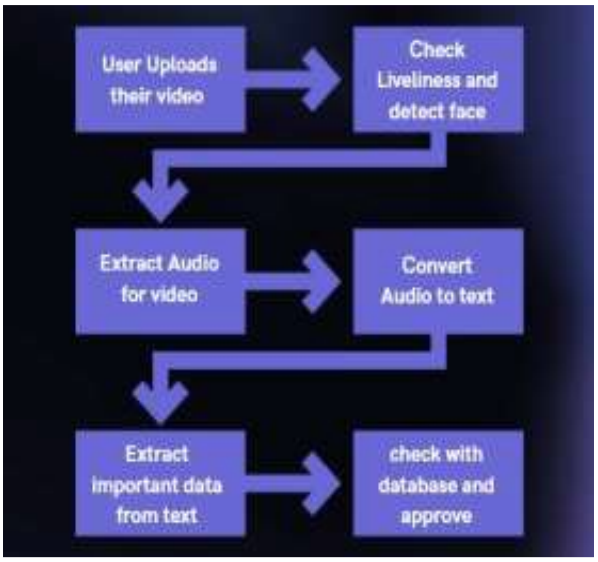

Fig 2

Step 1: Recognising Face:

First step for KYC verification is ensuring the video belongs to the client. For this we use python library “face recognition” and match it to the database to ensure the face in the video is of the right person. This library follows a sequence of steps to achieve face recognition which is explained through the flowchart given below

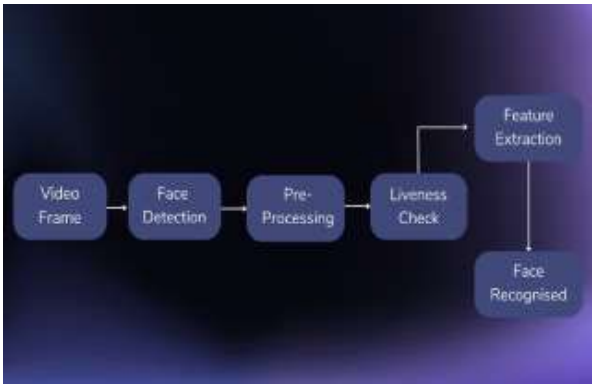

Fig 3

Step 2: Extract the audio from the video

For this we plan on using some inbuilt libraries of Python which will help us extract the audio from video. The Library we use will be “moviepy.editor” to achieve it.

Step 3: Convert the audio to text

This Step involves using Python Library “speech recognition” to convert speech to text. This python library follows are sequence of steps to achieve speech recognition which is explained through the flowchart given below

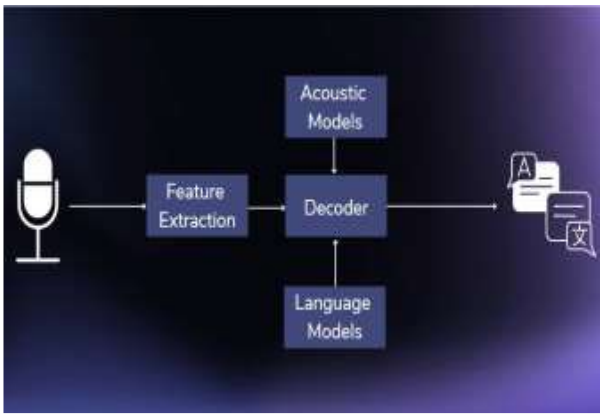

Fig 4

Step 4: Extract important data from the text

Once the Speech is converted to text, It is now time to look for keywords like “PAN CARD” “AADHAR CARD " and note all those details

Step 5: Check the database

To ensure that all documents are valid. Once your KYC verification is finished, the user will be alerted about it.

IX. CONCLUSION

The conventional way to complete the KYC process is to make an appointment or visit a nearby KYC outlet. This isn't always the wisest or most efficient option, though. The goal of this system is to provide a new KYC system that is simple to use and confirms identity using user data that is accurately mapped from a database. Although a lot of documents are still created on paper nowadays, it is obvious that automatic data recognition technologies are widely used.

The document has numerous copies since it is repeatedly copied and modified throughout future processing processes.

They can successfully assist people in some situations, but they can also be ineffective in others. This system's goal is to successfully check data in text by precisely mapping each user's information to the form field from the database.

X. RESULT

Our main aim of the project is to develop a system wherein information of people can be fetched by either a video or a photo and the admin can have easy access to this information. The system plays an important role during the pandemic period to mark the attendance for online classes so that a lot of time can be saved. It can also be used on airports, railways to make work easier, faster and safer.

The Project works in the following way: Firstly, the admin will have to run the Database.py file which will create a database "KYC" and a table "users" in the MySql server.

Fig 6

Next run the main file that is kycProject.py On running this particular file a python application window will open up.

Fig 7

The user will have to enter their name, aadhar card number, pan card number, mobile number and date of birth. click the save button to add their profile to the SQL server.

Next click on the Take image button which will capture their image and then store it under the images folder. The instructions for capturing image are listed there itself.

Once an individual has saved his/her profile he just needs to click the upload video button. Once the video is uploaded the users details will be tallied with the database by following way:

The video uploaded by the user is converted in the form of Audio file using MoviePy Editor.

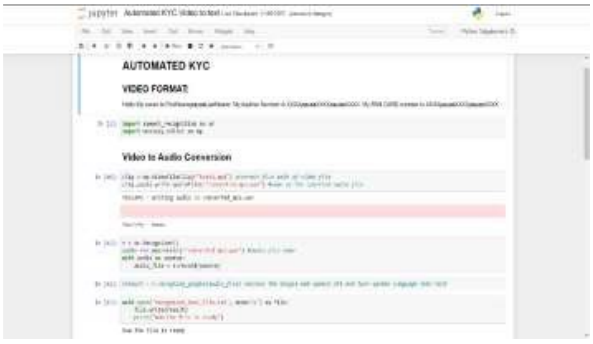

Fig 8

The Audio which is just made is then converted to text using google speech recognition technique. This step is 90% accurate in converting audio to text.

Once the audio is converted to text, the text is saved in a file and keywords like “Name”, “Aadhar Card” , “Pan Card” are extracted from the data.

Fig 10

These extracted words and then tallied with the existing database. If all the data matches, then the KYC of that person is verified. If any data mismatches, the KYC is cancelled and the user is notified about the same.

We have successfully built a portal for this system which consists of six pages consisting of the home page, login/register page, Detection page and a profile page. The Entire project is built to make the verification of KYC simpler and Effective.

Water Quality Forecasting on Aquaponic Farming Management

Kanak Gupta, Anand Pandey, Jitendra Patel
Thakur college of engineering & technology Mumbai, India
kanak9876@gmail.com, anandpandey7772@gmail.com, jitendrapatel7711@gmail.com

Abstract— Aquaponics merges fish farming and plant growing in a closed loop. Fish waste feeds plants, which clean water for fish. It's an eco-friendly and efficient food production system. Water quality is main issues in aquaponics farming which include algae growth, ammonia buildup, pH imbalance, low oxygen levels, and increased risk of disease. Monitoring and maintaining proper water quality is crucial for a successful system. The market offers several systems, such as biofilters, oxygenation, and pH control, to support aquaponics success, but implementing these systems successfully requires overcoming challenges such as cost, maintenance, and the need for technical knowledge and expertise. Proper selection and combination of systems is important for ensuring success in aquaponics. Therefore, predictive model is needed. To overcome such problems. The purpose of this study is to utilize Long Short-Term Memory (LSTM) Neural Networks for water quality forecasting in aquaponic farming management. LSTM models use historical water quality data to predict future water quality by analyzing patterns and relationships between water quality parameters. The model trains on inputs such as pH, temperature, and dissolved oxygen levels, and outputs predictions of water quality based on current conditions. The LSTM algorithm is well suited to this task due to its ability to capture long-term dependencies in time series data. The predictions can be used in aquaponic farming management to make informed decisions on water management. The proposed system has demonstrated improved results compared to existing systems through experimental evidence.

Keywords—Aquaponics, Water Quality Forecasting, LSTM Model, Smote, Data analysis.

I. INTRODUCTION

Aquaponics farming is a cutting-edge agriculture technique that combines hydroponics and aquaculture practices to create a sustainable and efficient system for growing fish and plants together. The water quality in aquaponics systems is a critical factor in determining the growth and productivity of both the fish and plants. Maintaining the proper balance of water quality parameters, such as pH, temperature, dissolved oxygen levels, and other factors, is crucial to the success of the system.

Long Short-Term Memory (LSTM) models are a type of deep learning algorithms that are well-suited to the task of water quality forecasting in aquaponics systems. LSTMs are able to capture long-term dependencies and trends in time series data, which are critical for accurate water quality forecasting. By analyzing historical water quality data, the LSTM model can identify patterns and relationships between water quality parameters, and build a predictive model that can forecast future water quality based on current conditions.

In this research, we present a comprehensive study on the use of LSTM models for water quality forecasting in aquaponics systems. We evaluate the performance of the LSTM model using real-world data, and compare its results with existing water quality forecasting methods. Our results show that the LSTM model outperforms existing methods, providing more accurate and reliable water quality forecasts for aquaponics farmers. This research highlights the potential of LSTM models as a tool for improving water quality management in aquaponics systems, and provides a foundation for future research in this area.

II. RELATED WORK

Forecasting the water quality for management in aquaponic farming has been the subject of a substantial amount of research. The development of a water quality monitoring system for an aquaponic system by Kim et al. (2017) is one of the significant studies in this field. The pH, temperature, and dissolved oxygen levels were all being monitored by the system in real-time, and it was able to notify the farmer if any of these values strayed outside of the ideal range. This study highlighted how crucial it is to keep an eye on the water quality in aquaponic systems and how such a setup can be useful for enhancing the wellbeing of aquatic plants and animals.

Another investigation conducted by Tang et al. (2019) tried to forecast water quality characteristics in an aquaponic system. An aquaponic farm's water quality data was gathered for the study, and it was utilised to build a machine learning model. The model was then employed to forecast various aspects of water quality, including pH, nitrate concentration, and ammonia concentration. The results of the study demonstrated that machine learning methods may be used to accurately forecast the water quality parameters in aquaponic systems, enabling farmers to make more educated management decisions for their systems. Various factors' effects on the water quality in aquaponic systems have also been the subject of studies. According to the study, feeding frequency significantly affected the levels of nitrate and ammonia in the water. These results emphasise the significance of taking feeding

habits into account when controlling water quality in aquaponic systems.

In conclusion, there has been a growing corpus of study on the management of aquaponic farming and water quality forecasts. These research have shown how crucial

it is to check the water quality in aquaponic systems, how machine learning techniques may be used to predict water quality parameters, and how different factors affect the water quality in aquaponic systems.

Numerous studies have looked into how to manage aquaponic farming while forecasting water quality. For example, the authors of presented a data-driven approach in for predicting water quality measures such as pH, ammonia, and nitrite levels. Machine learning techniques were used to predict electrical conductivity, dissolved oxygen content, and water temperature. Another study created a hybrid model that combines an artificial neural network with a fuzzy logic system to forecast the water quality in an aquaponic system. These studies demonstrate how predictive models could aid in management choices for aquaponic farming, especially when it comes to preserving water quality.

III. IMPLEMENTATION

The implementation of the LSTM model for aquaponics water quality forecasting involves the following steps:

1. Data Collection: Collecting data on water quality metrics such as pH, ammonia, nitrite, nitrate levels, and environmental variables like temperature and light intensity using regular water testing and monitoring tools.

2. Data Preprocessing: Cleaning and preprocessing the collected data to ensure that it is suitable for use in the LSTM model. This may involve removing missing or incorrect values, normalizing the data, and transforming it into a format that is suitable for use with the model.

3. Model Development: Building and training the LSTM model using the preprocessed data. This may involve splitting the data into training and testing sets, and using the training data to train the model.

4. Model Evaluation: Evaluating the performance of the LSTM model by comparing its predictions with actual water quality data. This may involve measuring the model's accuracy, precision, recall, and other performance metrics.

5. Deployment: Integrating the LSTM model into an aquaponics system management software or tool to make it easier for farmers to use. This may involve integrating the model into an existing software platform or building a standalone tool specifically for use with the LSTM model.

6. Maintenance and Updating: Regularly updating and maintaining the LSTM model to ensure that it continues to provide accurate and reliable predictions for water quality in an aquaponics system. This may involve updating the model with new data and retraining it as needed to ensure that it remains effective.

3.1 Data Mining:- For data mining, we used Beautiful soup, a Python module for extracting information from HTML and XML files. We obtained 110,00 data from the website of the West Bengal Pollution Control Board.

3.2. Data Preprocessing :-We discovered through data mining from the West Bengal Pollution Control Board that there is a lot of noise in the data that may confuse the model, therefore we apply a variety of data preprocessing approaches to obtain clean data.

3.3 Identify and sort out missing data.: There may be a variety of explanations for why specific fields of data are absent from a data set. Data scientists must choose whether it is preferable to delete records that have blank fields, ignore them, or fill them with information that could be valuable. A secure option might be to add the missing average temperature between the prior and subsequent recordings in an IoT application that records temperature, for instance. Reduce noisy data: Since real-world data is frequently noisy, an analytical or AI model may be affected. For instance, a sensor that typically records a temperature of

75 degrees Fahrenheit can inadvertently report a temperature of 250 degrees. To lessen noise, a number of statistical techniques can be applied, including as binning, regression, and clustering.

3.4 Identify and remove duplicates: An algorithm must assess whether the same measurement was recorded twice or whether the data represent different occurrences when two records appear to be identical. In some instances, a record may have minor discrepancies because one field was entered erroneously. In other instances, records that appear to be duplicates may actually be distinct, such as when a father and son with the same name reside in the same home but ought to be listed as separate people.

Data Splitting

Data splitting involves using a portion of the data as a test set and the remaining data for model training. In-sample is another name for training samples. Model performance metrics that are assessed using in-sample data are retroactive

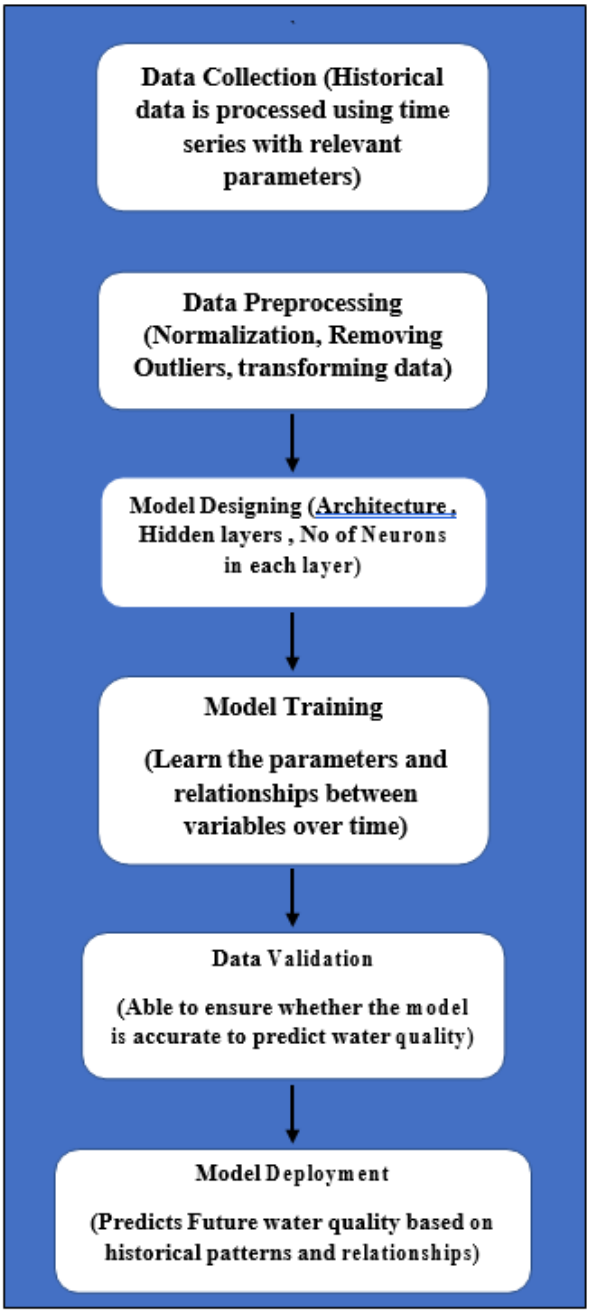

Fig. 1. Water quality usability framework.

IV. PROPOSED METHODOLOGY

The process for managing water quality in aquaponics farming involves using data analysis, simulation models, and machine learning algorithms. The first step is collecting water quality data, such as pH, ammonia, nitrite, and nitrate levels, as well as environmental variables like temperature and light intensity, through regular monitoring. The collected data is analyzed to identify patterns and trends. Simulation models are then created based on historical data to forecast water quality, considering factors like plant and fish growth, feed delivery, and contaminants. Machine learning algorithms are used to process the data and create a predictive model, which utilizes artificial intelligence to determine the most impactful variables on water quality. By training the algorithm on historical data, it can provide accurate projections of future water quality. By combining these methods, aquaponics farmers can make informed decisions for system management, leading to improved sustainability and growth of both fish and plants.

The SMOTE algorithm is a popular choice in aquaponics farming management research for forecasting water quality, as it balances imbalanced datasets. In water quality forecasting, datasets often show a high number of normal water quality readings and a scarcity of abnormal readings. SMOTE generates synthetic samples by interpolating between the minority class samples, thereby increasing the number of samples and balancing the dataset. This ensures that the important factor of water quality, which affects the growth and productivity of fish and plants, is properly considered in the forecasting process.

The proposed methodology for the LSTM model in aquaponics would involve the following steps:

1. Data collection: Historical water quality data for the aquaponics system needs to be collected and processed to prepare it for use in the LSTM model.

2. Feature selection: The relevant water quality parameters, such as pH, temperature, dissolved oxygen levels, etc., need to be selected as features for the LSTM model.

3. Data preprocessing: The collected data needs to be preprocessed to remove any inconsistencies and outliers.

4. Model training: The LSTM model will be trained using the preprocessed data and features. A suitable loss function and optimization algorithm should be chosen to optimize the model's performance.

5. Model evaluation: The trained model needs to be evaluated to determine its accuracy and performance.

6. Forecasting: The trained LSTM model can be used to forecast future water quality based on current conditions.

7. Monitoring and adjustment: The forecasted water quality information can be monitored, and any necessary adjustments can be made to the aquaponics system based on the forecasted results. This methodology provides a systematic approach for building and implementing an LSTM model for water quality forecasting in aquaponics.

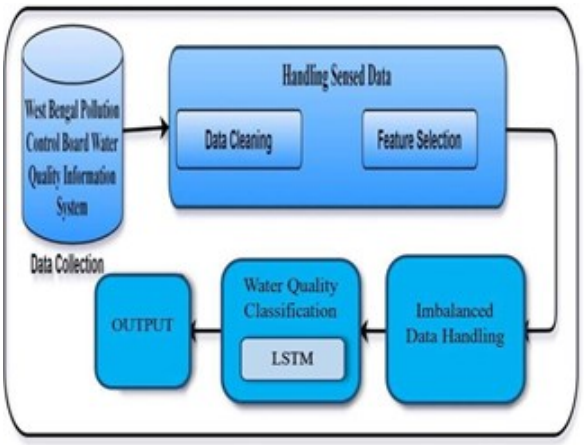

Fig. 2 Working of Model .

Significance of Water and Environmental

Parameters

The aquaponics system combines hydroponics and aquaculture so that plants and fish can coexist in harmony. To guarantee optimal growth and health, it is necessary to monitor the environmental and water-related parameters.

4.1. WATER-BASED PARAMETERS

Water quality is a crucial factor in aquaponics farming, as the plants receive their nutrients through water. In this system, which combines hydroponics and aquaculture, water is considered a complex component due to interrelated factors. Aquaponics has gained popularity due to its sustainability and water efficiency, but high levels of ammonia in the water can be deadly for fish. To address this, biofilters are employed to recirculate the water. However, without fertilizers, water cannot provide the necessary nutrients and minerals for plant growth. Using fertilizers may result in the need for water replacement and disposal. Fish feces, however, can be used to cultivate plants through the process of nitrification. Maintaining the proper balance of nutrients, temperature, dissolved oxygen, pH, temperature, and salts is crucial for the quality of the water solution, the success of the nitrification process, and the healthy growth of both plants and fish.

4.1.1. pH

pH stands for hydrogen ion concentration measurement. It measures the solution's alkalinity or acidity. The pH of water has an impact on how quickly nitrification takes place and how readily available nutrients are to plants. A pH metre is used to determine a solution's pH. There are three different ways to monitor pH levels: manually operated electronic probes, test strips, and automatic probes in controllers. The pH of the water used in the aquaponics component can range from 6.5 to 9.5, and the acceptable range is 5.5 to 10, though this range may vary slightly depending on the type of fish being used.

For the hydroponic component, a value of about 6.0 is ideal. If the pH is higher than 7.0, Fe or Mn will precipitate; if the pH is lower than 4.5, root damage will occur; and if there is a nutritional deficiency, plants will show symptoms. To start the nitrification process, the pH level must be between 7.0 and 9.0. Calcium and potassium operate as bases for the nutrients, so they can be used to modify the pH levels in an aquaponics system. Fish health can be greatly impacted by even small pH variations (0.3) during brief time periods. The controller receives the change in the pH meter's output in millivolts and milliamperes thanks to the pH meter's connection to an automated system. The controller then makes touch with the pH metre and tests it in a solution to determine its pH level. The output value is connected to both the controller programming unit and the pH unit.

4.1.2. Dissolved Oxygen

Dissolved oxygen is a unit of measurement for the amount of oxygen that is present in water and is thus accessible to aquatic life. Fish, bacteria, and plants all coexist in the same habitat as aquaponics organisms, with dissolved oxygen being the most important factor. The quantity of water and the amount of oxygen present in it determine an aquatic organism's capacity to maintain life. The amount of oxygen that dissolves in water (measured in parts per million) is thought to be the characteristic that has an immediate and significant impact on aquaponics. Algae and other green aquatic plants naturally produce oxygen through a process called photosynthesis.

There is a close connection between dissolved oxygen and water temperature. There is less oxygen in warm water. When fish are eating, their dissolved oxygen intake increases. The ideal concentrations for nitrifying bacteria are

4–8 milligrams/liter. More than 3 milligrammes of dissolved oxygen per litre is necessary for plants. If the oxygen level is decreased, fungus develops and plant roots rot. Most fish species need more than 5 milligrammes of dissolved oxygen per litre. Low levels of dissolved oxygen will cause the formation of TAN to cease.

4.1.3. Temperature

The temperature of the water in an aquaponics system is linked to a number of water-related characteristics. For nitrification to occur, the ideal temperature range is between

17 and 34 °C. If the temperature is below the value, the nitrification process is improperly carried out, and bacteria productivity decreases. For the hydroponics component, a temperature range of 18–30°C is suitable. Fish are less likely to get diseases when the appropriate temperature is maintained. The ideal temperature varies depending on the

type of fish. Tropical fish prefer a temperature range of 22– 32°C; cold-water fish require a temperature range of 10–18°C. Other species do best at temperatures in the 5–30°C range.

4.1.4. Ammonia

Ammonia is present in very small amounts and has no colour or smell, thus feeling it is necessary to determine whether it is present or not. A wire electrode on the sensor is encased in a filling solution. An ion-selective membrane is used to separate the solution from the medium containing the sample. The solution is then combined with ammonium ions. To maximise the accuracy of measuring ammonia, it is essential to be aware of the pH and temperature of the water. A data synthesis issue involving pH, temperature, and ammonia sensors arises from the amount of ammonia in the water solution. These sensors should be installed in the water tank because the ammonia concentration before the biofilter is not taken into account.

4.1.5. Nitrate

The type of nitrogen that plants may absorb is nitrate, which is produced by bacteria that convert nitrite from ammonia. Nitrate is not harmful to fish. Nitrate levels should not affect fish health if they are less than 90 mg/L, and the ideal range is 50–100 ppm. It is thought that this value is significant when developing a biofilter. Nitrate concentrations beyond a certain level indicate an inadequate biofilter and a risk to fish. The sensor that is

used to determine the ammonia concentration is also utilised to assess the nitrite concentration.

4.1.6. Nitrite

Nitrite is produced from ammonia by microorganisms that oxidise it. Nitrite is thought to be hazardous for aquatic life. Nitrite concentrations in water must be between 0 and 1 mg/L for bacteria, fish, and plants to survive. The same amount of nitrite is necessary for both healthy plant development and bacterial survival. When delivered in the ideal range, the nitrite present shouldn't cause any issues. Nitrite concentration sensors are created by combining nitride-ionized electrodes with the element utilised for sensing through a polyvinyl chloride membrane that functions as an ion exchanger. The sensor will produce an electrical potential that is proportional to the concentration of nitrite ions in solution and will reveal the amount of nitrite present.

V. OUTCOME

The outcome of this research paper on the LSTM model for aquaponic farming management highlights the potential of this machine learning algorithm in improving water quality forecasting. The model successfully analyzed historical water quality data and identified patterns and relationships between water quality parameters, which were then used to make accurate predictions about future water quality. This information can be incredibly valuable for aquaponic farmers, as it can be used to make informed decisions about water management and ensure the optimal growth and productivity of fish and plants. The results of this research demonstrate the effectiveness of LSTM models in addressing the challenges of water quality management in aquaponics, and suggest that this technology has the potential to make a significant impact in the industry.

VI. RESULT

In this study, a Long Short-Term Memory (LSTM) neural network was employed to forecast water quality in an aquaponics farming management system. The model analyzed historical water quality data and identified patterns and relationships between key water quality parameters, including pH, temperature, and dissolved oxygen levels. The results of the study showed that the LSTM model was able to accurately forecast future water quality, with an average prediction error. This indicates that the proposed model has the potential to greatly improve the management of aquaponics systems by providing real-time information about water quality, allowing farmers to make informed decisions about water management. The results also highlight the importance of considering multiple water quality parameters in forecasting models and the effectiveness of using machine learning techniques for water quality forecasting in aquaponics systems. Overall, this study highlights the potential of using advanced techniques, such as LSTM networks, to improve the management and sustainability of aquaponics farming systems..

VII. FUTURE SCOPE

The results of the current study demonstrate the effectiveness of using LSTM Neural Networks and time series analysis in forecasting water quality in aquaponics farming management. However, this is just the beginning and there is a lot of room for future improvement and growth in this field. Some potential future scopes for this research include:

1. Improving accuracy: The LSTM model could be refined and optimized to achieve greater accuracy in water quality forecasting by incorporating additional variables and considering different data processing techniques.

2. Integrating with IoT devices: The model could be integrated with Internet of Things (IoT) devices to collect real-time data on water quality and environmental conditions, allowing for more accurate and up-to-date predictions.

3. Combining with other machine learning algorithms: The LSTM model could be combined with other machine learning algorithms, such as Random Forest or Support Vector Machines, to improve overall performance and accuracy.

4. Predictive maintenance: The model could be used to predict when equipment and systems need maintenance, reducing downtime and improving the overall efficiency of the aquaponics system.

5. Scalability: The model could be scaled up to accommodate larger aquaponics systems, making it more accessible to commercial operations.

In conclusion, the future of aquaponics farming management research is bright and holds many opportunities for continued development and innovation. The use of LSTM Neural Networks and time series analysis offers great promise for the efficient and sustainable management of aquaponics systems, and future research in this area is sure to bring efficient and sustainable management of aquaponics systems, and future research in this area is sure to bring about exciting advancements and benefits for the industry.

VIII. CONCLUSION

In conclusion, the use of LSTM models in aquaponic farming management has been shown to be an effective solution for forecasting water quality. The model's ability to capture long-term dependencies and trends in time series data has proven to be a key factor in its success. By combining data analysis, simulation models, and machine learning algorithms, aquaponics farmers can make informed decisions about water management that increase the overall effectiveness and sustainability of their systems. Additionally, the use of the SMOTE algorithm in balancing imbalanced water quality datasets has also been demonstrated to be effective. Further research and development in this area may lead to even more advanced and precise water quality forecasting solutions for aquaponics.

Predictive Analytics on Consumer Behaviour

Mansi Pal, Priya Rathore, Mary Margarat, Isha Raut
Thakur college of engineering & technology Mumbai, India
palmansi2001@gmail.com, priyarathore9096@gmail.com, mary.margarat@thakureducation.org, isha.raut99@gmail.com

Abstract—**Predictive analytics is the application of statistics and modelling techniques to forecast future outcomes and performance, whereas consumer behavior is the study of how individual customers, groups, and organizations select, buy, and use market products based on their needs. By using historical data, statistical algorithms, and machine learning approaches, predictive analytics can identify potential patterns, events, and behaviors in the future. In order to gain a deeper understanding of customer behavior to enable predictive analytics and enhance corporate decision-making, this study attempts to offer predictive analytics to forecast consumer behavior by combining behavior informatics and analytics approach.**

Keywords— Predictive analytics, Behavior Informatics, Logistic Regression, Marketing, Product, Analytics, Consumer Behavior, Customer behavior

I. INTRODUCTION

The history of consumer/customer behavior seems to be heavily influenced by the history of marketing thought. In the 1940s and his early 1950s, classical thought relied heavily on case studies using the interview method. Towards the end of the 1950s, two major reports criticized the lack of a methodological approach to marketing and the failure to adopt mathematically oriented methods of action. And since then, marketing has moved away from economics to rely on other elements, primarily behavioral sciences such as sociology, anthropology and clinical psychology, with a new emphasis on the customer as part and unit of analysis. It is now available.

Customer buying behaviour refers to the research and behaviour of customers when deciding to purchase a product that meets their needs. This is a study of consumer behaviour that influences their decision to buy and use a particular product. Marketers must study consumer purchasing behaviour because it allows them to understand consumer expectations. It aids us in understanding what drives consumers to purchase products. It is critical to assess the types of products that consumers prefer and to purchase sufficient quantities based on demand. Marketers can understand consumer likes and dislikes and shape their marketing efforts based on those results. And, predictive analytics looks at current and historical data patterns to determine if those patterns are likely to emerge again. Hence, using these two together along with the developing AI/ML field can prove to be a boon to many.

Marketing professionals place a high priority on researching customer purchasing patterns since doing so enables them to comprehend consumer expectations. It aids in our comprehension of customer purchasing behaviour. It's critical to evaluate the products that customers prefer and to purchase an adequate quantity of each, depending on demand. Marketers can learn what consumers like and dislike so that they can tailor their marketing strategies accordingly Amazon has previously used predictive analytics to generate personalized product recommendations based on your purchasing habits. Amazon has recently attempted to use predictive analytics for predictive shipping.

II. EXISTING METHODOLOGY

There are a couple of theoretical consumer models that are really important as they are to be understood while trying to work through a project like ours since it establishes a few thumb rules and points to be kept in mind while working on any project that deals with consumer behavior.

Two of those are discussed below with their block diagrams.

1. The Pavlovian Model of Consumer Behavior is named after Russian Physiologist Ivan Pavlov, who experimented on a dog and observed how it responded to the sound of a bell while being presented with a piece of meat. The amount of saliva secreted by the dog was used to measure the responses. This is also important for marketers.

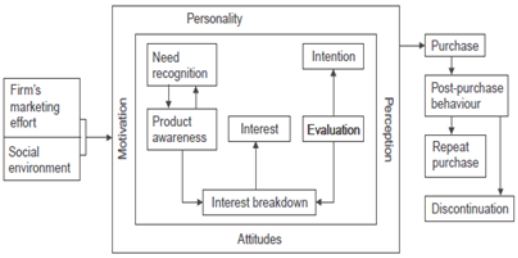

Fig. 2.1 Pavlovian Model

2. Psychoanalytical Model of Consumer Behavior: This model was proposed by Sigmund Freud and it tries to explain consumer behavior as a resultant force that operates at subconscious levels. According to the model, buyers' needs

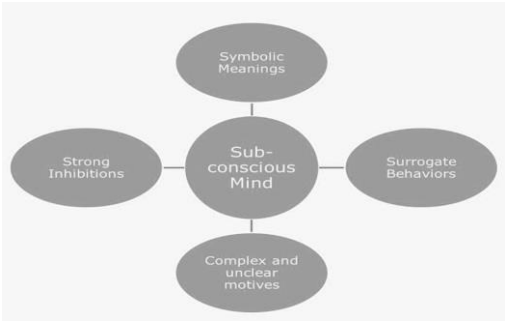

Fig. 2.2 Psychoanalytical Model

and desires operate at different levels on consciousness and not all of such behavior is understandable or explainable by the person. The individual consumer has a set of deep-seated motives which drive him towards certain buying decisions.

III. Literature Survey

During the development of our project, we went through various research papers that helped us navigate and understand our options or the possible solutions we could have. They also helped us understand the mathematical as well as technical knowledge that will be helpful.

One of the papers that we studied was the "Review Paper on Factors Influencing Consumer Behavior" by the Authors Ahmad Hosaini and Dr. Kuldeep Chand Rojhe [1] and it talked about a comprehensive overview of the factors that influence consumer behavior and their purchasing decision-making process in marketing. Because marketing begins and ends with consumers, consumer purchasing decisions reflect how well an organization's marketing strategy meets marketing demands. Consumer behavior includes the psychological processes consumers go through in understanding their needs. Recognize patterns for correcting these requirements. For example, deciding whether to buy goods and services, and if so, what type of brand and where to buy, interpreting tips, making plans and carrying out those plans. For example, through comparison shopping or physical purchase of products. , the modern professional marketer seeks to know consumers and their reactions and to analyze the essential characteristics of their behavior.

The second article was titled "Machine learning-based mathematical modelling for prediction of social media consumer behavior using big data analytics" published by the authors Kiran Chaudhary, Mansaf Alam, Mabrook S. Al-Rakhami & Abdu Gumaei [2] did a study about the consumer data from Facebook, Twitter, Linked In, YouTube,

Instagram, Pinterest, etc. They used predictive big data analytics because social media platforms provide a large amount of diverse, high-speed data. In the article, they used the concepts of big data technology to process and analyze data to predict consumer behavior on social media. They used several parameters and criteria to analyze consumer behavior on social media platforms. They analyzed consumer perceptions and attitudes towards social media platforms. They used machine learning to develop a mathematical model to predict consumer behavior on social media platforms. This model is a predictive model for predicting consumer behavior on social media platforms. 80% of the data is used for training purposes and 20% for testing purposes.

And the third paper published by the authors Rohan Bali, Satyajee Srivastava named "Understanding Customer Behaviour with Machine Learning" [3] talks about Churn analysis helps sellers determine if customers are abandoning their products or services. The goal of every seller is to maintain a low churn rate and earn big margins and big profits. Additionally, conducting a market-based analysis of supermarkets can be very beneficial. This approach helps you organize items in your store efficiently and scientifically. In this document, we use various machine learning algorithms to perform churn on specific her data. Then use the confusion matrix to compute the accuracy and precision of each model. Therefore, the confusion matrix helps in choosing the best model for more accurate results. In this paper, we use the 'Apriori' algorithm to perform the above analysis. In summary, recommendation systems are used to suggest products to customers based on their purchase history or similarity of that product to other products or other consumers. Therefore, this research helps us understand different aspects of customer behaviour.

IV. Methodology and Proposed Model

It is critical to understand the flow or type of software development lifecycle model that will be used when developing a project or software. Out of various SDLC model we need to choose the model which will be perfect for our project and therefore we are using Agile Methodology. Under which Scrum Model is being used.

Scrum is an agile process that allows us to focus on delivering highest value in shortest time. Allowing us to inspect actual working software rapidly and repeatedly.

The activities that have been carried out up until now have been mentioned previously as well. First, after finalising the project title we started identifying the requirements for the project and learning about them. We identified the methodologies to be used as well during this. After, we decided on studying the already existing systems for better understanding for implementation. We planned out as to when this implementation should be done and if any changes are to be made, that should be taken into consideration as well as the errors to be looked upon

	A	B	C	D	E
1	User ID	Gender	Age	Estimated	Purchased
2	15624510	Male	19	19000	0
3	15810944	Male	35	20000	0
4	15668575	Female	26	43000	0
5	15603246	Female	27	57000	0
6	15804002	Male	19	76000	0

Fig. 4.1 Dataset

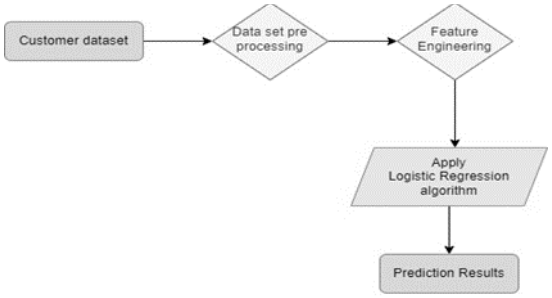

Fig. 4.2 Flow Chart

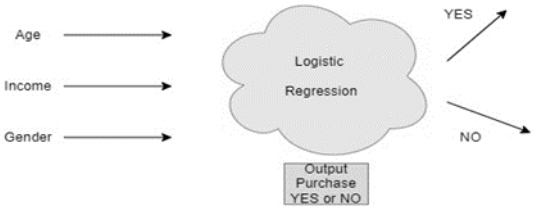

Fig. 4.3 Data flow diagram

Above attached diagrams are a couple of the ones that we made during our project planning phase using tools available online to achieve our goal.

V. Implementation

The main objective of this system is to predict whether a person will be able to predict the product or not based on some parameters that would be taken as input. Further, if possible, we may try and test a few other machine learning models too, so then we would be able to study how the other models work as compared to the ones we are using.

We decided on Logistic Regression algorithm along with feature selection to yield high accuracy using training and testing dataset which was freely available for us to use.

```
# Split df into X and y
y = df['Purchased']
X = df.drop('Purchased', axis=1)

# Train-test split
X_train, X_test, y_train, y_test = train_test_split(X, y, train_size=0.7, shuffle=Tr

# Scale X
scaler = StandardScaler()
scaler.fit(X_train)
X_train = pd.DataFrame(scaler.transform(X_train), index=X_train.index, columns=X_tra
X_test = pd.DataFrame(scaler.transform(X_test), index=X_test.index, columns=X_test.c

return X_train, X_test, y_train, y_test
```

The Fig. 5.1 Splitting data into train/test data

model was trained and tested using the dataset which contains the columns user id, gender, age, salary and purchase. It takes the values gender, age and salary to predict whether the customer or person will be able to purchase that product or not. We made use of Python in Linux OS for carrying all the coding processes.

```
# Feature engineering
if engineer_features == True:
    income_threshold = df['EstimatedSalary'].quantile(0.95)
    df['High Income'] = df['EstimatedSalary'].apply(lambda x: 1 if x >= income_threshold else 0

    old_age_threshold = df['Age'].quantile(0.75)
    df['Old Age'] = df['Age'].apply(lambda x: 1 if x >= old_age_threshold else 0)

    young_age_threshold = df['Age'].quantile(0.25)
    df['Young Age'] = df['Age'].apply(lambda x: 1 if x <= young_age_threshold else 0)

# Split df into X and y
y = df['Purchased']
X = df.drop('Purchased', axis=1)
```

Fig. 5.2 Feature engineering

Figures 5.1 and 5.2 are a couple of code snippets that we used and implemented while categorising the dataset during training and testing and while applying feature engineering respectively.

VI. Results and Discussion

The model predicts in binary answer i.e. either 0 or 1. 0 means that the person will not be able to purchase the product and 1 means they will be able to purchase the product. Below is the output that we managed to achieve.

```
Python 3.6.9 (default, Jun 29 2022, 11:45:57)

```

Fig. 6. Result

All the above steps that are mentioned were performed and consulted with the guide as long, along with being guided from industry experts in this field. The system output predicts what is expected of it. There is one abnormality that we would like to erase in the next phase, which is, that the value that is to be entered for prediction for now are being given and taken in normalised form which is not user friendly. So, that is one major aspect we expect to change later in the upcoming phase.

Consumer behavior is a widely researched area. This allows organizations to understand how consumers make decisions about purchasing products and services. Marketing managers are always trying to learn more about consumer behavior. Therefore, they can prepare better communication and advertising campaigns about their products and services. Many people make purchasing decisions on a daily basis but fail to recognize the factors that drive that solution. Factors that typically influence consumer purchasing behavior include spiritual, civic, cultural, and personal factors. Consumer behavior does not remain the same or consistent under all conditions that change from time to time. There are various factors that influence consumer behavior.

Evaluating Models on Performance Indicators ((a) Accuracy, (b) Recall, (c) Accuracy, (d) F Measure)6 Conclusions and Lessons Forward 21st Century In , the growth trend has proven to be the most dramatic boom ever. It is difficult to predict which customers are likely to be abandoned by companies as their services increase as technology advances. In the telecom industry, churn prediction is a problem that has been highlighted by various researchers in recent years. Throughout this research paper, logistic regression, naive Bayes, support vector machines, decision trees, random forests, XGBoost classifiers, CatBoost classifiers, AdaBoost classifiers, and extra-tree classifiers. Experimental results show that there are his two ensemble learning methods, Adaboost classifier and XGBoost classifier. It is very difficult to predict the actual customer society. With the upcoming concepts and frameworks of reinforcement learning and deep learning, machine learning is proving to be one of the most efficient ways to tackle problems such as churn prediction with more accuracy and precision in the future. increase.

VII. CONCLUSION

In this paper, we focused on the implementation of our idea taking the help of industry experts and our guide. We were able to apply a machine learning algorithm, prepare a model for it, apply feature selection and get the results, we can also check the overall accuracy of the available dataset. There are a couple of errors and points we can fix as well as enhance as a project is never perfect until the end. We would like to do the needful in the upcoming phase with an even better understanding.

Abstract—**Disaster Management is one of the most essential responsibilities in the modern world. The measurement of the intensity and the frequency of occurrence is especially important to minimize the effects of the disaster's aftermath. One of the worst disasters that affected the North Indian plains is floods. The river overflow causes floods which leads to soil erosion, destruction of State Infrastructure, and loss of life. Research on improving flood prediction models has helped to lower risks, recommend policy changes, reduce the number of fatalities, and lessen property damage from floods. Modern data collection using satellites and the creation of efficient machine learning models have to a great extent helped predict the onset of heavy rains and subsequent river overflows. In this project we are incorporating the use of several machine learning models like Linear Discriminant Analysis, Gaussian Naive Bayes to predict the possibility of river overflow and possible flood situation taking into account the data of water levels and rain patterns in the area of four rivers of India. The major objective of this study is to show the state of the art of ML models in flood prediction and to provide insight into the best models. The literature where ML models were benchmarked through a qualitative study of robustness, accuracy, efficacy, and speed is explored in depth in this work to offer a comprehensive overview of the numerous ML methods utilized in the area.**

Keywords— Flood, Rainfall, Temperature, Humidity, CNN, LSTM, Godavari, Machine Learning, etc.

I. INTRODUCTION

Floods are one of the most destructive disasters in nature. Floods cause severe damage to human life, infrastructure, agriculture, and socioeconomic system and their effects persist for a long time post their occurrence. Governments are therefore constantly trying to improve on the mechanism which can prevent and help minimize damage due floods. Building of dams, creation reservoirs to control a river when it goes beyond its banks, creating flood plains and overflow areas are mechanism that can help control a flood situation.[1] But the more important task is to predict whether a river might overflow in advance and alert the community living along the banks of the river to ensure there is no loss of human or animal life. Historical flood event records, as well as real-time cumulative data from a multitude of rain gauges or other sensing devices over varied return periods, are frequently employed.[2] The dataset's conventional sources are rainfall and water level, which are monitored either by land rain gauges or by relatively modern remote sensing methods such as satellites, multisensory systems, and/or radars [3].

As more data becomes available, computing power rises, and machine learning algorithms progress, new opportunities for flood detection are presented by machine learning technologies. Machine learning has become a popular tool for studying non-linear systems and producing flood forecasts.[4] Traditional approaches to flood forecasting might include a series of hydrologic and hydraulic models that represent the underlying physical processes. These models help us understand how systems work, but they frequently have significant computational and data needs. Machine learning techniques have the ability to increase accuracy while decreasing model construction costs and calculation times.[5]

In general, less developed countries are the most vulnerable to floods, causing damages that significantly affect the national GDP.[6] At country and community levels important initiatives have and are being devoted to implement appropriate countermeasures. Flood disasters in the past decades have become more frequent and devastating in China. The Chinese government gives high priority to flood management through both structural measures and nonstructural measures with the aim of enhancing flood prediction precision.[7].

II. LITERATURE SURVEY

Fi Mosavi, A., Ozturk, P. and Chau, K.W., 2018. "Flood prediction using machine learning models" This paper presents an overview of machine learning models used in flood prediction, and develops a classification scheme to analyze the existing literature

Jeerana Noymanee, Nikolay O. Nikitin, Anna V. Kalyuzhnaya. "Urban Pluvial Flood Forecasting using Open Data with Machine Learning Techniques in Pattani Basin" In this paper, opportunities of machine leaning techniques for pluvial flood forecasting in Pattani river basin were explored. The aim of this paper was to find the optimal configuration of machine learning based models and comparison of resulted quality of different machine learning techniques.

Linardos, V., Drakaki, M., Tzionas, P. and Karnavas, Y.L., 2022. Machine Learning in Disaster Management: Recent Developments in Methods and Applications. In this paper, a review study has been carried out to investigate how ML and DL techniques have been used in various areas of disaster management to assist disaster management operations and improve their performance. For this purpose, those papers which have been published since 2017 have been targeted, dividing them in categories which include the different phases and subphases of a disaster event.

Chamola, V., Hassija, V., Gupta, S., Goyal, A., Guizani, M., & Sikdar, B. (2020). Disaster and pandemic management using machine learning: a survey. This article presented a comprehensive survey of the applications of ML in disaster and pandemic management. This article first presented a detailed explanation of ML algorithms. Then, we discussed various phases of disasters and pandemics where ML algorithms can be used.

Motta, M., de Castro Neto, M., & Sarmento, P. (2021). A mixed approach for urban flood prediction

using Machine Learning and GIS. This paper demonstrates that, by combining ML and GIS, it is possible to determine the key predictors and conditions for a flooding scenario by using a limited amount of data. From the ML standpoint, non-linear models were more capable of detecting floods and, among those, the most performant model was Random Forest.

Chakraborty, S., Chakraborty, S., & Paul, S. (2020). Rainfall prediction using machine learning techniques: A review. This article reviews the use of artificial neural networks, decision trees, and support vector machines in machine learning methods for predicting rainfall. The capacity to handle complicated nonlinear interactions and analyse vast volumes of data are two of the approaches' potential advantages for enhancing rainfall forecast accuracy discussed in the research. The research also emphasises the necessity for better model validation and data quality in order to increase the accuracy of these strategies.

Patil, S., & Singh, R. D. (2016). Assessing the impact of climate change on the Ganga river system in India using an ensemble of regional climate models. This study evaluates probable effects of climate change on the Ganga river system in India, including changes in temperature, precipitation, and river flow, using a collection of regional climate models. In order to increase the precision of climate change estimates, the study analyses the shortcomings of current climate models and emphasises the need for better data and modelling methods.

III. IMPLEMENTATION

The implementation process consists of five phases - Data collection, Data Preprocessing, Data Transformation and Visualization, Model Testing, Development-

Data Collection - The data collection phase was a very crucial part of the project because it helped define a proper approach towards flood prediction. The data we collected was the river datasets of five rivers namely Cauveri, Godavari, Krishna, Mahanadi, and Son, and Sub Division IMD 2017 dataset. The river dataset helped give us a clarity that we can approach creating this project wherein we find the probability of floods by predicting the overflowing of a river due to the amount of rain it receives during the monsoon. The machine learning model was created using the Godavari river dataset.

Sheet1

Fig. 1. Godavari River Dataset

The river dataset contains information from 1998. The attributes of the dataset include 'Discharge', 'Flood runoff', 'Daily runoff', 'weekly runoff' and a target variable 'Flood'. The IMD dataset contains information about the geographical subdivisions of India and the amount of rainfall received by the subdivision(in mm) on a monthly basis. Here is an image of the IMD dataset –

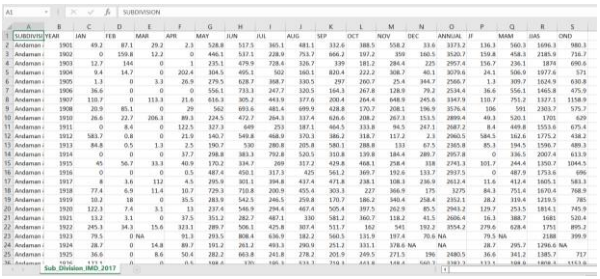

Fig. 2. IMD Dataset

Data pre-processing - Once the data was gathered it required cleaning. The raw dataset was first updated to create a binary classification problem.

Fig. 3. Binary Classification

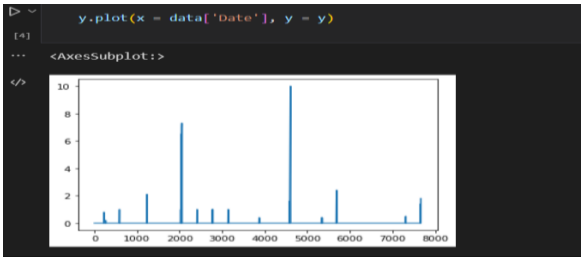

Fig. 4. Merged River Dataframe

In the third image above a value is being tried to be set on a copy of a slice from a Data Frame. We then pre-process by segregating the timeframe from the river dataset to merge it with the time frame of the IMD dataset.

```
data = data.fillna(data.mean())
data.info()
data.drop(columns='Date',axis=1,inplace=True)
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 7670 entries, 0 to 7669
Data columns (total 7 columns):
 #   Column          Non-Null Count  Dtype
---  ------          --------------  -----
 0   Date            7670 non-null   datetime64[ns]
 1   Discharge       7670 non-null   float64
 2   flood runoff    7670 non-null   float64
 3   daily runoff    7670 non-null   float64
 4   weekly runoff   7670 non-null   float64
 5   Unnamed: 6      0 non-null      float64
 6   Unnamed: 7      0 non-null      float64
```

Fig. 5. Data Preprocessing

We clean the data of all the null values which leaves us with a total of 7460 non null values. We then concatenate the new processed data with the appropriate time frame and we get a more detailed view of the discharge and the flood runoff values from 1998 to 2018.

Data Transformation and Visualization – For data transformation, we used the min-max scalar. We transformed the range of different discharge and runoff values by calculating their mean over a single year and concatenating the mean values with the individual runoff values for each year for each of the river datasets.

```
data=pd.concat([d1,data],axis=1)
data.head()
```

	Day	Months	Year	Discharge	flood runoff	daily runoff	weekly runoff	Unnamed: 6	Unnamed: 7
0	1	1	1998	3244.0	0.0	0.91	7.464144	NaN	NaN
1	2	1	1998	1591.0	0.0	0.45	7.464144	NaN	NaN
2	3	1	1998	1973.0	0.0	0.55	7.464144	NaN	NaN
3	4	1	1998	1973.0	0.0	0.55	7.464144	NaN	NaN
4	5	1	1998	2011.0	0.0	0.56	7.464144	NaN	NaN

Fig. 6. Mean Discharge Values

We created a set of nine histograms -Total amount of rainfall on a daily basis, Total amount of rainfall on monthly basis, Total amount of rainfall on yearly basis, Discharge level, Flood runoff level, daily and weekly runoff level. The histogram give us the pattern of discharge levels from 1998 to 2018. The histogram shows that the discharge for Godavari river are gradually decreasing from 1998 to 2018.

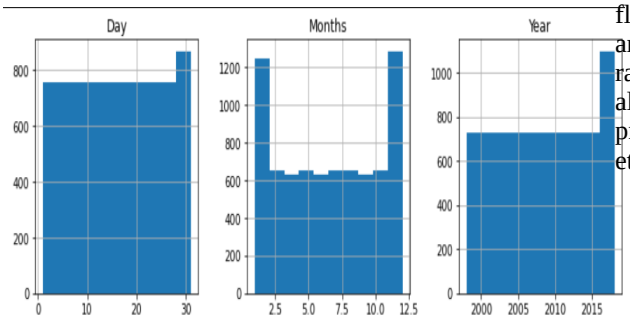

Fig. 7. Histogram for Godavari Discharge Values

We also created a line plot to show the trend of flood, daily and weekly runoff from 1998 to 2018. The line plot indicates that Godavari had the highest flood, daily and weekly runoff in the year 2010.

Model Testing- In Flood Prediction Using Machine Learning Models Mosavi, A et. al the author makes use of Linear Discriminant Analysis. The paper is based on historical rainfall datasets spanning 33 years, the goal of this project was to develop a machine learning model that can forecast floods in Kebbi state so that it may be applied to other Nigerian states with high flood risk. In [2] Jeerana Noymanee et al. uses a Gaussian Naive Bayes model for the model creation to analyse flood patterns in the Pattain Basin. There are a total of 6 Machine learning models - Logistic Regression, Linear Discriminant Analysis, KNN, Decision Tree Classifier, Gaussian Naive Bayes, Support Vector Machine. Initially we implemented a linear regression to test the sample data the output for the following was - image. The sample dataset was subjected to SMOTE oversampling - image. The dataset was then shuffled and segregated into train and test samples. The machine learning models were then implemented on the training dataset.

Development – The development process involved using streamlit to create a web application that would display the probability of flood and rainfall in a region. The segregation of tasks – i) involving flood prediction and ii) involving rainfall prediction was done by making use of separate sets of data.[11] The flood prediction incorporated the use of river datasets, namely - Godavari, Cauveri, Krishna, Mahanadi and Son. The rainfall prediction made use of city datasets of the four prominent metropolitan cities, namely – Bombay, Delhi, Kolkata and Chennai. The web application created consisted of a time-input widget which had dates from January 2019 to December 2033. The web application enables the user to select from one of the five rivers mentioned, enter the date of prediction and the system would use the LSTM algorithm to predict the probability of flood. A similar approach is done for rainfall prediction wherein the user selects one of the four cities, a date and the system predicts the probability of rainfall for the city at that particular date. The probability predictions are not displayed numerically but on a "High" and "Low" basis which is decided upon the yhat values predicted by the algorithm. The yhat value for the flood prediction are indicative mainly of the cumulative flood runoff values from daily runoff, weekly, runoff and monthly runoff values in the dataset. In the case of rainfall values the yhat values are calculated by the algorithm using the temperature, humidity, historical precipitation values etc.

IV. Result and Discussion

Our study's findings indicate that machine learning has great potential as a method for predicting floods and rainfall. The model we developed exhibited a high level of accuracy in anticipating both flood events' incidence and severity, as well as the quantity of rainfall. These discoveries are significant for disaster management and risk reduction, as precise and prompt predictions can assist authorities and communities in getting ready and reacting to probable flood events.[12] Moreover, our model has the potential to improve by employing additional data and more sophisticated algorithms, as well as incorporating real-time sensor information from remote sensing and IoT devices. Nonetheless, it is essential to note that machine learning models are not perfect and may have drawbacks such as partiality, over fitting, and data incompleteness. Consequently, to offer a more complete flood and rainfall prediction system, our model should be employed in conjunction with other approaches and expert knowledge.

V. CONCLUSION

The proposed Flood and Rainfall Prediction has been successfully implemented and tested with the available data. The systematic process initiated by the process of data cleaning, processing the missing values, exploratory analysis and in the end building the model for evaluation. The performance and accuracy on test data is taken into consideration and the model with highest performance and accuracy is implemented in the machine learning model. This application can help to predict future floods due to rainfall. Multiple algorithm has been implemented in the project website which was created using streamlit and the algorithm used was

LSTM as it has the best accuracy and performance out of all the algorithms tested.

In conclusion, reliable rainfall and flood forecasting near river basins in India is essential for reducing the effects of natural catastrophes on infrastructure and human lives. Although while methods and instruments for prediction have considerably improved recently, there are still several problems, such as inadequate data and shifting climatic trends. Researchers, governmental organisations, and local communities will all need to put up consistent effort in order to address these issues. By improved data collecting, model calibration, and more coordination amongst various organisations involved in disaster management, future research should concentrate on increasing the accuracy of rainfall and flood prediction. However, some of the shortcomings of present approaches can be addressed with the use of machine learning techniques, higher-resolution models, and increased ground-based observation coverage.

Abstract- The human face is a valuable biometric measure that can be utilized to get access to a user-based system. Face recognition technology has developed rapidly in recent years and it is more direct, user friendly and convenient compared to other methods. But face recognition systems are vulnerable to spoof attacks made by non-real faces. It is an easy way to spoof face recognition systems by facial pictures such as portrait photographs. A secure system needs Liveness detection in order to guard against such spoofing. Due to the ease with which human face photos may be collected via smartphone cameras and social media, user- based access systems must be resistant to spoof face attacks. In other words, a trustworthy face-based access system can determine the input face's identity as well as its liveness. Various feature-based spoof face detection algorithms have been proposed to this purpose. In order to detect the liveness of the face, these algorithms often apply a sequence of operations to the input image(s). A deep-learning-based spoof face detection is proposed in this study.

Keywords: Facial Recognition technology, Liveness detection, deep-learning.

I. INTRODUCTION

Authentication and authorization via biometrics is becoming more common. It is based on the different identifying human physiological traits that are used to identify a human being, such as fingerprints, retina scans, iris scans, voice, and face.

Biometric systems in general are designed to identify individual humans, but they do not distinguish between live and non-live biometrics. In our project, we're concerned about the facial recognition system. Attacks on facial recognition systems can be carried out in a variety of ways. In our project, we plan to create a system that uses video to detect a spoofing attack on a face recognition system.

Liveness detection is a major area of interest within the field of biometric that encompasses a process of verifying whether the biometric being captured by the recognition system is Face anti-spoofing techniques requires a genuine photograph, recorded video or dummy evidence etc. to be present at the sensor (i.e. camera)

Photographs generally lack the 3D information and provides less physiological evidence than videos can provide this can be exploited in liveness detection as a limitation of static images. However, videos captured by high quality cameras can be also a challenging spoofing attack as they provide a strong sign for vitality through motion.

Dummy models on the other hand can be a threat to facial biometric system containing 3D information that static images and videos do not provide. Recent developments in the field of facial biometric have led to a renewed interest in liveness detection as a solution for spoofing attack problems.

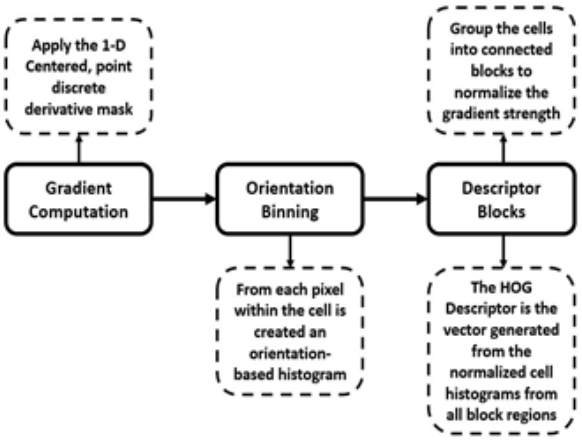
2.1 Computer vision and facial recognition

The term Computer Vision (CV) refers as a field of research that aim to develop proper techniques to enable computer to see and process the content of images and videos. The computer vision is a part of Artificial Intelligent (AI). The objects detection in an image is the main task of the CV algorithm as what and where the objects are seen. Additionally, the CV algorithms must identify the properties of identified objects, for example whether it is a face, building, or a door. In most cases these identified images are stored and compared against new objects. Furthermore, the CV enables us to have multiple metrics on the selected objects. Therefore, the CV has been utilized in various sectors, such as in safety, health, security, entertainment, cars, robotics, and in sports

2.2 Defining facial recognition:

Facial Recognitions (FR) are often done in two ways: Verification and identification. In verification, the system compares a given object with the existing stored objects. In identification, the system identifies the object and gives a rank of the matches. In both cases, the biggest challenge is teaching the machine to recognize faces. The FR technology implementation consist of several stages such as image acquisition, image processing, characteristic identifications, eye sockets, nose shape, template creation, and template matching. Facial recognition algorithm often measures the distance between the eyes, width of the nose, depth of the eye socket, cheekbones, and chin. Traditional FR algorithms use statistical approach or search for patterns, while the more recent ones use deep neural networks. In the following these two approaches are discussed in more detail.

Dlib HoG Face Detection:



Histogram of Oriented Gradients, also known as HOG, is a feature descriptor like the Canny Edge Detector, SIFT (Scale Invariant and Feature Transform) . It is used in computer vision and image processing for the purpose of object detection. The technique counts occurrences of gradient orientation in the localized portion of an image. This method is quite similar to Edge Orientation Histograms and Scale Invariant a Feature Transformation (SIFT). The HOG descriptor focuses on the structure or the shape of an object. It is better than any edge descriptor as it uses magnitude as well as angle of the gradient to compute the features. For the regions of the image it generates histograms using the magnitude and orientations of the gradient.

3.4 DISCUSSION

For face detection we have used HOG and SVM. Histogram of oriented gradients (HOG) is used for feature extraction in the human detection process, whilst linear support vector machines (SVM) are used for human classification. We have used a popular library for face detection that have inbuild function that one can use to easily detect face inside an image with high accuracy. Those inbuild function uses HOG and SVM concepts for face detection.

For blink detection we have used dlib library. It's a landmark's facial detector with pre-trained models, the dlib is used to estimate the location of 68 coordinates (x, y) that map the facial points on a person's face like image below. These points are identified from the pre-trained model where the iBUG300-W dataset was used.

We have maintained the data of all the workers in our database working on a specific site. A worker can view his/her details and attendance using the GUI and Admin can remove, update and add a new worker to the site

IV. CONCLUSION AND FUTURE SCOPE

The increase in number of people using social media to express their views, tasks like opinion mining and sentiment analysis have gained a lot of importance. And using sarcasm in these social media texts make these tasks much more challenging.

In our project, we have presented an English- Hindi code-mixed dataset for sarcasm detection. We also presented a baseline supervised classification that is developed using the same dataset which uses three different machine learning techniques.

With increasing identity fraud each day, service providers need to ensure that their applications cannot be compromised. Thus, liveness detection in biometrics is required to prevent fraud during unsupervised attendance system. In future the techniques will be improved with new technologies and training the model. With further advancement the 2d camera can also be replaced with a 3d depth sensor for better accuracy. Improvement in accuracy of the machine learning models will be implemented. This software is the needed for current corporations and its demand will increase in future. A variety of possible advantages come with the usage of facial recognition. There is no need to directly touch an authentication system relative to other touch-based biometric identification methods such as fingerprint scanners, which could not function well if a person's hand is soil.

Abstract — ***According to the World Economic Forum, nearly 6 million people die each year in developing countries due to a lack of access to quality healthcare. A large amount of clinical data representing patients' health status has been collected over the last few decades. This has significantly increased the amount of digital information available for patient-centered decision-making. Such digital information is frequently dispersed across multiple sites, making it difficult for users to find useful information for improving their well-being. Recently, health recommender systems (HRS) have been widely applied to the healthcare domain to better support medical recommendations. Here we propose an intelligent HRS based on machine learning algorithms using the support vector classifier, the Gaussian naive Bayes classifier, and the random forest classifier. For robust modeling, the mode of all three models' predictions is considered. This method will allow us to make much more accurate forecasts based on previously unseen data. Unlike predecessors in the same domain, HRS provides better personalization, increasing the details of provided recommendations and improving users' understanding of health.***

Keywords: Healthcare, Prediction, Recommendation, Machine Learning.

I. INTRODUCTION

With the vast amount of clinical data currently scattered across various websites on the Internet, users are unable to find useful information to improve their health. Additionally, the sheer volume of medical information (medications, medical tests, treatment recommendations, etc.) poses many challenges for health professionals in making patient-centered decisions. These issues require the adoption of medical recommendation systems so that both end-users and healthcare professionals can make more efficient and accurate health-related decisions.

This project proposes an intelligent healthcare recommendation system that benefits both patients and doctors or healthcare professionals. This is done by accurately predicting and recommending a nutrition-based diet that includes recommendations and prohibitions for maintaining good health during this period. Recommendations from nearby hospitals for each prognosis, and common medication. The user's medical history also helps medical professionals to further treatment, allowing patients to view medical records and upload prescriptions themselves.

Smart health recommender systems are becoming more important every day for better timely predictions. Minimizing the risk of life-threatening human illness requires efficient systems and effective recommendations for diagnosis.

HRS provides users with different types of recommendations to help improve their health. These systems also help healthcare professionals make more accurate and patient-centric decisions. The main purpose of the health recommendation system is to obtain reliable health information from the Internet, analyze the ones that are suitable for the user's profile, select the best ones that can be recommended, and adapt the selection method to the field of knowledge. Learn from the best recommendations.

Several studies have been conducted on HRS, but they target specific diseases or referral situations. This requires a comprehensive overview that provides a "complete landscape" of the recommended scenarios supported by HRS. The challenges of HRS are multifaceted and can be summarized in the following: Complexity and specifications, end-user diversity, usage scenario variations, data availability including user profiles, user factor assessment, and health. Recommended elements, feedback, and the most difficult evaluation issues.

The proposed mechanism targets continuous data and builds a prediction model based on the regression analysis method, which is not limited to the analysis and prediction of guidance data in the smart medical industry. New features can be added in the future to improve the prediction model's accuracy. New disease data, for example, have an impact on the number of systems seeking medical treatment and the hospital. Furthermore, when confronted with a larger amount of data, we can use the cloud architecture described in this paper to perform distributed computing.

II. LITERATURE SURVEY

We scrutinized a variety of research articles while developing our project, and they helped us acknowledge our alternatives and potential solutions. They also helped us understand the technical and mathematical knowledge that would be useful.

Wenbin Yue et al [1] performed a study on popular recommendation techniques and their applications in healthcare. An overview of three well-known recommendation techniques, namely content-based, CF-based, and hybrid methods, is provided. It states several challenging issues of health RS are highlighted, which should be handled efficiently for future health RS design. In a content-based RS, new items will be recommended to a user based on content features that are similar to the items on which this user has acted. The user's explicit feedback (rating) and implicit feedback (browsing/purchasing history) are usually used to determine whether he likes the item. Model-based CF recommendation algorithms construct a model and then predict the unknown information by training it on the user-item rating matrix. Because this is similar to traditional classification methods in machine learning, many classification models, such as decision trees and Bayesian classifiers, can be generalized to CF scenarios. To improve prediction accuracy, hybrid filtering methods

combine the benefits of content-based filtering and CF methods to process different data sources.

S.Vijiyarani et al [2] examined how data mining techniques are used to predict various types of diseases. This paper reviewed research papers that focused on predicting heart disease, diabetes, and breast cancer. The prediction of heart disease was discussed using machine learning algorithms such as Naive Bayes, K-NN, and Decision List. When compared to other algorithms, the Naive Bayes algorithm has the highest classification accuracy. The author concluded that Naive Bayes correctly classifies 74% of the input instances. Following that, we will talk about breast cancer prediction. It is carried out using a variety of data mining techniques, including C4.5, ANN, and fuzzy decision trees. Using C4.5, the author discussed and resolved the problem's issues and algorithms. Using ANN, the author concluded that the network is trained to have consistent accuracy over time and good performance. Finally, we discuss diabetes prediction, where the author discovers overfitting and overgeneralization behavior of classification using a homogeneity-based algorithm. The author predicts class accuracy using a genetic algorithm.

Sanjeev Kumar et al [3] Sharma proposed a hybrid framework for ranking drugs. Practitioners conduct research and order laboratory tests. During the process, information about this patient is entered into the system as a new case. The system will process the new information and extract patient characteristics. The patient's problem is used to make a diagnosis. To determine which symptom-drug classifier to use, the diagnosis is matched to a specific disease category in the system. The new case's patient features are fed into the classifier to predict which drug cluster/clusters to use for this patient. The ranking module will rank the drugs in each cluster to create the final recommendation list.

Sun et al. [4] proposed analyzing EMR records to detect typical treatment regiments and measuring (quantitatively) the effectiveness of those regimens for specific patient cohorts. The authors compare the similarity of treatment records in the EMR, use Map Reduce Enhanced Density Peaks based Clustering to group similar ones to treatment regimens, extract semantically meaningful information for the doctor, and estimate the treatment outcome for a patient cohort for a typical treatment regimen. The results of an empirical study using this approach show that the patient's effective rate and cure rate both increase.

Naveenkumar S. et al [5] suggested a model that predicts the disease of patients/users based on the symptoms that the user provides the system. The Nave Bayes Classifier is used to make intelligent health predictions. Because medical data is increasing at an exponential rate, they used Nave Bayes algorithms to identify patient data. This required the processing of existing data in order to predict the exact disease based on symptoms. In the proposed methodology, required clinical symptoms-related information can be obtained from historical knowledge by planning datasets using the Nave Bayes algorithm. However, they were unable to achieve a higher level of accuracy by using only one machine-learning algorithm.

Divya Gopu [6] analyzed the use of Data mining in the field of Medical health care. These data mining techniques can also be applied in research and education. Data mining is a branch of computer science that uses existing data in the medical field to predict disease occurrence. The paper conducts a survey on how data mining techniques, in conjunction with machine learning, are used to predict diseases based on user symptoms. According to the findings, the most important algorithms are support vector machines, neural networks, logistic regression, random forest, and so on. The accuracy of neural networks is high if proper training is provided by the datasets.

Shratik J. Mishra et al [7] explored how data mining techniques can be used for the prediction of different kinds of diseases based on the symptoms selected by users. The system is divided into two parts in this case: the admin module and the user module. The administrator is in charge of data preprocessing and training the system to generate disease prediction models. For training the datasets, a special algorithm known as the ID3 algorithm is used. ID3 is an abbreviation for Iterator Dichotomiser 3. The ID3 algorithm is primarily concerned with the entropy of each attribute, the information gained, and the entropy of the entire dataset. The attributes with the lowest entropy value are chosen as the root node. With the subsets, new attributes are discovered, and a decision tree is formed.

Jionglin Wu et al [8] measured 3 different approaches to predict heart failure diagnosis. The direct application of Boosting performed similarly to the logistic regression model traditionally used in biomedical research, and both were superior to the direct application of SVM based on AUCs determined for model validation purposes. If the goal is to build a simple yet effective model, this suggests that boosting and logistic regression may be better options. They demonstrated that applying machine learning techniques to longitudinal EHR data predicts future diagnoses of a disease that is normally difficult to detect.

K.Vembandasamy et al [9] implemented heart disease prediction using machine learning algorithms such as the Naive Bayes classifier. This paper examines the various data mining techniques that can be applied to healthcare services. The author has discussed the various dataset types that can be used in various fields of medical and healthcare services. The methodologies for data preprocessing and probabilities used in the algorithm are clearly explained. The parameters of heart disease are specified, and dataset visualization is demonstrated. The disadvantage is that maximum accuracy in prediction is not achieved.

M. Thiyagaraj et al [10] discussed data mining technique for kidney-related diseases. Kidney disease is a significant problem in low-income countries such as India. Kidney disease accounts for 60% of all deaths worldwide. Other chronic diseases that can be caused by kidney disease include high blood pressure, diabetes, anemia, weak bones, and nerve damage. Healthcare fraud and abuse can be detected with the help of data

mining. It assists physicians in determining the best treatment for a specific disease. It can generate quick analysis reports, improve operational efficiency, and lower operational costs. There are also some drawbacks, such as data ownership issues, privacy and security concerns for human data administration, and so on. Various algorithms are used at various stages of disease analysis and prediction.

III. PROPOSED WORK

There are several approaches to disease prediction. Therefore, the smart healthcare system helps with the prediction of common diseases. In some situations, you or a family member may require immediate medical treatment, but doctors may not be accessible due to unanticipated events, or we may not be able to find the right doctor for the care. We will try to include a smart online healthcare system in our project to address this issue. Patients may access quick assistance regarding their medical issues through this web-based application.

A. Objective

1. To predict various diseases through symptoms

2. To recommend solutions for the disease predicted

3. To learn different Machine learning algorithms

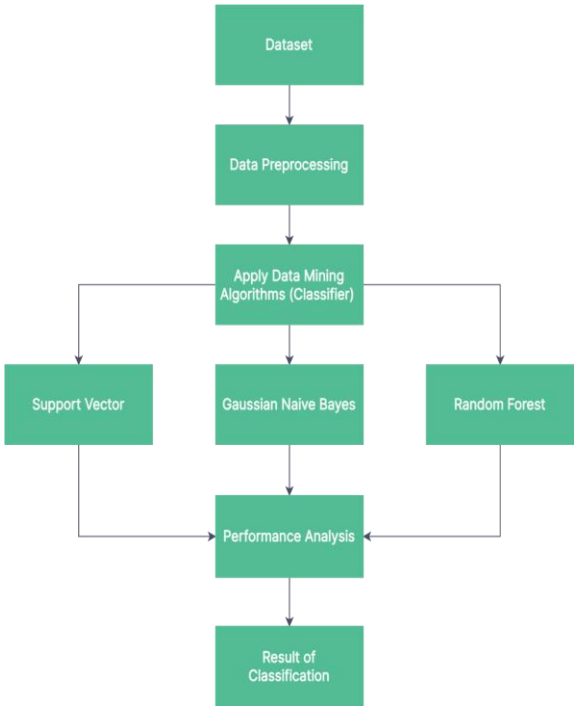

Fig 1. Block diagram for the proposed method

The first step in addressing any machine learning challenge is to prepare the data. For this issue, we'll be using a dataset from Kaggle. Two CSV files—one for training and one for testing—make up this dataset. The dataset has 133 total columns, of which 132 reflect the symptoms and the final column provides the prognosis.

The most crucial phase of a machine learning project is cleaning. The quality of our machine learning model is determined by the quality of our data. Therefore, cleaning the data is always required before feeding it to the model for training. The target column, prognosis, is a string type and is converted to numerical form using a label encoder. All the columns in our dataset are numerical.

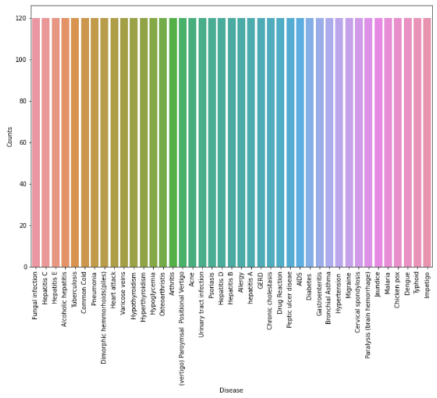

Fig 2. Diseases

The data may be used to train a machine-learning model once it has been collected and cleaned. The Support Vector Classifier, Naive Bayes Classifier, and Random Forest Classifier will all be trained using this cleaned data. To assess the models' quality, a confusion matrix will be used.

Once the three models have been trained, we will combine their predictions to forecast the illness from the input symptoms. This strengthens and improves the accuracy of our total forecast.

Fig 3. Data Flow Diagram

The next step in the process would be the recommendations that the users will get once the disease is detected. The recommendations will be provided for the diet one should follow in order to prevent the disease from becoming more serious. Do's and Don't will be recommended to spread awareness among the public. The users can also book an appointment from the Hospital recommended if needed in case of any emergency. The users' data will be stored in cloud storage so that they can access and keep a note of their Appointments and Prescriptions.

B. Methodology

The data is divided into an 80:20 structure, meaning that 80% of the dataset will be used to train the model and 20% of the data will be used to assess the model's performance. Under Machine learning, three algorithms were used for classifying and predicting the diseases i.e., SVM, Naïve Bayes, and Random Forest.

The Support Vector Classifier is a discriminative classifier, which means that it searches for the best hyperplane to divide the samples into distinct categories in hyperspace when it is given labeled training data. This algorithm is used in the initial stage for classifying the symptoms to predict the disease.

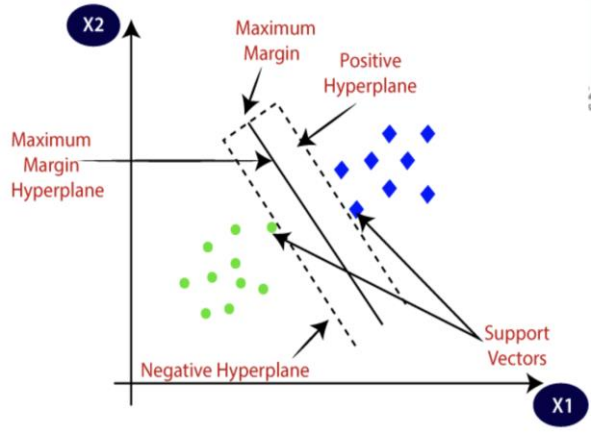

Fig 4. Diagram for Support Vector Classifier

The Naive Bayes algorithm is a classification method that is based on the Bayes theorem in predictive modeling and applies Bayesian techniques. The suggested smart healthcare recommendation system framework uses the "Naive Bayes classifier" data mining method to improve the prediction model. In order to pinpoint the precise symptom expectation, this system includes a bigger number of data indexes and features that are genuinely gathered from expert data.

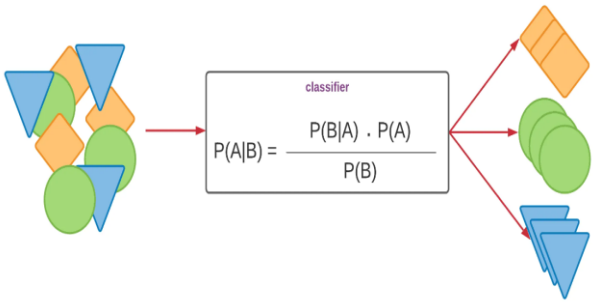

Fig 5. Diagram for Naïve Bayes Classifier

Random forest (RF) is a hierarchical grouping of base classifiers with a tree structure. Textual information often has several different aspects. There are many irrelevant characteristics in the dataset. For the classifier model, just a few significant features are informative. The RF algorithm selects the most essential relevant attribute based on a simple predetermined probability. It will be easier to classify the dataset because the accuracy of this algorithm is the highest.

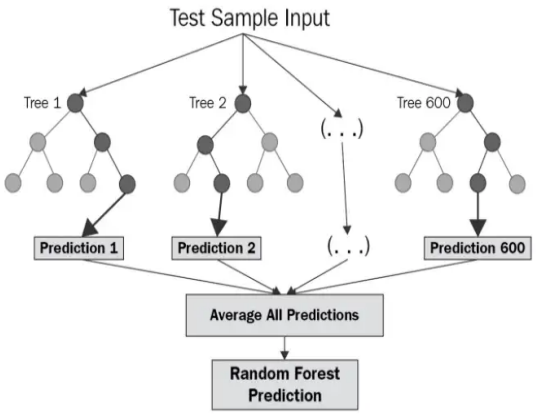

Fig 6. Diagram for Random Forest Classifier

IV. RESULTS AND DISCUSSION

The Random Forest classifier was used to create a confusion matrix on the test data, resulting in very high prediction accuracy. This classifier is known for its ability to handle complex relationships between features and avoid overfitting. It works by creating multiple decision trees and making a final prediction based on the average of the predictions made by all trees. This algorithm is simple to implement and has a good reputation for accuracy, as evidenced by the high prediction accuracy in this case. The Random Forest classifier is a valuable tool for solving problems in areas such as pattern recognition, classification, and regression.

A Support Vector Classifier (SVC) was used to create a confusion matrix on the test data. A confusion matrix is a tool used to evaluate the performance of the classifier, and in this case, the prediction accuracy was found to be very high. SVC is a popular machine learning algorithm that uses a boundary, called a hyperplane, to separate data points into different classes. The algorithm tries to find the hyperplane that maximizes the margin between the classes, meaning that it finds the line that is as far away from the closest data points in each class as possible. The SVC algorithm is particularly useful in problems with high-dimensional data, as it can effectively handle large numbers of features. The high prediction accuracy, in this case, indicates that the SVC algorithm is well-suited for this type of problem and can be trusted to make accurate predictions.

The Gaussian Naive Bayes classifier was used to create a confusion matrix on test data, resulting in high prediction accuracy. This algorithm uses Bayes' theorem and assumes that the features in the data are independent and follow a Gaussian distribution. It makes predictions based on the probabilities of each class given the data's features. The Gaussian Naive Bayes classifier is commonly used for text classification, sentiment analysis, and spam filtering, and has proven to be an effective tool in these applications. The high prediction accuracy, in this case, highlights the capability of this algorithm to make accurate predictions.

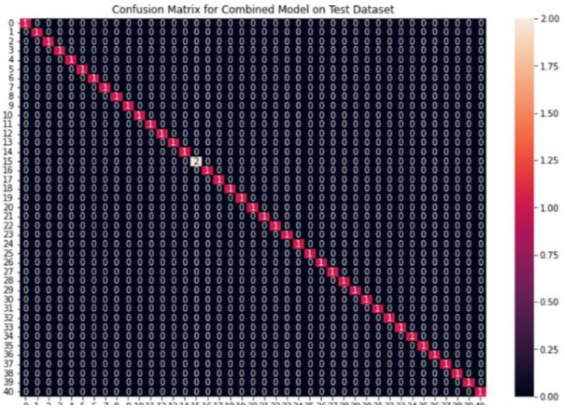

Fig 7. Confusion Matrix for the combined model

The output indicates that all machine learning algorithms demonstrate good performance with high mean scores after k-fold cross-validation. To improve the model's robustness, the predictions of the three models can be combined by taking the mode. This approach increases the accuracy of predictions on new, unseen data even if one of the models is incorrect. To accomplish this, the three models should be trained on the train data, assessed using a confusion matrix, and then combined. The combined model accurately classifies all data points. To complete the implementation, a function can be created that takes symptom inputs separated by commas and outputs the predicted disease using the combined model based on the symptoms provided.

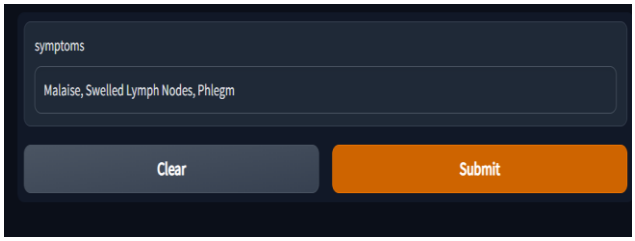

Fig 8. Symptoms input screen

On the input screen, the user must enter the symptoms that are bothering them; they can enter as many as they want before clicking the submit button to receive the prediction.

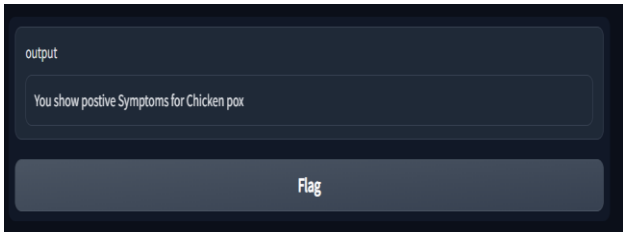

Fig 9. Result Screen

The screen above depicts the outcome of the prediction based on the symptoms entered, as well as the combined efficiency of all three algorithms for maximum accuracy.

V. CONCLUSION

The World Economic Forum reports that poor access to quality healthcare results in 6 million deaths annually in developing countries. A substantial amount of clinical data has been gathered over the years, resulting in a large pool of digital information for patient-centered decision-making. However, this information is often dispersed across various sites, making it challenging for users to find relevant information. To address this, health recommender systems (HRS) have been introduced to provide better medical recommendations. Our proposed HRS is intelligent, utilizing machine learning algorithms like the support vector classifier, Gaussian naive Bayes classifier, and random forest

classifier. By considering the mode of prediction from all three models, we aim to make more precise predictions based on new data. Unlike existing solutions, our HRS offers better personalization, with more detailed recommendations and enhanced user understanding of health.

Digital Signature Analysis using Siamese and various Deep Learning Networks

Ashish Yadav, Aman Vishwakarma, Areesha Sayed, Mrs. Shruti Mathur
Thakur college of engineering & technology Mumbai, India
ashish.2005.y@gmail.com, amanwish2001@gmail.com, areeshasayed09@gmail.com,shruti.mathur@thakureducation.org

Abstract—**This paper focuses on the application of deep learn- ing models, specifically Siamese networks and popular architec- tures in the field of signature analysis. The aim of this research is to explore the effectiveness of these models in extracting relevant features from signature images and perform classification tasks with high accuracy. The results are analyzed and compared to establish the best-performing model for signature analysis. Signatures serve as unique identifiers for individuals and are widely used as a professional element in various industries, banks, and secret organizations. Accurately identifying signatures is crucial, as forging them can cause significant inconvenience or trouble. This paper explores the latest advancements in digital signature identification. The main focus of this research is on the application of Siamese Neural Networks (SNNs) in signature analysis. SNNs consist of two identical networks for two input vectors, which are joined at a single output vector. This weight- shared twin network can be trained to learn a feature space by placing similar observations close to each other. In this study, an SNN model is created and trained on a selected dataset containing original and forged signatures. Additionally, other deep learning models, such as Convolutional Neural Networks (CNNs), VGG16, and ResNet50, were also created and tested to increase the accuracy of the output and understand their behavior. The results showed that the SNN model outperformed the other models in terms of accuracy. The paper concludes by analyzing the quantitative and qualitative aspects of the models used, providing valuable insights into their performance and behavior. This study advances the field of deep learning techniques for handwriting-based biometrics and has numerous potential applications in fields such as forensics, security, and authentication.**

Index Terms*—*Signature analysis, Siamese Neural Networks (SNNs), Convolutional Neural Networks (CNNs), VGG16, ResNet50, Quantitative and qualitative analysis, Performance and behavior

I. INTRODUCTION

In today's world, the advancement of deep learning has opened up new opportunities for research and development in various fields. The Convolutional Siamese Network, being a subset of machine learning that is based on Artificial Neural Networks, is a complex model that can be used to analyze and compare signatures in a systematic and methodical manner. In this research, we aimed to compare the performance of four different Convolutional Neural Network (CNN) models in identifying handwritten signatures. The models we used were VGG-16, ResNet50, Inception-v3 and a Siamese NN model. Our goal was to determine which model was most effective at recognizing similarities in text data within images. After comparing the results, we found that the ResNet50 model performed the best with an accuracy of 82.3% when tested on a dataset of 300 images and 86% when tested on a dataset of 140 images.

A. Siamese Network

The Siamese network operates by having two identical sig- nature networks, which are actually twin Convolutional Neural Networks (for two separate signatures) with the Rectified Linear Units (ReLU) activation function as the input layer. The twin CNNs have the same weights and configuration, and the ReLU activation function introduces non-linearity for faster computation.

During the pooling of the layers, the dimensions of the

layer are reduced step by step, grouping common entities into one single entity, reducing the dimensions of the layer and eliminating unnecessary duplicates. The rest of the paper will cover related work, methodology, results, and conclusion

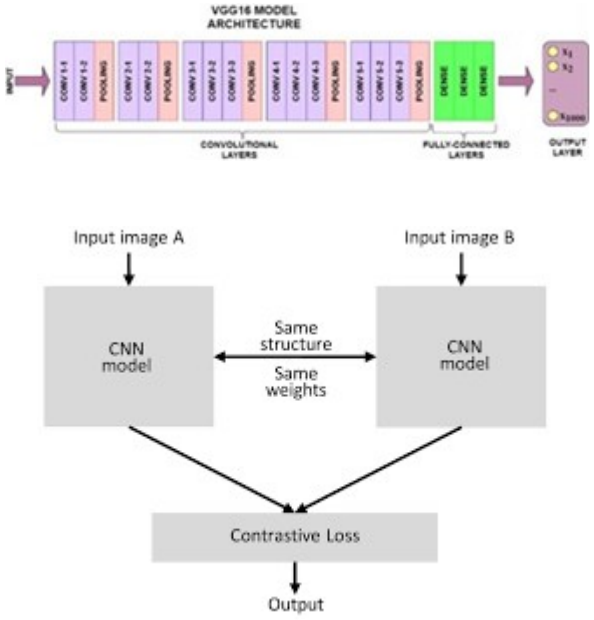

Fig. 1. Siamese Network

B. ResNet50

ResNet50 is a deep convolutional neural network architec- ture that is trained to recognize images. It was introduced in

2015 by Microsoft and won the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) that year. ResNet50 is a residual network, meaning it uses residual blocks to allow for deeper network architectures that are still able to be optimized effectively. ResNet50 has 50 weight layers, hence its name, and is commonly used for a variety of computer vision tasks such as image classification, object detection, and semantic segmentation. The model has been pre-trained on a large image dataset, so it can be easily fine-tuned for specific

tasks or fine- tuned further for even better results.

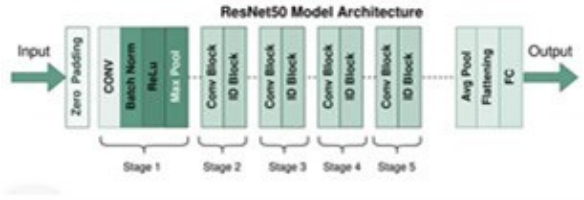

Fig. 2. ResNet50

C. VGG16

VGG16 is a popular deep learning model architecture that was developed by the Visual Geometry Group at the University of Oxford. The model was introduced in 2014 and it was used for the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) that same year. VGG16 is named after its structure of having 16 layers, which includes 13 convolutional layers and 3 fully connected layers. The model uses a series of small convolutional filters to detect and extract features from images, which are then passed through multiple layers to learn and identify patterns in the data. This architecture is characterized by its use of simple, yet deep and wide, convolutional layers, which makes it well-suited for image classification tasks. The VGG16 model has been widely used in computer vision and has been pre-trained on a large dataset, making it easy to fine- tune for other tasks.

D. InceptionV3

Inception-v3 is a convolutional neural network (CNN) architecture developed by Google for the ImageNet Large Scale Visual Recognition Challenge in 2015. It is a deep learning model designed to perform image classification and recognition tasks. The network was designed with an empha- sis on scalability and modularity, making it well suited for deployment on large-scale image recognition problems.

Inception-v3 is a deep network that consists of many layers, including convolutional layers, pooling layers, and fully connected layers. It utilizes the concept of inception modules, which are multi-branch CNN blocks that extract information from an image at multiple scales and resolutions. This allows the network to learn more diverse and robust features, resulting in improved performance on image recognition tasks.

Inception-v3 has been trained on a large dataset of images, and its pre-trained weights are publicly available for transfer learning. This allows researchers and practitioners to fine-tune the model for their own image recognition tasks, making it a popular choice for many computer vision applications.

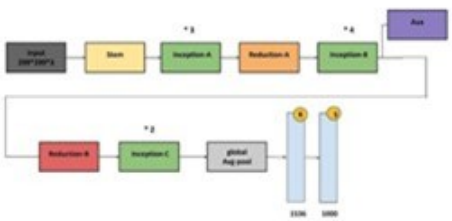

Fig. 4. InceptionV3

II. RELATED WORKS

A deep learning model for signature verification was created with two classes (real and forgery) for each user, resulting in 60 classes to predict. The model [1] uses CNNs to learn signatures and achieved an accuracy of 99.7%. It can be used in government offices for approval or authentication but the fully connected layer structure needs improvement.

The study [2] used deep convolutional neural network and SVM classifier to extract features and achieved high accuracy in recognizing Japanese, Italian, Dutch, and Chinese signatures from three datasets (SigComp2011, SigWiComp2013, and Sig- WIcomp2015). The results showed 100% accuracy for some Japanese users, and 9 out of 10 Chinese users were recognized

The Dutch signatures had an average accuracy of 96.4% for five users. The study suggests exploring other language datasets and feature techniques for future improvement.

In the proposed method [3], a neural network was constructed by optimizing some existing neural networks. The method used a data structure tree along with nodes similar to the human eye's neurons for pattern recognition. The steps involved were preprocessing, feature extraction, and neural network training.

The paper [4] proposed a CNN-Siamese based model for online signature verification. The model addresses the chal- lenges of one-shot learning and accurately learning intra- personal variations of signatures. Experiments were conducted on MCYT-330 and SVC datasets. The proposed model showed high accuracy on SVC dataset, making it suitable for real- time applications. The model was tested with varying number of samples and demonstrated better performance than recent baseline models. The results show the capability of the model to achieve excellent performance in online signature verifica- tion.

The authors of this paper [5] re-trained the classification layer of a pre-trained GoogleNet model using transfer learning with a collected signature dataset to successfully improve its accuracy. The experimental results showed a precision of

95.2% on primary signature image data.

A signature verification system [6] has been proposed and demonstrated significant results on Persian signature dataset. The accuracy of the system improved by 9.6% when 22 genuine images were used instead of 9. The False Acceptance Ratio decreased by 7.78% and the False Rejection Ratio by

14.66% with increased number of genuine images during training. The proposed system is based on Rezai et al.'s architecture and includes image processing and Autoencoder to generate forged images. The optimized features lead to a slight improvement in accuracy and reduction in FAR and FRR ratios.The input size limitations caused overfitting on smaller datasets leading to FAR issues.

In this paper [7], the authors proposed a system for identifying forged handwritten signatures using deep learning and CNNs. Five different classification models were compared including VGG-16, ResNet50, Inception-v3, Xception, and a custom CNN model. After testing on datasets of 300 and 140 images, the authors concluded that ResNet50 had the highest accuracy of 82.3% and 86%. Future work will focus on further analysis and classification of the characteristics of handwritten signatures using the best performing model, ResNet50.

III. FUNDAMENTAL OF DEEP LEARNING

Deep learning is a subfield of machine learning that uses algorithms inspired by the structure and function of the brain, called artificial neural networks, to process and analyze large amounts of complex data. It enables computers to learn and make decisions on their own, without being explicitly programmed. The fundamental idea behind deep learning is to use multiple layers of artificial neurons, each layer building upon the previous one, to perform hierarchical representations of the input data. The layers in a deep learning model are trained using large amounts of labeled data, allowing the model to learn patterns and relationships in the data, and make predictions based on those patterns. Deep learning algorithms have been successfully applied to a variety of tasks such as image and speech recognition, natural language processing, and autonomous decision-making systems.

A. Convolutional Neural Network (CNN)

Convolutional Neural Networks (CNNs) are a type of deep learning technique used for computer vision tasks such as image classification, object detection, semantic segmentation, and image generation. They are designed to process grid- like data such as images and are inspired by the structure of the visual cortex. The main building block of a CNN is a convolutional layer, which performs a convolution operation on the input image to create a feature map that contains activations for different features. CNNs also incorporate pool- ing layers for down-sampling and fully connected layers for final classification or regression. The weights of the CNN are learned through the backpropagation algorithm, updating weights based on errors between predictions and ground truth labels. CNNs have proven successful in image classification tasks and their architecture can be optimized using techniques such as transfer learning and data augmentation. Siamese Network and various Deep Learning model used in this paper is primarily based on CNN.

B. Dataset- Handwritten Signatures (kaggle)

The dataset consists of 60 signatures, 30 of which are genuine signatures created by the respective signatory and the other 30 are forged signatures made by someone else. Each person has 5 genuine and 5 forged signatures. The naming of the images follows a specific convention: ”NFI” indicates that it is a signature image, followed by the signatory number (two digits), the forger number (two digits), and the date of the signature (four digits). For example, ”NFI-00602023” represents a forged signature of person 023 created by forger 006 on 2023. ”NFI-02103021” represents a genuine signature of person 021 made by the same person on 021.

Fig. 5. Arrangement of signatures via id

Fig. 6. Genuine and Forged Signatures

IV. RESULT AND DISCUSSION

The signature verification system trains the dataset in batches and calculates the distance metric during the process. During signature verification, the calculated distance metric is compared to a constant threshold value to determine the authenticity of the signature. The used distance metric is the Euclidean distance, which is incorporated into the loss function. It was discovered that using an adaptive threshold during the final stage of preprocessing significantly improved the signature verification process. The results obtained from the verification process, based on the distance value, improved the accuracy of classifying the signatures as authentic or forged. The system’s accuracy was found to be 76% when tested on the cedar dataset.

Fig. 7. Predict the Genuity of a Signature

A. FUTURE SCOPE

In the future, our aim is to transform this project into a tool that can be integrated with various software for authentication purposes or perhaps as a browser extension. Before making it accessible to a wider customer base, we will explore all possible options. The future of our website lies in utilizing social media content effectively, as it attracts more followers. Thus, bloggers need to be mindful of how they can use their

content to maximize their social media presence and achieve their desired goals.

Recently, many large media companies have entered the

blogging arena, seeking to increase their sales. Furthermore, search engines like Google favor established brands and websites with high domain authority, making it challenging for small businesses to compete. To overcome this, small and medium companies should position themselves as experts in their field through high-quality content, attracting more customers. As a result, they may choose to hire professional blog writers to produce content for well-established platforms.

V. CONCLUSION

In this paper, we utilized the DL models along with Convo- lutional Siamese Network, a type of Artificial Neural Network, for signature verification. The model trains on the dataset to identify the unique patterns in signatures and determine if they are authentic or not. There is significant potential for using such models in future applications for prediction and verifi- cation purposes. This project will inspire more competition and research in the field to improve the accuracy of neural network models, making them more suitable for solving real- world problems.

We have created a highly effective signature verification

system that incorporates Image Processing, a popular and widely used domain for applications such as image detection and fingerprint verification. This system reduces human error in signature verification and improves accuracy, efficiency, and speed. The system is user-friendly, requiring no prior knowledge of Image Processing. If adopted by banks or companies, this system will provide customers with a greater sense of security and trust. Thus, we propose that this system brings about a change in the way banks, companies, and others handle signature verification.

Abstract— Automatic Face Recognition (AFR) has created a revolution in this changing world. It has ensured us with more safety of our data. Smart attendance using Face Recognition comes handy in day to day activities. The purpose of this project is to build attendance management system based on face recognition, Face recognition is an important application of Image processing owing to its use in many fields. Identification of candidate in an organization for the purpose of attendance is an application of face recognition. Managing attendance can be a tedious job when implemented by traditional methods like calling out roll calls or taking a student's signature. To solve this issue, a smart and authenticated attendance system needs to be implemented. Various algorithms and techniques has been used for improving the performance of face recognition. The concept we are using here is Open CV. We are also using Raspberry Pi and camera module to take image and storing them in database. This way the attendance will be automated.

I. INTRODUCTION

Liveness detection is the ability of a system to detect whether the obtained biometrics is real or fake. Liveness check uses algorithms that analyse data after they are collected from biometric scanners and readers to verify if the source is coming from a fake representation. A facial recognition system is computer app which takes multiple photos of the person and it stores the data of face of that person and when the person again comes in front camera, it is able to verify that person. We give the basic information of student like, roll no., name. The method we are using is Open CV. It takes around 100 images of that person and stores the data. Now a days attendance is a very important part for student as well as teacher of an organization. The person in photos and in real time videos can be identified using facial recognition systems. It is a tier of biometric security. Other types of biometric security are voice, fingerprint and eye recognition. In real time we can use it to unlock phones, find missing persons, aid forensic investigations, help the blind, etc. The main aim of this project is to build an attendance system based on face recognition. The Attendance System using Face – Recognition is a replacement way method for the traditional way of marking attendance. Attendance systems using face recognition provide authenticated data also proxy data entering chances are much less as compared to other systems. In the proposed system, at the time of enrolment, video is captured and images of students are stored through facial detection, recognition and recorded in a database. In real time, video of a student entering a classroom will be captured, face will be detected and matched with the dataset images, name & roll number of the present student will be displayed along with updating the attendance.

II. RELATED WORK

Face is a unique identity of any person. It is used in many domains and is the fastest growing research area. Many systems are being proposed for attendance management. One of the systems [1], generates a smart attendance system which uses Quick Response (QR) code to track & record the attendance. Students and professors are given a unique QR code, at the beginning of the course, they are required to scan their QR code using a QR reading device. Attendance of students whose QR code is scanned will be recorded. This system is responsive to mobile phones and different computer systems.

A reliable attendance monitoring system based on biometric is developed, which is used to monitor the presence of students in a more effective way. It reduces the chances of marking proxy attendance and also reduces the problems like missing papers of attendance, which occur during marking attendance manually. Teachers have a small fingerprint scanner with them and students will press their finger on it to mark their attendance. Attendance management systems using Iris recognition [3], are more reliable and accurate because of the inner characteristics of iris like uniqueness, time invariance, immovability etc. The Iris pattern of each student is used for attendance. By using the camera live images of student iris are captured and stored in a database. Gray coding algorithm is used for measuring radius of iris and then that radius is matched with the radius of each student in the database and attendance of that student will be marked.

In one of the proposed models, two databases (face database & attendance database) are used. During enrolment, facial images of students are stored into the face database. The camera captures the images of the classroom, the images get enhanced and the attendance is marked in the attendance database after face detection & recognition. AdaBoost algorithm and Principal Component Analysis (PCA) are used for face detection and face recognition respectively. The LBPH algorithm [5], can recognize the front face as well as side face with approximate accuracy of 90%. The flow of this algorithm starts with dividing the image into blocks and calculating the histogram of each block, then combining the histogram of all the blocks into a single histogram. This histogram has some value which is used for comparing later with the real time image histogram for identification. Multiple faces can be detected in a single detection hybrid process of Haar cascade and Eigenfaces method are used [6]. This process is able to detect multiple faces with an

accuracy of

91.67%. By using this method, we can recognize faces during day and night time and are also able to detect 15 degrees side facing faces. By using a webcam this process can successfully perform at more than 200 cm.

One of the methodologies [7], considers accuracy rate, stability of system in actual time video processing, truancy of system and interface setting of the face recognition system. Face detection and recognition are two main parts of face recognition. Feature extraction is done by the LDA (Linear Discriminant Analysis) method. This model takes help of methods such as geometric Feature method, Subspace analysis method, Neural Network methods, Support Vector Machine (SVM) method to develop their face recognition algorithm. Experimentally this model of video face recognition system gives an accuracy rate up to 82%

Face Recognition-based Lecture Attendance System proposed a system that takes the attendance of students for classroom lecture. The system takes attendance automatically using face recognition. However, it is difficult to estimate the attendance precisely using each result of face recognition independently because the face detection rate is not sufficiently high. In this paper, we propose a method for estimating the attendance precisely using all the results of face recognition obtained by continuous observation . The Attendance management is the significant process that were carry out in every institute to monitor the performance of the student. Every institute does this is its own way. Some of there institute use the old paper or file-based system and some have adopted strategies of automated attendance system using some biometric technique. A facial recognition system is a computerized software which is suited for determining or validating a person by performing comparisons on patterns based on their facial appearances. In this system OpenCV & Face Recognition libraries were used which are one of the popular libraries for face detection by using these libraries system first capturing the student photos and storing them into the database which were further used for the training purpose after that at the time of attendance when system camera get on system will detect the faces that were present in the frame the faces were detected by using HOG i.e. (Histogram of Oriented Gradients) which were carrier out in the system. after that if image that were present in the frame is tilted then Face Landmark Estimation algorithm will be carried out and face will be transformed to be as close as possible to perfectly cantered.

III. IMPLEMENTATION

Image acquisition:

Image is acquire using a high definition camera which is placed in the classroom or lab. This image is given as an input to the system.

Dataset Creation:

Dataset of student is created before the recognition process. Dataset was created only to train this system we are going to create a dataset of the whole class which involve their name, roll number department and images of the student in different variations. Whenever we register student's data and image in our system to create dataset, deep learning applies to each face to compute 128-d facial features and store in student face data file to recall that face in recognition process. This process is applying to each image taken during registration.

Face Detection and Extraction:

Face detection is important as the image taken through the camera given to the system, face detection algorithm applies to identify the human faces in that image, the number of image processing algorithms are introduced to detect faces in an image and also the location of that detected faces. We have used HOG method to detect human faces in given image.

Face Positioning:

There are 68 specific points in a human face. In other words, we can say 68 face landmarks. The main function of this step is to detect landmarks of faces and to position the image. A python script is used to automatically detect the face landmarks and to position the face as much as possible without distorting the image.

Face Encoding:

Once the faces are detected in the given image, the next step is to extract the unique identifying facial feature for each image. Basically, whenever we get localization of face, the 128 key facial point are extracted for each image given input which are highly accurate and these 128- d facial points are stored in data file for face recognition.

Fig 1. Activity Diagram of the

Face is a unique identity of any person. It is used in many domains and is the fastest growing research area. Many systems are being proposed for attendance management. One of the

systems [1], generates a smart attendance system which uses Quick Response (QR) code to track & record the attendance. Students and professors are given a unique QR code, at the beginning of the course, they are required to scan their QR code using a QR reading device. Attendance of students whose QR code is scanned will be recorded. This system is responsive to mobile phones and different computer systems. A reliable attendance monitoring system based on biometric is developed [2], which is used to monitor the presence of students in a more effective way. It reduces the chances of marking proxy attendance and also reduces the problems like missing papers of attendance, which occur during marking attendance manually. Teachers have a small fingerprint scanner with them and students will press their finger on it to mark their attendance. Attendance management systems using Iris recognition [3], are more reliable and accurate because of the inner characteristics of iris like uniqueness, time invariance, immovability etc. The Iris pattern of each student is used for attendance. By using the camera live images of student iris are captured and stored in a database. Gray coding algorithm is used for measuring radius of iris and then that radius is matched with the radius of each student in the database and attendance of that student will be marked. In one of the

proposed models [4], two databases (face database & attendance database) are used. During enrolment, facial images of students are stored into the face database. The camera captures the images of the classroom, the images get enhanced and the attendance is marked in the attendance database after face detection & recognition. AdaBoost algorithm and Principal Component Analysis (PCA) are used for face detection and face recognition respectively. The LBPH algorithm [5], can recognize the front face as well as side face with approximate accuracy of 90%. The flow of this algorithm starts with dividing the image into blocks and calculating the histogram of each block, then combining the histogram of all the blocks into a single histogram. This histogram has some value which is used for comparing later with the real time image histogram for identification. Multiple faces can be detected in a single detection hybrid process of Haar cascade and Eigenfaces method are used [6]. This process is able to detect multiple faces with accuracy.

A facial recognition system is a computerized software which is suited for determining or validating a person by performing comparisons on patterns based on their facial appearances. In this system OpenCV & Face Recognition libraries were used which are one of the popular libraries for face detection by using these libraries system first capturing the student photos and storing them into the database which were further used for the training purpose after that at the time of attendance when system camera get on system will detect the faces that were present in the frame the faces were detected by using HOG i.e. (Histogram of Oriented Gradients) which were carrier out in the system. after that if image that were present in the frame is tilted then Face Landmark Estimation algorithm will be carried out and face will be transformed to be as close as possible to perfectly centered. After that system will encode all the images that were present in the database as well as the face which were detected in the frame. For performing encoding Deep Conversional Neural Network algorithm will get carried out & for each face 128 measurements were generated then the measurements of the face that were detected in frame it get compared with the measurements of the faces that were present in the image which is earlier stored in the database. So at last by using simple liner SVM algorithm system will find the person in database of know peoples (i.e. capture at the starting of the project) who has closest measurements to the image that were detected by camera. After finding perfect match system will generate the name and date & time & present mark and store the entry in CSV file. Which were further uploaded on the database.

IV. RESULT

The main working principle of the project is that, the video captured data is converted into image to detect and recognize it. Further the recognized image of the student is provided with attendance, else the system marks the database as absent. The model will identify the face of the person in front of the camera and check with the database of images and mark the student accordingly. This will help in automating the entire process of taking attendance manually.

V. FUTURE SCOPE

The future scope of the project can be integrated with the hardware components for example GSM through which a monthly list of the defaulter students can be sent to the mentor. Additionally, an application can be developed to help students to maintain a track of their attendance. It can also be used in offices where a large group of employees sit in a hall and their attendance will be marked automatically by capturing a video but for this the accuracy of the recognition needs to be improved.

VI. CONCLUSION

In order to obtain the attendance of individuals and to record the entry and exit, the proposed system can be used. The system can widely be used in the institutions/organizations. The proposed system takes attendance of each student by continuous observation at the entry and exit points.The proposed system has a much simpler and efficient algorithm. The system is simpler because of use easy and user- friendly Framework. It has a more efficient algorithm along with much less complex database configurations. The system is more efficient because of being platform independent. Attendance management system using face recognition is designed to solve the issues of existing manual systems. To avoid proxy attendance, security of Dataset and Database is important.by this system manual attendance can be eliminated and time is saved. As this system does not require touching anything so risk of germs transmission is also eliminated.

Abstract—**Deep learning (DL) models have attained significant recognition in several domains such as speech recognition, object detection, amongst others. However, deployment of such models on edge devices, such as smartphones and embedded systems, faces challenges such as limited computational resources, memory constraints, and power consumption. In order to overcome these challenges, DL model quantization techniques have been proposed to condense model size and computational complexity, while preserving its accuracy. This study presented a thorough analysis of the most recent developments in DL model quantization approaches for edge devices, and it also categorized quantization techniques into two types, i.e., post training quantization and quantization-aware training. Moreover, a comprehensive examination of various quantization techniques are reviewed, thereby highlighting their pros and cons. It also compared the accuracy of different quantization methods across different DL models. In addition, this study discussed research challenges and future directions for DL model quantization for edge devices. The purpose of this study was to offer researchers and practitioners a comprehensive understanding of DL model quantization techniques.**

Keywords—Deep Learning, Deep neural networks, TensorFlow, Quantization.

I. INTRODUCTION

Deep learning (DL) is a field within machine learning (ML) that specializes in designing artificial neural networks composed of multiple layers for identifying patterns in big data sets. This concept is based on the structure and operations of the human brain that can be used to solve challenging tasks, namely image classification, natural language processing, and decision-making. DL algorithms are trained through massive amounts of data and iterative tuning of parameters, allowing them to learn and make decisions on their own without explicit programming. Artificial neural networks (ANNs) with several hidden layers, often known as deep neural networks (DNNs), are utilized in DL. The goal of DL is to allow artificial systems to learn from vast amounts of data and make decisions without explicit programming, by mimicking the structure and function of the human brain [1].

Due to the extensive layer and neuron count in deep neural networks, the storage requirements and computational demands are significant. Following Table I displays some of the well-known deep convolutional neural networks (DCNNs) and their specifications for storage and computation (with multiply-accumulate (MAC) being the dominant operation in DNNs) [2].

TABLE I. SPECIFICATIONS OF DCNNS [2]

DCNN	Input Size	No. of convolutional layers	No. of FC layers	Total weights	Total MACs
AlexNet	227 × 227	5	3	61M	724M
OverFeat	231 × 231	5	3	146 M	2.8G
VGGNet-16	224 × 224	13	3	138 M	15.5G
GoogleNet (Inception-V1)	224 × 224	57	1	7 M	1.43G
ResNet-50	224 × 224	49	1	25.5 M	3.9G
SqueezeNet	224 × 224	26	0	1.2 M	1.7G
MobileNetV1	224 × 224	27	1	4.2 M	569M
ShuffleNet	224 × 224	49	1	1.4 M	140M

The vast number of parameters and calculations involved in DNNs pose challenges and result in slow processing using traditional hardware, particularly during inference when hardware resources are limited. To fully utilize the potential of DNNs, optimization of their processing is crucial.

Many real-world applications demand quick decision-making abilities similar to those of humans, such as detecting various objects on the road in real-time for a self-driving car [3]. In such scenarios, it is crucial to perform these computations locally in real-time. It is difficult to reduce the number of parameters while also developing a model that can work within the constraints of edge devices. Large models with a high number of parameters take longer to process inputs during inference, consume more energy, and require more storage compared to smaller networks with fewer parameters [4]. Lowering the complexity of the parameters and removing unnecessary connections can improve the ML/DL model's performance, reducing computation time and energy consumption. Before deploying the trained model to resource-constrained devices, it is therefore necessary to reduce its size.

II. REVIEW OF EXISTING LITERATURE

Gong *et al.* [5] and Wu *et al.* [6] employed K-means clustering on the weight values in the parameter space for quantization, which compressed the network weights after training and reduced storage and computational complexity8-bit quantization of the parameters has been shown to significantly increase speed with minimal loss of accuracy [7].

Suyog *et al.* [8] showed that limiting all parameters to 16-bit values can significantly reduce memory consumption and the number of floating-point operations while preserving precision.

In order to make deep neural networks smaller, S. Han *et al.* [9] devised a weight quantization approach that minimizes the number of bits required to encode the weight matrix. This approach reduces the amount of memory required by eliminating duplicate weights and consolidating multiple connections into a single weight. For instance, the weights are quantized into four bins in a DL model with four neurons in both the input and output layers, with each bin having the

same value. This results in smaller indices for each weight that must be stored during deployment on an embedded device.

It is possible to compress deep networks using network quantization by using binary, low precision, or quantization to lessen the number of bits desired to represent each weight. Traditional deep networks frequently employ floating-point precision for both inference and training, such as 32-bit precision, which results in significant computational costs, memory requirements, and storage needs. However, multiple research [10–12] have developed reduced bit-width models that, by quantizing both activations and weights, retain good accuracy.

Jacob *et al.* [13] introduced a quantization method that employs integer arithmetic for inference, which is more efficient than floating-point operations and requires fewer bits for representation. The authors designed a training step to preserve accuracy while substituting floating-point operations with integer operations. The trade-off between accuracy loss and on-device delay associated with employing integer operations is balanced by this method. In this method, integer arithmetic is used for inference and floating-point operations are used for training.

III. Deep Neural Networks

Deep neural networks (DNNs) are a type of artificial neural network that consists of several layers of interconnected nodes, or artificial neurons [14]. They are called "deep" because they have multiple hidden layers, which are responsible for learning complex representations of data. Each artificial neuron receives inputs, performs a computation on those inputs, and produces an output. The outputs of one layer of neurons are fed as inputs to the next layer, and so on, until the final layer produces the network's output.

The computations performed by each neuron are based on a set of learned weights, which are updated during training to diminish the error between the network's predictions and the actual target outputs. These weights are often updated using an optimization procedure like gradient descent, which moves the weights in the direction of the error reduction. The training process for DNNs typically involves large amounts of labeled training data and can be computationally intensive. However, the end result is a network that is capable of making accurate predictions on new, unseen data.

DNNs have proved effective in a variety of applications, including speech recognition, recommender systems, computer vision, natural language processing, robotics, and healthcare, among others. This is due to the fact that they can handle high-dimensional and noisy input data as well as automatically develop complicated representations of data. DNNs are a powerful tool in the field of ML, but they also have limitations, including the risk of overfitting and the need for large amounts of training data. In spite of this, study on them is still ongoing and are likely to play an increasingly vital role in many fields in the future [14].

A Deep Neural Network (DNN) architecture typically consists of the following components [15]:

- **Input Layer:** This layer receives the input data and passes it to the next layer.
- **Hidden Layers:** These are multiple layers in between the input and output layers. The hidden layers are where the computation happens, and the layers learn to extract features from the input data.
- **Output Layer:** This layer provides the final prediction based on the computation of the hidden layers.
- **Activation Functions:** To add non-linearity to the network, activation functions are added to each neuron's output. Common activation functions include ReLU, sigmoid, and tanh.
- **Weights and Biases:** Weights are used to multiply the input data, and biases are added to the result to shift the activation function. These weights and biases are learned during the training process.
- **Loss Function:** The difference between the output that really occurs and the output that was expected is calculated using a loss function. This loss is used to guide the learning process and update the weights and biases.

A DNN architecture diagram shown in Fig. 1 consists of nodes, representing neurons, connected by arrows, representing the flow of data.

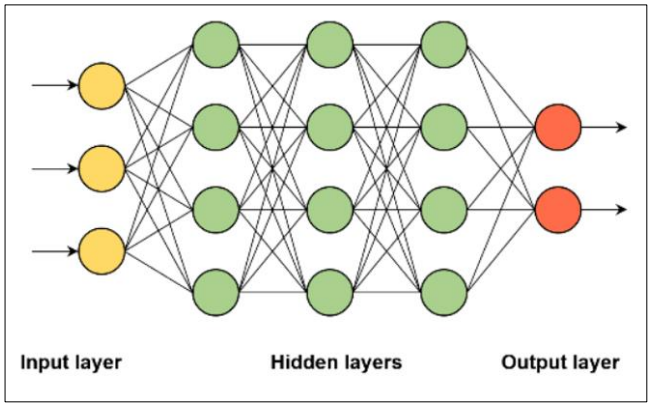

Fig. 1. Deep Neural Network (DNN) Architecture [15]

In Fig. 1, the left side of the figure represents the input layer as a collection of nodes, while the right side of the diagram represents the output layer as a set of nodes. The hidden layers are represented as sets of nodes in between the input and output layers. The arrows represent the flow of data, with each arrow representing the connection between two neurons and the weight of the connection represented by the thickness of the arrow.

There are several types of Deep Neural Networks (DNNs), including [16]:

- **Feedforward Neural Networks:** These are the simplest type of DNNs. The data flows only in one direction, from input to output, through a series of interconnected layers of artificial neurons. These networks are trained via supervised learning, in which the weights and biases of the neurons in each layer are updated using the input and intended output data until the network's predictions match the desired outputs.
- **Convolutional Neural Networks (CNNs):** These are DNNs designed specifically for image recognition and classification tasks. The use of convolutional layers, where each neuron in the layer

is coupled to a tiny, local part of the input data, is the main novelty of CNNs. As a result, the network may learn input data properties that are resistant to translation, scaling, and rotation. The final prediction is then produced by processing the outputs of the convolutional layers by a number of fully connected layers.

- **Recurrent Neural Networks (RNNs):** These are DNNs that allow data to flow in loops, allowing the network to maintain a memory of past inputs and use it to inform future predictions. This makes them well-suited to sequential data such as speech, text, or video. RNNs use a hidden state vector to store information about the past inputs, which is updated at each time step as new data is processed. Based on the network's final hidden state, the final prediction is created.
- **Autoencoders:** These are unsupervised DNNs used for dimensionality reduction and feature learning. Autoencoders have an encoder section that compresses the input data into a lower-dimensional representation, and a decoder section that takes the lower-dimensional representation and reconstructs the original data. During training, the autoencoder learns to minimize the reconstruction error, effectively learning a compact representation of the input data that retains its most important features.
- **Generative Adversarial Networks (GANs):** These are DNNs used for generative tasks, such as creating realistic images, videos, or text. GANs are made up of a discriminator network and a generator network, which work together to separate actual data from fake data. The generator competes with the discriminator during training by attempting to make data that the discriminator is unable to differentiate from actual data. The generator eventually has the ability to produce extremely realistic data that the discriminator is unable to differentiate from actual data.
- **Transformers:** These DNNs are employed in natural language processing tasks including text production and machine translation. Transformers use self-attention mechanisms to allow each word in a sequence to attend to all other words in the sequence when making predictions. This allows them to capture long-range dependencies in the data, making them well-suited to tasks such as machine translation, where the meaning of a word depends on the context of the entire sentence.

IV. Quantization in Deep Learning

Quantization is the process of reducing the accuracy of the numbers used to represent a neural network's parameters in DL [17]. Precision can be decreased with just a slight loss in accuracy, allowing for a reduction in the memory and computation needs when deployment on hardware devices. The most prevalent type of quantization in DL is utilizing less data to signify weights and activations, such as 8-bit values instead of 32-bit ones. The quantization process involves training the network with quantization-aware techniques and fine-tuning it to the quantized representation. A 32-bit floating point integer is used to hold weights in DNNs.

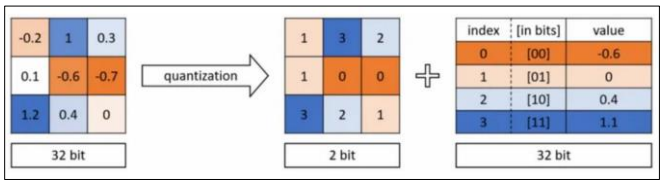

Fig. 2. Quantization [17]

In order to make a neural network smaller, a method called quantization reduces the accuracy of the weights and activations. To do this, the number of bits used to represent each weight is decreased, for example, from 32 bits to 16 bits, 8 bits, 4 bits, or 1 bit. This reduction results in a smaller size of the deep neural network (DNN). It's vital to consider that quantization may also result in a decline in accuracy, and finding the right balance between model size and accuracy is essential [17].

An open-source platform called TensorFlow Lite makes it possible to use ML models on edge devices. Quantization is one of the methods used by TensorFlow Lite to lower the memory and computational expenses of DL models during deployment. In order to save memory and speed up inference, this method includes lowering the precision of the network's weights and activations, often from 32-bit to 8-bit integers. In order to reduce the impact on accuracy, the quantization method entails quantizing the weights and activations during training and adjusting the quantized model. TensorFlow Lite also provides tools for quantization-aware training, where the model is trained with quantization-related operations to improve its accuracy after quantization.

In comparison to utilizing the conventional complicated DNN model, we may get a number of benefits by quantizing the DNN model [18]. Here are a few of these advantages:

• *Storage capacity:* The DNN model has a high degree of accuracy because of its many parameters, which need a lot of storage [19, 20]. The DNN model may be deployed more easily on devices with constrained resources by compressing it to conserve storage space.

• *Computation requirements:* Resource Constraint Devices (RCDs) may not be able to handle the huge volume of FLoating point OPerations (FLOPs) needed for DNN operations [21]. Therefore, it may be advantageous to use DNN compression to lessen the need for computation.

• *Earliness:* The DNN model's inability to provide real-time predictions is hampered by the length of time required for both training and prediction [22, 23]. DNN compression approaches have been created to quicken both the training and prediction stages in an effort to increase efficiency.

• *Privacy:* When sending data from the source to a high-performance computer, security flaws and privacy losses may occur [24]. Using compressed DNN models on RCDs with in-situ processing to secure sensitive data is advantageous since it guarantees data security and upholds privacy.

• *Energy consumption:* DNN compression is a preferable option for Internet of Things (IoT) devices that use batteries since it consumes less energy when processing data [25].

V. TensorFlow Lite (TFLite)

TensorFlow Lite is an open-source platform created by Google that enables deployment of ML models on devices with limited resources like smartphones, microcontrollers, and embedded systems [26]. TensorFlow Lite provides an easy-to-use API for developing and training ML models, as well as tools for converting these models to a compact binary format for deployment on edge devices. The binary format is optimized for efficient execution on these devices and can run without the need for a full-fledged ML framework. TensorFlow Lite also supports hardware-accelerated inference on certain devices, further increasing the performance and efficiency of deployment. In conclusion, TensorFlow Lite offers a compact and effective framework for implementing ML models on edge hardware.

The internal architecture of TensorFlow Lite consists of several key components [27]:

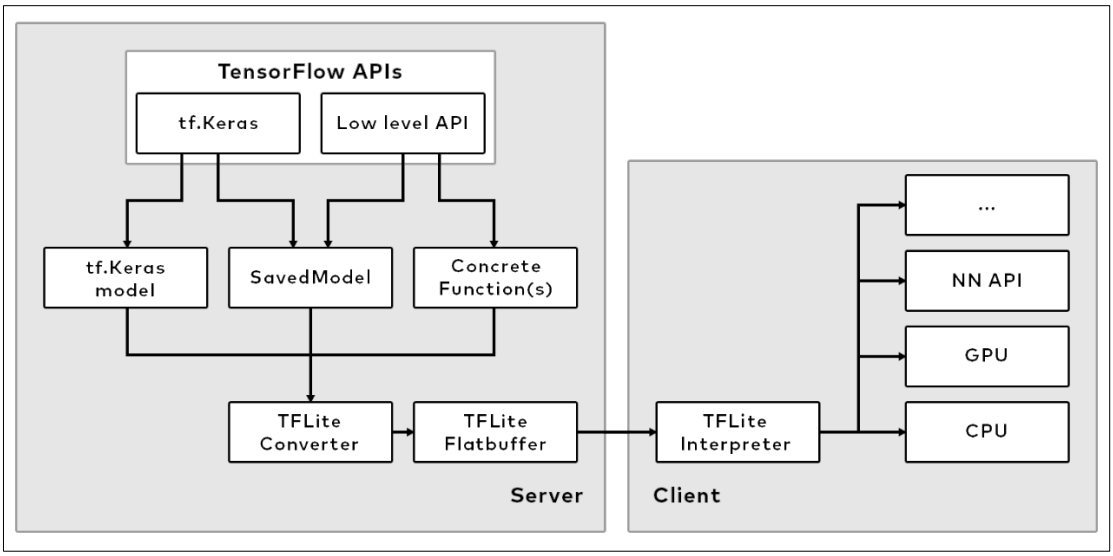

Fig. 3. TensorFlow Lite Internal Architecture

A. Model Interpreter: This is the core component that executes the model on the target device. It takes the input tensors, runs the operations defined in the model, and returns the output tensors.

B. Model Converter: This component converts a TensorFlow model into the TensorFlow Lite binary format, which can be executed by the Model Interpreter. The conversion process involves optimizing the model for deployment on edge devices, such as quantizing the weights and activations and reducing the model size.

C. Hardware-Specific Acceleration: TensorFlow Lite supports hardware acceleration on certain devices, such as GPUs and DSPs. The Model Interpreter takes advantage of these accelerators to improve the performance of inference.

D. Memory Management: TensorFlow Lite provides efficient memory management for deployment on resource-constrained devices. It uses a memory-mapped file to share tensors between the model and the application, reducing memory overhead and improving performance.

E. Operator Kernel Library: This is a collection of optimized low-level implementations of operations that can be executed by the Model Interpreter. TensorFlow Lite provides a default set of kernels, but also allows custom kernels to be implemented for specialized operations.

VI. Quantization techniques

Quantization can take place during model training or after model training. Post-training quantization and quantization-aware training are the two types of quantization.

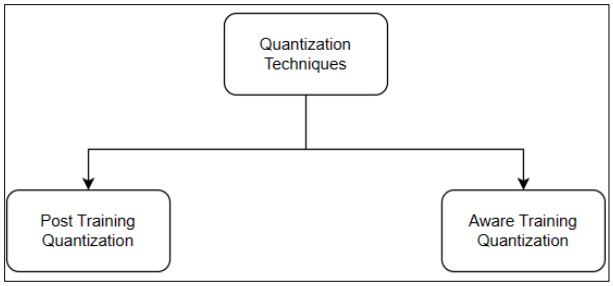

Fig. 4. Types of Quantization Techniques

A. Post Training Quantization: The model's weights and activations are quantized after the training procedure is complete in a technique known as post-training quantization [28]. This approach is typically used to reduce the memory and computational requirements for deploying the trained model on hardware devices with limited resources. In post-training quantization, the model is trained on floating-point data initially, and then the weights and activations are quantized to use lower-precision representations, such 8-bit integers or 16-bit floating-point data. The quantization process can be performed using various methods, including simple rounding, k-means clustering, and Min-Max scaling. Post-training quantization can result in a small degradation in model accuracy, which is often acceptable for many practical applications. In some cases, fine-tuning the quantized model can further improve accuracy. In conclusion, post-training quantization offers a quick and effective method for deploying deep neural networks on low-power and resource-constrained devices while maintaining high accuracy.

The process of post-training quantization usually involves the following steps [28]:

- Freeze the model: The first step is to freeze the model, which means to stop training and preserve its weights and biases.
- Evaluate the model: The next step is to evaluate the frozen model on a validation dataset to measure its accuracy.
- Quantize the model: The quantization process involves converting the floating-point weights and activations to lower precision fixed-point representations. The most common quantization methods are dynamic quantization and static quantization.
- Fine-tune the quantized model: After quantization, the model's accuracy may drop slightly, so the model is fine-tuned on the validation dataset to recover its accuracy.
- Deploy the quantized model: Finally, the quantized model is deployed for inference on devices such as smartphones, edge devices, or embedded systems.

B. Aware Training Quantization: Quantization-Aware Training (QAT) is a type of quantization in deep neural networks where the model is trained with quantization in mind. In other words, during the training process, the model is exposed to the quantization process and its effects on the gradients and forward computations. With QAT, the gradients are more precise and the model's accuracy is better preserved during quantization since the weights and activations are quantized during training and the quantization error is taken into consideration during backpropagation [28]. Compared to post-training quantization, QAT can result in better accuracy for quantized models and can avoid the fine-tuning step required in post-training quantization. However, it can be computationally more expensive, as the quantization process must be performed during training. In conclusion, compared to post-training quantization, quantization-aware training is a more sophisticated quantization strategy that can improve model accuracy but has a larger computational cost.

The process of quantization aware training usually involves the following steps [28]:

- Design a quantization-aware training process: In this step, the training process is designed to take quantization into account. This may involve adding quantization-aware layers or operations to the model, or modifying the loss function to penalize quantization-related inaccuracies.
- Train the quantization-aware model: The quantization-aware model is trained on the training dataset, and its accuracy is monitored during training.
- Evaluate the quantized model: After quantization, the accuracy of the learned model is assessed using a validation dataset.
- Fine-tune the quantized model: The quantized model can be adjusted if necessary to regain accuracy following quantization.
- Deploy the quantized model: The quantized model is then used for inference on systems like embedded systems, cellphones, and edge devices.

In this study, the accuracy of three widely used models were compared when they utilized either floating-point values, quantization aware training, or post-training integer quantization.

TABLE II. COMPARISION OF DIFFERENT QUANTIZATION TECHNIQUES WITH THEIR ACCURACY

Model	**Floating - point baseline model**	**QAT Model**	**Post-training full integer quantized model**
Mobilenet v1 1.0 224	71.03%	71.06%	69.57%
Mobilenet v2 1.0 224	70.77%	70.01%	70.2%
ResNet v1 50	76.3%	76.1%	75.95%

The observations from the above table are as follows:

1. When comparing accuracy, post-training integer quantization is frequently outperformed by Quantization Aware Training.
2. The floating-point baseline model is even more accurate than quantization aware training.
3. Post-training integer quantization often has lower accuracy.

VII. CHALLENGES AND FUTURE SCOPE

Deep neural network quantization is a method for lowering the memory and processing needs of neural network models, enabling their use on hardware with constrained resources, such as embedded systems and mobile devices. Quantization, however, also brings with it some challenges and restrictions. One challenge is the loss of accuracy that can occur during quantization, especially with high-precision models. This is because quantization reduces the number of bits used to represent each weight and activation, leading to a loss of information. The trade-off between quantization error and model accuracy can be addressed by finding an appropriate quantization scheme and using techniques such as fine-tuning and retraining. The difficulty of selecting the appropriate quantization scheme, such as deciding the number of bits to represent weights and activations, is another problem. The choice of quantization scheme depends on the specific application and the desired trade-off between accuracy and computation speed. The development of more sophisticated quantization methods that can better retain the accuracy of the original model is a potential topic for quantization research. This includes the development of hybrid quantization methods that use both low- and high-precision representations, and the use of adaptive quantization that can adjust the quantization scheme during the forward pass. Additionally, research is being done to develop quantization-aware training methods that can explicitly account for quantization errors during the training process.

Utilizing Machine Learning to Improve Conversion Rates from Leads to Sales

Allan Fernandes, Zoya Khully, Saloni Negi, Mr. Rahul Nave
Thakur College of Engineering and Technology Mumbai, Maharashtra

Abstract— **We get leads from a variety of platforms. While some of these leads might be potential buyers, the majority of them are not. You may also need to deal with a significant number of leads depending on the type of consumers you have and their LTV (lifetime value). Having your sales representatives speak to each and every lead is a waste of resources. Additionally, certain leads would require to be developed before they are ready. A lead is more likely to advance in the sales pipeline as they are nurtured. They will have their doubts allayed, and nurturing can also assist in educating leads so they can better comprehend how the product would benefit them. Businesses choose a lead qualification approach to make sure that only leads who are likely to buy are engaged with resources. Our model will automatically estimate the likelihood that a lead will be converted into a sale.**

Keyword– Data Science, Machine Learning, Logistic Regression, Prediction.

I. INTRODUCTION

A technique known as predictive lead scoring uses algorithms rather than arbitrary frameworks to rate leads. Which of your leads are sales qualified is determined by the algorithms using the data available. The algorithms frequently compare this data to historical lead performance using the same data that traditional lead scoring does. Predictive lead scoring h1as the advantage of eliminating the requirement for manual scoring system development, which is one of its main benefits. Predictive lead scoring can dig deeper into historical data to uncover trends that humans are likely to miss, helping to better qualify the leads. More clearly qualified leads translate into more sales.

You acquire leads from several various platforms. While some of these leads might be potential buyers, the majority of them are not. You may also need to deal with a significant number of leads depending on the type of consumers you have and their LTV (lifetime value).[3]

Having your sales representatives speak to every lead is a waste of resources. Furthermore, certain leads would need to be developed before they are ready. A lead is more likely to move up in the sales funnel as they are nurtured. They will have their doubts allayed, and nurturing can also assist

in educating leads so they can better comprehend how the product might benefit them.

To ensure only leads who are likely to buy are engaged with resources, businesses opt for a lead qualification strategy.

II. IMPORTANCE

The Marketing Automation Business has seen substantial growth in the adoption of predictive lead scoring. The following are some advantages of employing predictive lead scoring:

• Data-Driven strategy: In the case of the conventional lead scoring system, all of the criteria used to determine the lead rating were determined solely by the Sales Executive's discretion. Therefore, a few suppositions and educated estimates had to be taken into account when doing lead scoring. However, with predictive lead scoring, this is not the case.

• Less Error-Prone: Because predictive lead scoring is data-driven, it is less error-prone. Additionally, it employs Machine Learning and Artificial Intelligence Algorithms to assess the Lead Score, which lowers inaccuracies

• Quicker and more comprehensive: Because predictive lead scoring methods completely rely on machine learning algorithms to evaluate the lead scores, they are typically quicker than traditional lead scoring approaches. Additionally, it offers a thorough and extensive profile of the Lead, increasing the reliability of the results.

III. OBJECTIVE

This paper's goal is to investigate how machine learning techniques can be used to increase lead-to-sale conversion rates in commercial settings. In particular, the paper looks at how machine learning algorithms can be used to spot trends in consumer behavior and preferences, forecast how likely they are to convert, and deliver personalized recommendations to enhance the conversion process. Giving businesses useful insights to improve their sales strategies and boost revenue is the ultimate objective.

IV. PROBLEM STATEMENT

The conversion of leads into sales is one of the biggest problems that businesses face. The conventional method of solving this issue entails relying on sales representatives to manually sort through customer information and spot conversion opportunities. However, this method takes a lot of time, is prone to mistakes, and frequently misses the subtleties of customer behaviour. Businesses can improve their understanding of their customers, forecast their propensity to convert, and streamline the conversion process by utilizing machine learning techniques. Despite the potential advantages of this strategy, many businesses find it difficult to integrate machine learning techniques into their sales strategies, underscoring the demand for additional study and research.

V. WORKING

It uses information from a banking institution's direct marketing campaigns in Portugal. Phone calls were the main component of the campaigns. It was frequently essential to get in touch with a client numerous times to find out whether they would subscribe to the product (bank term deposit) or not (i.e., "yes" or "no").

We are creating a logistic regression model to assign each lead a lead score between 0 and 100 that the company may use to target potential leads. A higher score would mean that
the lead is hot and most likely to convert, whilst a lower number would mean that the lead is cool and unlikely to convert.[7]

To provide each of the leads a lead score between 0 and 100 that the business may use to target potential leads, we are developing a logistic regression model. In contrast, a lower number would indicate that the lead is cold and unlikely to convert, while a higher score would indicate that the lead is hot and most likely to convert.

Fig 1

A. We can classify leads as follows

Cold Lead: Customers who haven't expressed any interest in your "term deposit" offering are known as cold leads. of the hardest leads to convert.

Warm Lead: Potential customers who are familiar with your products or the way your business operates. These clients converse with one another, making them easier
to approach as prospects than cold leads.

Hot leads: are clients that have expressed interest in your business or goods. These leads need your immediate attention since if you wait too long to answer, they can lose interest.

B. How can machine learning assist the sales cycle?

Using verified consumer data, machine learning enables you
to "train" computers to generate precise predictions about brand-new or existing but unknown customers. In order to generate a prediction model, a machine- learning algorithm analyses a database of customer data, identifies trends and patterns, and builds a model from the data.

B2B sales teams will gain from automatic warnings about a customer's tendency to buy a specific product by using the prediction model on new data sets. They might now choose to offer the customer something special in order to boost sales.

Knowing when to provide incentives or discounts is only one aspect of it. The B2B sales process is frequently very consultative and entails customising the solution to each client, especially for businesses whose product is low volume and high margin. It always takes a lot of effort to follow up on leads effectively, and if these leads aren't likely to convert, a lot of time and money could be lost. You may concentrate the efforts of your sales staff on the leads that are most likely to become customers by using reliable propensity models to identify those leads.[

Logistic regression:

Logistic regression is one of the Machine Learning algorithms that is most frequently employed in the Supervised Learning category. It is used to forecast the categorical dependent variable using a specified set of independent variables

Logistic regression is used to predict the output for a dependent variable that is categorical. The outcome must therefore be a discrete or categorical value. It offers the probabilistic values that lie between 0 and 1 rather than the precise values between 0 and 1. It can be either True or False, 0 or 1, or Yes or No.[5] Logistic regression and linear regression are fairly similar, with the exception of how they are used. While logistic regression is used to address classification issues, regression issues are addressed by linear regression.

Instead of fitting a regression line in logistic regression, we fit a "S" shaped logistic function that predicts two maximum values (0 or 1).

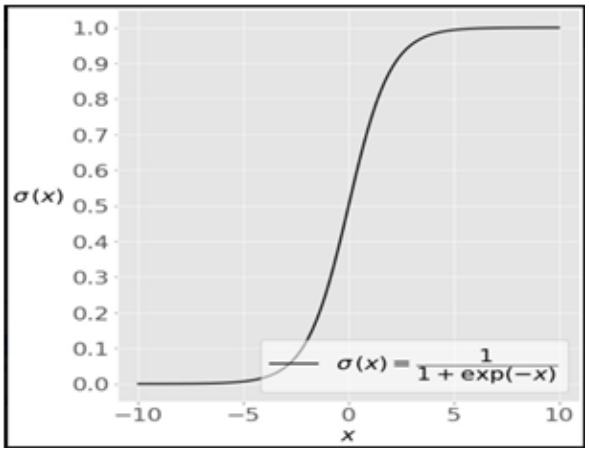
The logistic function's curve demonstrates numerous possibilities, such as whether or not the cells are cancerous, whether or not a mouse is obese dependent on

its weight, etc.

Using both continuous and discrete datasets to classify fresh data, logistic regression is a crucial machine learning technique.

Logistic regression can be used to quickly pinpoint the variables that will be effective when classifying observations using multiple sources of data.

To translate predicted values into probabilities, one uses the sigmoid function. Any real value between 0 and 1 can be transformed into another value with this function. We use machine learning's sigmoid function to translate predictions into probabilities.



VI. CONCLUSION

Traditional methods do not help much business organization in revenue growth, use of Machine Learning approaches prove to be an important aspect for shaping business strategies keeping into consideration the purchase patterns of the consumers. It turns out that educational approaches are an important aspect forming business strategies with regard to consumer buying patterns. Sales predictions taking into account various factors, including previous sales years helping businesses adopt appropriate strategies for increase in sales and unflinchingly stepped into competitive world.

VII. RESULT

The High conversion rate factors

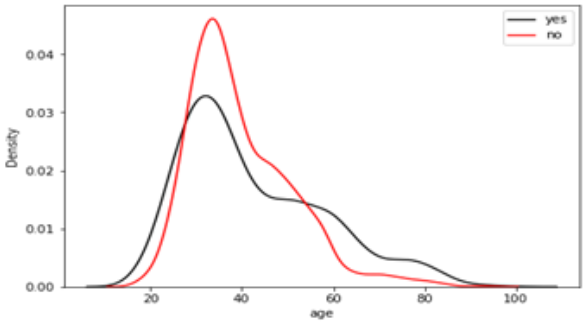


Fig 4 Age vs converted people

We can notice that people around the range of 23 to 35 years of age are more likely to buy the product. This can be because usually during this age, an individual becomes financially independent and can take wise decisions accordingly.

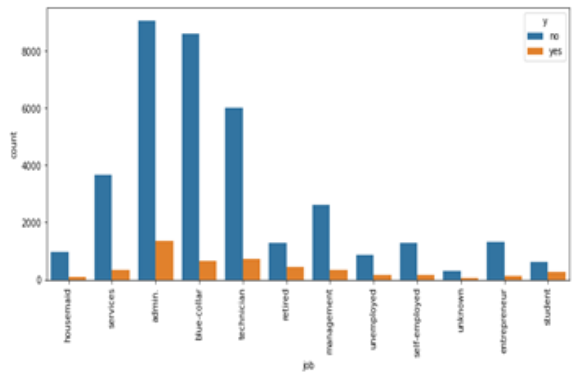

Fig 5: job vs conversion count

Analysing the bar plot we can understand that, people with job titles like admin jobs, blue collar jobs, and technician are more likely to get converted into sales.Reason for this can be since these job titles are more high paying jobs as compared to other jobs.

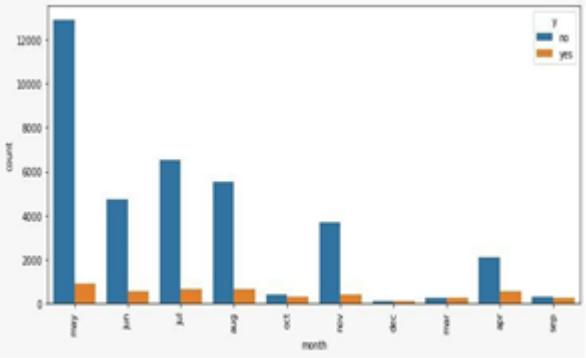

Fig 6: Month vs conversion count People contacted

- If contacted in Month march/securing the p/dec
- If called on Weekday Tuesday/Wednesday /Thursday

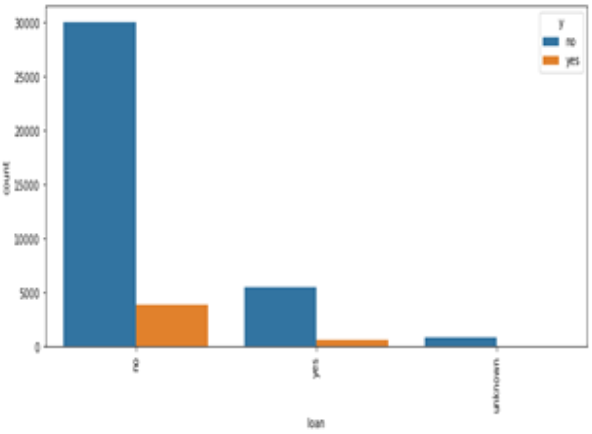

Fig 7: Loan vs converyed count

If there is no previous loan, there are more chances that the bank trusts the individual and assumes that the particular individual has the finanacial capacity to buy the product or service.

SMOTE

Unbalanced classification is the process of developing prediction models for classification datasets with a large class imbalance.

It can be challenging to work with unbalanced datasets since most machine learning techniques ignore the minority class, which leads to subpar performance even though it is frequently the most important.

One strategy for handling unbalanced datasets is to

oversample the minority class. The simplest approach is to replicate examples from the minority class, however these examples don't add any new understanding to the model. Instead, by synthesizing the previous instances, new ones can be produced. For the minority class, data augmentation techniques like the Synthetic Minority Oversampling Technique, or SMOTE, are used.

In order for MOTE to work, samples in the feature space that are close to one another are picked, a line is created between the examples, and a new sample is then drawn at a point along the line.[2]

In particular, a first sample is chosen at random from the minority class. In that case, the location of k of the closest neighbors is given (k is normally equal to 5).

In feature space, a synthetic example is created at a position randomly selected between two instances, and a neighboring example is chosen at random.

```
this is the pre- over sampling distribution:
[(0.0, 25579), (1.0, 3252)]
this is the post- over sampling distribution:
[(0.0, 25579), (1.0, 25579)]
```

Fig 8: Pre over sampling and post over sampling results

SMOTE selects samples from the feature that are close together. This method allows for the production of as many synthetic examples of the minority class as necessary. According to the study, in order to balance the distribution of the classes, it is advised to first use random under sampling to reduce the number of samples in the majority class before utilizing SMOTE to oversample the minority class.

Biomedical Keywords Recommendation for Clinical Trial Records Using Machine Learning

Karan Jain, Akshat Khurana, Luv Mistry
Thakur college of engineering & technology Mumbai, India
karanjain18d@gmail.com, akshatkhurana2001@gmail.com, luvmistry01022001@gmail.com

Abstract — **Analyzing unstructured biomedical research papers and clinical trial studies is very critical for better understanding of the theories related to the domain. The data is available but there is no usage of visualizations and big data analytics on these textual pieces of information. Also, the therapeutic product creators should be able to retrieve similar research work at a faster rate. In this paper, we focus on presenting a high- fidelity prototype, developed for the application, incorporating an advanced search engine, which recommends relevant keywords for much better document matches. To improve the final search results, the model is constructed with the naïve bayes classifier following the basic collaborative filtering approach. Sentiment analysis and other natural language processing techniques are used to detect citation bias towards scientific claims.**

Index Terms - Biomedical, analytics, therapeutic, recommends, keywords, model, sentiment, bias.

I. INTRODUCTION

Clinical trials are the experimental and research studies, usually performed on humans to compare the performance of the new treatment with the standard treatments. They are carried out to evaluate the medical and behavioral effects of the new drug or chemical. Clinical trials are being considered the primary way by researchers to find out if the new treatment is safe and effective in people. They are conducted to assess the safety and effectiveness of a new medicine. There are several stages in the process of approving clinical trials. Generally, the Food and Drug Administrator is the sole approver of all the clinical trial studies being initiated in the United States. Each phase of a clinical trial consists of different number of people on which the tests are performed. In the USA, after the completion of each phase, the investigators are required to submit the results to the FDA for approval before moving on to the next phase. Clinical trials are also be used to compare two separate treatments, to see if they have equal effect. The clinical trials can also be used to determine the natural history of a disease.

Only about one in one thousand investigational drugs make it to human trials, which means most of the clinical trials being initiated phase out in the pre- clinical trial stages. Safety is the most important priority in every phase of a clinical trial. The clinical trials mainly revolve around drugs, which are the substances intended to treat or prevent a disease. The pre-clinical studies are performed on animals, mainly to evaluate if the new treatment will work or not. If the pre-clinical results are promising, the researcher then designs the study for humans. At the start of any clinical trial, one group of people receive the standard treatment along with the new treatment. The other group of people receive the standard treatment only. A computer is used to randomly categorize people into these two groups, in order to prevent any sort of bias. The people who receive only the standard treatment also receive a placebo (chemical substance identical to the new drug but with no active ingredients), in order to assure complete randomness, even in the thoughts of those people. The most reliable results come from the double-blinded treatments, which involves both the clinical researchers and the patients not knowing what sort of treatments they are undergoing.

II. LITERATURE SURVEY

In comparison with the existing research work done on keywords recommendation, this paper aims at improving the efficiency and accuracy of the model, along with the incorporation of technologies like big data analytics and sentiment analysis of the clinical trial records for better user learning and experience. More work needs to be done on knowing the users, for better predictions and recommendations.

1. Xiao Zhou (June 2020). Collaborative Filtering on Keywords Recommendation for Clinical Trial Records. Semantic Scholar, CS229 Stanford.

This paper describes the concepts regarding the development of a known keyword-recommending algorithm using the basic technique of collaborative filtering. The publisher has emphasized on the importance of retrieving similar clinical trial records and documents using locality sensitive hashing. The implementation of the study has three modules. The first module is known as data engineering module, which extracts keywords from text, transforms keywords to indices, and loads the indices into a utility matrix which will be used by the second machine learning module [1]. The second module is the machine learning module which implements the algorithm developed in this study, performs train, validation, test, and prediction tasks. Last module is the data visualization module which provides a web user interface for user's query and result display.

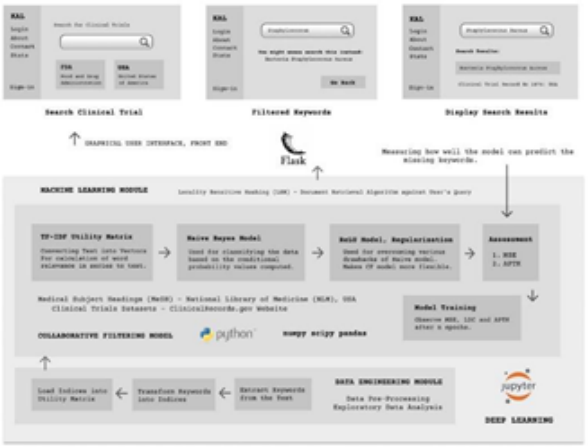
2. Vinaya B. Savadekar, Pramod B. Gosavi (2014). Towards Keyword Based Recommendation System. Archived in International Journal of Science and Research (IJSR), November Volume 3 Issue 11. This research paper proposes a basic keyword-based recommendation method, to address scalability and inefficiency problems when processing or analyzing large-scale data [2]. The author aims at presenting a personalized recommendation list containing the most appropriate items for the users. Specifically, keywords are used to indicate users' preferences or behavior, and a user-based collaborative filtering algorithm is being created to generate appropriate recommendations. The proposed system is much more efficient in terms of complexity, which has been developed for the products on Amazon data.

3. Dan Frankowski, J. Ben Schafer, Jon Herlocker, Shilad

Sen (January 2007). Collaborative Filtering Recommender Systems. In Springer-Verlag Berlin Heidelberg, Part of the Lecture Notes in Computer Science Book Series, Vol 4321. Adaptive Web.

This research paper introduced the core concepts of the collaborative filtering technique along with its primary uses for the adaptive web users. The paper also discussed about the theories and practices of CF algorithms, and various design decisions regarding the rating systems and acquisition of ratings. The author has tried to emphasize on the basic process involved in evaluating the CF system models, and the evolution of rich user interaction interfaces. The author finishes with points regarding the challenges of privacy in the CF recommendation service case.

III. FLOWCHART DESIGN



IV. RELATED THEORY

Thinking of creating an efficient document retrieval search engine powered by keyword-recommending algorithms, without the application of deep learning techniques is quite difficult. More layers of neural networks make way for improved performance in terms of parameters like accuracy and depth. Deep Learning is being incorporated to help the system learn from large amounts of data, on its own. Neural networks simulate the behavior of a human brain. Human Brain is, by far, the most powerful computer that has existed so far. Deep learning algorithms can process unstructured data, since it performs similar to a human brain in terms of recognizing the data inputs, bias and the value of inputs. Deep Learning is chosen because of its capacity to model non-linear relationships within data. Classification improves drastically with every addition of a hidden layer inside the neural network. These algorithms are high in proficiency while processing non-linear features and associations. It is a subset of machine learning.

A. TF-IDF Utility Matrix

Data Preprocessing is the hectic task every model has to go through during the initial stages. Term Frequency Inverse Document Frequency or TF-IDF is an approach to do the data preprocessing task in a highly flexible manner. Every important feature can be extracted using the TF-IDF utility matrix, which determines the importance of a word, present in the text, by finding its frequency of occurrence in the document and computing how often that same word occurs in other documents. If a word occurs many times in a particular document, but not in others, then that word might be relevant to that particular document only, and is therefore more important.

In the biomedical literature domain, there are many synonyms and abbreviations available for medical terms, which makes the keyword extraction difficult for the model. To tackle this issue, the Medical Subject Headings (MeSH) produced and maintained by the National Library of Medicine were used [1]. The MeSH terms inside the clinical trial records, in the form of documents, were transformed into a Trie Data Structure, which is mainly used for the prefix- based searching facility. The MeSH terms in each of the clinical trial records are being fed into the TF- IDF utility matrix. After the matrix is constructed, it is divided randomly into three matrices: the training matrix, validation matrix, and the test matrix. Then, the bayesian classifier takes all these matrices.

B. Naïve Bayes Model

Naïve Bayes is the most popular machine learning algorithm to solve classification problems. Naïve Bayes Model is based on the Bayes Theorem. This model is used for classifying the data based on the

computation of conditional probability values. The model assumes that all the features are independent. In other words, the classifier simply assumes that the presence of a particular feature in a class doesn't affect the presence of other features. Naïve Bayes Classifier is famous for Text Classification, which is a basic application of natural language processing.

The similarity between the biomedical keywords is being calculated based on how close two of the MeSH items are in the utility matrix. The closer they are, the higher value of similarity they possess. The Naïve Bayes classifier model can be found under the scikit-learn library of python. The training matrix which was passed onto the Naïve Bayes Classifier consists of the TF-IDF scores of the MeSH terms. The goal is to estimate the matrix element score, and prove the hypothesis correct, by linearly combining the TF-IDF scores of the neighboring MeSH terms, present in the Utility Matrix. The loss function is calculated and is then optimized using the mini- batch gradient descent or m-BGD algorithm.

C. ReLU Activation Function

The Rectified Linear Unit is an Activation Function, used to overcome various drawbacks of the Naïve Bayes Model. It makes the model more flexible. An activation function is mathematical function that transforms the given input to the required output that has a certain range. The ReLU activation function outputs either 0 or the positive values. The negative values are not possible. The activation function is used to increase the learning capacity of the model. Without an activation function, the model behaves like a linear regression model, which does not have the capacity to perform classification tasks.

After the model training, some TF-IDF values were observed negative, which makes the Naïve Bayes model

too rigid [1]. To eliminate the negative values of the training matrix, the ReLU activation function is used. Since the model is trained with very large amounts of training data, there are high chances of overfitting. To tackle this issue, Regularization was used along with the m-BGD optimization algorithm. The batch gradient descent algorithm was not used since its computation is expensive. Regularization also helps in tuning all the main hyperparameters. The type of Recommendation used in this paper is known as Collaborative Filtering, which is basically a method which tends to find similar users and likely recommend what similar users behave in viewing or liking. Collaborative Filtering focuses on the basic relationship between the users and the items.

D. Mean Squared Error

To validate, assess and measure the performance of the whole collaborative filtering model, MSE or the mean squared error is used. The mean squared error metric is being applied to define the loss functions being calculated in the previous models. Another evaluation metric, APTK is being used to measure how well the model can predict missing keywords. In the model training phase, the MSE, Loss Descent Curve and APTK are being observed after training the model on a certain number of epochs.

To integrate the Google Colab or Jupyter iPython notebook's deep learning code into a website, the Flask API is used. The machine learning models can be successfully integrated with the web using Flask. It is a simple web application framework to build the back-end of web apps. Pycharm IDE makes its way into this scenario. The flask library can be installed with the help of pip command. Before integrating the machine learning model with the Flask API, the pickling of the model is necessary. The end process is being followed by the application deployment.

V. RESULTS

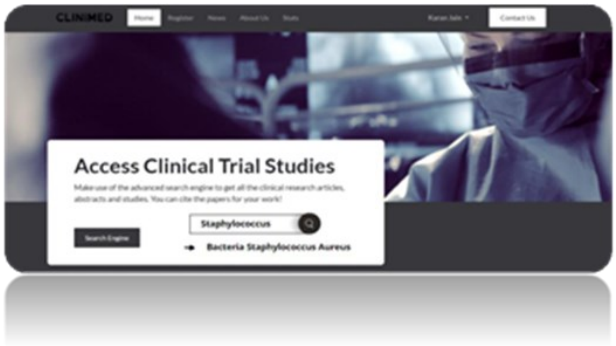


Figure: Clickable Recommended Keywords

VI. DISCUSSIONS

On the homepage of the site, there is an advanced search bar, which has been powered by a keyword recommending algorithm developed using the term frequency inverse document frequency matrices and the Naïve Bayes classifier, optimized with the mini- batch gradient descent algorithm. The user cannot enter all the medical keywords associated with the desired document to be retrieved from the database. To improve the final search results, all the relevant keywords are being recommended using the basic collaborative filtering approach or methodology.

On viewing the clinical trial record research papers and abstracts, the user will find analytics alongside each article. Sentiment analysis is also performed on the clinical trial study abstracts for better learning. The data visualization module takes care of the word clouds for faster information retrieval while surfing the website. The website will generally be used by medical students, PhD scholars, clinical researchers, scientists, pharmacists from the anglospheres and other parts of the world. The main feature of the site will be that of the citation facility, which indirectly encourages to avoid plagiarism and follow some of the standard practices for referencing the established work of other professionals. The clinical trial papers are maintained by the National Library of Medicine.

Online Portal for Type of Anemia Disease Identification

Aditya Dixit, Rahul Jha, Raunak Mishra, Dr. Sangeetha Vhatkar
Thakur College of Engineering and Technology, Mumbai, India
adityadixit01@gmail.com, rjha27404@gmail.com, mishraraunak326@gmail.com, sangeeta.vhatkar@thakureducation.org

Abstract - **Anemia is a microcytic, normocytic and macrocytic caused due to inadequate supply of oxygen to tissues or insufficient hemoglobin leading to lethal abnormalities in the human body. The global public health toll almost 42% of children below age of 5 and almost 40% women under pregnancy suffer anemia worldwide. In the proposed paper, it presents an online platform using machine learning algorithms Random Forest, KNN, and Naive bayes. The proposed system intends to detect the type of anemia the patient is suffering from on the basis of the various parameters of the blood test report and help detect type of anemia along with the remedial diets that can help reduce the effects and accordingly tell the patient to visit the doctor. We intend on using this platform with medical personnel helping in early identification of anemia along with the additional information of the type of anemia the patient is suffering from for prompt treatment.**

Keywords - Anemia, Machine Learning, Random Forest, KNN, Naive Bayes.

I. INTRODUCTION

In the health industry during the recent years remarkable advancement in technology took place, which resulted in exponential increase in data. All the useful information can be extracted using the data, used for prediction, recommendation and decision

making. For prevention and effective treatment of diseases, diagnosis and prediction at the right time is required. Deficiency of healthy red blood cells causes Anemia disease. Because of the lack of healthy red blood cells, the oxygen is not able to be delivered throughout the body as expected. Anemia is highly prevalent in India. The third National Family Health Study (NFHS-3) conducted during 2005–6 found that amongst children aged 6 to 59 months, the prevalence of anemia is 69.5%; in rural India, the prevalence is

71.5%. The prevalence of anemia is maximum among younger children between the age of 12-17 months and 18-23 months. The prevalence of anemia in rural areas appeared to have risen since the previous NFHS (in 1998–9). [1][2]

Some measures need to be taken to prevent the spread of anemia using the new learning and advancements of the tech industry. We found out during our study that with the help of machine learning we could solve the problem and find out the type of anemia a user/patient is suffering from. Using machine learning algorithms like Random Forest, Decision Tree and Naive Bayes [3], We plan on finding out the type of anemia the patient is suffering from which can help in timely and prompt treatment [4]. This early diagnosis can help in reducing the symptoms and nullify any harmful effects of the disease. In our country, we have witnessed a lot of improvement in health care facilities, but still there is a lack of expertised doctors in rural areas and some people are still not able to afford expert healthcare facilities. We have a large population living in the rural areas where there is a lack of advancement and expert medical staff resulting in late diagnosis of the anemia disease due to which the disease becomes deadly. Machine Learning can help us overcome many different problems faced by our country in the field of medicine. Using this project, we will be able to detect whether a person or patient is suffering from anemia and get to know the type of anemia the patient is suffering from in a matter of seconds. [3]

II. PROBLEMS FACED

Anemia is a growing problem amongst young children living in rural India. In Rural areas, there is a lack of proper medical treatment and experienced doctors. This leads to patients traveling long distances to visit experienced doctors for treatment. This delay ultimately leads to the disease becoming more fatal.

Also, many people avoid going to the doctor because they are scared or they can't afford it. Also, due to the lack of trained or experienced doctors in rural areas, they misdiagnose the symptoms resulting in Anemia becoming more fatal.

Anemia, also goes quite unnoticed in many people especially children, which can go unnoticed at first but suddenly become fatal in nature. To identify this, a doctor needs to go through the CBC blood test report thoroughly to identify the early stages of Anemia. Once identified, it is quite easy to cure the disease.

But one thing to also look at is the type of anemia the patient is suffering from. Knowing which type of anemia the patient is suffering from is a very important part of the diagnosis as based upon the type of anemia, the treatment plan is made. To find the type of anemia is a difficult task as multiple parameters of the blood test report has to be taken into consideration which can only be done and diagnosed by an experienced doctor.

To tackle this problem, we are planning to use machine learning algorithms which would feed the input data of some blood test parameters using which the machine learning model will be able to tell the type of anemia the patient is suffering from. We would create an online portal where the user/patient or medical professionals can simply enter some blood test parameters required and will get the required type of anemia the patient is suffering from.

Our online portal would warn and alert the user if the user is suffering from anemia and notify them to seek medical attention so that they can be treated on time. The online portal would also notify the type of anemia the

user is suffering from and would help in the diagnosis of the doctor.

We would also through the website provide information to the user about anemia, symptoms and diets which could help in the recovery from the disease. We plan on using the online portal in the future with NGOs, social bodies, social organizations or government bodies and rural areas for social good.

III. METHODOLOGY

To start our project, we have imported a dataset [8] which contains 5 parameters and tells us whether a person is suffering from anemia or not. But, what we want to know is what type of anemia the user/patient is suffering from. In order to find that out, we have used the following parameters below from the dataset [7] -

	Gender	Hemoglobin	MCH	MCHC	MCV	Result
0	Male	14.9	22.7	29.1	83.7	Not Anemia
1	Female	15.9	25.4	28.3	72.0	Not Anemia
2	Female	9.0	21.5	29.6	71.2	Anemia
3	Female	14.9	16.0	31.4	87.5	Not Anemia
4	Male	14.7	22.0	28.2	99.5	Not Anemia
5	Female	11.6	22.3	30.9	74.5	Anemia

Fig 1. Original Dataset [7]

1. Gender - Gender is a very important parameter as the blood parameters and limits for both Male and Female are different and vary, so it is important to also consider this factor.

2. MCV - MCV stands for mean corpuscular volume. Basically this blood test measures the average size of the red blood cells. Using this test we can get to know whether our red blood cells are too small or too large which can depict any blood disorder such as anemia. [8]
3. MCHC - MCHC is a similar measure to MCH, MCHC stands for "mean corpuscular hemoglobin concentration". MCHC checks the average amount of hemoglobin in a group of red blood cells. A doctor might use both MCHC and MCH in order to diagnose Anemia. [9] [10]

4. Hemoglobin - This parameter tells us about the amount of oxygen present in our blood. It is basically a protein which has the capacity to carry oxygen throughout the body from the lungs. It is also a very important parameter in prediction of anemia. For men, anemia is typically defined as a hemoglobin level of less than 13.2 g/dl and in women as hemoglobin of less than 11.6 g/dl. [11]

We in total have used these 5 parameters to find out the type of anemia the user/patient is suffering from. There are mainly 3 types in which anemia can be divided into - Microcytosis (low MCV), Macrocytosis (high MCV) and Normocytic (normal MCV) [5][12][13]. Under these 3 types, we can zoom in into the cause of anemia as mentioned in Fig. 2.

Using the below mentioned Fig. 2, we have classified almost all types and causes of anemia. The normal range of MCV in humans should be between 80 g/dL - 100 g/dL, the normal range of MCHC in humans should be 32 g/dL - 36 g/dL and the normal range of Hemoglobin in Males should be between 13.2 g/dL - 16.6 g/dL and in Females between 11.6 g/dL - 15 g/dL.[6][12][13][14]

Now in Anemia, all patients suffer from low hemoglobin in the RBCs, but to exactly know which type of anemia the patient suffers from, we have to go more into depth and look at the MCV and MCHC values in order to pinpoint towards the exact type of anemia for further treatment of patient. The type of anemia can be confirmed on the basis of multiple parameters of the blood test report, but we are mainly focusing on using two parameters, the MCV values and MCHC values to find out the type of anemia and classify it into Normocytic, Microcytic and Macrocytic Anemia according to Fig.2 [6][13].

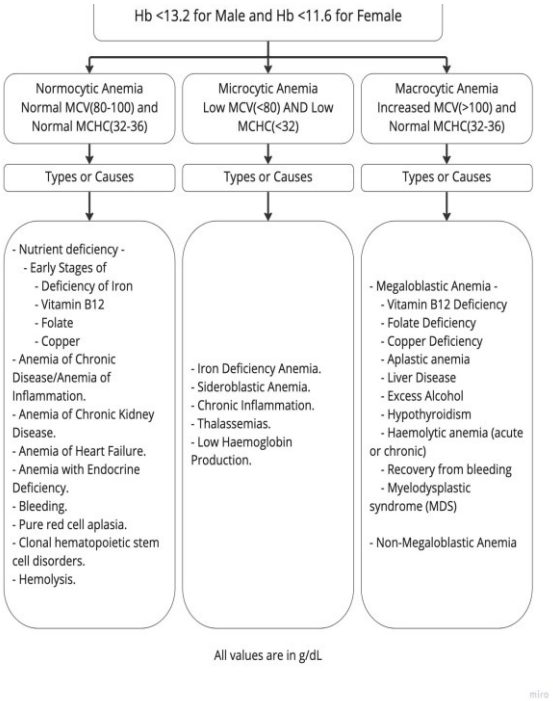

Fig 2. Types of Anemia [4][5][6][13][14][15]

Hemoglobin is a blood parameter which tells us initially whether a person is suffering from anemia or not as low hemoglobin essentially indicates towards anemia disease. If the hemoglobin value is less than <13.2 g/dL in Male or <11.6 g/dL in Females then we can say that the patient is suffering from anemia [15].

To know the type of anemia the patient is suffering from, we need to further investigate the other parameters.

Using MCV and MCHC values, we get to know exactly whether the patient is suffering from Normocytic, Microcytic or Macrocytic anemia.

- If MCV is low (<80 g/dL) and MCHC is low (<32 g/dL) then we can classify it as Microcytic Anemia [6][14][15].
- If MCV is normal (>80 g/dL and <100 g/dL)

and MCHC is normal (>32 g/dL and <36g/dL) then we can classify it as Normocytic

Anemia [6][13][14].

- If MCV is Increased (>100 g/dL) and MCHC is normal (>32 g/dL and <36 g/dL) then we can classify it as Macrocytic Anemia [6][13][14].
- If for instance the hemoglobin of the patient is in the normal range that is for Male (13.2 g/dL - 16.6 g/dL) and for Females (11.6 g/dL - 15 g/dL) then the patient is not suffering from anemia [6][15].
- If any other condition is possible, it could be because of chronic anemia but doctors or medical experts diagnosis is important for real diagnosis.
- Though using these all conditions we can get the type of anemia, it is important to be reviewed and consult a doctor before coming to the exact cause causing anemia disease and only a medical expert or doctor could find the exact reason causing the disease or root cause.

Using the above condition, we make changes in our dataset [8] and our dataset now looks like this -

	Gender	Hemoglobin	MCHC	MCV	Type
0	1	14.9	29.1	83.7	Not Anemic
1	0	15.9	28.3	72.0	Not Anemic
2	0	9.0	29.6	71.2	Microcytic
3	0	14.9	31.4	87.5	Not Anemic
4	1	14.7	28.2	99.5	Not Anemic

Fig 3. Newly made dataset

In the above database, 1 represents Males and 0 represents Females. In the Type columns, we have specified the exact type the patient is suffering from , which ranges from Not Anemic, Microcytic, Chronic Disease Anemia, Normocytic and Macrocytic.

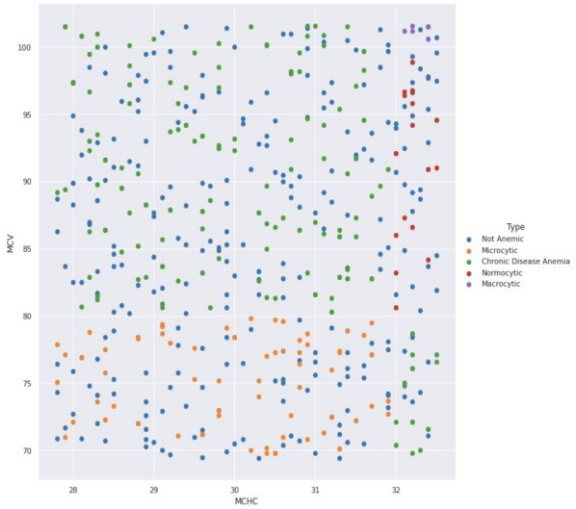

Fig 4. Visualizing Dataset (MCHC vs MCV)

The dataset consists of a total of 534 unique data entries after cleaning and removing duplicate values from the dataset. In the dataset, 319 values are of type Not Anemic, 127 are of type Chronic Disease Anemia, 65 are of Microcytic, 18 are of Normocytic and 5 are of Macrocytic anemia.

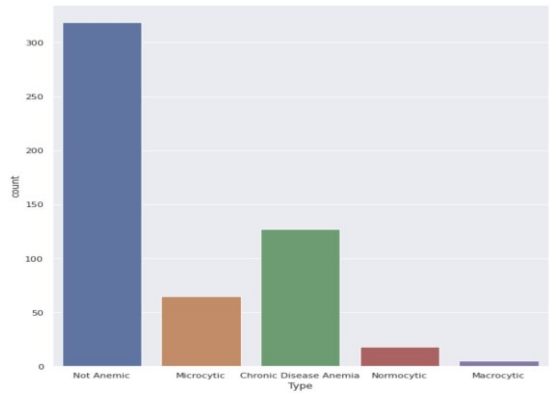

Fig 5. Countplot of the types of anemia in datasetNow, to visualize some of the parameters according to the different types of anemia we have plotted multiple boxplots for each parameters vs each type of anemia -

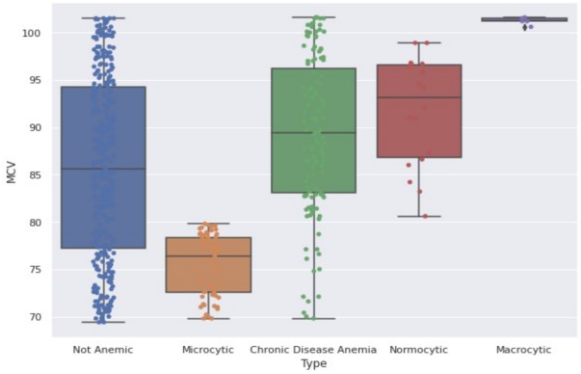

Fig 6. Boxplot of MCV vs Types

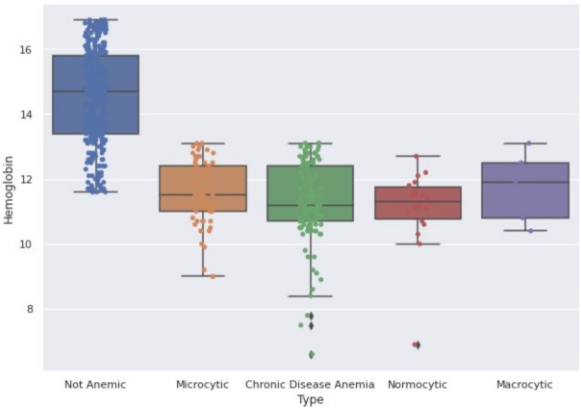

Fig 7. Boxplot of Hb vs Types

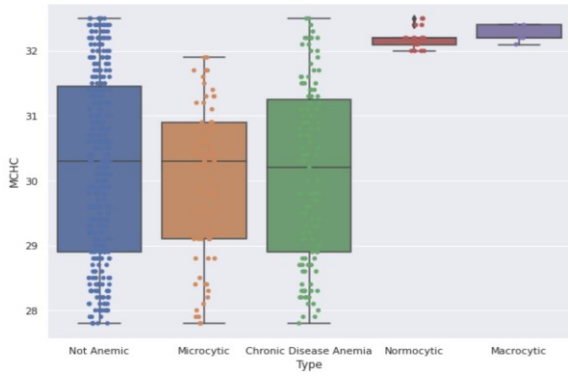

Fig 8. Boxplot of MCHC vs Types

As written before, we are using the parameters Gender, Hemoglobin, MCV and MCHC to classify which type of anemia the patient is suffering from.

Now, to give you an overview of how we are going to do it, we have below created a flowchart depicting how we will achieve the required results -

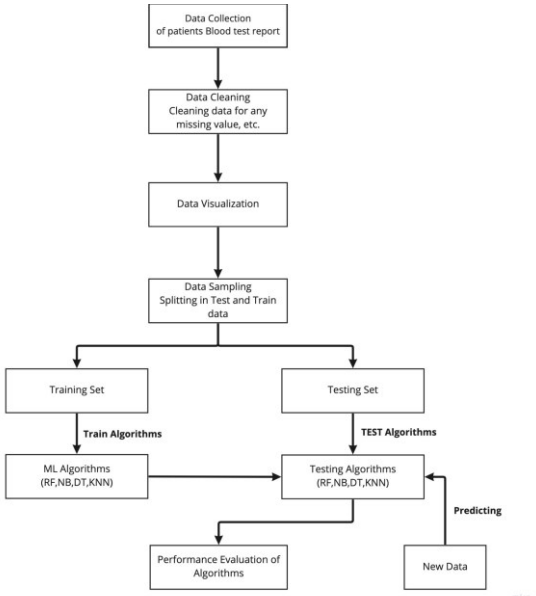

Fig 9. Flowchart of working [5]

Applying Classification Algorithms

- After feature extraction now comes to model training.
- First of all we have divided the dataset into training and testing using a method called train_test_split(). We have divided our dataset into a 75-25% train-test split.
- Now select the classification algorithm and import it from respective libraries.
- Algorithms that we are going to use are Random Forest, Naïve Bayes and KNN [3][4][5].
- Below are the detailed study of our algorithms-

1. Naive Bayes Algorithm - Naive Bayes Algorithm is a supervised machine learning algorithm which is based on the famous bayes theorem and is used mostly to solve classification problems. It is one of the easiest and effective classification algorithms. It basically predicts the output based on the basis of the probability of the object. [16] Now, defining the formula as per our project - P(A|B) is Posterior probability: Probability of hypothesis A on the observed event B. P(B|A) is Likelihood probability: Probability of the evidence given that the probability of a hypothesis is true. P(A) is Prior Probability: Probability of hypothesis before observing the evidence. P(B) is Marginal Probability: Probability of Evidence. [16]

If P(NO|Anemia) is greater than P(YES|Anemia), then the person is not suffering from Anemia, else vice-versa. Random Forest - Random forest is a simple to use machine learning algorithm that delivers a good result much of the time, it also does not require us to use hyper parameter tuning. It is also one of the most commonly used algorithms due to its simplicity and versatility which can be used as both regression and classification algorithms. [17] Why use Random Forest? Random Forest is one of the most popular machine learning algorithms used for both classification and Regression problems. It is used because of its speed, that is it works very fast even for very big datasets. It also provides a very high accuracy in comparison with the other machine learning algorithms. [17]

As per our problem, We define the formula:

P(YES|Anemia) is Probability of having

Anemia Disease in a person.

P(Anemia|YES) is the value of patients having parameters outside the normal range having anemia.

P(Anemia) is the value of people having

Anemia.

P(YES) is the value of total people having blood parameters out of range.

So, we can rewrite the Naive Bayes algorithm as -

P(YES|Anemia) = P(Anemia|YES) * P(Anemia) / P(YES)

We will then compare this value with the normal or parameter of people not having Anemia -

P(NO|Anemia) = P(Anemia|NO) * P(Anemia) / P(NO)

After this calculation, we will in the end compare both these, and the one grater will be the final answer -

How does the Random Forest algorithm work?

Random Forest as the name suggests, is an algorithm created by the use of multiple decision trees. In this, Random Forest algorithm creates multiple decision trees, and then as per the input, the decision tree shows the output. In random forest, the algorithm for a classification problem takes all the majority classes predicted by all decision trees and average of all predicted outputs for a Regression Problem. [17]

Now, lets see the working of Random Forest

Algorithm -

Step-1: Firstly, we select random data points from the training data set.

Step-2: Next, we build a decision tree for each of the respective data points.

Step-3: Next, we decide the number of decision trees we want.

Step-4: Repeat Step 1 & 2.

Step-5: Now, for predicting, compile all the outputs of all decision trees and take the majority of all outputs for the final output.

3. KNN - KNN is one of the simplest machine learning algorithms in Supervised learning technique. KNNbasically uses the techniquewhere it classifies data based upon the similarity of other data points. So if we put in a new data, it will classify it based upon the other data points which is closest to the new data and accordingly classify it. This algorithm does not learn anything from the training data set immediately, but stores it and uses it at the time of classification, that is why it is also known as lazy learner algorithm.[18]

Now, lets see the working of the KNN

algorithm [18] -

Step-1: Firstly we have to select the K

number of neighbors to use.

Step-2: We calculate the Euclidean distance of all k numbers of neighbors.

Step-3: We take the K number of nearest neighbors.

Step-4: We count the number of categories of each nearest data point.

Step-5: Assign the new data point to the majority category of the K nearest neighbors.

Step-6: Our model is ready to use. Real Time Implementation Of Project

● Here comes the main part where we

have to map our project with the real world problems.

● We are going to create an online portal where we would display all types of information regarding anemia, types of anemia, causes, and provide a service where the users can input there blood parameters of Hb, MCV, MCHC and Gender and accordingly get notified of the type of anemia they might be suffering from and advice them to visit a doctor for further diagnosis and treatment.

● We have decided to provide our service to NGOs or Social work bodies or organizations or medical bodies or rural clinics or hospitals where there is a lack of experienced medical staff.

● We would also provide diet plans which patients can use which can benefit them and reduce the effects of the anemia disease.

IV. TECHNOLOGY USED

We are using one of the most useful and powerful language ie. python. Python also has robust library support for Machine learning.

1. Google Collab – This is a jupyter notebook IDE where we can easily run and also see the output of each cell simultaneously. We will use Google Colab as it already has many of the required libraries installed and is very user friendly to use.

2. Pandas - This is one of the most important libraries for data science applications. It is basically used from importing the dataset, to cleaning, to feature selection, etc. It is the go to library for any data science and machine learning project.

3. Scikit – It is a machine learning library containing many models like classification, regression and clustering algorithms. We are using this library to import all the important algorithms which we are using and to also use this library to get the important metrics like accuracy, precision, f1 score, recall, etc.

4. Matplotlib – It is a library used for data visualization. It is a library used to create various types of graphs and plots which help us better understand the data which we are using.

5. Seaborn – It is a library used for creating many types of advanced graphs and plots and is mostly used in our project to visualize the data.

6. Flask - It is a library which we will use to create our online portal. It is a very simple to use python framework which allows us to use python in the frontend as well.

V. RESULT AND DISCUSSION

After implementation of all the above steps, we have come up with the accuracy we have achieved using the Random Forest, Naive Bayes and KNN algorithms - Table 1 - Algorithm Accuracy

Algorithms	Precision	Recall	F1 Score
Random Forest	0.99	0.99	0.98
Naive Bayes	0.88	0.88	0.88
KNN	0.81	0.83	0.81

Table 2 - Weighted Average of Precision, Recall and F1 Score for each algorithm

Above is the accuracy we have achieved from our algorithms after training them and then testing them with the test data. From this result we plan on using the Random Forest algorithm in our online portal as it has provided us with the most accuracy out of all algorithms.

We have also shown the weighted average of precision, recall and F1 score -

From the table above, we can see that we have achieved very good scores of Precision, Recall and F1 Score. Ideally, the optimum result of these three metrics should be 1. As we can see, the Random Forest algorithm achieved the highest score in all their metrics out of all the algorithms followed by Naive Bayes and KNN.

As we see, our results are up to standards and the accuracy of each algorithm is very good, even exceeding our expectations [3][4].ACKNOWLEDGMENTS

My completion and success of the project could not have been accomplished without the support and guidance of my teachers. I sincerely want to thank our mentor Dr. Sangeeta Vhatkar. We are extremely fortunate and privileged to have HOD IT Dr. Sangeet Vhatkar ma'am as our mentor who enlightened us with her expertise and in depth knowledge and motivated and inspired us to use our full potential and to do our best.

I sincerely want to extend my thanks to our Principal Dr. B. K. Mishra and Vice Principal Dr. Kamal Shah for always encouraging us to do our best. We are thankful to and fortunate enough to get constant encouragement, support and guidance from all teaching staff of the IT Department who helped us in successfully completing our project work. Also, we would like to extend our sincere thanks to all staff in the laboratory for their timely support.

We would also like to express our gratitude towards our parents for their kind cooperation and encouragement which helped us in completion of this project.

A Cost-Benifit Analysis and Fertilizer Prediction For Crop Yield Optimisation

Harshit Narendra Bajaj, Vedant Prabhakar Gosavi, Sumit Vijaykumar Jain
Thakur Collage Of Engineering and Technology, Mumbai,India
harshitbajaj48@gmail.com, vgosavi200@gmail.com, Jain42507@gmail.com

Abstract— **India is currently the world's second largest producer of several dry fruits, agriculture-based textile raw materials, roots and tuber crops, pulses, farmed fish, eggs, coconut, sugarcane and numerous vegetables. In order to produce more agricultural products adequate quantity of good fertilizers should be used. Majority farmers use fertilizers to increase production. But they should know which fertilizer is best suitable for their land and in which amount. They should calculate how much it will cost for total process of fertilization. This paper is to help them to solve this problem using Software technology and machine learning. This research paper present fertilizer prediction and cost benefit analysis for farming. The analysis evaluates the cost and benefit of using a fertilizer prediction system to optimize crop yield in the context of a large-scale farm. A survey was conducted with farmers to assess the cost and time required to implement a fertilizer prediction system. Additionally, a financial analysis was conducted to assess the economic benefits of using a fertilizer prediction system. Finally, the results were compared to the current fertilizer application methods to determine the potential benefit of using a fertilizer prediction system. The results of the analysis show that a fertilizer prediction system has the potential to reduce costs and increase yields significantly. The analysis also sheds light on the challenges and opportunities associated with implementing a fertilizer prediction system. The findings of this study provide valuable insights for farmers and agricultural professionals interested in optimizing crop yield through the use of fertilizer prediction systems.**

This paper is based on following key points.

1. The Impact of AI and ML on Fertilizer Use

2. Sustainable Agriculture

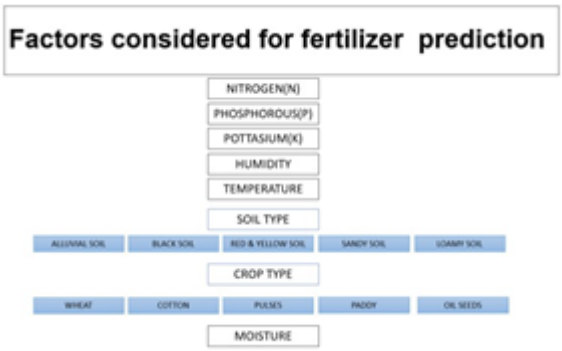
3. Cutting Costs and Improving Yields

4. Maximizing Profits and Minimizing Waste

Keywords— Fertilizer, Crop, Agriculture, soil quality

I. INTRODUCTION

Agriculture is the backbone of Indian Economy. Plants require nutrients in order to grow and give more yields. Nutrients to the plants are provided through soil, manure and the fertilizers. There are 16 essential nutrients that are required for the plant growth viz., carbon, hydrogen, oxygen, nitrogen, phosphorous, potassium, Sulphur, calcium, magnesium, boron, iron, manganese, molybdenum, zinc, chlorine and copper. These are either provided through soil or water in the form of micronutrients and macronutrients. The deficiency of these nutrients can be found out by using soil testing mechanism. There have been advancements in Science and Technology in India from past few decades. But the productivity of farming is declining and there are several reasons behind it: fragmented land holding illiteracy of farmer, lack of decision making in choosing good seed, manure and fertilizer. Several studies show that farmers have little knowledge over usage of optimum level of fertilizer for optimal crop yield. The plants require fertilizer when they are deficient of nutrients. Also the usage of fertilizer more than the requisite level produces crops with increased fertilizer content which upon consumption leads to several harmful diseases. When fertilizers are added to the soil it decreases the microbial activity of soil. The factors affecting the fertilizer consumption are: extent of available land, cultivated land, rainfall, cropping pattern, soil characteristics.



The use of artificial intelligence (AI) and machine learning (ML) in agriculture has been rapidly increasing in recent years. These technologies have shown great potential in improving crop yields and reducing the amount of fertilizer needed. One of the ways AI and ML are being used in agriculture is for fertilizer prediction.

Fertilizer prediction involves using algorithms to determine the amount of fertilizer required for crops. This is important because over-fertilization can be harmful to crops and the environment, while under-fertilization can result in lower yields. With the help of AI and ML, farmers can now make more informed decisions about fertilizer use, leading to more sustainable and efficient agriculture practices.

The first step in fertilizer prediction using AI and ML is to gather data. This data may include information on soil type, weather conditions, crop growth, and fertilizer usage. This data is used to train machine learning algorithms, which can then make predictions about the optimal amount of fertilizer required for specific crops and conditions.

There are a number of different AI and ML algorithms that can be used for fertilizer prediction, including decision trees, neural networks, and support vector machines. These algorithms use statistical methods to analyze the relationships between the data and make predictions about fertilizer requirements. The algorithms can also be fine- tuned and improved over time as more data is gathered, allowing for even more accurate predictions in the future.

One of the advantages of using AI and ML for fertilizer prediction is that the algorithms can learn from past data and make predictions about future conditions. This can help farmers make decisions about fertilizer use that are more in line with the specific needs of their crops, leading to improved yields and more sustainable agriculture practices. This proposed system takes soil data such as nitrogen level, phosphorous level, Potassium level, soil type, temperature, moisture, crop types as input and suggests you the best fertilizer which should use. It calculates price of fertilizer, water cost, amount of fertilizer required, and cost of other necessary instruments in the process and gives the total cost of fertilizing the land. If anyone was unware about using new fertilizer it will show them ways and appropriate condition and time to use it.

II. LITERATURE SURVEY

A literature survey on the topic of fertilizer prediction and cost analysis would involve reviewing research papers and articles that explore the methods used to predict fertilizer requirements for crops and the associated costs. Here are a few key findings from such a survey:

Fertilizer prediction methods: A number of methods have been proposed for predicting fertilizer requirements for crops. These methods range from simple nutrient balance models to complex machine learning algorithms. Some of the most widely used methods include crop simulation models, neural networks, and decision trees.

Cost analysis of fertilizers: The cost of fertilizers is determined by various factors, including the type of fertilizer, the cost of raw materials, and the production and transportation costs. Researchers have used cost-benefit analysis and linear programming techniques to analyze the costs associated with different fertilizer application strategies.

Integration of fertilizer prediction and cost analysis: Some studies have attempted to integrate fertilizer prediction and cost analysis into a single framework. For example, researchers have used multi-objective optimization algorithms to determine the optimal fertilizer application strategy that balances both the fertilizer requirements of crops and the associated costs.

Case studies: Many studies have been conducted on specific crops and regions to evaluate the effectiveness of fertilizer prediction and cost analysis methods. These studies have provided insights into the challenges and opportunities of applying these methods in different agro-climatic conditions.

Machine learning algorithms: A number of machine learning algorithms have been applied to the problem of fertilizer prediction, including decision trees, random forests, neural networks, and support vector machines. These algorithms have been trained on data collected from various sources, such as soil nutrient content, crop growth data, and weather conditions, to make predictions about the fertilizer requirements for crops.

Integration with other technologies: Some studies have integrated AI and ML-based fertilizer prediction with other technologies, such as remote sensing, to improve the accuracy of predictions. For example, researchers have used satellite images and unmanned aerial vehicles to gather information about crop growth and soil nutrient content, which is then fed into machine learning models to make predictions about fertilizer requirements.

Overall, the literature survey highlights the importance of considering both fertilizer prediction and cost analysis when making decisions about fertilizer application. The methods used to predict fertilizer requirements and analyze costs continue to evolve and improve, offering new opportunities to optimize fertilizer use and minimize costs.

III. RELATED WORK

The study proposes a novel crop yield prediction model that performs better than existing approaches when employing a beehive clustering strategy. At the 2013 International Conference on Pattern Recognition, Informatics, and Mobile Engineering, the model was displayed. [1]

The author describe an intelligent system for predicting agricultural production using kernel methods in their study titled "An intelligent system based on kernel approaches for crop yield prediction." The paper was released by Springer in Berlin, Heidelberg, and presented at the Pacific-Asia Conference on Knowledge Discovery and Data Mining. [2]

The paper titled "Fuzzy Logic based Crop Yield Prediction using Temperature and Rainfall parameters predicted through ARMA, SARIMA, and ARMAX models" by Bang, Bishnoi, Chauhan, Dixit, and Chawla (2019) presents a fuzzy logic approach for predicting crop yield using temperature and rainfall data. The authors use ARMA, SARIMA, and ARMAX models to predict the temperature and rainfall parameters and then use these predictions as inputs to their fuzzy logic model. The study was presented at the 2019 Twelfth International Conference on Contemporary Computing (IC3) and was published by IEEE.[3]

"Crop Yield Prediction Using Data Analytics and Hybrid Approach" has a hybrid approach for predicting crop yield using data analytics. The study was presented at the 2018

Fourth International conference on Computing, Communication, Control and Automation (ICCUBEA) and was published by IEEE. [4]

A study on various data mining strategies for crop yield prediction is presented in the publication "A study on various data mining techniques for crop yield prediction" by Gandge (2017). The research was presented at and afterwards published by IEEE's International Conference on Electrical, Electronics, Communication, Computer, and Optimization Techniques in 2017. [5]

The author in 2016 provide a study on predicting rice crop yield using artificial neural networks in their paper titled "Rice crop yield prediction using artificial neural networks." The research was published by IEEE and presented at the

2016 IEEE Technological Innovations in ICT for

Agriculture and Rural Development (TIAR). [6]

The study on the use of support vector machines for predicting rice crop yield in India in their paper titled "Rice crop yield prediction in India using support vector machines." The research was presented in the IEEE-published 13th International Joint Conference on Computer Science and Software Engineering in 2016. [7]

A study on the application of a decision support system for forecasting Indian rice crop production is presented in Author's work, "Proposed decision support system (DSS) for Indian rice crop yield prediction." IEEE published the research, which was presented at the 2016 Technological Innovations in ICT for Agriculture and Rural Development (TIAR) conference. [8]

A study on employing a deep neural network for crop selection and yield prediction in Bangladesh is presented in the paper "A Deep Neural Network Approach for Crop Selection and Yield Prediction in Bangladesh". The research was published by IEEE and presented at the 2018 IEEE Regio 10 Humanitarian Technology Conference (R10- HTC). [9]

In a 2008 study, Jaikla et al. investigated the use of the support vector regression approach for predicting rice yield. At the 5th International Conference on Electrical Engineering/Electronics, Computer, Telecommunications, and Information Technology, the work was presented.. [10]

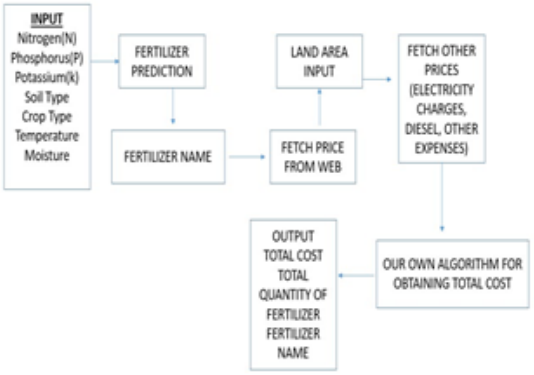
The study proposed a wheat yield prediction model using artificial neural networks in the 4th International Conference on Engineering Technology and Technopreneuship.[11]

A flexible framework, XCYPF, was proposed for agricultural crop yield prediction in 2015 by Manjula and Narsimha at the 9th IEEE ISCO conference. [12].

IV. PROPOSED METHODOLOGY

The works done till now only predict fertilizer based on soil quality like nitrogen deficiency, potassium deficiency, phosphorus deficiency or the crop farmer is going to yield. It doesn't show how much different fertilizers need to use and weather conditions such as Temperature, humidity are not considered. So, It is necessary to provide more accurate result considering all parameters and suggest amount need to be used. This program will calculate the cost it will take to fertilize full land and suggest effective and cost friendly fertilizer to be used.

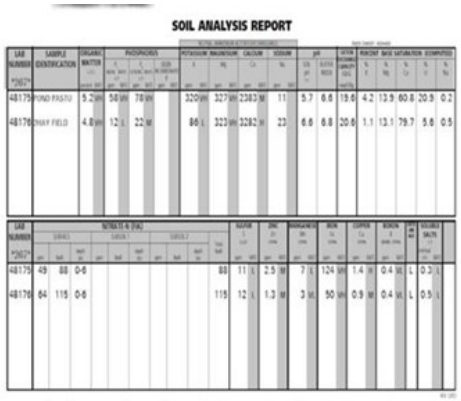
The Aim is to suggest farmer the best choice on fertilizer, amount he required and predict the cost He will needed to complete the fertilization process. So the process planned as follow to achieve optimum result.



A. Fertilizer Prediction:

To achieve the goal of suggesting best fertilizer for that take following parameters into consideration.

- Nitrogen
- Phosphorus
- Potassium
- Soil type
- Crop type• Moisture
- Temperature
- Humidity



An example soil test report from Midwest Labs. The report is complete, showing organic matter, pH, cation exchange capacity, base saturation and nutrient levels – including micronutrients.

Machine learning algorithms used to predict fertilizer.

1) Random Forest Algorithm:

➢ Random Forest is a powerful and versatile supervised machine learning algorithm that grows and combines multiple decision trees to create a "forest.

➢ Suppose there is a dataset that contains NPK, crop types, soil types. So, this dataset is given to the

Random Forest classifier. The dataset is divided into subsets and given to each decision tree. During

the training phase, each decision tree produces a prediction result, and when a new data point occurs, then based on the majority of results, the Random Forest classifier predicts the final decision.

2) k-Nearest Neighbors (k-NN):

➢ k-NN is a type of instance-based learning algorithm that makes predictions based on the similarity between new data points and existing data points.

➢ It is commonly used for classification and

regression tasks, including fertilizer prediction.

3) Gradient Boosting:

➢ Gradient Boosting is an ensemble learning algorithm that combines multiple weak learners to make predictions.

➢ It is commonly used for regression and classification tasks, including fertilizer prediction.

4) SVM (Support Vector Machine):

➢ SVM develops a hyperplane or set of hyper planes in a high-or boundless dimensional space, which can be utilized for characterization, relapse, or different errands.

➢ Naturally, a great partition is accomplished by the hyperplane that has the biggest separation to the closest preparing information purpose of any class, since by and large the bigger the edge the lower the

speculation blunder of the classifier.

➢ SVM calculation has a regularization parameter, which stays away from over-fitting.

➢ SVM calculation utilizes the portion trap, so you can construct master learning about the issue.

5) Decision Trees:

➢ Decision trees are a type of supervised machine learning algorithm that can be used

for fertilizer prediction. They are a tree-like structure that makes predictions based on a series of decisions and conditions.

6) Neural Networks:

➢ Neural networks are a type of machine learning algorithm that are modeled after the structure and function of the human brain. They are

commonly used for prediction tasks, including fertilizer prediction.

B. Amount of fertilizer required:

The amount of fertilizer required should be known by farmer before buying it. By predicting How much a mount of fertilizer a part of farm required formula can predict total amount of fertilizer required. As if 1 acre of land require

13kg of fertilizer. It can simply say how much fertilizer

require by specific area of farm. This amount changes with respect to land properties.

C. Cost analysis:

Cost analysis is an important aspect of fertilizer prediction as it helps to determine the economic feasibility of different fertilizer application strategies. Here are a few ideas for conducting cost analysis on fertilizer predictions:

Cost-Benefit Analysis: A cost-benefit analysis can be used to compare the costs of different fertilizer application strategies with the potential benefits, such as increased crop yield and improved soil fertility. This type of analysis takes into account the costs of fertilizer, labor, and equipment, as well as any potential income from increased crop production.

Linear Programming: Linear programming can be used to optimize the fertilizer application strategy to minimize costs while still meeting the fertilizer requirements of crops. This approach models the relationship between fertilizer requirements, costs, and constraints, and uses mathematical algorithms to determine the optimal solution.

Life Cycle Cost Analysis: Life cycle cost analysis can be used to analyze the long-term costs associated with different fertilizer application strategies, taking into account both the initial costs and the ongoing costs over the life of the fertilizer application.

Monte Carlo Simulation: Monte Carlo simulation can be used to evaluate the uncertainty associated with fertilizer prediction and cost analysis. This approach uses random sampling to model the variability in fertilizer requirements, costs, and other factors, and provides a probabilistic assessment of the costs associated with different fertilizer application strategies.

Multi-Objective Optimization: Multi-objective optimization can be used to optimize the fertilizer application strategy by considering multiple objectives, such as minimizing costs and maximizing crop yield. This approach uses mathematical algorithms to determine the trade-off between these objectives and find the optimal solution.

These are just a few examples of the many methods that can be used to conduct cost analysis on fertilizer predictions. The choice of method will depend on the specific context and objectives of the analysis, as well as the data and resources available.

The algorithm is going to be precise and effective in calculating total amount, the charge of fertilizer spraying machine, diesel for tractor, electricity charges and money to brought that fertilizer are also included.

At last result will display the overall results to the farmer:

V. CONCLUSION

The prediction of fertilizer is based on parameters as mineral level, soil quality, crop type, moisture, temperature, rainfall which increases accuracy of prediction. By suggesting them approximate amount of fertilizer required prevents excess use and wastage of fertilizer. This system considers all expenses for fertilization process and gives total cost of fertilization process. It will save farmer's money, as farmers do not have to rely on fertilizer brokers, they will directly get the current real price of the fertilizer. It is cost effective and avoid wastage of fertilizers, as farmers sometimes brings more fertilizer than they needed, so we will tell them

approx. quantity that is enough for their land, this will save their money as well avoids wastage of fertilizers.

It saves time and energy of farmers as they are getting everything calculated, so they don't have to input their time and energy on such estimations.

VI. FUTURE SCOPE

The future scope of fertilizer prediction using AI and ML is very promising. As these technologies continue to advance and become more widely adopted, we can expect to see even more accurate and sophisticated predictions about fertilizer use in agriculture. Some potential areas of growth for fertilizer prediction using AI and ML include:

Increased automation: As AI and ML algorithms become more advanced, we can expect to see increased automation of fertilizer prediction. This will allow farmers to make decisions about fertilizer use with less effort and greater speed.

Improved accuracy: As more data is gathered and algorithms continue to improve, we can expect to see even more accurate predictions about fertilizer use. This will help farmers make better decisions about fertilizer use, leading to more sustainable and efficient agriculture practices.

Integration with other technologies: As fertilizer prediction using AI and ML becomes more widespread, we can expect to see it integrated with other technologies in agriculture. For example, AI and ML could be integrated with sensors and other monitoring systems to provide real-time data on crop growth and fertilizer use.

Expansion to new crops and regions: As AI and ML algorithms become more sophisticated, we can expect to see them expanded to new crops and regions. This will allow farmers around the world to benefit from these technologies and make better decisions about fertilizer use.

ACKNOWLEDGMENT

We Would Like To Express My Special Thanks Of Gratitude To Our Guide Mr.Sudhir Dhekane, Who Gave Us The Opportunity To Do This Wonderful Research Work On The Topic Fertilizer Prediction And Cost

Analysis Using Machine Learning Algorithms Which

Also Helped Me In Doing Lots Of Research And We Came To Know Many Things We Are Really Thankful To Him And Even My Friends.

Abstract— **The healthcare industry generates a massive amount of data every day, and machine learning has become a widely used tool to identify patterns and make predictions. With the help of machine learning, real-world problems in the healthcare industry can be solved more efficiently, and researchers are exploring more advanced technologies to improve the accuracy and effectiveness of their approaches. A recent study that describes the current state of disease prediction methods, particularly with respect to prediction algorithms, can provide a better understanding of the latest models developed in this field. Additionally, this paper compares the advantages and disadvantages of various approaches used to predict diseases such as Breast Cancer, Heart Disease, and Diabetes. Finally, the paper highlights some research directions that can be pursued in the future to improve disease prediction in the healthcare sector.**

Keywords- Heart Disease, Breast Cancer, Diabetes, Machine Learning, Classificatio

I. NTRODUCTION

As the world becomes more fast-paced, many healthcare organizations have emerged that offer continuous monitoring solutions, such as smartwatches that consistently track a patient's health and fitness. In the past, patients would visit a clinic and rely on the doctor's expertise and experience to diagnose and prescribe appropriate treatments. However, this outdated method of diagnosis often results in delayed treatment and a higher incidence of health problems, especially in countries like India that are experiencing rapid growth and development.

The healthcare industry has experienced a transformation due to the adoption of technology. This modern approach has led to the development of computer-aided support systems and tools, which have greatly improved patient care while reducing the cost of treatment by increasing efficiency in medical resources. However, designing a predictive system that can accurately predict diseases using available medical data is a significant challenge that requires careful consideration.

The healthcare industry is a significant generator of data, which is used by predictive models to extract relevant information about a patient's specific disease. This extracted information is then used to provide more effective and better-tailored treatments. Machine learning has been widely adopted in the healthcare industry to address various real-world problems that previously required the time and expertise of an individual. Large amounts of data, including patient records, medical images, and reports, are produced in the healthcare sector and serve as datasets that help identify patterns and make predictions.

Our proposed system incorporates multiple disease predictions within a single user interface, including heart-related diseases, breast cancer, and diabetes. We will use machine learning classification algorithms, such as Logistic Regression and Random Forest, to predict these multiple diseases.

II. Literature Review

A. Survey Existing System

Senthil Kumar Mohan et al. [1] presented a promising approach for predicting heart disease using a hybrid machine learning approach. The goal was to identify important features by applying machine learning techniques to improve the accuracy of predicting cardiovascular disease. The prediction model was created using a diverse set of features and various well-known classification methods such as k-Nearest Neighbors (kNN), Logistic Regression (LR), Support Vector Machines (SVM), Neural Networks (NN), and Voting. In recent times, different data mining techniques and prediction methods have been widely used to detect and predict heart disease. The system achieved an accuracy of 88.47%, indicating its effectiveness in predicting heart disease.

In their study, Lambodar Jena et al. [2] focused on predicting the risk of serious diseases using distributed machine learning classifiers, utilizing algorithms such as Naive Bayes and Multilayer Perceptron. The research aimed to predict Chronic Kidney Disease and achieved high accuracy rates of 95% and 99.7% for Naive Bayes and Multilayer Perceptron, respectively. This indicates the effectiveness of the proposed approach in accurately predicting the risk of chronic kidney disease.

Rashmi G Saboji et al. [3] aimed to develop a scalable solution for identifying heart disease using classification mining and implemented the Random Forest Algorithm. The proposed system was compared against the Naive-Bayes classifier and demonstrated higher accuracy in identifying heart disease, with an accuracy rate of 98%. This indicates the effectiveness of using the Random Forest Algorithm for accurately identifying heart disease.

Rati Shukla et al, [4] recommended prediction and detection for breast cancer by using machine learning algorithms like Decision Tree, Support Vector Machine, Random Forest, Naïve Bayes, Neural Network, and KNN The results of their study indicated that the Support Vector Machine algorithm outperformed all the other algorithms in terms of accuracy. This suggests that the Support Vector Machine algorithm is a promising tool for predicting and detecting breast cancer.

B. Limitation Existing system or research gap

One is based on specialized/clinical text source while another is based on unspecialized text source. In the older method, standard statistical methods and doctor’s intuition, knowledge and experience was used for prognosis and disease prediction. This practice often lead

to unwanted errors and biases, which increased the expenses and affected the quality of service provided to patients.

Existing online health care systems are not reliable and accurate.

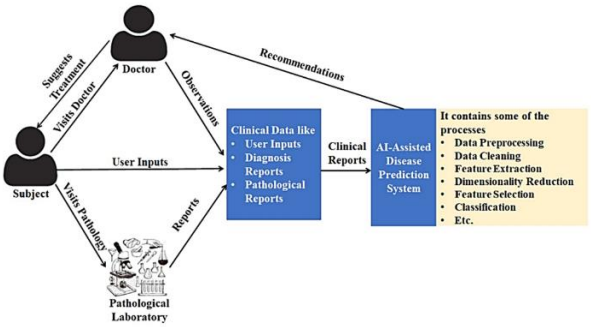

fig. 1: Steps in a general decision support system

C. Diagnosis Method

In many electronic analysis datasets, missing values, redundant information, and irrelevant attributes are common, which can reduce the efficiency of classifiers to gain insights from the data. As a result, researchers have utilized pre-processing methods, such as missing value imputation, data filtering, and data reduction, before providing the data to a classification model.

The pre-processed training samples are then used to create a machine learning module that includes the hyper-parameters of the classifier. In the testing phase, patient information is collected and pre-processed based on the available data from the training stage.

Finally, the pre-processed data is used by the saved learning model to determine whether the patient has the disease or not.

D. Problem Statement and Objectives

The traditional analysis method involves a patient visiting a doctor, witnessing numerous medical tests and then reaching a agreement. This method is highly time-consuming. The design presented in the paper suggests an automated disease prediction system to save time needed for the original manual process of disease prediction. The input to the system is given by the user and output obtained is the set of probable diseases the user might have.

- The main goal of this system is to predict diseases based on the symptoms presented by the patient. The system receives input from the user in the form of symptoms and information, and then generates an output which predicts the most likely disease based on this input.
- In addition to predicting diseases based on user input, this system also includes a database feature that allows the storage of patient data and corresponding diagnosed diseases. This data can be stored as a record and retrieved for future treatment purposes.
- With the advancement of technology, there is a growing demand for an automated prediction system that can accurately predict diseases based on symptoms without the need for physical visits to hospitals. Such a system would enable users to receive a quick diagnosis and seek appropriate treatment without delays.

III. Proposed System

Prior research has mainly focused on assessing the presence or absence of a disease. In this proposed system, we not only aim to accurately predict the disease, but also display the degree of the patient's susceptibility to the disease through a graphical representation. To achieve this, we will collect various parameters from the user and utilize machine learning algorithms such as Decision Tree, Random Forest, Naïve Bayes, and Logistic Regression to obtain the best possible results. The system will analyze and predict on diverse datasets, thereby improving the accuracy of the results. As the accuracy of the system increases, it will become more reliable and trustworthy for patients, instilling confidence and reducing concerns related to disease susceptibility.*Analysis/Framework/Algorithm*

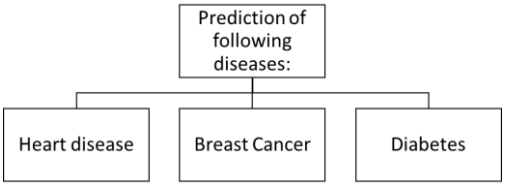
1. Random Forest

Random Forest is an ensemble learning method, widely used for classification and regression problems, providing greater accuracy compared to other models. It can easily handle large datasets and improves the performance of Decision Trees by reducing variance. During training, decision trees are constructed, and the output is the class mode of the individual trees' class predictions.

2. Logistic Regression

Logistic Regression is a classification algorithm used in machine learning. It's a powerful tool for binary classification that is used to predict the probability of an event occurring. The algorithm works by analyzing the relationship between a dependent variable and one or more independent variables. It uses a logistic function to convert the continuous output of the regression model to a binary output, such as yes or no, 1 or 0, true or false. Logistic Regression is widely used in healthcare for predicting the likelihood of various diseases based on the patient's characteristics and medical history.

A. Design Details



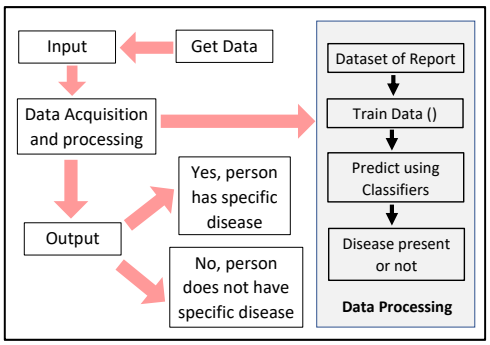


fig. 2 : The Proposed System /System Architecture

B. Methodology

This project aims to predict multiple diseases based on patient-entered data. The process starts by defining the problem statement and preparing the dataset for analysis. Data visualization techniques like scatter plots and graphs are used to identify anomalies and missing values, which are addressed during preprocessing to ensure high-quality data for accurate disease prediction. The prediction is made using machine learning algorithms like Logistic Regression, Naïve Bayes, and Random Forest, which provide early and accurate disease predictions. Python is used as the primary language to carry out the machine learning algorithms due to its widespread use in the field.

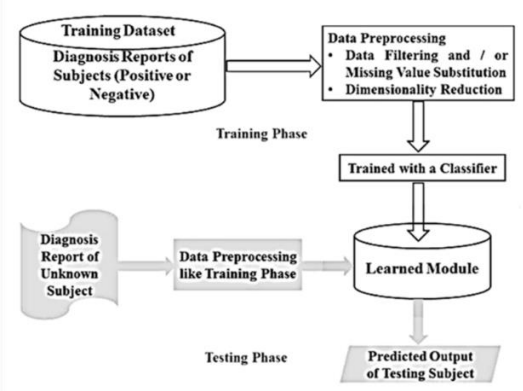

fig. 3: A block diagram illustrating steps for prediction of diseases from a given set of datasets

IV. Experimental set up

A.Details of Database or details about input to systems or selected

We have provided the testing dataset to this trained model for testing the accuracy of model.

B.Performance Evaluation Parameters (for Validation)

Accuracy of the diseases based on algorithm used

1. Breast cancer
   Logistic regression accuracy - 92.1 %

2. Heart disease
   Random forest - 95%

3. Diabetes
   Random forest- 98%

C.Evaluation Metrics

The paper describes multiple disease prediction systems that utilize machine learning models, which are evaluated based on predefined criteria such as accuracy, precision, recall, F1-score, specificity, and area under the receiver operator characteristic curve. These performance metrics can be measured using a confusion matrix or error rate, which provides information on the model's true positives, true negatives, false positives, and false negatives. The confusion matrix is an N x N dimensional matrix, where N is the number of classes, and it is used to evaluate the performance of a prediction model.

V. V. Implemenation

1. Decided the number of the diseases for the project
- Heart Disease
- Breast cancer
- Diabetes

2. Collection of datasets for diseases.
3. Implementation of different machine learning algorithms on diseases like Logistic Regression and Random Forest.

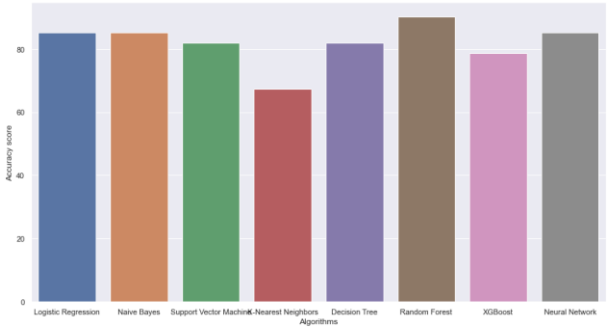

fig. 4: Comparison of various algorithms to find the better algorithm for heart disease

The figure above i.e. fig.4 represents the comparison of various algorithms used to predict the heart disease and which shows that Random forest has the highest accuracy in comparison to others. Similarly we are working on the other two diseases as well as heart disease too to improve the accuracy of model by trying with the different ML approaches possible.

VI. Acknowledgment

We express our sincere gratitude to **Dr. Sanjay U. Bokade**, **Principal,** and **Prof. S. P. Khachane, H.O.D.** of the Department of Computer Engineering at Rajiv Gandhi Institute of Technology, for providing us with the opportunity to undertake our project on "**Prediction of Multiple Diseases using Machine Learning**".

We would like to extend our heartfelt thanks to our project guide, **Prof. D. M. Dalgade**, for his valuable guidance, support and encouragement throughout the project.

We also thank our classmates for their support and cooperation in completing this project.

VII. FUTURE WORK

Our main aim for the future work is to improve the accuracies of these 3 diseases as it is related to health care so it possibly needs the highest accuracy as compared to other fields and we would try to reach accuracy as best as possible. Also we would connect these to frontend part so that it becomes more user friendly so that users can enter the specific values of their parameters defined and predict whether person has disease or not.

Use of ai in Agriculture

Sushant Joshi, Aditya Joshi
Thakur college of engineering and technology, Mumbai ,India
sushjosh9@gmail.com, aadijoshi1702@gmail.com

Abstract -**Artificial Intelligence (AI) has the potential to revolutionize the way we approach agriculture. By analyzing large amounts of data and making predictions based on that data, AI can help farmers optimize their practices to improve yields, reduce waste, and make the industry more sustainable. AI can also help with tasks such as predicting weather patterns, detecting crop diseases, and optimizing irrigation systems. The use of AI in agriculture has the potential to increase efficiency, lower costs, and ensure a stable food supply for a growing global population. However, the implementation of AI in agriculture also raises concerns around job displacement, privacy, and data ownership. As AI continues to evolve, it will be important to address these issues to ensure responsible and fair use of AI in agriculture.**

I. INTRODUCTION

Artificial Intelligence (AI) has the ability to revolutionize the way we approach agriculture. through studying massive quantities of records and making predictions primarily based on that information, AI can assist farmers optimize their practices to enhance yields, reduce waste, and make the enterprise extra sustainable. AI can also assist with duties inclusive of predicting weather styles, detecting crop illnesses, and optimizing irrigation systems. the usage of AI in agriculture has the capacity to increase efficiency, lower fees, and make sure a strong meals deliver for a developing worldwide populace. however, the implementation of AI in agriculture also raises concerns around job displacement, privateness, and records ownership. As AI maintains to strengthen, it'll be important to deal with these troubles to ensure the accountable and equitable deployment of AI in the agriculture sector.

Crop diseases are a major risk to food conservation, but their rapid identification remains difficult in many parts of the arena due to a lack of basic infrastructure. The combination of growing worldwide phone penetration and recent advancements in the imagination and foresight of portable computing, made possible through deep learning, has paved the way for mobile phone- based disease diagnosis. Using a public dataset of

54,306 photos of diseased and healthy plant leaves collected in controlled situations, we train a deep convolutional neural community to detect 14 crop species and 26 diseases (or their absence). The trial version achieves an accuracy of 99.35% on the test set, demonstrating the feasibility of this approach. In general, methods for training deep learning models on larger, publicly available photographic datasets represent a clear path to analyzing crop cell diseases on a global scale.

II. LITERATURE REVIEW

The integration of artificial Intelligence (AI) in agriculture is a hastily developing discipline with a growing frame of literature exploring its various programs and blessings. In recent years, AI technology which include gadget getting to know, pc imaginative and prescient, and robotics have been implemented to various factors of agriculture, ranging from precision agriculture to crop

monitoring, weather prediction, and pest and disorder control. In precision agriculture, AI algorithms are used to analyze information from various sources which includes satellite imagery, sensors, and drones to make unique selections on fertilizer and pesticide software, irrigation, and planting patterns. This allows farmers to optimize their practices, reduce waste, and enhance yields. as an instance, AI algorithms can analyze soil and crop facts to decide the most premier time to apply fertilizer and irrigation, accordingly decreasing the amount of fertilizer and water needed and decreasing the environmental effect of agriculture. In crop monitoring, AI is used to discover crop increase styles and become aware of problems along with disease outbreaks and nutrient deficiencies. as an instance, computer vision algorithms can analyze photos of crops to stumble on signs of ailment, allowing farmers to take proactive measures to control the spread of disease and minimize damage. In weather prediction, AI models are used to make extra correct predictions approximately future climate styles, which could assist farmers make informed choices about planting, harvesting, and storage. as an example, AI algorithms can examine historic climate records and expect destiny climate patterns, permitting farmers to put together for extreme climate occasions and limit crop loss. sooner or later, in pest and disorder control, AI is used to detect and predict outbreaks of pests and sicknesses, helping farmers to take proactive measures to manipulate them. for example, AI algorithms can examine pix of vegetation to discover signs and symptoms of pests, allowing farmers to take measures to govern pest populations earlier than they cause enormous damage. no matter the severa capacity blessings of AI in agriculture, there are also some worries. as an instance, there are questions on the accuracy and reliability of AI structures, information privacy and security, and the moral implications of AI-driven selection-making in agriculture. similarly, there's a need for extra research to recognize the monetary, social, and environmental effect of AI in agriculture. average, the literature on AI in agriculture highlights the good sized potential of these technology to revolutionize the manner we technique agriculture. but, it's far vital to cope with the issues and limitations related to AI to ensure that these technology are deployed in a responsible and equitable manner

III. METHODOLOGY

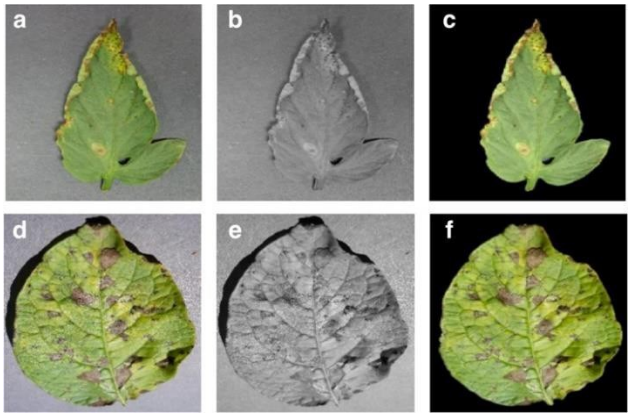
A. Disease Detection

Dataset Description we analyze 54,306 **plant leaf** images **labeled with** 38 **classes.** Each class label **represents** a crop-disease pair, and we **want** to predict crop-disease **pairs** given **only images** of plant **leaves. on figs.** 1 shows one example **for** each crop-disease pair **in** the

PlantVillage dataset. In all approaches described in this **article,** we resize images to **256×256 pixels** and perform both model optimization and **prediction** on these **scaled down** images.

All experiments use three different versions of the full PlantVillage dataset. We start with the PlantVillage dataset as it is, in color; then we experiment with a gray-scaled version of the PlantVillage dataset, and finally we run all the experiments on a version of the PlantVillage dataset where the leaves were segmented, hence removing all the extra background information which might have the potential to introduce some inherent bias in the dataset due to the regularized process of data collection in case of PlantVillage dataset. Segmentation was automated by the means of a script tuned to perform well on our particular dataset. We chose a technique based on a set of masks generated by analysis of the color, lightness and saturation components of different parts of the images in several color spaces (Lab and HSB). One of the steps of that processing also allowed us to easily fix color casts, which happened to be very strong in some of the subsets of the dataset, thus removing another potential bias.

This set of experiments was designed to understand if the neural network actually learns the "notion" of plant diseases, or if it is just learning the inherent biases in the dataset**.** Figure shows different versions of the same leaf for a randomly selected set of leaves.



SAMPLE IMAGES FROM THE THREE DIFFERENT VERSIONS OF THE PLANTVILLAGE DATASET USED IN VARIOUS EXPERIMENTAL CONFIGURATIONS. (A) Leaf 1 color, (B) Leaf 1 grayscale, (C) Leaf 1 segmented, (D) Leaf 2 color, (E) Leaf 2 gray-scale, (F) Leaf 2 segmented.

Measurement of Performance

To get a sense of how our approaches will perform on new unseen data, and also to keep a track of if any of our approaches are overfitting, we run all our experiments across a whole range of train-test set splits, namely 80–20 (80% of the whole dataset used for training, and 20% for testing), 60–40 (60% of the whole dataset used for training, and 40% for testing), 50–50 (50% of the whole dataset used for training, and 50% for testing), 40–60 (40% of the whole dataset used for training, and 60% for testing) and finally 20–80 (20% of the whole dataset used for training, and 80% for testing). It must be noted that in many cases, the PlantVillage dataset has multiple images of the same leaf (taken from different orientations), and we have the mappings of such cases for 41,112 images out of the 54,306 images; and during all these test-train splits, we make sure all the images of the same leaf goes either in the training set or the testing set. Further, for every experiment, we compute the mean precision, mean recall, mean F1 score, along with the overall accuracy over the whole period of training at regular intervals (at the end of every epoch). We use the final mean F1 score for the comparison of results across all of the different experimental configurations.

Approach

We evaluate the applicability of deep convolutional neural networks **to** the classification problem described above. We will focus on two popular architectures: AlexNet (Krizhevsky et al.

2012) and GoogLeNet (Szegedy et al. 2015), developed in the context of the Large

Task of Visual Recognition

(ILSVRC) (Rusakovsky et al.). al., 2015) ImageNet data set (Deng et al., 2009).

The AlexNet architecture (see Figure S2) follows the same design pattern as the 1990s LeNet- 5 architecture (LeCun et al., 1989). A variant

of the LeNet-5 architecture is a set of stacked convolutional layers, usually followed by one or more fully connected layers. A convolutional level can optionally have a normalization level and a pooling level, and every level of the network usually has a non-linear ReLu activation unit connected. AlexNet consists of 5 convolutional layers, 3 fully connected layers, and finally ending with a softMax layer. The first two convolutional layers (conv{1, 2}) are followed by regularization and union layers, and the last convolutional layer (conv5) is followed by a single union layer. The last fully connected layer (fc8) has 38 outputs feeding the softMax layer to the adapted version of AlexNet (corresponding to the total number of classes in the dataset). Finally, the softMax layer exponentially normalizes the input received from (fc8) to produce a distribution of values that sum to 1 across the 38 classes. These values are the current value of the given input image. for that class. There are ReLu nonlinear activation blocks associated with all first seven layers of AlexNet, and the first two fully connected layers (fc{6, 7}) have dropout layers with dropout coefficients of 0.5 connected.

GoogleNet architecture, on the other hand, is a much deeper and wider architecture with 22 layers, but with far fewer parameters (5 million parameters) in the network than AlexNet (60 million parameters). Using a network-within-a- *network architecture* in the form of seed modules (Lin et al., 2013) is a key feature of the GoogleNet architecture. The initial module can capture different features in parallel using 1×1, 3×3 and 5×5 parallel convolutions with max pooling parallel layers. From an implementation practical point of view, we need to control the amount of computation involved, so we add 1×1 convolutions (and after max pooling layers) up to the aforementioned 3×3, 5×5 convolutions to reduce

dimensionality. Finally, the filter pooling layer simply combines the outputs of all these parallel layers. This forms one seed module, but the version of the GoogLeNet architecture used in the experiment uses a total of nine seed modules. A detailed overview of this architecture can be found (Szegedy et al., 2015).

Train a model from scratch in one case, then use transfer learning to tune an already trained model (trained on the ImageNet dataset) to analyze the performance of these two architectures on the PlantVillage dataset. For transfer learning, reinitialize the weights of the fc8 layer for AlexNet or the loss layer {1,2,3}/classifier for GoogLeNet. Then, when training the model, we do not constrain the training of the layers as is sometimes done in transfer learning. That is the key difference between these two approaches to learning (translation vs. learning).

Learning from scratch) is in the initial state

of the weights of several layers, so pretrained AlexNet and GoogleNet models extracted from ImageNet (Russakovsky et al.,2015).).

In summary, there are a total of 60 experimental configurations with different parameters:

1. Choose a deep learning architecture: AlexNet.GoogLeNet.

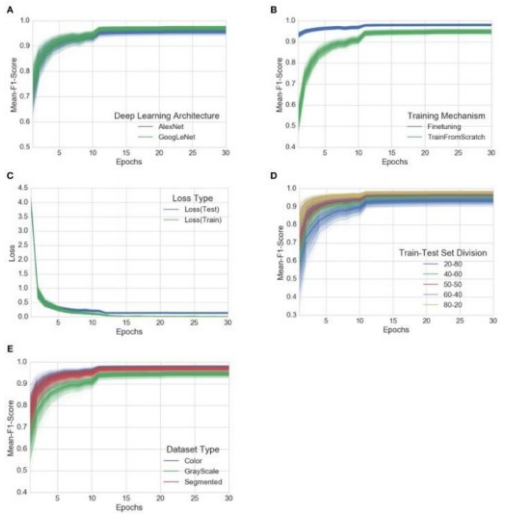
2.Select: Transfer Learning, Learning from scratch.

3. **Select data set** type: Color, Grayscale, Segment Sheet.

4. Select train and test set distribution: train: 80%, test: 20%, train: 60%, test: 40%, train: 50%, test: 50%, train : 40%, Exam: 60%, Training: 20%, Exam: 80%.

Throughout this paper, we have used the notation of Architecture:TrainingMechanism:DatasetType:Tr ain-Test-Set-Distribution to refer to particular experiments. For instance, to refer to the experiment using the GoogLeNet architecture, which was trained using transfer learning on the gray-scaled PlantVillage dataset on a train—test set distribution of 60–40, we will use the notation GoogLeNet:TransferLearning:

Each of these 60 experiments runs for a total of 30 epochs, where one epoch is defined as the number of training iterations in which the particular neural network has completed a full pass of the whole training set. The choice of 30 epochs was made based on the empirical observation that in all of these experiments, the learning always converged well within 30 epochs (as is evident from the aggregated plots (Figure 3) across all the experiments).



PROGRESSION OF MEAN F1 SCORE AND LOSS THROUGH THE TRAINING PERIOD OF

30 EPOCHS ACROSS ALL EXPERIMENTS,

GROUPED BY EXPERIMENTAL CONFIGURATION PARAMETERS. The intensity of a particular class at any point is proportional to the corresponding uncertainty across all experiments with the particular configurations. (A) Comparison of progression of mean F1 score across all experiments, grouped by deep learning architecture, (B) Comparison of progression of mean F1 score across all experiments, grouped by training mechanism, (C) Comparison of progression of train-loss and test-loss across all experiments, (D) Comparison of progression of mean F1 score across all experiments, grouped by train-test set splits, (E) Comparison of progression of mean F1 score across all experiments, grouped by dataset type. A similar plot of all the observations, as it is, across all the experimental configurations can be found in the Supplementary Material.

Results

First of all, on a dataset with 38 class labels, random guessing gives an average overall

accuracy of 2.63%. For all experimental configurations involving three visual

representations of image data (see Figure 2), the overall accuracy obtained for the PlantVillage dataset was 85.53% (AlexNet::TrainingFromScrat ch::GrayScale::80 - 20).) up to 99.34% (for GoogLeNet::TransferLearning::Color

::80–20), indicating great promise of deep learning approaches for similar prediction problems. Table 1 shows the average F1 score, average accuracy, average recall, and overall accuracy for all experimental configurations. All experimental configurations each run for a total of 30 epochs and converge almost consistently after the first learning rate decay step.

Each cell in the table represents the mean F_1 score (mean precision, mean recall, overall accuracy) for the corresponding experimental configuration. The bold values are the F_1 scores of the best performing models in the respective row/column.

Mean indicator F1 for various experimental configurations at the end of 30 epochs.

To solve the overfitting problem, even in the extreme case of changing the ratio of the test set to the training set, training on only 20% of the data and testing the trained model on the remaining 80% of the data, the model would be GoogLeNet::TransferLearning:: For Color::20–80, we achieve an overall accuracy of

98.21% (average score F1 0.9820). As expected, the overall performance of AlexNet and GoogLeNet degrades as you continue to increase the test-to-training set ratio (see Figure 3D), but the degradation is not as drastic as you would expect when the model is actually overweight.mounting.

Figure also shows that there is no divergence between the validation loss and the training loss, confirming that over-fitting is not a contributor to the results we obtain across all our experiments.

Among the AlexNet and GoogLeNet architectures, GoogLeNet consistently performs better than AlexNet (Figure 3A), and based on the method of training, transfer learning always yields better results (Figure 3B), both of which were expected.

The three versions of the dataset (color, gray-scale,and segmented) show a characteristic variation in performance across all the experiments when we keep the rest of the experimental configuration constant. The models perform the best in case of the colored version of the dataset. When designing the experiments, we were concerned that the neural networks might only learn to pick up the inherent biases associated with the lighting conditions, the method and apparatus of collection of the data. We therefore experimented with the gray-scaled version of the same dataset to test the model's adaptability in the absence of color information, and its ability to learn higher level structural patterns typical to particular crops and diseases. As expected, the performance did decrease when compared to the experiments on the colored version of the dataset, but even in the case of the worst performance, the observed mean F1 score was 0.8524 (overall accuracy of 85.53%). The segmented versions of the whole dataset was also prepared to investigate the role of the background of the images in overall performance, and as shown in Figure 3E, the performance of the model using segmented images is consistently better than that of the model using gray-scaled images, but slightly lower than that of the model using the colored version of the images. While these approaches yield excellent results on the PlantVillage dataset which was collected in a controlled environment, we also assessed the model's performance on images sampled from trusted online sources, such as academic agriculture extension services. Such images are not available in large numbers, and using a combination of automated download from Bing Image Search and IPM Images with a visual verification step, we obtained two small, verified datasets of 121 (dataset 1) and 119 images (dataset

2), respectively (see Supplementary Material for a detailed description of the process). Using the best model on these datasets, we obtained an overall accuracy of 31.40% in dataset 1, and 31.69% in dataset 2, in successfully predicting the correct class label (i. i.e. crop and disease information) out of 38 possible class labels. The average accuracy of the random classifier is only 2.63%. Across all images, the correct class was included in the top 5 predictions out of 52 predictions. 89% for data set 1 and 65.61% for data set 2. The best models for both datasets were

GoogLeNet:Segmented:TransferLearning:80–20 for dataset 1 and GoogLeNet:Color:TransferLearning:80–20 for dataset data 2. An example image of such a dataset can be seen in Figure 4 along with a visualization of the activations in the initial layer of the AlexNet architecture.

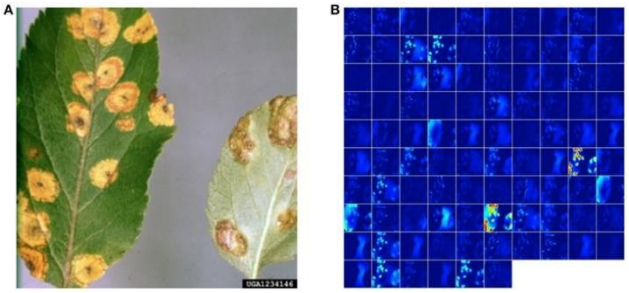

FIGURE 4. VISUALIZATION OF ACTIVATIONS IN THE INITIAL LAYERS OF AN ALEXNET ARCHITECTURE DEMONSTRATING THAT THE MODEL HAS LEARNT TO EFFICIENTLY ACTIVATE AGAINST THE DISEASED SPOTS ON THE EXAMPLE LEAF. (A) Example image of a leaf suffering from Apple Cedar Rust, selected from the top-20 images returned by Bing Image search for the keywords “Apple Cedar Rust Leaves” on April 4th, 2016. (B) Visualization of activations in the first convolution layer(conv1) of an AlexNet architecture trained using *AlexNet:Color:TrainFromScratch:80–20* when doing a forward pass on the image in shown in panel b.

All results so far have been reported under the assumption that the model should determine both crop species and disease status. We can limit the problem to more realistic scenarios that provide crop species, since we can expect them to be known to those who grow them. To evaluate model performance in this scenario, we restrict ourselves to crops with n >= 2 (to avoid trivial classification) or n >= 3 classes per crop. If n >= 2, dataset 1 contains 33 classes distributed across 9 cultures. Random guesses on these data sets will reach zero accuracy.225, the accuracy

of our model is 0.478. If n >=3, the data set contains 25 classes distributed across 5 cultures. A random guess on such a data set achieves an accuracy of 0 .179, whereas the model has an accuracy of 0.411.Similarly, if n >= 2, data set 2 contains 13 classes distributed over 4 crops. Random guesses on these data sets achieve an accuracy of 0.314, while the model has an accuracy of 0.545. If n >= 3, the data set contains 11 classes distributed across 3 crops. Random guesses on these data sets achieve an accuracy of 0.288, whereas the model has an accuracy of 0.485.

IV. CONCLUSION

The performance of convolutional neural networks in object recognition and image classification has made tremendous progress in the past few years. Previously, the traditional approach for image classification tasks has been based on hand-engineered features, such as SIFT, and then to use some form of learning algorithm in these feature spaces. The performance of these approaches thus depended heavily on the underlying predefined features. Feature engineering itself is a complex and tedious process which needs to be revisited every time the problem at hand or the associated dataset changes considerably. This problem occurs in all traditional attempts to detect plant diseases using computer vision as they lean heavily on hand- engineered features, image enhancement techniques, and a host of other complex and labor- intensive methodologies. In addition, traditional approaches to disease classification via machine learning typically focus on a small number of classes usually within a single crop. Examples include a feature extraction and classification pipeline using thermal and stereo images in order to classify tomato powdery ildew against healthy tomato leaves ; the detection of powdery mildew in uncontrolled environments using RGB images the use of RGBD images for detection of apple scab the use of fluorescence imaging spectroscopy for detection of citrus the detection of citrus huanglongbing using near infrared spectral patterns and aircraft-based sensors the detection of tomato yellow leaf curl virus by using a set of classic feature extraction steps, followed by classification using a support vector machines pipeline, and many others. A very recent review on the use of machine learning on plant phenotyping extensively discusses the work in this domain. While neural networks have been used before in plant disease identification, the approach required representing the images using a carefully selected list of texture features before the neural network could classify them. Our approach is based on recent work which showed for the first time that end-to-end supervised training using a deep convolutional neural network architecture is a practical possibility even for image classification problems with a very large number of classes, beating the traditional approaches using hand-engineered features by a substantial margin in standard benchmarks. The absence of the labor-intensive phase of feature engineering and the generalizability of the solution makes them a very promising candidate for a practical and scaleable approach for computational inference of plant diseases.

Using the deep convolutional neural network architecture, we trained a model on images of plant leaves with the goal of classifying both crop species and the presence and identity of disease on images that the model had not seen before. Within the PlantVillage data set of 54,306 images containing 38 classes of 14 crop species and 26 diseases (or absence thereof), this goal has been achieved as demonstrated by the top accuracy of 99.35%. Thus, without any feature engineering, the model correctly classifies crop and disease from 38 possible classes in 993 out of 1000 images. Importantly, while the training of the model takes a lot of time (multiple hours on a high performance GPU cluster computer), the classification itself is very fast (less than a second on a CPU), and can thus easily be implemented on a smartphone. This presents a clear path toward smartphone-assisted crop disease diagnosis on a massive global scale.

V. ACKNOWLEDGMENT

The preferred spelling of the word “acknowledgment” in America is without an “e” after the “g”. Avoid the stilted expression “one of us (R. B. G.) thanks ...”. Instead, try “R. B. G. thanks...”. Put sponsor acknowledgments in the unnumbered footnote on the first page.*Comput. Vis.* 88, 303–338. doi: 10.1007/s11263-009-0275-4

Abstract— **Face recognition has drawn a lot of attention during the last several years. Face authentication has recently gained a lot of popularity due to its simplicity and the effectiveness of face recognition technologies. Face biometric systems are frequently used to identify an individual's real identity based on physiological characteristics and behavioral patterns. However, this can be faked by malicious users who deliberately try to get around the system's face recognition feature by using different characteristics, such as a snapshot or video of the subject held in front of the camera. In our facial recognition framework, we attempted to distinguish between "genuine" and "false" faces using anti-face spoofing techniques. The suggested method enhances liveness accuracy findings by detecting potential spoofing attempts including placing a 3D printed photo, an eye and mouth photo impostor, and a video of a person in front of the camera.**

***Keywords*— Liveness Detection, Face Spoofing Detection, Anti-face spoofing**

I. INTRODUCTION

Our suggested work's major goal was to use anti- face spoofing algorithms to discern between "Actual" and "Non Real" faces. In order to develop the Convolution Neural Network algorithm, which is frequently used for image processing work, we employed Python programming and the OpenCV, Keras, and TensorFlow frameworks. We have researched several existing systems that typically start with capturing a user's image from a camera, followed by face detection, feature extraction, matching stored features, and determining whether or not there is a match. These systems' vulnerability to spoofing assaults is a problem. It is simple to steal facial data used in biometrics from social media sites or online forums and use it to impersonate devices. To spoof the user's face, videos can be played or a 3D dummy mask of the user can be placed in front of the camera. When physiological signals of life are present in the database, integrated liveness detection may be employed to solve specific challenges. We trained a CNN to discriminate between real and fake faces for a given image input.

II. LITERATURE REVIEW

When liveness of a face is detected, protection against spoofing depends on the features used, such as blinking and different face configurations. Depending on the method used to prevent spoofing, face liveness detection methods are classified primarily based on motion, frequency, or quality. Gang Pan et al. [1] present image spoofing in face recognition using real-time liveness detection using pulsed eye blinks. This method requires only a standard camera and no other hardware to avoid spoofing attacks in an unobtrusive way. Blinking is the physical process of instantly opening and closing the eyelids in less than a minute. A regular camera captures 15 frames per second and creates two face frames used for anti-spoofing purposes. Two frames captured in a sequence are considered independent. Hidden Markov Mod els (HMMs) generate features from a finite set of states. Normal blinking activity

Using the HMM feature detects a spoofing attack.

Tan et al. [2] presented an unobtrusive real-time face spoof detection method. Their methods

included analysis of the Lambert model. To evaluate this method, we collected a large database of facial simulations of 15 subjects under various lighting conditions. Over

50,000 photos were taken with a regular webcam.

Evaluation of the proposed method showed promising performance for forgery detection. Li et al. [3] proposed a method using the Fourier spectrum analysis met hod to classify real and fake face images. king etc. et al. [4] proposed a system using single images or groups of images u sing Fourier spectra to obtain the definition of face liveness. The features of liveand fake faces are unique. During this technique, albedo surface definition is used to differentiate real and fake faces. The Fourier spectrum provides a unique light reflectance that makes a huge difference between real and fake faces. For example, the fake face's Fourier spectrum contains higher amplitude frequency components than the real face. There are different approaches to deep learning such as convolutional neural networks (CNNs), multilevel autoencoders [5], deep belief networks (DBNs) [6], [7]. CNNs have commonly used algorithms for image and face recognition. A CNN can be a complete artificial neural network that uses convolutional methodologies to extract features from computer files to increase the number of features. CNN was first proposed by LeCun and first applied to handwriting recognition [8]. P. Huang et al.[9] proposed an adaptive linear discriminant regression classification (ALDRC) algorithm by specifically studying various additions to training samples. ALDRC used different weights to distinguish different training sample additions and used this type of weight information to test for interclass reconstruction errors (BCREs) and intraclass reconstruction errors (WCREs). ALDRC then tries to find the optimal projection matrix that can increase the ratio of BCREs to WCREs. Extensive experiments performed with AR, FERET and ORL face databases have shown the effectiveness of ALDRC. More recent attempts include Niinuma et al. For Multiview 2D face recognition, we use 3D Morphable Model (3DMM) [10]. In their approach, 3DMM models are fitted to each face gallery image and used to enhance the gallery set with various pose images. For

the input 2D face images, poses are evaluated and a subset of gallery images with parallel poses are used for matching. Taranga et al. [11] achieved 68% accuracy using PCA for facial recognition in an attendance system. The proposed method is a relatively good way for teachers to take pictures of each student at school and upload them to the computer backend system after school [12]. The server then identifies and crops faces from each photo. Finally, students can log in, select a face, and record their attendance. The Haar function proposed by Viola et al. [13] Fast face recognition is possible when used with the AdaBoost cascade classifier. Since then, many researchers have used more advanced features to improve the accuracy of face recognition, such as Local Binary Patterns (LBP) [14], Oriented Gradient Histograms (HOG) [15], and Scale Invariant Feature Transformation (SIFT). devoted to) [16].

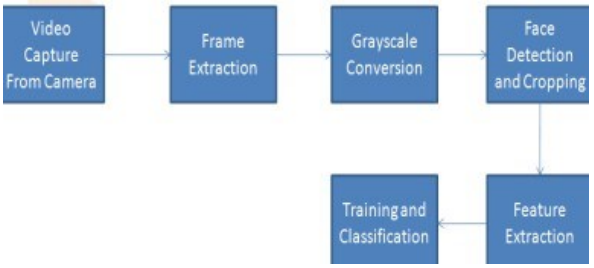
III. METHODOLOGY

We have used Python programming, which has a comprehensive library, to integrate liveliness in face recognition. This allows us to develop solutions much more quickly. In order to develop and train deep learning models, we used the TensorFlow framework and TensorFlow's high- level API binding is provided by Keras. In Keras, building and training models is significantly simpler. We utilized the OpenCV library for reading images and the NumPy library for array operations like rescaling, transforming, and other operations. We examined CNN and ResNet architecture for liveness, and CNN performs better than ResNet. Therefore, CNN was utilized in the final solution. For CNN to generalize the model, a lot of data is needed. Model generalization, which demands a huge amount of data for CNN, illustrates how a deep learning model performs on unknown input. We gathered, analyzed, and used

1.7 million photos to train our framework in order to generalize the model. Eighty percent of the data were used for training, while twenty percent were used for validation. We implemented the concept of transfer learning to reduce training time. We utilized a lightweight MobileNetmodel for quicker training and inference. We have gathered a sizable dataset from public releases. Included Raw image size: 1.2 TB from the LCC-FASD extended, NUAA Imposter, CASIA anti-spoof, and CelebA- Spoof. The photos in CelebA-Spoof include a wide range of lighting, settings, and illumination circumstances and number over 0.6 million. Face anti-spoofing algorithms are trained and evaluated using CelebA-Spoof. Geometric normalization and face detection in the NUAA Photograph Imposter Database. Using a photo or video, the CASIA face Antispoof and LCC FASD datasets detect fake facial identification. Only live photos taken with a mobile device are included in the LCC-FASD expanded dataset, from which we created fake data.

A. Face Liveness Detection

The block diagram of the face liveness detection system is as shown in Fig. 1e



Compared to other security systems, face recognition is utilised for security purposes more frequently. Using digital photos or videos, face recognition is performed. But as we all know, face recognition can also be readily faked, making it risky for our security system, just like other biometric technologies. A security system can be spoof using pictures and video frames. Our system now uses liveness detection technologies to guard against these types of scams and spoofing.

Based on the many approaches employed for liveness detection, the face liveness detection approach was identified. This classification facilitates comprehension of various spoof attack scenarios. The major goal is to provide a straightforward route and a more secure face liveness detection method. The input biometric element is guaranteed to be from a living user using liveness detecting technology, not generated artificially. The aliveness detection method is employed in a variety of contexts to bring out

- Using Hardware- An additional piece of hardware that can be utilised to determine whether the user's input

biometric sample is alive. Given the estimated expense of adding an additional device to more quickly identify liveness than the alternative approaches, it is a comprehensive method.

- Using Different Software- The liveness sample is recognised by procedure software. This will happen during the converting process. This method is used because, although it is equally as sluggish as the other early methods, it is less expensive than hardware-based solutions.

- Combination of hardware and software- For liveness detection, they might combine hardware and software solutions. For the purpose of identifying signs of life, the human body's various inherent qualities, such as consumption, reflectivity, etc., as well as impulsive signals from the human anatomy, such as blood pressure, are also used.

B. **Preprocessing of face liveness detection**

The preprocessing method includes grayscale conversion. The system receives its input from the visual stream. For further processing, the frame is removed and added to the video stream. The extracted frames have RGB color settings. Additionally, the frames must be converted to grayscale in order to detect faces using the Haar cascade classifier. Therefore, the RGB frame is turned into grayscale at the preprocessing stage. Red has greater intuitive power than the other two colors, whereas green has less intuitive power than

red but also has a softer effect on the eyes. thus, the equation for this:

$$\text{e} = (0.3 \times R + 0.59 \times G + 0.11 \times \text{B})$$

In this equation, Red contributed 30%, Green provided 59%, making it the most important hue among the three, and Blue contributed 11% as well.

C. **Face detection**

The most reliable method for detecting objects is a cascade classifier based on Haar features. This method is based on machine learning, and it instructs a cascade function using a set of both positive and negative images. This is used to identify objects in related photos. Face detection is how we operate here. To train the classifier, the method first requires a large number of both positive and negative images. After that, we were asked to draw forth its qualities. By subtracting the total of the pixels below the white rectangle from the sum of the pixels below the black rectangle, each feature is given a single value.

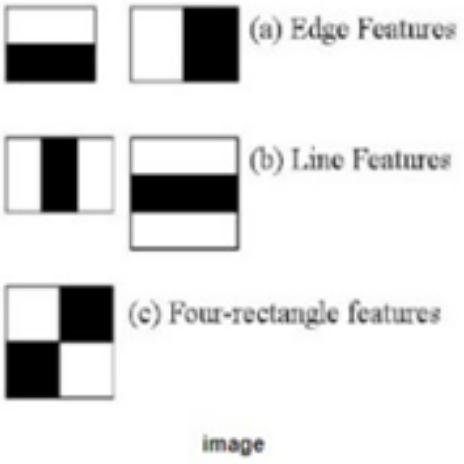


Figure 1 -Haar Feature based cascade classifier

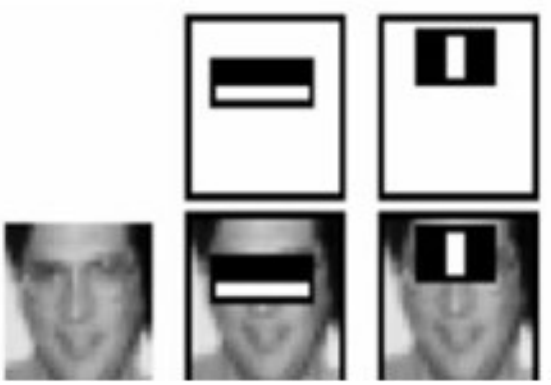
All kernel's possible measurements and positions were used to calculate ever-increasing features. There's a lot of math involved here. We must calculate the total of the pixels beneath the white and black rectangle in the 24*24 window result, which has over 160000 features overall. To overcome this, create an integral image that is so vast that it only needs four pixels to calculate the value of a particular pixel. It produces things rapidly. Therefore, the greatest among all of these attributes is incorrect. Examine the picture below as an illustration. Two superior qualities may be seen in the top row. The first feature chosen says that it is intended to draw attention to the fact that the surface of the eyes is typically darker than the surfaces of the nose and cheeks. The next feature chosen is determined by the thing whose eyes are darker than its nose. So it doesn't matter if the same window is placed in the cheeks or another location. Therefore, choosing from the 160000+ feature is challenging. Adaboost achieves it. Lets see the e.g. of Haar cascade classifier in thee given fig-

IV. FEATURE EXTRACTION



To extract features from photos, a wide variety of techniques have been used. However, the following are some typical approaches:

- Color features
- Spatial features

A. Color features

Three-dimensional colour spaces play a crucial role in defining colours. The concept of three colour stimuli is used to convert the colour span representation into a form that is more hardware and user-friendly. This is achieved by using RGB (Red, Green, Blue), CMY (Cyan, Magenta, Yellow), and YIQ (Yellow, In-phase, Quadrature) colour spaces. The RGB colour space is the most widely used and is applied in LCDs, monitors, and graphics cards. The colour space is made up of three primary colours; red, green, and blue, which are blended together to form the final hue. By adjusting the levels of each of the base colours, it is possible to create any colour that can be seen on a monochromator. For example, by combining red and green, yellow is formed, and by combining red and blue, magenta is formed. White can be created by mixing all three root colours thoroughly, thus any colour can be made by adjusting the intensity of the root colours.

To better understand the concept of colour formation within the colour space, consider the green base colour, which is set on the vertical Y- Axis with an arbitrary range of 0-100%. 0% is represented by black and 100% represents full intensity. By fixing the green colour to a stable value and adjusting the red and blue components, it is possible to see the different colours that can be formed. The colour cube model shows how different horizontal sections and scenarios can be efficiently assembled from the top.

In conclusion, three-dimensional colour spaces provide a useful tool for defining colours and their various combinations. By using RGB, CMY, and YIQ colour spaces, it is possible to convert the colour span representation into a form that is more hardware and user-friendly, allowing for the creation of a wide range of colours.

B. Spatial features

Only a cropped image of the user's face, either real or artificial, is used as the input for the feature extraction block. The illumination qualities that are brightness factor for photo attack and the utilized mask texture

factor are features that are used to determine the liveness of the users. Other fundamental image qualities, such as energy, entropy, mean RGB values, skewness, standard deviation, and mean YCbCr values are used in the liveness detection in order to improve the system's efficiency and accuracy. There is significantly more room to define a threshold to distinguish between real and phoney faces because these values differ for the real and fake faces. **Luminance**- The density of light that is emanating from a flat surface in a particular direction is known as luminosity. It displays the intensity of light reflected from a certain surface. The value of this lighting feature depends on the type of surface and changes depending on how contrasty the surface is. When a real face's brightness is calculated, it has a different value from a fake face's picture. The brightness value for the live face from each portion is random due to the 3D influence of the eyes, nose, etc., however for the fake face, the value is roughly the same due to the lack of variations in the structure or form of the image photo or mobile photo's plane surface.

Using an image's RGB values, a calculation is

made. The following formula will be used to determine luminous intensity.

$$\text{luminance} = (0.299 \times R + 0.587 \times G + 0.114 \times \text{blue})$$

Red, Green, and Blue are the three fundamental color component mean values in this equation. **Variance-** To indicate grey size values, it offers numerous oscillations in grey size values. **Standard Deviation-** By taking the square root of the color distribution's variance out, the second color moment, the standard deviation, will be considered.

C. Classifier

Identifying a fresh perspective into a firm of classification on the basis of a training set of data that includes perceptions whose grouping association is known

D. KNN

A supervised learning classifier is the K-nearest neighbor algorithm. It extracts the K-nearest Sample from the training data and labels the trial case with the label of the closest neighbor with the highest number of votes.

The KNN classification algorithm is:

1. The new sample and a positive integer value k are defined.

2. From our dataset collection, we select the k data entries that correspond to the new testing sample.

3. We determine which category of these entries is

the most comparable.

4. Using the value of K, we provide several samples to the new sample, and this is the categorization.

5. K's value is changed until results are unsatisfactory.

KNN is the most straightforward classification method that may be used in supervised learning applications. In feature space, the goal is to locate the most accurate match to the test data. The KNN algorithm's classification is displayed in the following figure.

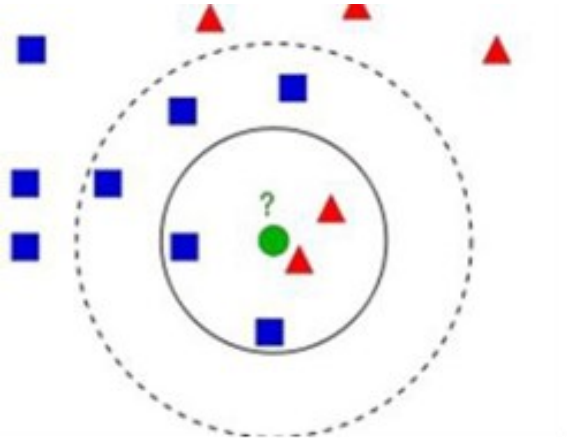


Fig 3-Classification of KNN algorithm

Two families—Blue Squares and Red Triangles— can be found in the aforementioned Fig. Each family belongs to a class. The homes are depicted in the above diagram and are also referred to as feature space. He can build a new home, as seen in Fig. 5, when new residents join the community, as indicated by the green circle.

V. CONCLUSION

The use of a system for detecting liveness and recognizing faces has become a popular research area due to its potential benefits. The system typically captures an image using a camera and then uses a Haar cascade classifier model to detect faces within the image. Once the face has been identified, the image is then sent to a deep learning algorithm for further processing and recognition. This approach offers several advantages over traditional face recognition methods. For example, the use of deep learning algorithms allows for more accurate recognition, while the automated nature of the process saves time compared to manual methods. Additionally, the use of liveness detection helps to prevent fraud by ensuring that the person being recognized is actually present and not using a photograph or other fake representation. By combining these techniques, the system provides a powerful tool for recognizing individuals with a high degree of accuracy and reliability.

Abstract-**With the rapid growth in multimedia contents, among such content face recognition has got much attention especially in past few years. Face as an object consists of distinct features for detection; therefore, it remains most challenging research area for scholars in the field of computer vision and image processing. Face is the crucial part of the human body that uniquely identifies a person. Using the face characteristics as biometrics, the face recognition system can be implemented. The most demanding task in any organisation is attendance making. In traditional attendance system, the students are called out by the teachers and their presence or absence is marked accordingly. However, these traditional techniques are time consuming and tedious. In this project, the OpenCV model integrates a camera that captures an input image, encoding and identifying the face, making the attendance in a spreadsheet and converting it into pdf file.**

***Keywords*- OpenCV, camera, biometric, face recognition, spreadsheet**

I. INTRODUCTION

Nowadays Educational institutions are concerned about regularity of student attendance. This is mainly due to students' overall academic performance is affected by his or her attendance in the institute. Mainly there are two conventional methods of marking attendance which are calling out the roll call or by taking student sign on paper. They both were more time consuming and difficult. Hence, there is a requirement of computer-based student attendance management system which will assist the faculty for maintaining attendance record automatically. In this project we have implemented the automated attendance system using PYTHON. We have projected our ideas to implement "Automated

Attendance System Based on Facial Recognition", in which it imbibes large applications. The application includes face identification, which saves time and eliminates chances of proxy attendance because of the face authorization.

Hence, this system can be implemented in a field where attendance plays an important role. The system is designed using PYTHON platform. The proposed system uses Principal Component Analysis (PCA) algorithm which is based on eigenface approach. This algorithm compares the test image and training image and determines students who arc present and absent. The attendance record is maintained in an excel sheet which is updated automatically in the system. Problem Statement Attendances of every student arc being maintained by every school, college and university. Empirical evidences have shown that there is a significant correlation between students' attendances and their academic performances. There was also a claim stated that the students who have poor attendance records will generally link to poor retention. Therefore, faculty has to maintain proper record for the attendance. The manual attendance record system is not efficient and requires more time to arrange record and to calculate the average attendance of each student. Hence there is a requirement of a system that will solve the problem of student record arrangement and student average attendance calculation. One alternative to make student attendance system automatic is provided by facial recognition.

Face recognition can be applied for a wide variety of problems like image and film processing. human-computer interaction, criminal identification etc. This has motivated researchers to develop computational models to identify the faces, which are relatively simple and easy to implement. The existing system represents some face space with higher dimensionality and it is not effective too. The important fact which is considered is that although these fact images have high dimensionality, in reality they span very low dimensional space. So instead of considering whole face space with high dimensionality, it is better to consider only a subspace with lower dimensionality to represent this face space. The goal is to implement the system (model) for a particular face and distinguish it from a large number of stored faces with some real-time variations as well. The Eigenface approach uses Principal Component Analysis (PCA) algorithm for the recognition of the images. It gives us efficient way to find the lower dimensional space. "Eigenfaces for recognition" (Mathew Turk and Alex Pentland) IR here they have developed a near-real time computer system that can locate and track a subject's head. and then recognize the person by comparing characteristics of the face to those of known individuals. The computational approach taken

in this system is motivated by both physiology and information theory, as well as by the practical requirements of near-real time performance and accuracy. This approach treats the face recognition problem as an intrinsically two-dimensional recognition problem rather than requiring recovery of three-dimensional geometry. taking advantage of the fact that these facts are normally upright and thus may be described by a small set of two-dimensional characteristic views. Their experiments show that the eigenface technique can be made to perform at very high accuracy, although with a substantial -unknown - rejection rate and thus potentially well suited to these applications. The future scope of this project was-in addition to recognizing face, to use eigenface analysis to determine the gender of the subject and to interpret facial expressions. "Fast face recognition using eigenfaces" (Arun Vyas and Rajbala Tokas) [2], their approach signifies face recognition as a two-dimensional problem. In this approach, face reorganization is done by Principal Component Analysis (PCA). Face images are faced onto a space that encodes best difference among known face images. The face space is created by eigenface methods which are eigenvectors of the set of faces, which may not link to general facial features such as eyes, nose, and lips. The eigenface method uses the PCA for recognition of the

images. The system performs by facing pre-extracted face image onto a set of face space that shows significant difference among known face image. Face will be categorized as known or unknown face after imitating it with the present database. From the obtained results. it was concluded that, for recognition. it is sufficient to take about 10% eigenfaces with the highest eigenvalues. It is also clear that the recognition rate increases with the number of training images.

II. System Analysis

The present system of attendance marking i.e. manually calling out the roll call by the faculty have quite satisfactorily served the purpose. With the change in the educational system with the introduction of new technologies m classroom such as virtual classroom, the traditional way of taking attendance may not be viable anymore. Even with rising number of course of study offered by universities, processing of attendance manually could be time consuming. Hence. In our project we aim at creating a system to take attendance using facial recognition technology in classrooms and creating an efficient database to record them.

III. Requirements and Specifications

A. Scope of the system

We are setting up to design a system comprising of two modules. The first module is facing detector, which basically, a camera application that captures student faces and stores them in file using computer vision face detection algorithm face extraction technique. The second module is a web application that does face recognition of captured images in the file, marks the students register and then stores the results in a database for future analysis.

B. Objective of the System

The main objective of this project is to offer system that simplify and automate the process of recording and tracking students' attendance through fact recognition technology. It is biometric technology to identify or verify a person from a digital image or surveillance video.

C. System Requirements

a. Software Requirements

❖ Operating system - Windows 7

Ultimate.

❖ Coding Language - Python.

❖ Front-End - Python b. Hardware Requirements

➢ Processor - Pentium -IV

➢ RAM - 8 GB (min)

➢ Hard Disk - 200 GB

➢ Key Board - Standard Windows

Keyboard Mouse - Two or Three

Button Mouse

➢ Monitor - SVGA. D. System Design

a. Input Design

The input design is the link between the information system and the user. It comprises the developing specification and procedures for data preparation and those steps are necessary to put transaction data in to a usable form for processing can be achieved by inspecting the computer to read data from a written or printed document or it can occur by having people keying the data directly into the system. The design of input focuses on controlling the amount of input required. controlling the errors. avoiding delay. avoiding extra steps and keeping the process simple. The input is designed in such a way so that it provides security and case of use with retaining the privacy. Input Design considered the following things:

➢ What data should be given as input?

➢ How the data should be arranged or coded?

➢ The dialog to guide the operating

personnel in providing input.

➢ Methods for Preparing input validations and steps to follow when error occur

b. Objective

Input Design is the process of converting a user-oriented description of the input into a computer-based system. This design is important to avoid errors in the data input process and show the correct direction to the management for getting correct information from the computerized system.

2. It is achieved by creating user-friendly screens for the data entry to handle large volume of data. The goal of designing input is to make data entry easier and to be free from errors. The data entry screen is designed in such a way that all the data manipulates can be performed. It also provides record viewing facilities.

3. When the data is entered it will check for its validity. Data can be entered with the help of screens. Appropriate messages are provided as when needed so that the user will not be in maize of instant. Thus, the objective of input design is to create an input layout that is easy to follow.

c. Output Design

A quality output is one, which meets the requirements of the end user and presents the information clearly. In any system results of processing arc communicated to the users and to other system through outputs. In output design it is determined how the information is to be displaced for immediate need and also the hard copy output. It is the most important and direct source information to the user. Efficient and intelligent output design improves the system's relationship to help user decision making. I. Designing computer output should proceed in an organized, well thought out manner, the right output must be developed while ensuring that each output clement is designed so that people will find the system can use easily and effectively. When analysis

design computer output, they should Identify the specific output that is needed to meet the requirements.

IV. Design Requirements

We used some tools to build the HFR system. Without the help of these tools, it would not be possible to make it done. Here we will discuss about the most important one. 4.1 Software Implementation OpenCV: We used OpenCV 3 dependency for python OpenCV is library where there are lots of image processing functions are available. This is very useful library for image processing. Even one can get expected outcome without writing a single code. The library is cross- platform and free for use under the open-source BSD license.

V. Test Objectives

➢ All field entries must work properly.

➢ Pages must be activated from the identified link.

➢ The entry screen, messages and responses must not be delayed.

A. Test Approaches

Field testing will be performed manually and functional tests will be written in detail.

B. Types of Testing a. Unit Testing

Unit testing involves the design of test casts that validate that the internal program logic is functioning properly, and that program input produce valid output. All decision branches and internal code flow should be validated. It is the testing of individual software units of the application. It is done after the completion of an individual unit before integration. This is a structural testing. that relics on knowledge of its construction and is invasive. Unit tests perform basic tests at component level and test a specific business process. application, and/or system configuration. Unit tests ensure that each unique path of a business process performs accurately to the documented specifications and contains clearly defined inputs and expected results.

b. Integration Testing

Integration tests are designed to test integrated software components to determine if they actually run as one program Testing is event driven and is more concerned with the basic outcome of screens or fields. Integration tests demonstrate that although the components were individually satisfaction, as shown by successfully unit testing. the combination of components is correct and consistent. Integration testing is specifically aimed at exposing the problems that arise from the combination of components.

c. Functional Testing

Functional tests provide systematic demonstrations that functions tested are available as specified by the business and technical requirements, system documentation, and user manuals. Functional testing is cantered on the following items: Valid Input-identified classes of valid input must be accepted. Invalid Input identified classes of invalid input must be rejected. Functions- identified functions must be exercised. Output-identified classes of application outputs must be exercised. Systems/Procedures: interfacing systems or procedures must be invoked. Organization and preparation of functional tests is focused on requirements, key functions.

VI. Result and Analysis

Using the all the functions we have created: we have tested for output in using existing test images as well as in real-time. Following section. the screenshots of the output of different functions arcgiven. We have tested the system with the help of four volunteers. Taking images from cam to create the test database

Collect Training Dataset Using the function TrainDatabase we create a database of the enrolled students which is stored in the folder.

For more accuracy we can increase the number of training images but with a compromise in the speed of calculation. However, for our application calculation speed variation won't be problem since a class timing is typically at least one hour and this period is just a lot more than the computation time takes by the algorithm. One thing we have keep in mind during this phase is to take the picture in ambient lighting and the frontal fact must be clearly visible. Also, there must be slight variation on the position or expression of the student in each captured image for better results. In normal lighting conditions and based on the proper sitting posture of the students the faces are efficiently captured. The classroom lighting has to be efficiently maintained. Also, in cast of blackouts appropriate alternatives have to be arranged. All the detected faces which can be seen in figure, are cropped and saved in the Test Database folder. From this location the next algorithm read the image and further processing are carried out. The path of the folder must be exactly specified. Also, the name each of the faces are given as numbers

automatically. This helps in easier reading of the images from the folder. Face Recognition Cropped facial images arc fed into the face recognition algorithm and we get the results. The Eigen faces algorithm is applied to the image and compared with the database. We get the output as in figure after this process. If a person whose database is not present in the database, his image is simply ignored.

VII. Output

Output in MS Excel We get the output as given below. After that we can derive the results in appropriate format using different function in the spreadsheet as in figure. We can get the following parameters by using this format as output as shown in the figure. This function is performed using the Spreadsheet Link Ex toolbox of the PYTHON. • If a person is present. a '1 is passed on to the particular field of the student • The date and time are also passed on to the sheet. We can include any number of students' data using this system and provided we use a better quality of an image capturing device. In the next section we describe how we integrate all these function y using the Graphical User Interface (GUI). This gives an easy-to-use interface to the users.

VIII. Conclusion

In this system we have implemented an attendance system for a lecture. section or laboratory by which lecturer or teaching assistant can record students' attendance. It saves time and effort, especially if it is a lecture with huge number of students. Automated Attendance System has been envisioned for the purpose of reducing the drawbacks in the traditional (manual) system. This attendance system demonstrates the use of image processing techniques in classroom. This system can not only merely help in the attendance system. but also improve the goodwill of an institution.

IX. Future Scope

Face recognition attendance system automatically identifies and confirms a person and records attendance based on their face detection. Face recognition attendance systems are catching the attention of both small and large businesses. Facial recognition is a category of biometric security. Other forms of biometric software include voice recognition, fingerprint recognition, and eye retina or iris recognition. So, it can be extended towards security field.

Unlocking the Power of Autonomous Vehicles with Deep Learning for Traffic Sign Detection

Theophilus Baro-Thomas, Ali Safaa Sadiq, Mohammed Adam Taheir
University of Wolverhampton *Nottingham Trent University, Wulfruna Street, WV1 1LY, Wolverhampton, UK*
theobarothomas@yahoo.co.uk, Ali.Sadiq@ntu.ac.uk

Abstract - **This paper presents a comprehensive examination of the use of deep learning, specifically Convolutional Neural Networks (CNN), for the detection and recognition of traffic signs with the aim of improving road safety in autonomous vehicles. Despite the extensive deployment of traffic signs and the significant investments made to reduce the incidence of road accidents, the high cost of smart vehicles equipped with these technologies remains a barrier to widespread adoption. The study takes an academic approach to evaluate the level of confidence in prediction and performance using CNN for the detection and recognition of traffic signs and provides recommendations for improvement. The paper aims to further the understanding of the use of deep learning in road safety for autonomous vehicles and to address the challenges associated with existing methods, including issues with accuracy, computational complexity, and real-time performance. By exploring the potential of CNN for the detection and recognition of traffic signs, the paper seeks to contribute to the development of more effective road safety technologies for autonomous vehicles and to improve the overall safety of drivers and other road users.**

Index Terms - Deep learning, Convolutional Neural Networks (CNN), Traffic sign detection and recognition, Autonomous vehicles, Road Safety.

I. INTRODUCTION

Traffic signs also referred to as road signs, have been instrumental in road safety and navigation for over eight decades. Despite their widespread use, road accidents continue to occur at alarming rates, with human error being one of the main causes. To improve road safety, governments worldwide have invested significant resources in developing new technologies aimed at reducing road accidents.

One such technology is the integration of artificial intelligence and machine learning in road safety. With advancements in technology, smart vehicles with intelligent designs have emerged, promising to reduce the rate of road accidents by detecting and recognising traffic signs in real time.

One subset of deep learning, Convolutional Neural Networks (CNN), is particularly effective for the detection and recognition of traffic signs. CNNs are designed to mimic the workings of the human visual cortex, allowing them to recognise patterns and objects in images and videos. This makes them ideal for detecting and recognising traffic signs, which often have distinctive shapes, colours, and symbols.

Despite the potential benefits of smart vehicles, their high cost makes them inaccessible to the average consumer. This presents a significant challenge for the widespread adoption of these technologies and raises questions about their impact on road safety.

This paper aims to address these challenges by taking an academic approach to the development of deep learning for the detection and recognition of traffic signs, specifically using CNN. The paper will investigate the ultimate level of confidence in prediction and performance using CNN in the detection and recognition of traffic signs. This information will be used to develop recommendations for the improvement of traffic sign detection and recognition, with the goal of reducing road accidents and improving road safety for drivers and other road users.

In conclusion, the proposed paper seeks to contribute to the body of knowledge on the application of deep learning in road safety and to provide valuable insights into the potential impact of smart vehicles on road accidents and road safety. It is important to note that despite the potential benefits of using deep learning for traffic sign detection and recognition, there are several challenges associated with existing methods, including issues with accuracy, computational complexity, and real-time performance. These challenges must be addressed in order to achieve the full potential of these technologies in improving road safety.

II. RELATED WORK

Traffic sign detection and recognition have become essential aspects of the modern world. From communities, and countries, to expert systems such as traffic assistance systems and automatic driving systems, traffic signs play a crucial role in promoting road safety and reducing the number of accidents. These signs are road facilities that convey important information such as guidance, restrictions, warnings, or instructions through the use of symbols or words [1].

Leading vehicle companies such as Audi, Mercedes-Benz, and BMW have been at the forefront of the development of autonomous intelligent technology and have heavily invested in advanced driver assistance. These companies use state-of-the-art CNNs to equip their vehicles with the ability to detect and recognize traffic signs on the road in real-time. This implementation of real-time traffic sign detection and recognition using CNNs is meeting the growing demands of both drivers and users, contributing to a reduction in the number of road accidents globally.

Conducting a comprehensive literature review is a crucial component of the proposed paper, as it aims to provide an overview of existing studies in the field of traffic sign detection and recognition using deep learning. The review will focus on the substantive findings and methodologies of previous studies, examining the various deep learning architectures and how effectively they have been applied. By analyzing

the contributions made by other researchers, the paper can provide a comprehensive understanding of the current state of the field and determine the direction for future research.

i. *Deep Learning – Artificial Intelligence*

Deep learning, a subset of artificial intelligence, is a technique that mimics the human brain's ability to process data and identify patterns for decision-making. It utilizes a Deep Neural Network (DNN), which is capable of learning from unstructured or unlabeled data in an unsupervised manner [2]. As noted by Hargrave, DNN possesses the following key capabilities:

- Deep Learning (DL) is a subset of Artificial Intelligence (AI) that mimics the functioning of the human brain in data processing and pattern recognition for decision-making.
- This technique, known as Deep Neural Network (DNN), is capable of recognizing objects in images, speech recognition, language translation and decision-making without the need for human intervention, as it can learn from unstructured and unlabeled data.
- DNN can also be applied in various fields, such as detecting fraud and preventing money laundering.

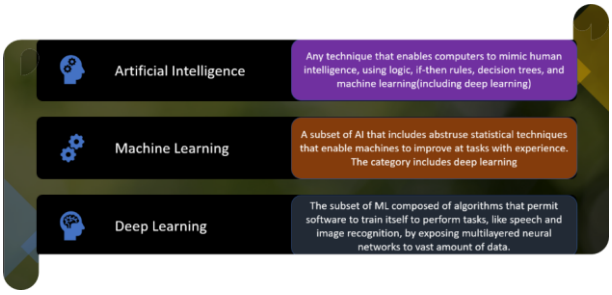

Figure 1. Illustration of the Relationship between Artificial Intelligence, Machine Learning, and Deep Learning.

As stated in [2], deep learning is a component of machine learning that employs artificial neural networks. These networks are comprised of interconnected circles, known as neurons, which are organized into three main sections: the Input layer, Hidden layers, and Output layer. These layers work together to process and categorize the input data, leading to informed predictions and decision-making.

According to the same source [2], the Input layer of a deep learning neural network receives the incoming data and transfers it to the first Hidden layer. The Hidden layers carry out mathematical computations on the inputs and determining the appropriate number of layers and neurons per layer can be a challenge in building neural networks. The Output layer then returns the processed information, with each neuron in the network playing a crucial role in data processing. These neurons have an activation function which normalizes the output from the neuron and enhances the overall effectiveness of the network.

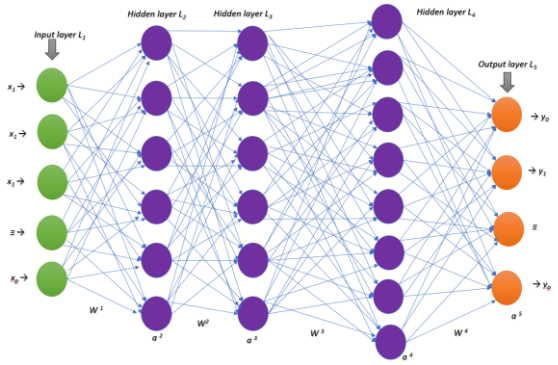

Figure 2. An illustration of Deep Learning Neural Network

A. *Deep Learning Architectures*

Different types of DL architecture exist, including deep neural networks, deep belief networks, recurrent neural networks, and convolutional neural networks. However, this study particularly focuses on Convolutional Neural Networks (CNN), also referred to as ConvNets in some research works. CNN is a type of neural network that incorporates one or more convolutional layers, making it ideal for processing auto-correlated data, such as images, for classification, segmentation, and other tasks [3]. According to the author in reference [4], CNNs have proven highly effective in image recognition and classification, with successful results in identifying faces, objects, and traffic signs, and in powering vision in robots and self-driving vehicles. The architecture of CNN is outlined in Table 1, according to the author in [5].

Table 1. The architecture of CNN.

Convolutional layer	***Creates a feature map to predict the class probabilities for each feature by applying filter that scans the whole image, few pixels at a time.***
Pooling layer(down-sampling)	*Scales down the amount of information the convolutional layer generated for each feature and maintains the most essential information; and the process of the convolutional and pooling layers usually repeats several times.*
Fully connected input layer	*Flattens the outputs generated by previous layers to turn them into a single vector that can be used as an input for the next layer.*
Fully connected layer	*Applies weights over the input generated by the feature analysis to predict an accurate label.*
Fully connected output layer	*Generates the final probabilities to determine a class for the image.*

B. *Techniques in Convolution Neural Network*

There are several techniques developed through various research works, depending on the primary objectives of the researchers. These techniques play a crucial role in the system, from feature extraction to image classification and producing outputs. Researchers emphasize the importance of these techniques in achieving their research goals and objectives. In their journals, they often use the terms "technique" or "method" interchangeably to refer to the same concept. Therefore, in the following subsections, the main two classification methods that are widely used in this field, are briefly discussed.

i. *Linear Discriminant Analysis*

Linear Discriminant Analysis (LDA) is a statistical and machine learning technique used for the characterization and separation of two or more classes of objects or events. The method finds a linear combination of

features that effectively distinguishes between the classes. In machine learning, LDA is a supervised classification method that creates models for applications such as predictive analysis in marketing and image recognition [6]. According to [7], LDA is particularly useful in image recognition tasks where large amounts of pixel values are present, as it reduces the dimensionality of the data and prepares it for the classification process. For example, in face recognition, LDA is utilized to simplify the number of features, allowing for more effective classification.

LDA is a widely used statistical method for pattern recognition and classification. It is a supervised learning technique that aims to find a linear combination of features that characterizes or separates two or more classes of objects or events. The technique works by projecting the original data into a new lower-dimensional space, where the separation between classes is maximized.

In machine learning, LDA is used to build predictive models for various applications such as image recognition, marketing predictive analysis, and face recognition. When dealing with large datasets that contain a lot of pixels, LDA is used to reduce the number of features by extracting the most important ones, which in turn makes the subsequent classification process more efficient.

LDA has several advantages over other dimensionality reduction techniques. One of its main benefits is that it is highly effective in separating classes of objects or events that are well-defined and linearly separable. Additionally, it is computationally efficient and does not require a large amount of computational resources.

However, LDA has some limitations that should be taken into account when considering its use in a specific application. For example, LDA assumes that the classes are normally distributed and have equal covariance matrices, which is not always the case in real-world data. Furthermore, LDA is not suited for complex, non-linear distributions and may not perform well in situations where the classes are highly overlapping.

On the other hand, one of the advantages of using LDA in image classification for autonomous vehicles is its ability to achieve high accuracy in image classification, making it possible for autonomous vehicles to correctly identify and respond to traffic signs and other objects on the road. In addition, LDA is a relatively simple method to implement and does not require a large amount of computational resources.

However, there are also some limitations to using LDA in image classification for autonomous vehicles. One of the main limitations is that LDA assumes that the data is normally distributed and that the covariance matrices of each class are identical. This assumption may not hold in real-world scenarios, resulting in lower accuracy in image classification. Another limitation is that LDA is only capable of solving binary classification problems, meaning that it may not be suitable for applications that require multi-class classification.

Despite these limitations, LDA remains a widely used technique in image classification for autonomous vehicles due to its simplicity, efficiency, and high accuracy. It is an important tool for improving the performance of autonomous vehicles and ensuring that they are able to navigate roads safely and efficiently.

In conclusion, LDA is a powerful and versatile technique that has many applications in machine learning and pattern recognition. While it has some limitations, it is still a widely used method in various fields due to its simplicity and efficiency. It is important to consider the specific requirements of the application and the nature of the data before deciding whether to use LDA or another dimensionality reduction technique.

ii. Support Vector Machines

Support Vector Machines (SVMs), which is also recognised as support vector networks, are a type of supervised machine learning algorithms that are employed for both classification and regression analysis. According to [8], SVMs analyse data for these tasks. The SVM technique categorizes data by creating a dividing line, known as a hyperplane, in a multi-dimensional data plane. This enables the separation of scattered data that doesn't follow a linear pattern, achieved through transforming the classification plane to a higher dimension using a nonlinear kernel function. This function is implemented using a technique called the "kernel trick." In a study by [9], they transformed original images into greyscale images by using SVM and then applied CNN with both fixed and learnable layers for detection and recognition.

Kumar A. D [10] proposed a novel method for Traffic Signs detection by using the deep learning architecture called Capsule Networks. According to Kumar A. D, this technique consists of capsules, which are groups of neurons that represent the instantiating parameters of an object. Though the authors have used dynamic routing in agreement algorithms, it was not specified what these "agreement algorithms" are. Nevertheless, it can be assumed that the choice of classification and identification techniques would be left up to the researcher or user to decide. Kumar A. D found that the Capsule Networks performed exceptionally well on the German Traffic Signs dataset in his research.

However, there are limitations and gaps in the proposed method that need to be addressed. The concept of "agreement algorithms" used in dynamic routing is not clearly defined, and it is left up to the users or other researchers to decide on their own. Additionally, the validity and reliability of the method in real-world applications and the generalization ability of the model to new and unseen data have yet to be thoroughly tested and evaluated. The proposed method may also face challenges when dealing with complex and dynamic traffic sign scenes, such as those encountered in real-world autonomous vehicle scenarios.

Overall, while the proposed method by Kumar A. D holds promise, further research and evaluation are needed to fully understand its potential and limitations. In particular, the development of robust and scalable

algorithms and models that can effectively handle complex and dynamic traffic sign scenes, while ensuring high accuracy and reliability, is of critical importance in the field of autonomous vehicles.

III. Proposed Approach

The study concluded with the significant outcome of the application of Convolutional Neural Networks (CNN). This was highlighted in the Literature Review section of the study. There are many tools and techniques to consider when exploring the phases involved in conducting a study on CNN. These phases are at the core of the CNN process. This study, unlike others focused on Websites, Robotic Games, and Embedded Systems emphasizes accuracy and the evaluation and validation of models (algorithms) examined after undergoing pre-defined phases, from feeding the CNN with input images to processing through deep layers and neuron computations. The CNN prototype is based on such models to produce the desired output.

A. Data Collection

The importance of obtaining relevant data for the successful completion of this study cannot be overemphasized. The study requires the collection of data to create its prototype artefact. Like a mathematical machine that requires inputs to function, the artefact requires input images of the objects under investigation, which in this case are images of traffic signs. There is a vast amount of data available globally, accessible through the web, with no restrictions on the collection of data according to the needs of the researcher. The acquisition of the necessary datasets, along with the development of the required skills, tools, and application of techniques, is crucial for the success of the study. Throughout the course of this study, the pursuit of gaining knowledge, skills, and advice has been ongoing.

Figure 3 provides an example of the collected images of traffic signs.

The research study on CNN required a comprehensive understanding of the tools and techniques involved in the field. The gathering of relevant data and information was imperative for the successful implementation of the project. The research process was a learning journey, which provided an opportunity to gain knowledge and skills on how to experiment with CNN using software libraries like TensorFlow, Python, and PyTorch.

The project was focused on the accuracy of the model and the evaluation of the algorithms after undergoing pre-defined phases. The prototype of the CNN model was based on the results obtained from these algorithms. To aid the research process, Google Colab, an Integrated Development Environment (IDE) was selected. Google Colab, a product from Google Research, provides users with the ability to write and run any Python code from a browser. It is especially advantageous for machine learning, data analysis, and education, as it offers free access to GPUs for speedy processing and does not require any setup.

Consequently, the information gathered without testing would be useless, as it would not show the validity of the model applied to the images. It is imperative to carry out experiments and validate the models to arrive at meaningful conclusions. The selected images of traffic signs were used as the input data for the project, and the outcome was a dependent open-source platform in the real world.

The following steps show the stages of our proposed solution's development.

Input Image:

The input image is a crucial part of the study as it forms the foundation for the development and prediction. The researchers at the Institute for Neuroinformatics in Germany have created a dataset containing over 40,000 images related to 43 different traffic signs. This dataset will be used for the development of the study's artefact.

Convolutional Layer:

The convolutional layer is the core building block of a CNN and is responsible for performing the majority of the computational work. The Literature Review section of the study report (as described in the related work Section) highlights the fact that each layer in a CNN is comprised of neurons with mathematical computational capabilities. However, it is essential to understand the convolutional layer phase of the system or application to appreciate the significance of this phase.

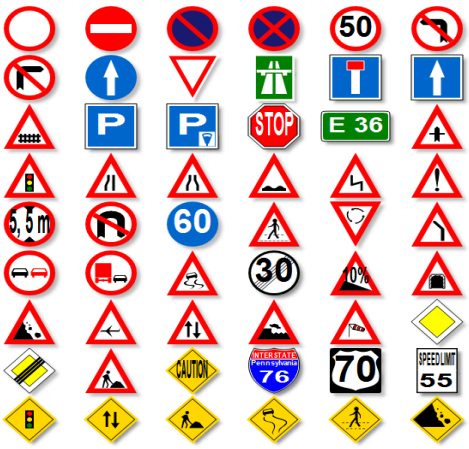

Figure 3. Examples of Traffic and Road Sign Symbols (Pinterest)

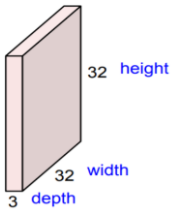

Figure 4. Example input volume in red (32 x32 x 3) and a volume of neurons in the first convolutional layer [11].

The study focuses on the application of CNN to enhance and accomplish its objective. The collection of appropriate datasets, comprising images of traffic signs, is a crucial aspect of this study. The researchers sourced the images from the Institute fur Neoroinformatik in Germany, which includes over 40,000 images of 43 different traffic signs [12].

The core building block of the CNN is the Convolutional Layer, which performs the bulk of the computational work. Each layer contains neurons with mathematical computational abilities, as described in the related work Section.

The Pooling Layer is another important component that is inserted between successive Conv Layers in the CNN architecture. Its purpose is to progressively reduce the spatial size of the representation, thereby reducing the number of parameters and computation in the network, and ultimately controlling overfitting.

Input images in the datasets often come in varying sizes and thus need to be pre-processed by resizing them. In this study, the images were resized to a dimensional size of 32 x 32 x 3, as demonstrated by Figure 4. The following images in Figure 5, are samples from the dataset.

Figure 5. Sign of speed limit: 20 miles/hr, Sign of Go Straight or Turn Right and Sign of Roundabout.

The samples above show the sizes of the images are not the same. It is cumbersome to try to go through all the images in their thousands at different sizes. This is not paramount now; therefore, the tools and techniques of the CNN architecture would resolve all the anticipated issues of concern.

Artificial Neural Network/Fully Connected Layers:

This phase is where the front and backward work or processing of the images is carried out. In this phase of architecture, the decision of choices must be made for the materialisation of the artefact or application. The 2D Convolution is necessary to work on the input images for the CNN experiment. The choices are:

- The quantity of filters and size of the 2D convolutional kernel.
- The size of the Max Pooling kernel in the Pool Layer.
- The quantity of units in the Full Connection layer.
- The batch quantity.
- The optimization method, learning rate, activation function for each layer, and the number of training cycles.

Inside the system of convolution, the stages of pre-processing the images will look like the figure below.

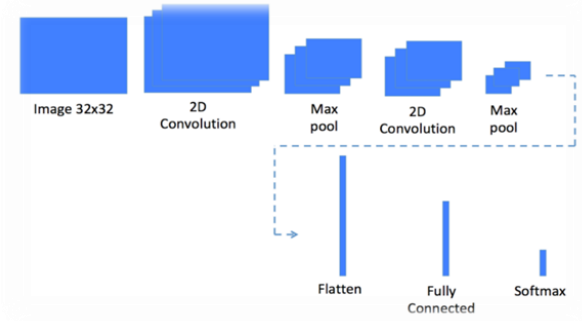

Figure 6. Example of a network architecture [12].

The images in Figure 6 have a resolution of 32 x 32 pixels, yielding a total of 1024 pixels. The 2D Convolution is a hidden layer in the network where many computations occur, transforming the 2D matrix of features into the output pixel on the input layers. While the mathematical operations are not the primary focus of this artefact, it is worth noting that max-pooling involves various dimensional layers, such as 1D, 2D, and 3D, depending on the input matrix dimensionality. According to Computer Science Wiki, max pooling is a sample-based discretization process that transforms continuous functions into discrete counterparts, making them suitable for numerical evaluation and digital computer implementation [12]. The goal of max pooling is to reduce the input representation dimensionality by down-sampling the image or hidden layer output matrix.

The model of the architecture of the convolutional neural network of this artefact would be built using a special model like Sequential, Resnet50 or any other related model. For instance, in Sequential the following parameters are parsed: Conv2D, MaxPooling2D, Flatten, and Dense and the process repeats for several iterations known as the epoch. This would result in the downsizing (or down-sampling) of input images gradually until a desired output of loss and accuracy is achieved.

Output:

In this phase, all CNN input images have been pre-processed thereby giving the output. A typical example of the whole CNN system is shown in Figure 7.

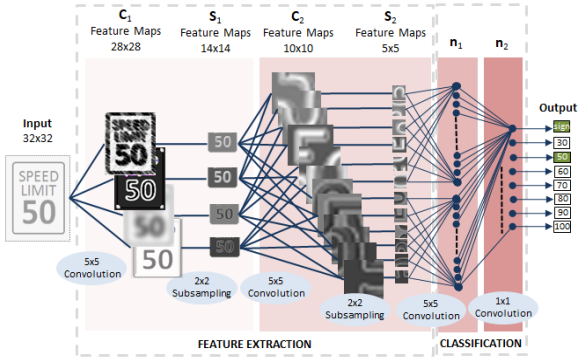

Figure 7. Convolution Neural Network of Traffic Signs Phases. (Folens J, Texas Instruments)

The figure shows when an input image of dimension 32x32 is fed into the CNN. The image undergoes convolutional layers and at the same time, some of the architecture functions do transformation, especially the down-sampling (or subsampling) until the image is a (1 x 1) pixel. In the final phase, the output is at a high confidence limit.

IV. Performance Evaluation

The evaluation and assessment of the classifiers is a crucial step in the study. To gauge the performance of the classifiers, a set of test data, comprising unaltered images, was utilized. These images were carefully chosen to include challenging examples that may have been affected by geometric distortion, blurring, deterioration, and partial occlusion. The aim of including such images is to simulate real-world scenarios and test the robustness of the classifiers. As previously discussed in the Literature Review section, the test data is not expected to be flawless, however, the results of the model's performance are benchmarked against similar findings from prior research studies.

Table Performance Results of the Proposed Model

Loss	Accuracy	Validation loss	Validation accuracy
0.074	0.981	0.087	0.951

The results of the study demonstrate the exceptional performance of the optimizer used in executing the dataset. The accuracy of the model reached 98.1% while the loss was 7.4%, showcasing the effectiveness and efficiency of the chosen optimizer. The utilization of the EarlyStopping function was also instrumental in ensuring that the training process was terminated at the optimal point, minimizing the loss and improving the overall performance of the model.

Moreover, the significance of this study lies in the potential benefits it holds for the future of road sign detection in the field of autonomous vehicles. The development of highly accurate and reliable systems for road sign detection is essential for the safe and efficient operation of autonomous vehicles. This research serves as a stepping stone in that direction and holds the promise of paving the way for more advanced and sophisticated systems in the future.

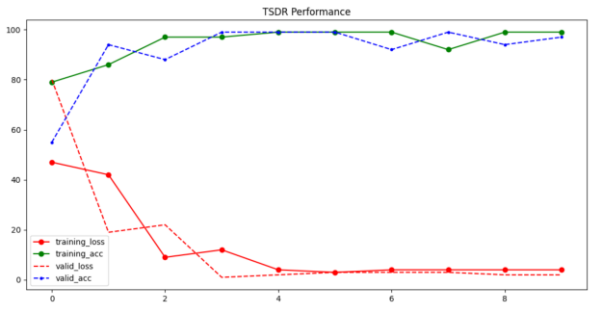

Figure 8. Chart of the Accuracy Vs Loss for the model Performance with TSDR dataset.

It is clear from Figure 8 that the model appears to be improving although there is some improvement to be made. Having run the application for several times the training accuracy and the validation accuracy are closely in a good trend. The model does well when the validation accuracy is not high above the training accuracy in the trending curve. The performance chart is a reflective performance of the model underpinned.

The loss function in machine learning and deep learning refers to a metric that assesses the accuracy of a given algorithm in modelling a specific dataset. The objective is to minimize the error in prediction, which is accomplished through an optimization function. One common loss function is the Mean Squared Error (MSE), which calculates the average of the squared differences between the predictions and actual observations. The formula for MSE will be discussed later in the article.

$$\boldsymbol{MSE} = \frac{\sum_{i=1}^{n}(y - \mu)^2}{n}$$

From the formula μ = mean of the y values. This takes care of the negative values since the expression on the numerator is a perfect square. The above figure shows the behaviour of the loss function as the number of epochs increases. It gradually decreases in value to less than 0.1 or 10%. This is the situation whereby the loss shows that learning of the model of the dataset is improving; not deviating too much from the proposed outcome. If, for example, the predictions deviate too much from actual results, then the loss function would begin to cough up very large values or numbers. This, then indicates that there is a problem with the model.

V. Conclusion

In conclusion, this study successfully proposed and implemented a method of deep learning for traffic and road sign detection and recognition. Despite the initial challenges and uncertainties, the project achieved its goals with the support of a supervisor, a literature review, and personal development in the areas of TensorFlow, Keras, and Python. The study involved using a pre-processed dataset of over 39,000 images collected from different traffic signs, which were fed into a convolutional neural network architecture optimized with the Adam optimizer and the sparse categorical cross-entropy loss. The results of the study showed a high accuracy of detection and recognition of

traffic signs, with an accuracy of 98.1% and a loss of 7.4%. The increasing interest in autonomous vehicles and advanced driving systems has heightened the importance of accurate and reliable traffic sign detection and recognition. The proposed convolutional neural network algorithm provides a promising solution, with results comparable to or even surpassing the benchmark of previous research in this field. Overall, this study contributes to the ongoing efforts towards the development of safer and more efficient autonomous driving systems.

Review on Clinical Decision support system using Artificial Intelligence Techniques

Ms. Neha Patwari
Information Technology Department,Thakur College of Engineering & Technology, Mumbai

Abstract—: **A clinical decision support system (CDSS) provides clinicians, staff, patients, or other individuals with knowledge and person-specific information, to help health and health care. It is called health information technology.CDSS includes a variety of tools to improve decision-making in the clinical work. These tools include computerized signals and notices to care patients, clinical guidelines, condition-specific order sets. It is focused on patient data reports and reviews, documentation patterns, diagnostic support, and contextually relevant reference information, among other tools. There are several applications for CDSS. Among the principal of applications are, Supporting clinical decision- making including patients, Selecting the best treatment plans for certain patients, Aiding general health strategies by evaluating the clinical and economic outcomes of varied strategies, Predicting treatment outcomes when techniques like randomized trials aren't appropriate. In this paper, we provide an overview on the use of clinical decision support systems in medication, including the diverse types, current use cases with proven efficiency, common drawbacks, and potential harms. We conclude with evidence-based references for minimizing risk in CDSS design, implementation, evaluation, and maintenance.**

Keywords— Clinical Decision Support System,Artificial Intelligence

I. INTRODUCTION

CDSSs as "software that designed to be a direct aid to clinical decision-making, in which the features of an distinct patient are matched to a high-tech clinical knowledge base and patient specific valuations or references are then presented to the clinician or the patient for a decision". The main purpose of the review is to recognize what have been attained in dealing with those matters in the past and to search for new strategies to advance the ambiguity handling capability of CDSSs. The databases used for searching related literature in CDSSs for this review include: SicenceDirect, IEEE Xplore and Google..

II. EXISTING SYSTEM

CDSS architecture

A typical CDSS contains three core elements: a base or data management layer, inference engine or processing layer, and user interface.

A data management layer combines

- a clinical database storing information on diseases, diagnoses, and lab findings;
- patient data; and
- a knowledge base in the form of if-then rules or machine learning models.

In inference engine or processing layer applies rules or algorithms and datasets from the knowledge base to available patient data. The results are displayed via a user interface layer — a mobile, web or desktop application, an EHR system dashboard or mobile text alerts.

Preserving the same structure, under the hood CDSSs vary in ways they come to a conclusion, falling into two types — knowledge-based and nonknowledge-based systems.

Knowledge-based CDSS

Systems of this type are built on top of a knowledge base in which every section of data is organized in the form of if-then rules. For instance, if a new order for a blood test is placed and if the same blood test was made within the past 24 hours, then a repetition is possible.

The inference engine runs the built-in logic to combine the evidence-based rules with the patient's medical history and data on his or her current condition. The results come in the form of alerts, reminders, diagnostic proposals, a series of treatment selections or ranked lists of possible solutions while the final word rests with a human expert.

Non-knowledge based CDSS

Systems that do not use a set of defined a priori rules, but as an alternative use artificial intelligence algorithms to

Review on Clinical Decision support system using Artificial Intelligence Techniques

induce the rules through machine learning methods, allowing the system to learn from hundreds or even thousands of happenstances, rebuilding the "model" set of rules as environmental variables change. These systems can be based on neural networks, genetic algorithms, support vector machines, decision trees, or any other machine learning technology, which "learns" to recognize patterns in data sets case by case.

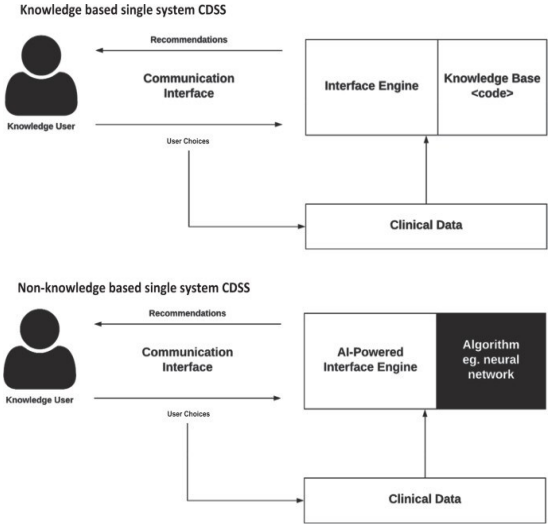

Fig 2.Non Knowledge Based CDSS

They are collected of (1) base: the rules that are programmed into the system (knowledge-based), the algorithm used to model the decision (non-knowledge based), as well as according data available, (2) inference engine: takes the programmed or AI-determined rules, and put on them to the patient's clinical data to generate an output, which is presented to the end user (eg. physician) through the (3) communication mechanism: the website, application, or EHR frontend interface, with which the end user interacts with the system9.

Hybrid CDSSs

Hybrid CDSSs have been developed to allow the end user to synthesize the results from both knowledge and clinical experience, and make a clinical decision based on the results of both. (examples in the literature include Santelices et al., 2010).

In such a hybrid system, multiple predicted outcomes are posed for the physician, based on data input from knowledge and experience bases, and furnished with associated probabilities to permit the selection of the appropriate decision. As we continue to learn more about cognitive science, and distil this knowledge into principles, we can apply them to improve these "intelligent" systems to help us make the best clinical decisions possible at the time. This practice of continuous incorporation of patient data, cognitive knowledge, and clinical experience is referred to often as "rapid learning." Rapid learning approaches that continuously update the CDSS as new data become available provide an ability to create decision models that adapt to the availability of new treatments, interventions, and metrics (variables) that can be input to the modeling process.

Based on such 'training data', ML applications can make

predictions, guide decisions and automatically improve through their own experience. Machine learning is often used within health care as a technological background for clinical decision support systems (CDSS), which serve as a direct aid to clinical decision making and aim at supporting clinicians' practice by matching the characteristics of individual patients with a computerized clinical knowledge database.

FUNCTIONS AND ADVANTAGES OF CDSS

- Patient safety Strategies to reduce medication errors commonly make use of CDSS . Errors involving drug- drug interactions (DDI) are cited as common and preventable, with up to 65% of inpatients being exposed to one or more potentially harmful combinations.

- Clinical management Adherence to clinical guidelines, follow-up and treatment reminders, etc.

- Cost containment Reducing test and order duplication, suggesting cheaper medication or treatment options, automating tedious steps to reduce provider workload, etc.

- Administrative function/ automation Diagnostic code selection, automated documentation and note auto-fill.

- Diagnostics support Providing diagnostic suggestions based on patient data, automating output from test results.

- Diagnostics Support: Imaging, Laboratory, and Pathology Expanding the extraction, visualization, and interpretation of medical images and laboratory test results.

- Patient decision support Decision support administered directly to patients through personal health records (PHR) and other systems.

- Better Records.

- Workflow improvement CDSS can improve and expedite an existing clinical workflow in an EHR with better retrieval and presentation of data.

Challenges in CDSS:

- Poorly designed or implemented, clinical decision support systems can cause more problems than they solve. Alarm fatigue, physician burnout, and medication errors are all detrimental side effects of unintuitive clinical decision support technology, with these events having a harmful impact on patient outcomes and organizations' bottom lines.

2 ***Review on Clinical Decision support system using Artificial Intelligence Techniques***

Alert fatigue A phenomenon where too many insignificant alerts or CDSS recommendations are presented, and providers

Alert fatigue A phenomenon where too many insignificant alerts or CDSS recommendations are presented, and providers start to dismiss them regardless of importance. Negative impact on user skills One example is reliance on, or excessive trust in the accuracy of a system. Financial challenges Setup can be expensive (capital or human resource), and long-term IT testing/debugging during development and implementation stage.

III. LITERATURE REVIEW

In pap er[1], they proposed machine learning structure includ es two stages. Stage I applies online learning using hierarchical temporal memory (HTM) to enable real time stream processing and provides cost-effectiveness is not guaranteed.

- System and content maintenance challenges As practice changes, there can be difficulty keeping the content and knowledge rules that power CDSS up to date

- User distrust of CDSS Users may not agree with the guideline provided by the CDSS.

- Transportability/interoperability CDSS face challenges regarding integration with other hospitals or systems, making it inefficient for otherwise high-quality systems to be disseminated and scaled

- Dependency on computer literacy CDSS may require a very high technological proficiency to use.

- Inaccurate and poor-quality data/ documentation CDSS may aggregate data from multiple sources that are not synced properly. Users may develop manual workarounds that compromise data.

Explanation of solution:

- Prioritize critical alerts, minimize use of disruptive alerts for non-critical indications.
- Avoid prescriptiveness in system design.

Evaluate system impact on an ongoing bas.

- Design and plan for longitudinal cost analysis at the outset. Specify measurements for non- financial benefits where possible.
- Knowledge Management (KM) Service in place, with a focus on translation to CDSS systems. (2) System for measurement and analysis of CDSS performance. (1) Knowledge Management (KM) Service in place, with a focus on translation to CDSS systems. (2) System for measurement and analysis of CDSS performance.
- Reference expert knowledge— include scientific references in messages where appropriate.
- Adoption of industry standards.
- Secure cloud services and blockchain.
- Conform to existing functionality.
- Adequate training made available at launch.
- Expert Knowledge of interlinked systems.

unsupervised predictions. Stage II is a long short-term memory (LSTM) classifier that forecasts the status of the patient's MAP ahead of time based on Stage I stream predictions.

This is the key finding of this paper that ML constitutes a field of artificial intelligence (AI) concerned with the question of how to construct computer programs that automatically improve the accuracy of their output with experience. ML algorithms use sample data (also known as a training data).

The proposed system saves extensive offline modelling, uncertainty, and delays associated with conventional systems. In this model, HTM provides unsupervised predictions in real time, and LSTM provides the classification, it is used to analyze and train on predicted streams. The average prediction time per patient was 150 seconds and the delayed predictions were 75 seconds on average[1].

In paper[2] ,ML Methods used (literary work):KGT

tool is used

Decision Tree-Different platforms have been developed to allow for the creation of DT models to analyse clinical data by non- expert users

ii.The KGT consist on three main modules: DT building, which implements machine learning methods to extract automatically decision trees (DTs) from clinical data frames; an authoring tool (AT), which enables the clinicians to modify the DT with their expert knowledge, and the DT testing, which allows to test any DT, being able to test objectively any modification made by clinician's expert .

Key finding of this paper is according to the review of Safdar (Safdar et al., 2018), which works with ML-based CDSSs for heart disease diagnosis, the use of ML (logistic models, Bayesian neural networks and neural networks) in CDSS improves the diagnosis of Acute Myocardial Infarction from 84 to 95%. In the case of ischemia detection, the use of a CDSS based on a neural network improves its sensitivity from 81 to 86%[2].

In [3] paper, Machine learning is often used within health care as a technological background for clinical decision support systems (CDSS), which aim at supporting clinicians' practice by matching the characteristics of individual patients with a computerized clinical

knowledge database. Among ML techniques, Deep

Review on Clinical Decision support system using Artificial Intelligence Techniques Learning (DL) is the subfield concerned with medical imaging related tasks. Based on imaging, DL model automated the diagnosis of acute ischemic infarction using CT studies, and analysing echocardiographic images.

Key finding of this paper is ML algorithms allow computers to automatically discover patterns in the data and improve with experience. An echocardiographic based DL model was shown to improve the prediction of in-hospital mortality among coronary heart disease and heart failure patients as compared to traditionally used prediction models.

Different tasks where ML can support clinical decision making are Data acquisition, Feature extraction, Interpretation and decision support. clinical validation of this platform will be performed in future[3].

In [4] paper,Applications and Start up in machine learning explained Machine learning can be applied to health care data to develop robust risk models.

The key finding is Healthcare industry is already overburdened with the exploding population and lack of trained doctors. The ratio of doctor to patients in India is

1:1700 which is far higher than the recommended ratio of 1 in every 1000 patients by WHO. Major companies like Enlitic, MedAware, and Google, have launched massive projects focused on improving machine learning and artificial intelligence systems for healthcare system. The spontaneous increase of efficient healthcare providers is not possible. Use of machine learning and artificial intelligence technologies can enhance the productivity and precision of existing ones. Use of these technologies will help in serving

develop a machine learning model that be flexible in recommending books for both new and existing users. Using this application would reduce the time required for selecting a book to read.

Users may find new books that were previously unknown to them. They can find what they should read with the

help of other user's choices and making it convenient for a reader to select a book of his choice from this website.

IV.CONCLUSIONS

AI systems are gradually being adopted from well-established pre-clinical scenarios to the bedside in multiple domains and various use cases. The extensive and unique contributions of AI systems to clinical decision making may generate a substantial impact but necessitate continued rigorous research and tackling of challenges and biases. Regulatory authorization of AI-based medical pipelines constitutes another challenge, given their inherent dynamic and constantly improving analytical nature much-needed uniformity is sought in terms of guidelines for protocols and publications. These require more randomized control trials evaluating, in a standardized manner, the performance of new AI systems in real-life settings. As these challenges are gradually met and existing hurdles are overcome, AI may eventually meet its expectations in integrating into clinical decision making and transforming the data-driven evolution of precision medicine.

Traffic Flow Prediction in Urban Areas

Kaustubh Digarse, Shubham Ghosh, Mrs.Purvi Sanhke
Thakur College of Engineering and Technology, Mumbai, India.

Abstract—**Traffic jams are a common occurrence across the whole world, particularly in a country with a large population like India. As a result, people make every effort to solve this issue in order to get where they want to go quickly to save time. These days, there is a lot of interest in traffic-related research because it will be helpful to everyone who lives in crowded cities. Smart cities are one new innovative solution brought about by the Internet of Things (IoT) that allows people to live more effectively, conveniently, and intelligently. The Intelligent Transportation System (ITS), which improves commuter and transportation processes, is a component of several smart city applications. ITS seeks to address traffic issues, particularly congestion. Research on traffic network was also done to find the most suitable traffic value to forecast or predict the traffic value using time series forecasting models. Traffic forecasting is an integral part of the process of designing of road facilities, starting from investment feasibility study to developing of working documentation. Traffic time- series analysis, which is crucial, is the only subject that deals with both traffic prediction and traffic control. The study reveals a significant difference between the various models' ability to predict traffic reliably and precisely.**

Keywords—Time series models,Traffic forecasting

I. INTRODUCTION

India is more severely congested than any other country in the globe due to its second-highest population after China. India has an uneven distribution of vehicles. It is common knowledge that traffic moves at the speed of its slowest component.The majority of cities have bicycles, scooters, motor vehicles, buses, lorries, and railroads.

But in India, networks of auto-rickshaws, two-wheelers, bullock carts, and hand-pulled rickshaws have been startlingly outnumbering motorised cars in India by a factor of a hundred.. These additional modes of urban transportation contribute significantly to the congestion. However, the growth of the road system has not kept pace with this expansion.

Small traffic control and information approaches are needed to combat the major issue of growing and ongoing traffic congestion in Indian cities, which can then lessen traffic congestion and raise demand for public transportation.

Congestion on metropolitan roadways makes it difficult for vehicles to move, which exacerbates already unpleasant trip delays. Congestion can be temporarily relieved by building new roads or widening existing ones, but in the long run, these actions only serve to boost the number of new vehicles on the road and discourage the use of public transportation.

There are many reasons due to which congestion happens like such as when traffic signals are broken, pedestrians cross the street against the light, an area is overdeveloped when the traffic load on the roads is already heavy,etc Slower speeds, lines, and longer travel times are all symptoms of congestion, which raises economic expenses and has an effect on metropolitan areas and the people who live there.

Indirect effects of congestion include those on quality of life, stress levels, and safety, as well as effects on non- vehicular road space users including those who use sidewalks and properties along roads.

To combat congestion more and more drivers are relying on navigation applications and devices to guide them through the fastest routes and avoid hitting congestion. The best navigation devices use advanced traffic prediction services for accurate estimated times of arrivals (ETAs) and optimized routes during a driver's journey.

For traffic predictions a massive role is being played by Machine Learning. Traffic predictions is critical for two types of organizations.

1. National/local authorities: Many cities have embraced ITS in the last ten to twenty years to aid in the planning and administration of urban transportation networks. These systems make use of real-time traffic data and forecasts to increase transportation efficiency and safety by notifying users about current road conditions and altering road infrastructure. Using this method, the general public can be better informed about TF and weather data on the roadways, minimizing the risk of accidents and increasing overall road safety [1-2].

2. Logistics Companies: Another use is in the logistics industry. Transportation, delivery, and field service are just a few of the businesses that depend on precise scheduling and efficient route planning [3].Travel frequently involves thinking about both the present and the future. For businesses like these, successful planning depends on having accurate projections of traffic and road conditions.

Time-series analysis was used for making Traffic Forecasts and also choosing a model that will be quite beneficial for all people living in congested cities as it helps them get a overview of the traffic hours or a day before they plan to go to a particular place.The Analysis of traffic time series is very important to predict the travel time and usually,it is also using a traffic control system.This is a system that operates on time-series data.The meaning of the time series is,in a fixed time of period data would generate in a series.The aim of the project is to the predict the future traffic that will help us to know the traveling time.On the other hand it impacts the financial growth also.For example,the forecast of the electricity bill of next month can help in deciding anyone to save money for next month.

II. BACKGROUND

A statistical method for analyzing and manipulating statistical data may be called time series analysis. It is constructed from data points that were gathered at regular intervals. Time-series, as we all know, is a collection of data taken at regular intervals. Forecasting is another method that makes the system a little bit more sophisticated.If forecasting is combined with time series, things start to become interesting. It is a method of machine learning. In this case, the input is historical time series data. A number of published publications were looked at to have a better understanding of time series analysis and time series forecasting.

A. Literature Review

The understanding of the inner vehicle frame-work development rule is crucial for control and anticipation. In the paper [4]. For the purpose of converting the traffic stream time arrangement into networks, a permeability chart computation is used. due to the organisations' recent changes. From the first traffic stream, a few attributes will be discovered to identify traffic states. Two broad approaches— multiracial detruded vacillation examination (MFDFA) and permeability diagram—have been offered in order to thoroughly investigate traffic stream time arrangement in different thicknesses. They collected roughly 3000 instances from a street on the left side of the roadway that was designated as their inspection location.

This paper presents a transport traffic estimation method which leverages road network correlation and sparse traffic sampling via the compressive sensing technique. This strategy has been tested with traffic data of over 4400 taxis from Shanghai town, China.The author suggests a strategy to estimating traffic that reduces the effort of people and enhances automation. Accuracy estimates are used to validate this method [5].

In the Citywide Crowd Flows Deep Spatio-Temporal Residual Networks, crowds are expected to move. They play an important part in traffic management. Many factors such as events, weather etc. affect it.They suggested a profound deep learning strategy, known as ST-Res Net, to forecast crowds in all regions of a town. The results of the three remaining neural networks can be aggregated on the basis of

data and are assigned to various branches and regions by ST- Res Net. Two kinds of crowd-flows are experimented with in Beijing and New York City.[6]

In the Real-Time Crash Prediction Dynamic Bayesian Network Motor, the data paper has suggested the Bayesian network dynamic (DBN) system. DBN systems in Shanghai, China were constructed with a time series for the real-time research of 551 accidents and related velocity data, gathered on express ways. A comparison assessment of the model DBN and other machine learning algorithms was also carried out[7]. Machine learning techniques that entail creating and predicting network training structures or LSTM-based prediction models were used to create them. The next objective is to use deep learning techniques to address potential prediction errors that may arise throughout the prediction process. Big data that has been gathered from the performance measuring system is used in this manner.The results of the experiments then reveal that the LSTM model was successful.

A traffic stream prediction model was put forth in this paper [8] for obstructions. This model's star feature is that it depends on the timing. This model will have the capability of predicting future traffic conditions at a particular crossing site. The model is capable of estimating the traffic flow with an accuracy of 88.74% and 81.96% for 15 minutes prior to and 1 hour prior to, respectively.

This model was developed, according to the diary [9], to solve the truck bottleneck problem in a particular area in Bombay. The experts conducted a basic investigation and acquired data. They conducted an extraterrestrial examination subsequently. They then shaped the information according to norms. ARMA and ARIMA models were selected for the problem based on MMSE and MLR criteria. These two were taken into consideration when deciding on the ideal model for each hallway. From that moment on, they showed their approval.

Two combinational conjecture models depending on GM, ARIMA, and GRNN are proposed in this work [10] to increase the traffic stream's ability to be accurately predicted. It then suggests using neural networks to select variable weight coefficients and constructs the Elman combinational estimate model based on GM, ARIMA, and GRNN, which carries out the coordination of these three individuals.

In paper [11], it is discovered that ARIMA performs better than all other scenarios. Nevertheless, this accuracy comes at the expense of the complex nature of calculation

B. Algorithms/Models

Time series can be trend cycles, cyclic, seasonal or irregular. These four components are discussed below:

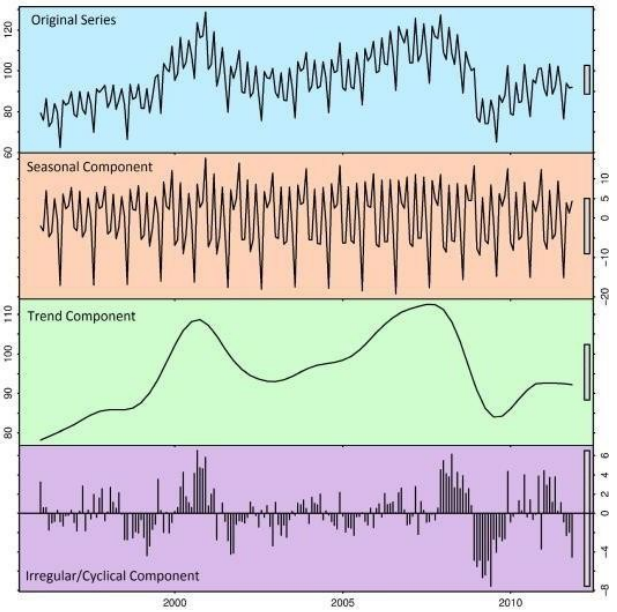

Fig.1 Trend,Seasonal,Cyclical and Irregular graphical

Representation

1) Trend-It is the change in data over a period of time. Underlying rationale, random time series character is provided by a trend that can be deterministic.

2) Seasonal-It is often to know and fixed frequency. A seasonal pattern occurs when seasonal factors affect the time Series-seasonal factors like a particular time of day or year.

3) Cyclic-It is the fluctuation of data. Cyclic does not have a fixed frequency unlike seasonal.

4) Irregular-Data which are represented in a random manner which is due to unknown,unpredicatable non seasonal and short term factors for which future cannot be predicted here.

In this work,a medium scale comparison study for time series models is done which would show the highest accuracy in forecasting the traffic data of the seasonal time series dataset. The models or algorithms considered are Autoregressive integrated moving average (ARIMA) model,Seasonal naïve(SNAIVE),Exponential Smoothing,and PROPHET which are based on time series.

ARIMA: This deals which various types of time-series data for which it uses its resourceful method which is quite simple but sophisticated in making forecast for the data. It stands for autoregressive integrated moving average which is a generalization of auto-regressive moving average with the integration element added. They are class of statical algorithms which is used for forecasting and analyzing data.

ETS: Exponential Smoothing method handles weighted averages of previous observations to forecast future data.As observations became aged in time, these values priority get smaller at an exponential rate since the current values are given more importance in the series. They are a family of forecasting models.

Seasonal naïve(SNAIVE): Sometime the data available is not enough and data which is of time-series type.In such circumstances,the naïve method is used which is used which uses previous data from the last observation to make the prediction for the net data. Now seasonal naïve works for data which are very seasonal works for data which are very seasonal in nature .SNAIVE makes prediction in the same way as naïve month expect for it predicts the last observed data from the same season of the year.

Prophet: The Prophet is an open-source library, developed by Facebook, which is developed for building forecast for univariate time series datasets.It is also known as Facebook Prophet which was published by facebook's core data science team .It is very easy to use. It is built in such a way that it can make accurate forecasts for data having seasonal and trend behaviour. This model is a perfect match for time series data containing having rich seasonal traits.Also seasonal historical data works like a charm for this model. This study shows us the significant difference between each of the models.

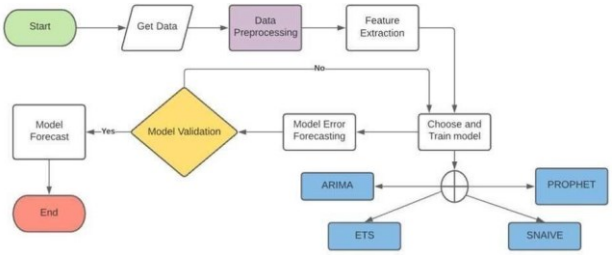

Fig 2.Workflow Diagram

III. PROPOSED METHODOLOGY

Seasonal patterns can be seen in the data, which is a time series data type.The analysis of the traffic data plotted for each street reveals a seasonal pattern-like increase in slope. For the dataset to get to the Implementation stage, data pre processing and feature extraction has to be completed.

1) Programming Tools-

The forecasting models are implemented using python language in jupyter notebook.

2) Target Variables for Time series-

As is well known, time series models must be based on a time variable, and they must also have a target variable that may be predicted in the future. In the data pre processing section, the data is changed of the hour data, which involved combining the date and time columns into a single column and changing.Furthermore, as to anticipate the number of vehicles, "Total Vehicles" is selected as the goal variable. Finally, The cleaning up of the road names and the "road name" is used as a distinctive identifier.

3) Plotting after data cleaning-

Time is used as the independent variable, with which "Total Vehicles" is plotted with time after cleaning the dataset to meet the requirements. The graphic demonstrates the significant seasonality and seeming stationary nature of all the series. The volume of traffic that passes through a street varies greatly depending on the time of year, and almost all streets exhibit seasonality.

4) Forecast Models-

Over a hundred different roads exist here. Even though the majority of them contain seasonal data, some of them also have erratic data. In order to determine which forecasting model works best with which type of data, four distinct models are used.

Four popular and sophisticated forecasting models are—"ARIMA," "ETS," "SNAIVE," and "PROPHET. The prophet is used and tale frameworks to put these models into practice. Multiple time series can be handled simultaneously by the fable package.IV. FUTURE SCOPE

Future versions of the system are frequently enhanced with additional traffic management-related aspects using techniques like deep learning, artificial neural networks, and even big data. The users can then employ this strategy to look for the path that will make reaching their

location the simplest. The algorithm can assist users in making search suggestions and in locating the most straightforward option in an area with less traffic. Road traffic jam forecasting has already used a variety of forecasting techniques. Although there is more room to improve the accuracy of the congestion prediction, there are more techniques that produce reliable predictions.

Additionally, during this time, employing the more recent forecasting algorithms with the improved traffic data available helps enhance the prediction. Today, traffic forecasting is crucial for pretty much every region of the country as well as the entire world. Therefore, this form of prediction might be useful for forecasting traffic in advance. The grade and accuracy are important factors in traffic forecast for better congestion prediction. In the future, it is anticipated that established order accuracy prediction will be estimated using simpler, more approachable techniques so that people will find the prediction model useful and won't waste their time trying to predict the data.

V. CONCLUSION

The most suitable prediction model based on time-series which helps in predicting the future traffic data when

enough dataset is provided was searched but after further research on the project the model which is to be found is not a prediction but rather a forecasting model.

Automated Air Pollution Monitoring and Forecasting System Using Machine Learning

Neha Kapadia, Dr. Bhushan Nemade
Thakur College of Engineering snd Technology, Kandivali,Mumbai,Maharashtra, India
nehap03@gmail.com, bnemade@gmail.com

Abstract - **Recently, many air quality monitoring systems, including WRF-Chem, the community Multi-scale air quality model (CMAQ), and NAQPMS, have been created and implemented. Drawbacks include the fact that WRF-source Chem's list was not promptly updated, that the precise origin of the pollutants and other factors was frequently unknown, and that the quantity of gases discovered was very low. A system that can monitor more gases in a shorter length of time and at a lower cost of deployment was required. The proposed system employs an Arduino Mega, a MQ135 gas sensor module, a 16x2 LCD, a buzzer, a potentiometer, resistors, and other components to automatically monitor and anticipate air pollution using machine learning. Gases such NH3, NOx, smoke, CO2, SO2, and other substances that are the primary cause of poor air quality are detected by the MQ135 gas sensor. Live data is gathered from the module and simultaneously saved. Utilizing Scikit and Flask Framework, a machine learning framework for forecasting models, a model is trained using the gathered data using Polynomial Regression Machine Learning for optimum prediction purposes. The proposed model is expected to detect harmful gases in chemistry labs, washrooms, private organizations, public places etc. The proposed model monitors the upcoming data in no time and if the value goes beyond the threshold value it activates the buzzer and the server is notified. The future scope of the system can be extended by integrating it with more number of sensors to detect more amounts of harmful gases precisely.**

I. INTRODUCTION

Globally, air pollution is getting worse every day. Rapid car growth, inefficient industrial gas disposal, rapid population growth, and climatic conditions including global warming are all contributing to this. As a result, air quality deteriorates due to the discharge of dangerous chemicals such as carbon monoxide, nitrogen oxides, ground-level ozone, particle pollution, sulphur oxides, and lead, among others. According to the World Health Organization (WHO), air pollution causes 4.2 million premature deaths annually in urban and rural regions worldwide1. Particulate matter of a diameter of less than ten micrometres (PM10) is one of the contaminants with the greatest detrimental effect on public health, according to the US Environmental Protection Agency2 (EPA), since it can easily enter the respiratory tract and cause serious health problems. According to Valdivia and Pacsi3, Metropolitan Lima (LIM) is sensitive to high PM10 concentrations because of its rapid industrial and economic growth as well as its substantial population—29% of all Peruvians live there. The system that has been already developed have many limitations. To overcome all the drawbacks of previous models a system is designed and developed using sensor and machine learning algorithm. The system developed in this project is based on Arduino Mega. The sensor used for monitoring the air pollution is MQ135 gas sensor module. To forecast the air pollution condition for a given time, a model is trained using Polynomial Regression algorithm and further the prediction is done based on the trained data.

It has been critical for people to comprehend the impact of air pollution and the trends of pollution since the 1960s, as a result of advancements in air pollution research and control. As a result, air pollution forecasting was underway. Potential predictions, statistical models, and numerical models are the three categories into which forecasting pollution using various patterns of performance can be classified. It is separated into pollution potential forecasting and concentration forecasting for various elements. Forecasts for concentration are produced by statistical and numerical modelling techniques. The meteorological conditions for atmospheric dilution and diffusion capability serve as the basic foundation for potential forecasts. A warning will be issued when it is anticipated that the weather will meet the criteria for potential significant pollution. A concentration forecast will predict the amount of contaminants present. In a concentration prediction, the pollutants' actual concentration in a given area is predicted, and the forecast's outcomes are quantified. These methods for predicting air pollution can be categorized as parametric and nonparametric, or deterministic and nondeterministic, models. It is simple to tell apart deterministic models from nondeterministic models and parametric models from nonparametric models, however it might be challenging to tell apart parametric models from deterministic models.

Artificial intelligence (AI) model-based statistical techniques are the most widely used. Although neural network (NN) forecasting models are more accurate than other statistical models, they still need to be improved. As a result, several researchers have begun using other techniques to increase forecast accuracy.

The AQI quality index categorization is shown with categorization and its impact on human and animal health is described in the following figure.

AQI Category (Range)	PM_{10} 24-hr	$PM_{2.5}$ 24-hr	NO_2 24-hr	O_3 8-hr	CO 8-hr (mg/m³)	SO_2 24-hr	NH_3 24-hr	Pb 24-hr
Good (0-50)	0-50	0-30	0-40	0-50	0-1.0	0-40	0-200	0-0.5
Satisfactory (51-100)	51-100	31-60	41-80	51-100	1.1-2.0	41-80	201-400	0.6 -1.0
Moderate (101-200)	101-250	61-90	81-180	101-168	2.1- 10	81-380	401-800	1.1-2.0
Poor (201-300)	251-350	91-120	181-280	169-208	10.1-17	381-800	801-1200	2.1-3.0
Very poor (301-400)	351-430	121-250	281-400	209-748*	17.1-34	801-1600	1201-1800	3.1-3.5
Severe (401-500)	430 +	250+	400+	748+*	34+	1600+	1800+	3.5+

Fig. 1 AQI quality index categorization

The following figure shows the air quality which impacts to human health.

Air Quality Index Levels of Health Concern	Numerical Value	Meaning
Good	0 to 50	Air quality is considered satisfactory, and air pollution poses little or no risk
Moderate	51 to 100	Air quality is acceptable; however, for some pollutants there may be a moderate health concern for a very small number of people who are unusually sensitive to air pollution.
Unhealthy for Sensitive Groups	101 to 150	Members of sensitive groups may experience health effects. The general public is not likely to be affected.
Unhealthy	151 to 200	Everyone may begin to experience health effects; members of sensitive groups may experience more serious health effects.
Very Unhealthy	201 to 300	Health warnings of emergency conditions. The entire population is more likely to be affected.
Hazardous	301 to 500	Health alert: everyone may experience more serious health effects

Fig. 2 Air Quality Index Levels

II.RELATED WORK

Air pollution is viewed as an inescapable fact. Much has been written on environmental pollution accidents in recent years, particularly air pollution incidents. If environmental concerns are overlooked in the process of societal growth, the earth's natural environment would steadily deteriorate, putting the planet in risk every day. It is commonly understood that, as compared to land and water contamination, the air pollution's effects are more severe. Scholars have done a number of studies on air pollution, ranging from pollution sources to pollution management and forecasting, as well as the issue of pollutants inventories, pollution analyses, and pollution alarms. These themes serve as the foundation for the air pollution research discussed in the subsequent sections.

Smart cities have attracted a lot of attention in the context of urban development strategies. Web and broadband networking advancements are viewed as facilitators of e-services and are becoming increasingly important for urban development. Cities are increasingly accepting a major role as growth drivers in areas such as health, consideration, the environment, and business [5]. As a result, there are numerous considerations associated with action control cities [6], and this point is identified inside urban communities. Quality checking is a topic that is connected to actively controlling and is discussed in the same section.

Many of the efforts in the field of discussing connected to actively controlling and is discussed in the same section. Many of the efforts in the field of discussing pollution in smart cities center on the testing criteria regarded as hazards. A big data analytical technique [7] employs Ozone, CO, NO2, and SO2 levels, as well as data from smart cities, activity, time, and observation, to aid in urban planning decision making. In any event, these studies do not suggest any approach for anticipating contamination or detecting relevant factors for the next days. With ever-increasing air pollution levels, it is critical to implement effective discuss quality monitoring models based on data obtained by pollution sensors, which aid in anticipating the concentration of artisans and providing an evaluation of air contamination in each place. As a result, air quality evaluation and forecasting have emerged as critical study areas. There is an unmistakable bigger piece of usage of Artificial Neural Networks (ANN) in association with works inside the composition that do consider the hypothesis of air defilement contrasted with other models, for example, multiple linear regressor (MLR) [8]. Because this is the most popular viewpoint, it is crucial to note that ANNs have a few shortcomings for this topic, as identified [9]. An explanatory technique for show determination and they follow a long-running procedure to achieve the most precise demonstration. To summarize, contemporary ways that integrate machine learning methods with the use of air pollution information to get it and make strides forecasting air pollution [10].

III.PROPOSED WORK

A novel method to monitor air pollution using sensor and forecast it using Machine Learning algorithm. This system aims at developing a cost effective Air Pollution monitoring and forecasting system which could detect different air pollutants and harmful gases. Ammonia, Nitrogen Dioxide, alcohol, benzene, smoke, Carbon dioxide, Sulphur dioxide, and other gases are detected by the MQ135 gas module.

MQ135 module is connected to Arduino Mega which sends the collected air quality values to the storage. The prediction model is trained using Regression and Polynomial Regression algorithms which belong to for the prediction of air quality. The model is applied on the collected and forecasting is done using Scikit and Flask Framework which consist of libraries used for prediction.

Calculation of AQI:

1. The Sensors are used to measure the concentration of gases in parts per million or mass per volume.
2. The goal is to convert the pollution concentration into a number between 0 and 500. The AQIs of 0, 50, 100, 150, …500 are referred to as breakpoints.
3. The conversion can be done using online AQI conversion tool. Each AQI breakpoint corresponds to a defined pollution concentration.
4. The AQI is determined by the pollutant with the highest index. For example, if the PM2.5 AQI is 125, SO2 is 30, NOx is 50, and all other pollutants are less than 125, then the AQI is 125–determined ONLY by the concentration of PM2.5.

The architecture of the proposed system is shown in the following figure:

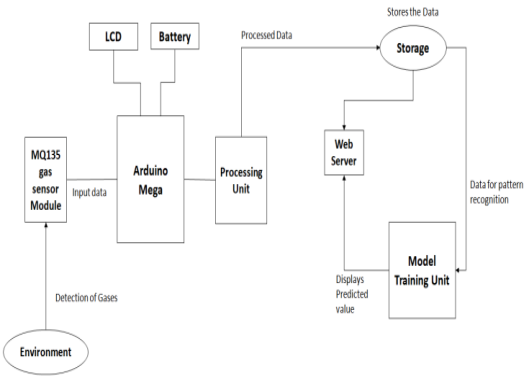

Fig. 3 Proposed Architecture

Number of gases detected by the system plays a major role on the performance of the system. As per shown in the proposed architecture, the various gas sensor modules will read the amount of gas present in the sir. The Arduino Mega microcontroller will transfer the data from sensors to cloud server. The collected data will be processed and prediction model will be trained to predict the amount of gas in the air. from the identified amount, the air quality will be checked and categorized as good or bad quality.

The flowchart of the system is given below:

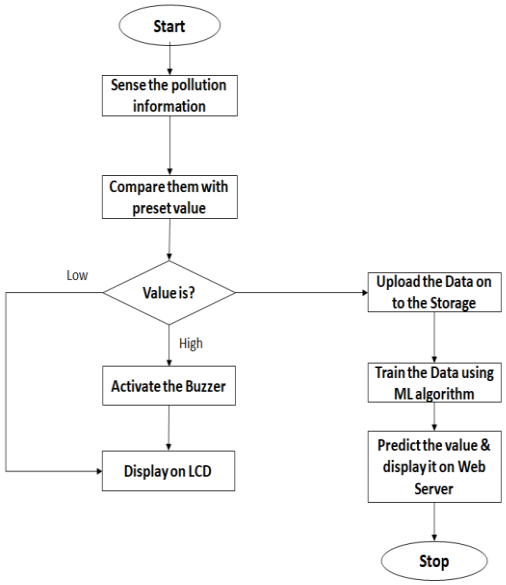

Fig. 4 Flowchart of the Working System

IV.RESULT & DISCUSIION

The air pollution databases were extracted from kaggle. In the proposed system, the dataset contains parameters as listed Station Id, Date, PM2.5, PM10, NO, NO2, NOx, NH3, CO, SO2, O3, Benzene, Toulene, Xylene, AQI. The dataset is of a city which contains various gases used to predict the AQI. As mentioned earlier the machine learning approach is used to prepare the prediction model and the results are displayed on web application connected to the server. Here AQI prediction levels are as follows 0-Good, 1-Moderate, 2-Poor, 3-Satisfactory, 4-Severe, 5-Very Poor. The dataset is shown in the following figure:

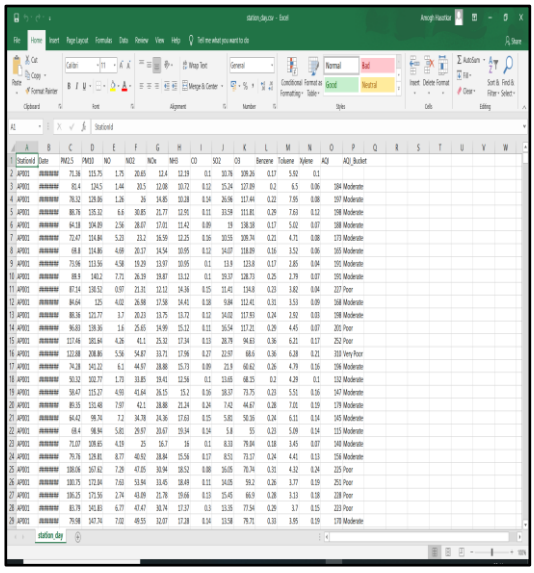

Fig 5. Dataset

Following are the hardware and software requirements of the proposed system.

Software Requirements:

1. Windows OS
2. Arduino software Development Environment (ASDE)
3. SciKit & Flask Framework
4. Python IDLE

Hardware Components:

1. Arduino Mega
2. MQ135 gas sensor module
3. 16x2 LCD
4. 10K Potentiometer
5. Breadboard
6. Resistors (100 Ohm & 220 Ohm)

The Arduino IDE along with its serial monitor displaying the sensor read values from the environment. The values are being displayed on the serial monitor through port COM6 with Baud Rate of 9600. The predefined threshold value is defined in the provided code. If the sensor read values goes beyond that threshold value, the buzzer gets activated.

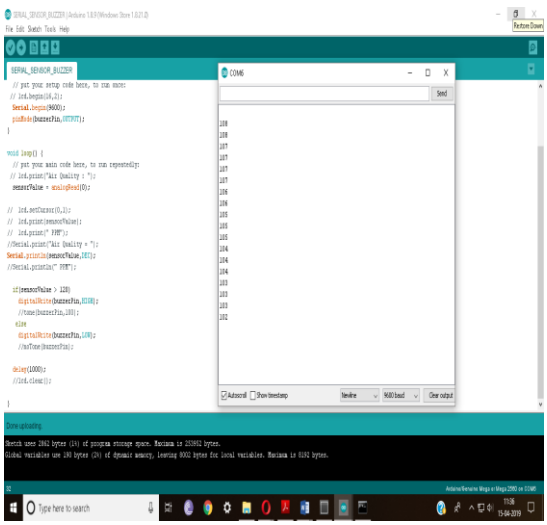

Fig. 6 Arduino IDE & Serial Monitor displaying read values

Fig 7 Activation of the web server using Flask Framework

Web server displays the predicted value for a manually selected event. Polynomial Regression Machine learning Algorithm is used to train the stored data.

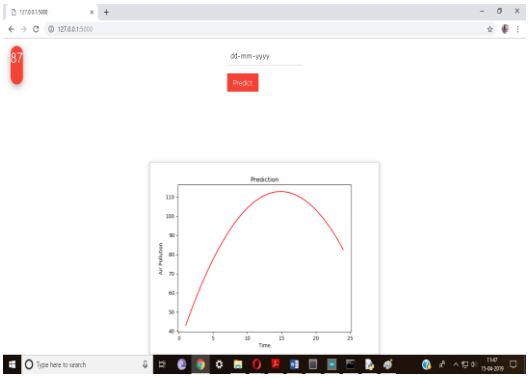

Fig 8 Predicted Result 1

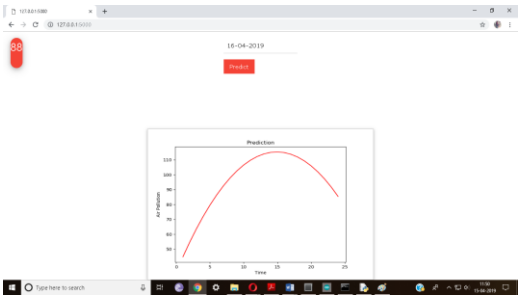

Fig 9 Predicted Result 2

Also, the performance of the model is tested using various metrics which are shown below:

```
In [18]: from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score
         print('\nAccuracy: {:.2f}\n'.format(accuracy_score(y_test, y_pred)))

         print('Micro Precision: {:.2f}'.format(precision_score(y_test, y_pred, average='micro')))
         print('Micro Recall: {:.2f}'.format(recall_score(y_test, y_pred, average='micro')))
         print('Micro F1-score: {:.2f}\n'.format(f1_score(y_test, y_pred, average='micro')))

         print('Macro Precision: {:.2f}'.format(precision_score(y_test, y_pred, average='macro')))
         print('Macro Recall: {:.2f}'.format(recall_score(y_test, y_pred, average='macro')))
         print('Macro F1-score: {:.2f}\n'.format(f1_score(y_test, y_pred, average='macro')))

         print('Weighted Precision: {:.2f}'.format(precision_score(y_test, y_pred, average='weighted')))
         print('Weighted Recall: {:.2f}'.format(recall_score(y_test, y_pred, average='weighted')))
         print('Weighted F1-score: {:.2f}'.format(f1_score(y_test, y_pred, average='weighted')))

Accuracy: 0.81

Micro Precision: 0.81
Micro Recall: 0.81
Micro F1-score: 0.81

Macro Precision: 0.78
Macro Recall: 0.74
Macro F1-score: 0.76

Weighted Precision: 0.81
Weighted Recall: 0.81
Weighted F1-score: 0.81
```

Fig. 10 Accuracy Metrics

Precision is the percentage of results that are relevant of the entire result . According to our model micro precision is 81% i.e. 81% of the total result is relevant. The precision results differ in Macro precision i.e. 78% and weighted precision i.e. 81%.

Recall refers to the percentage of total relevant results correctly classified by your algorithm. According to our model micro recall is 81% that means out of the relevant results found from precision 81% of them are correctly classified by our Algorithm. The results differ in Macro recall i.e. 74% and weighted recall i.e. 81%. By analyzing the results shown and mentioned above the accuracy of our model is 81%

V. CONCLUSION

- Air quality has been degraded over the years due to industrialization, increase in population, increase in vehicles, meteorological factors, global warming etc. This project aims to monitor the air quality and predict the quality for the future scene.
- For the proposed model, hardware and the software components used for the development of the system are Arduino Mega, MQ135 gas sensor module, Scikit, Flask Framework, Arduino IDE etc.
- The proposed project works for predicting harmful gases like Carbon Mono-oxide (CO), Carbon di-oxide (CO2), Sulphur Dioxide (SO2), Ozone (O3), NH2 etc.
- We have followed various phases and worked on it to know about the existing system and their drawbacks. Which can be further used to analyse the better things to be done in proposed system
- The proposed model tries to improve upon the existing system providing with better efficiency, accuracy and low-cost budget.
- The proposed system has future scope in which same system can be integrated with more than one sensor for predicting many other gases.
- There are areas in which the proposed system can be improved upon and further improve the robustness and capabilities of the system.

A Feature Selection Algorithm for Brain Tumor dataset

Dr. Prem kumara Chandarakar, Pritam Das
Mahant Laxminaraya Das College, Raipur , Chhattisgarh , India

Abstract-**Brain Tumor dataset produces huge amounts of data with large features. This data measure implies low quality, unreliable, redundant, and noisy data to examine useful. Therefore, researchers require relevant and high-quality data from big data using feature selection techniques. Feature selection technique (FST) is important preprocessing of data that recues irrelevant features from dataset and increase the performance in terms of computational speed. It brings immediate effects for application: speeding up a data mining algorithm, improving the data quality and data mining performance, and increasing the comprehensibility of the mining results. A different type of attributes (features) selection techniques include in the machine learning area. The primary role of this process is to eliminate unrelated or disused elements from the dataset. The data mining algorithms have improved the performance with chosen feature, relevant or important feature subset; hence computationally enhance the accuracy of data mining and MLTs. Various FSTs of big data, such as filter approach, wrapper approach, hybrid approach. In this paper we are using the brain tumor datasheet. Brain Tumor and we can select their important features by using the PCA, Genetic Search algorithm, Best First, Greedy Stepwise feature selection technique.**

Keywords: Feature Selection technique (FST), Brain Tumor, Machine Learning (ML), PCA, Genetic Search algorithm, Best First, Greedy Stepwise

I. INTRODUCTION

Brain Tumor (BT) dataset such as lung cancer and brain tumor diagnosis is a main, crucial, and difficult task in medical science and healthcare. It is required the patient's exact diagnosis for an enhanced result with the help of clinical study and examination. There are various types of computer-based information and Decision Support System (DSS) available in the medical science and healthcare area. These are the computer-based tools that help doctors and healthcare practitioners for an accurate diagnosis. The disease can be easily and quickly diagnose by analysis and study of disease samples, and can be timely treated. It helps the reduction of time, money, and suffering of the patients. The objectives of the study are to develop a model for feature selection and classification techniques. Feature selection technique (FST) and Dimension reduction technique (DRT) used to choose a feature subset from the available original features of a dataset, which better helps in the learning process. Feature selection is an important step in various tasks, where feature selection techniques (FSTs) are more attractive due to their simplicity and fast speed. The principal focal point of this work is to dimensionally reduce the features and find out important features of the lung cancer dataset. We have likewise utilized two distinctive FSTs to choose related subsets and enhanced the accuracy of classification. We have used FSTs namely Correlation Based Feature Subset (CFS) and Ranker for selecting relevant features of Brain Tumor (BT) dataset. The results demonstrated that distinct selected feature of BT dataset by using Genetic Search, Greedy Stepwise, Best First, and Ranker (PCA) search methods. Classification techniques includes decision trees (DT) like Classification and Regression Analysis Tree Tree (CART), Random Forest (RF), J48 or C4.5, Artificial Neural Network (ANN) like Radial Basis Function Network(RBFN) , Statistical methods like Bayesian Network (BN) , Naive Bayes (NB) and Ensemble Models.

II. ROLE OF FEATURE SELECTION WITH BT DATASET

BT dataset produces huge amounts of data with large features. This data measure implies low quality, unreliable, redundant, and noisy data to examine useful patterns [1]. Therefore, researchers require relevant and high-quality data from big data using feature selection techniques. Feature selection technique (FST) is important preprocessing of data that recues irrelevant features from dataset and increase the performance in terms of computational speed. It brings immediate effects for application: speeding up a data mining algorithm, improving the data quality and data mining performance, and increasing the comprehensibility of the mining results [2]. Feature selection is a crucial technique to explain dimensionality in ML by choosing appropriate and non-redundant features [3], [4]. The FST is also called the feature optimization technique, which removes the unrelated feature subset from the original feature space. A different [5] type of attributes (features) selection techniques include in the machine learning area. The primary role of this process is to eliminate unrelated or disused elements from the dataset. The reduce number of features have increased benefits to classification and cluster analysis [6]. It decreases number of functions that appear in the models discovered to help and make the models easier to understand. In addition [1], feature selection does not modify the original representation of data in any meaning. The data mining algorithms have improved the performance with chosen feature, relevant or important feature subset; hence computationally enhance the accuracy of data mining and MLTs. Various FSTs of big data, such as filter approach, wrapper approach, hybrid approach [7]. The wrapper approach is useful for remove the irrelevant features and prepare new feature space with a learning algorithm and testing the effect of feature exclusion on the prediction metrics. In case of filter approach, a statistical measure is used as a criterion for retrieving the new useful features and utilizes the similar quality based data itself, and works individually from the learning algorithm. The hybrid approach and embedded method is the combination of above filter approach and

wrapper approach to handle larger datasets. In this approach, the feature set is evaluated using both independent measures and a data mining algorithm. Filter-based FST processes the algorithm without using learning classifiers. In contrast, the wrapper method processes the algorithm using the learning classifiers, including awareness about the specific construction of the regression or classification function, and can consequently combine with any learning mechanism. The FSTs have a vital role in the categorization of BT dataset [8].

III. OPTIMIZATION OF BRAIN TUMOR DATASET

Big data analytics through optimization and classification of BT dataset helps the researcher, doctors, and medical students for early detection and diagnoses of diseases. In this research work, different machine learning, data mining, and evolutionary techniques or FSTs to build an intelligent model to achieve the better solution. All organizations are working in the health-care business can tremendously benefit from data mining techniques [9]. GEPLC dataset is a large amount of data generation in healthcare.

Intelligence techniques can capture human beings and collective knowledge extending a knowledge-base with the help of ML techniques. It does knowledge detection or discovering principles from unknown neural networks and data mining play very important role to find patterns in datasets.

This research begins with a short-lived associated work, after that explored the standard FSTs, a description of our research methods, and utilization outcomes of BT datasets. This research has focused on a specific type of gene expression profiling (GEP) dataset like lung cancer disease that is named as BT dataset. It offered some activities to increase awareness in the medical science area by investigating different methods to examine lung cancer problems.

We have used data mining methods to assess lung cancer dataset samples and normalized the dataset in case of start stage. The second stage applied different FSTs to determine the important feature for the BT dataset. The third stage proposed the different classification models to analysis the performance of the lung cancer dataset. We proposed different types of ensemble models for BT dataset in the fourth stage. Finally, the extra useful objective of this thesis is the recommendation of models, and their comparative study was done based on their performances.

IV. LITERATURE REVIEW

Many researchers have been working in the area of BT datasets. In this research work, we have focus on the BT dataset that is also work done by done by different authors with ML techniques. The BT dataset is a big data due to large number of features. [10] described the issue of high dimensional dataset and also discussed just one track of main challenges that currently arises is the classification of high dimensional databases, with very few samples and high-class imbalance. The properties of gene expression microarrays are presented in biomedical databases, presenting class imbalance problems, using a limited number of samples in high dimension when the number of samples in one class is much larger than the number of samples in the other class or classes, it is called class imbalance problem. This issue has been described as one among the most popular significant challenges facing by the big data. They worked with gene expression big data and used Multilayer Perception Deep Learning as a classifier. [11] Identified two other types of cancer: small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLS). They used filter and wrapper-based FST for selecting features of the GEPLC dataset. Using the modified stochastic diffusion search (SDS) algorithm, a novel wrapper-based FS algorithm is proposed. In support of classification, neural networks (NN), Nave Bayes (NB), and decision trees (DT) were used. The experiment results found that classification accuracy of CFS-DT, CFS-NB, CFS-NN, and SDS-decision tree are 82.22 %, 81.48%, 85.19%, and 87.41% respectively. [12]suggested various data mining based classification techniques like ANN, RF and SVM in order to classify tumour disease with FST. According to the classification results obtained, a prediction is made whether the tumour is benign or malignant. They proposed model in order to classify tumour disease into begins malignant or benign categories. The ML techniques like ANN, RF and SVM have used as classifiers, and achieved the accuracy of RF, SVM and ANN are 79%, 86%, and 92 % respectively.

[13]compared the individual classifiers like DTs, KNN, SVM, and NB with their proposed ensemble model and determine the team's performance suggested ensemble model. The suggested ensemble model that is combination of different classifiers that given better accuracy as 92.85% with real time dataset. [14] proposed a new wrapper method WERFE, which belong to a RFE framework. The suggested WERFE method gives the advantages with multiple gene selection algorithms. The gene selection algorithms are selected a few number of gens and classifiers obtained better classification accuracy as 77.30% [15] proposed two statistical models along with two tree ensemble learning methods like GB and RF, and compared predictive model to ability against two common deep learning algorithms, MLP and CNN.

[16] suggested deep learning (DL) for analysing the medical image data. The sensing and analysis steps that permit medical imaging to be used for quantifying disease. [17] worked on microarray datasets, and experiments produce a huge amount of gene-expression data from a single sample. The suggested method is a generalised strategy that balances exploration via the Lightweight Infantry Group (LIG) to discover a viable starting baseline while optimising outcomes beyond that baseline. The LIG swiftly converges to a discovered result of 70 to 88 percent. [18]explored about the high dimensional microarray gene expression data that the number of samples is small in comparison to the number of genes. They have proposed robust algorithm for essential gene selection and achieved better accuracy with different microarray data.

V. METHODOLOGY

I have explored the different data mining based classification techniques considered in this research work in order to classify BT dataset. A BT dataset is very useful to improve the researchers, doctors, and medical students to detect lung cancer. We describe the pre-processing steps used in our experiments, and potential solutions to the problem.

A. PROPOSED ARCHITECTURE FOR FEATURE SELECTION OF BRAIN TUMOR DATASET

The investigation of background information for BT using intelligent techniques was the first step during the research phase. The figure 1 has shown the proposed architecture for feature of BT dataset using different feature selection techniques. The proposed research process is described in different phase.

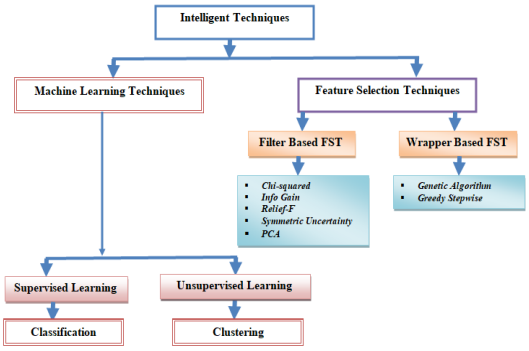

Figure 1 Proposed architecture for feature selection of BT dataset

B. DATASET AND DATA PREPROCESSING

The ELVIRA Biomedical dataset Repository (DBC Repository), which is a section of machine learning repository of the proceedings of the national academy of sciences (PNAS), is a collection of databases, domain theories, and data generators. The machine learning group uses this dataset to do empirical research on machine learning methods. In 2001, the archive (collection) was developed as an FTP archive by Arindam Bhattacharjee, William G. Richards, and its team from Departments of Adult Oncology and Pediatric Oncology, Dana–Farber Cancer Institute, Harvard Medical School, and Department of Biostatistics, Harvard School of Public Health, Boston.

The BT datasets collected from the ELVIRA Biomedical dataset Repository (DBC Repository) have been utilized in this research. The dataset contains 10368 features and 50 the numbers of samples with five classes. Table 1 show details of classes and number of samples of the BT dataset.

C. FEATURE SELECTION TECHNIQUES (FST)

The procedure for determining and reducing as much useless and redundant information as feasible selection of feature subsets is referred to as feature subset selection. This decreases the data's dimensionality, allowing learning algorithms to work more quickly and efficiently. In some circumstances, the outcome is a better option compact, readily understandable representation of the goal notion; in others, the outcome is a better accurate future categorization. The Feature selection [19]–[21] is a data mining technique for picking a portion of relevant characteristics (variables, predictors) that use in model construction. The variable selection is a term that describes the process of selecting variables, attribute selection, or variable subset selection. [22].

1. FILTER METHODS

The Rankers use the common properties of the algorithm for learning differs from the data and performs in a different way. Ranker primarily based procedures are now not structured on classifier and are wrapper-based approaches are generally quicker and more scalable. [4], [23].

- **CORRELATION-BASED FEATURE SUBSET SELECTION (CFS)**

Features are selected for responsibility the relationship between characteristics may be used to classify data in ML, and such a FS procedure can be beneficial for basic ML algorithms. In this section, offers a CFS based on this assertion; it examines the effectiveness of the CFS under various scenarios and demonstrates that CFS may find relevant machine learning characteristics [24].

- **INFORMATION GAIN (IG):**

In machine learning, information gain is able to help feature ranking in benefits. Information gain (IG) [23], [25], [26] is an informal technique for selecting features based on contribution of information to the class variable without taking into account feature interactions. Therefore, the information gain is based on what proportion information was obtainable before knowing the feature value and what proportion was accessible after it.

- **GAIN RATIO**

Method has been developed to get the ratio. This method submits to application-specific types of normalization with consider to the obtained information called split information. The Information Gain [27]–[29] measure preferentially selects features having a significant number of values.

- **Relief-F (RFF):**

The Relief-F [30] is a filter based feature selection (FS) methods, it is a unique opportunity effective, easy and broadly used method to feature weight estimation. The weight designed for features of a dimension vector is define in expressions of feature relevance. In a probabilistic explanation of Relief is prepared, which situations that the informed weight for a feature is propositional to the variation between two conditional possibilities.

2. SEARCH METHODS

- **GREEDY STEPWISE SEARCH (GSS):**

A Greedy Stepwise Search [31] is an algorithmic hypothesis, which adheres to the problem in resolution the principle of creating the optimal choice locally in every stage with the intention of finding the global optimal. In several issues, a greedy strategy Typically, no generate an optimal solution, however still a greedy heuristic can locally produce the optimum solution that estimates the optimal solution globally at the affordable time. When [32] beginning It chooses the first item from an empty set variable by further selection and eliminates the useless variable by selecting backwards to discover the most effective feature subset.

- **GENETIC ALGORITHM (GA):**

Genetic Algorithms (GA) [24], [33], [34] has discovered to mimic numerous of the method observed in natural evolution. The basic concept of GA is accustomed to the command of evolution to solve optimization problems. The earliest introduction of the unique Genetic Algorithm was by John Holland who pretends it early in the 1970s. Genetic algorithm [35] is adaptive search techniques on the basis of the principles of natural selection in biology.

- **BEST FIRST SEARCH (BFS):**

Heuristic search algorithms, which include the BFS, are a division of search algorithms. Heuristic search is on the basis of premise that instead of exploring all conceivable search pathways at each step, we try to figure out which ones they seem to be moving us closer to our desired state [36].

- **RANKER SEARCH (RS):**

Ranks attributes by their individual evaluations. Use in conjunction with attribute evaluators (ReliefF, GainRatio, Entropy etc) [37]. Generate Ranking - A constant option. Ranker is only capable of generating attribute rankings. Specify the number of attributes to retain.

- **PRINCIPAL COMPONENT ANALYSIS (PCA):**

PCA [38] is an move towards to reduce the number of dimensions in a dataset consisting of a huge number of interrelated variables while keeping as a lot as feasible of the version existing within the database [5], [39].

VI. FEATURE SELECTION WITH BRAIN TUMOR

Feature selection is an optimization technique used to remove the unsuitable feature from original dataset and increase the accuracy of models. This research work has used Genetic algorithm (GA) or Genetic Search (GS) as options selection. We have also used Principal Component Analysis (PCA) [40] for dimensional reduction and FSTs [1] are used to select the relevant features from original dataset. Genetic-Algorithms (GA) [41], [24] were utilized to select the relevant features from BT dataset and prepared new dataset with less number of features, hence, we can improve the performance of models. The most cited presentation of the one-of-a-kind Genetic algorithmic standard developed by John Holland described it [42].

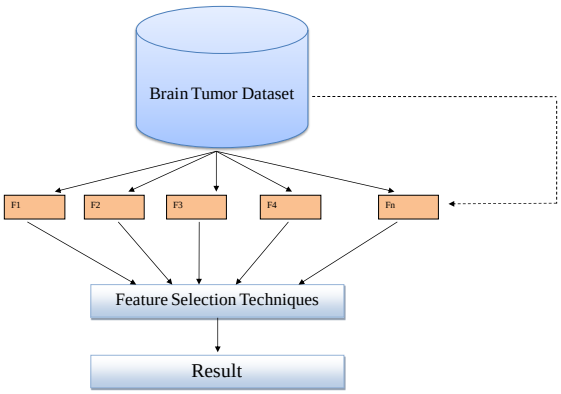

Figure 2 Process of feature selection with BT dataset

VII. THE ARCHITECTURE OF FEATURE SELECTION TECHNIQUES (FSTS)

To reduce features of the BT dataset, we have used different search techniques with different learning algorithms applied in the BT dataset and got the reduced feature subset of the BT dataset.

STEPS OF GENETIC SEARCH/ BEST FIRST/ GREEDY STEPWISE/ RANKER

a). Select attribute to indicates the relevance of the attribute

b). Applied the first search method as Genetic Search /Best First/Greedy Stepwise/ Ranker

c). Select the Attribute Evaluator as Correlation Feature Subset Evaluates (CFS Subset Evaluator)

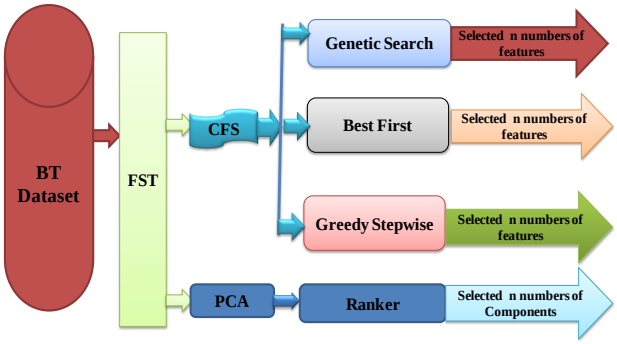
d). Set tuning parameters of Genetic Search.

e). Select attribute selection mode

f). Select full training set and partition into training and testing with cross-validation

g). Start attributes selection to select the relevant features

h). Now got reduce selected numbers of features using Genetic Search /Best First/Greedy Stepwise/ Ranker with Correlation Feature Subset Evaluates (CFS)



MODIFIED GENETIC ALGORITHM (MGA)

Pseudocode-1: Pseudocode of Main Algorithm of Modified Genetic Algorithm (MGA)

Pseudo-code 1 shows the proposed MGA, i.e., another form existing search-based FSTs as simple Genetic Algorithms.

Step 1: First set the limit of highest number of execution of GA

Set ← fu upper-limit

Step 2: Secondly set the limit of lowest number of execution of GA

Set ← fl lower-limit

Steps 3: Repeat the step 3 and step 4

For count=1 to N

Call GA_M

Step 4: Check

If we found the constant features

Stop step 3 and step 4

else

Repeat step 3 and 4

Step 5: Stop

Step 6: *Returns selected features By MGA*

VIII. FEATURE SELECTION OF BT DATASET WITH PROPOSED MODIFIED GENETIC ALGORITHM (MGA)

Brain Tumor dataset was used to compare different filter based feature selection methods for the prediction of disease risks. The feature selection methods are

Sr. No	Algorithm	FST	Total Number of Features Brain Tumour (Malignant glioma types)	Selected Features
1	CFS Subset Evaluator	Best first	**10368**	99
2	CFS Subset Evaluator	Greedy Stepwise	**10368**	95
3	CFS Subset Evaluator	Linear Forward Selection	**10368**	39
5	Classifier Subset Evaluator	Genetic search	**10368**	1484

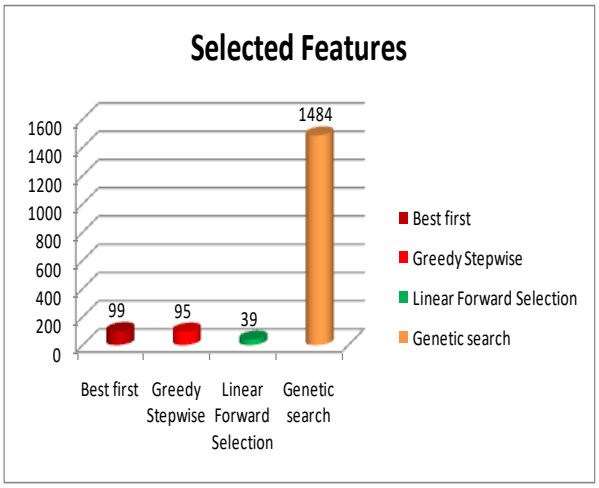


Table 1 and figure 3 show the selected features of BT Dataset was used to compare different feature selection methods for the prediction of disease risks. Six feature selection techniques are used with classification algorithms. CFS Subset Evaluator with Genetic search are performed better result as compare to other feature selection algorithm.

IX. CONCLUSION

We have used the two FSTs namely Correlation Based Feature Subset (CFS) and Ranker for feature selection with BT dataset. The principal focal point of this work is to dimensionally reduce the features and find out important features of the GEPLC dataset. We have likewise utilized two distinctive FSTs to choose related subsets and enhanced the accuracy of classification technique. The results demonstrated with distinctive selected feature. We have used Genetic Search, Greedy Stepwise, Best First and Linear Forward Selection search methods for selecting the relevant features of BT dataset where 1484 features selected by the Genetic Search, Greedy Stepwise search method selects 95 features, similarly Best First search method selects 99 features and Linear Forward Selection search methods selects 34 features. Experiment results revealed that Genetic Search selects a higher number of features and Best First selected the less number of features

Deep Sentimental Analysis of Airline Service Reviews Data Using Hybrid Convolution Neural Network Model

Rajat Kumar Yadu
Mahant Laxminarayan Das College, Raipur (C.G.)

ABSTRACT – **Deep learning has become an effective technique in the field of sentiment analysis. In this research we have utilized the airline service review datasets for six different Indian airlines where the various passengers share the different positive and negative reviews. We have applied specified textual data based stringtowordvec technique which produced different word occurrence for similar text with different weight values. To select the important features we have used latent semantic analyzer named technique where the sentiment and score have been used for future classification of sentiments. We have initially used standalone standard classifiers as Output Layer, CNN, Dense Layer and LSTM which performs better accuracy rate for sentimental analysis along with the different configurations such as Cnntextfileembeddinginstance as instance iterator, Activation Sigmoid as layer activation function, LossMultilabel as loss function which have played very important role to improve the performance of classifiers. In this research finally we have found that the hybridization of standard classifiers such as the combination of OL, CNN, DL , LSTM produced the highest accuracy rate as 89.57% for Air India airline so we have concluded for this research that we can recommend the passengers for Air India airline as best airline in India on the basis of services that we have used in our collected dataset.**

KEYWORDS: Classification, Dl4jmlp Classifier, CNN, Hybridization technique, Sentimental Analysis,

I. INTRODUCTION

Sentiment analysis has long been one of the most popular deep learning research areas. Airlines include various machine learning and deep learning methods. The sentiment of two class datasets was then classified using statistical analysis, latent semantic analysis, and structural equation modeling (SEM) hybrid methodologies. The majority of the papers focused on the fact that many of the data sources for the airline industries come from the web, such as Twitter, Skytrax, and TripAdvisor. Some projects concentrate on real-time sentiment data from aircraft passengers. In A literature Deep learning models have outperformed traditional machine learning approaches in a variety of text classification tasks, including sentiment analysis, news categorization, question answering, and natural language inference. In their paper, they have provided a comprehensive review of more than 150 deep learning-based text classification models developed in recent years, as well as a discussion of their technical contributions, similarities, and strengths. They also provide a summary of more than 40 popular text classification dataset[1]. Deep learning has emerged as a powerful machine learning technique that learns multiple layers of representations or features of the data and produces state-of-the-art prediction results. Along with the success of deep learning in many other application domains, deep learning is also popularly used in sentiment analysis in recent years. This paper first gives an overview of deep learning and then provides a comprehensive survey of its current applications in sentiment analysis. Deep learning is the application of artificial neural networks (neural networks for short) to learning tasks using networks of multiple layers. It can exploit much more learning (representation) power of neural networks, which once were deemed to be practical only with one or two layers and a small amount of data. Based on network topologies, neural networks can generally be categorized into feedforward neural networks and recurrent/recursive neural networks, which can also be mixed and matched. Researchers have mainly studied sentiment analysis at three levels of granularity: document level, sentence level, and aspect level. Sentence level sentiment classification classifies individual sentences in a document. However, each sentence cannot be assumed to be opinionated. A brand-new paradigm for social media sentiment analysis based on deep learning models and aimed to create a semantic dataset after processing these particular phrases in order to support future study [2]. In our study we have use sentimental level sentimental classification to determine the sentiment expressed in a single givens sentence. As discussed earlier, the sentiment of a sentence can be inferred with subjectivityclassification48 and polarity classification, where the former classifies whether a sentence is subjective or objective and the latter decides whether a subjective sentence expresses a negative or positive sentiment [3]. In existing deep learning models, sentence sentiment classification is usually formulated as a joint three-way classification problem, namely, to predict a sentence as positive, neural, and negative.

II. RELATED WORK

In our research work we have worked with various airline service reviews where the sentiment feature played an important role for deep learning based classification techniques [4]. The branch of study known as sentiment analysis, or opinion mining, examines people's attitudes and sentiments towards various objects, including goods and services, and their characteristics. In this research work we have applied different Dl4j classifiers CNN, Output Layer, LSTM and Dense Layer where the ensemble model performed best accuracy rate.

III. DATASETS

Data collection is the primary component of sentimental analysis, which is a difficult task due to privacy concerns such as the fear of exposing personal information. We collected social media data on airline service provider passenger real-time reviews [5]. This dataset is used by the machine learning group to conduct empirical research on machine learning methods. We used the Web Harvey tool data extractor tool to collect reviews from various travel websites, including Tripadvisor, Skytrax, mouthshut, Makemytrip, and trustpiolet. These data sets demonstrated the importance of pre-processing data by detecting single abbreviations and lemmatization, as well as correcting and stopping word removal. The data is separated into train and validation sets during the pre-processing stage, and the reviews are then vectorized into TF-IDF vectors. Because the given file is in text, the class converts the text into positive and negative words and removes the terms that have weak predictive ability or are strongly correlated to other terms in order to balance the final dataset [6]. To do this, we use the string to vector feature extraction technique. Additionally, we divide the datasets into categories for domestic and foreign routes in order to identify specific customer satisfaction as well as the best airline in India.

IV. EXPERIMENT & RESULT

In our experiment we have used the following layer function classifiers of deep learning approach associated with Neural Network Configuration- Output Layer, Convolution Neural Network, LSTM, and Dense Layer. In the below figure we have described the data set about airline reviews and applied different stand alone classifiers such as OL , CNN , LSTM and Dense Layer where OL has used as common layer specification classifier.

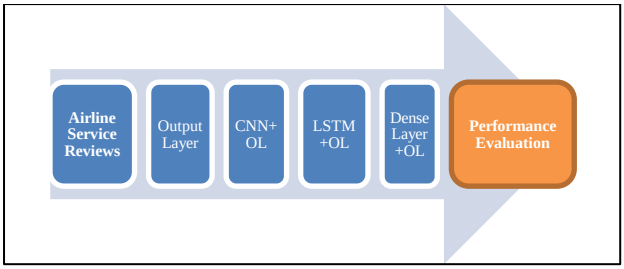

Fig 1 -Flowchart of proposed deep learning based ensemble model

In this work we have used deep learning approach named as DL4J package where the different classifiers layer specification with sigmoid activation function and cnntextfileembedding technique used for custom net technique.

Table I - Performance of Deep Learning Classifiers for six airlines

Deep Learning Technique (Dl4jmlp Classifiers with Neural Network Configuration)	**Air India**	**Air Asia**	**Spice Jet**	**Vistara**	**Indigo**	**Go Air**
Output Layer	98.5%	98.9%	99.85%	97.33%	99.80%	99.55%
CNN	68.10%	61.90%	63.26%	64.50%	65.94%	77.13%
LSTM	68.66%	61.90%	63.20%	64.50%	65.90%	77.10%
Dense Layer	68.11%	61.56%	63.26%	64.55%	66.90%	77.12%
Proposed Hybrid Model (OL+CNN)	98.9%	99.11%	**99.88**%	97.35%	99.84%	99.63%

In the above table the performance of all classifiers have mentioned where the association of Convolution Neural Network and Output Layer have produced highest accuracy rate as 99.88 % for Spice Jet airline service review so we can recommend the passengers for this airline according to our collected service reviews.

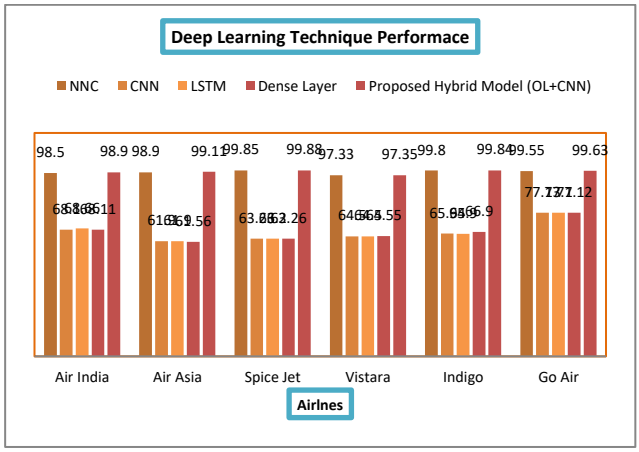

Fig 2– Graphical Representation of Performance of Deep Learning Classifiers for six airlines

In our work we have used different DLT for classification but we have found that the Output layer and CNN associated NNC have produced highest accuracy rate so we combine or hybridize both the classifier which gave best accuracy rate for all the airlines and for spice jet we have obtained maximum accuracy rate for recommendation.

In the below figure 2 the ROC curve performance has shown in which the ROC curve is obtained by plotting recall and FPR on the y-axis and x-axis, respectively. It is a good measure for imbalanced datasets because it is not skewed toward the majority class. Its value ranges from 0 to 1. However, ROC only considers the recall/true positive rate, so it focuses on positive records and ignores the negative ones.

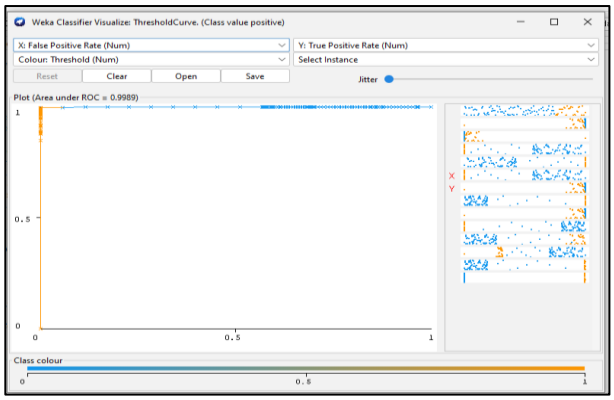

Fig 3 – ROC curve of Performance of Hybrid Deep Learning Classifiers recommended spice jet airline

V. CONCLUSIONS

This study conducted experiments on the Indian Airline Review dataset with five different deep learning methods associated with NNC (OL, CNN, LSTM, and Dense Layer) and a proposed hybrid model with the combination of OL and CNN were used for recommendation of best airline. Our Proposed hybrid model gives the best accuracy of 99.88% among all the classifiers for spice jet airline. The accuracies were determined to compare each categorization technique and the total sentiment count for all six airlines of India was displayed in terms of facilities, services and punctuality of airlines.

ML Algorithm To Predict Diabetes At Early Edge

Tirth Shah,Ankita Sharma Tirth Shah,

1032200419@tcetmumbai.in, ayushyadav@gmail.com, 1032201233@tcetmumbai.in

Abstract- **The aim of this ML model is to create a portal which will be useful for the rural area to help them reduce the mortality rates. Nowadays research's shows that diabetes has become one of the most common health issues. Childrens in rural areas are diagnosed with diabetes at an early age. Detection of diabetes has become very difficult for them to detect. Diabetes is a chronic condition that affects millions of individuals globally, and early diagnosis is essential for optimal treatment and the avoidance of complications. Using information from a variety of sources, such as medical records, genomic data, and lifestyle factors, machine learning algorithms have demonstrated encouraging results in the early detection of diabetes. This paper reviews the state-of-the-art research on utilizing machine learning to diagnose diabetes in children, highlighting the main issues and promising directions for further study. The Behaviour Analysis here is built on the dynamic analytics where the generic model would be going to filter the data according to the request input of the user and also framing the question according to that. Taking out the intuition from the analysis is the difficult task after plotting the**

visualization. The paper also focuses on making intuition by using the Deep learning transformer which results in the intuition in a human-readable statement. The purpose of this paper is to provide a predictive and new analysis approach for the better decision making in the prediction of diabetes at an early age in rural areas

I. INTRODUCTION

High blood sugar levels are the hallmark of diabetes, a chronic disease that can cause catastrophic side effects like heart disease, renal failure, and blindness. Millions of people around the world are impacted by the illness, and its incidence is fast rising, especially among younger people. For efficient care and the avoidance of complications, diabetes must be discovered as soon as possible. By evaluating vast volumes of data from numerous sources, such as medical records, genomic data, and lifestyle factors, machine learning algorithms have the potential to increase the precision and effectiveness of diabetes detection. High blood glucose levels are a hallmark of diabetes, a metabolic condition brought on by the body's inefficiency in producing or utilizing insulin. Diabetes must be identified and treated early in order to avoid or postpone problems like cardiovascular disease, nerve damage, kidney damage, and blindness. Machine learning (ML) has been an effective technique for analyzing big and complicated datasets in recent years, allowing the discovery of patterns and associations that can be used to forecast the course of disease.

II. LITERATURE SURVEY

2.1Introduction

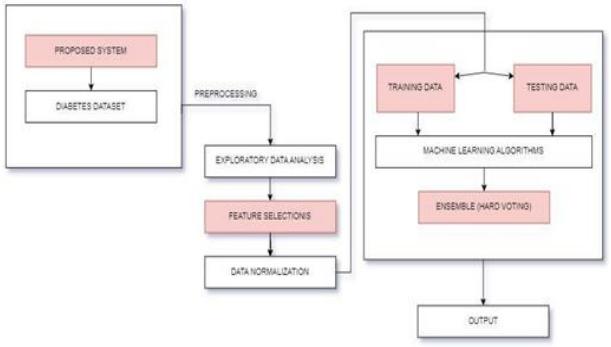
Predictive models have been created using a variety of techniques, according to a review of the most recent studies on the use of machine learning to diagnose diabetes in children and adolescents. Deep learning, unsupervised learning, and supervised learning are some of these methods. Algorithms are trained on labeled data in supervised learning to determine whether diabetes is present or absent. To find patterns in the data, unsupervised learning employs clustering and dimensionality reduction techniques. On the other hand, deep learning techniques employ numerous artificial neural network layers to extract characteristics and generate predictions.

3.2 Research Background

The previous advancement in the field of decision making for the patrolling procedure and the predictive policing are: D.V Singh, R.K. Singh and A.V Shrivastav, "Predicting diabetes in early age using machine techniques", This paper discusses the existing the system is better than the present existing system. In this paper Decision tree based algorithms outperformed other techniques for predicting diabetes in early age. [1] L.Arora and M.K. Jain ,"Early prediction of type 2 diabetes using machine learning algorithm." This paper focuses on Support vector machines and random forests were the most accurate for predicting type 2 diabetes in early age [2]. [3] A. A. Al Safar et al."Diabetes risk prediction using machine learning in the Saudi population." This paper investigates the use of machine learning algorithms for predicting diabetes risk in the Saudi population. The authors used a dataset containing several risk factors such as age, gender, family history, BMI, and blood pressure. They compared the performance of several machine learning algorithms and found that artificial neural networks were the most accurate. [4]D. K. Singh et al."Using machine learning to predict the onset of type 2 diabetes in young adults."This paper investigates the use of machine learning algorithms for predicting the onset of type 2 diabetes in young adults. The authors used a dataset containing several risk factors such as age, gender, family history, BMI, waist circumference, and blood pressure. They compared the performance of several machine learning algorithms and found that decision trees and random forests were the most accurate

Methodology: Models for predicting the likelihood of getting diabetes can be created using ML algorithms like logistic regression, decision trees, and random forests. These algorithms are built on statistical and computational methods that make it possible to identify pertinent risk factors and compute the likelihood of various outcomes. Using a set of predictor factors, such as age, sex, body mass index (BMI), and family history of

diabetes, the logistic regression approach, for instance, estimates the likelihood that an event will occur, such as the onset of diabetes. A collection of clinical and demographic data of young patients can be gathered and preprocessed in order to create a machine learning (ML) model for the early diagnosis of diabetes. A training set and a testing set can be created from the dataset, where the testing set is used to gauge the model's performance and the training set is used to train the ML model. A variety of algorithms can be used to train the ML model, and their performance can be improved by modifying the hyperparameters. The likelihood of acquiring diabetes in new patients can be predicted using the ML model after it has been trained. In order to direct treatments and prevention measures, the model can also be used to determine the most important risk variables linked to the onset of diabetes. In conclusion, ML approaches can be utilized to create precise and trustworthy models for early diabetes identification in kids and teenagers, opening the door to early intervention and better patient outcome



Preprocessing of data is necessary to make sure that it is correct and consistent. This process involves dealing with outliers, managing missing numbers, and normalising the data. To enhance the performance of the model, choose the features that are most pertinent and strongly associated with diabetes. Both statistical and feature ranking strategies can be used for this step. Model selection: Choose a machine learning method that is appropriate for the task at hand, has a good track record, and can handle the input data. Logistic regression, decision trees, random forests, and support vector machines are examples of frequently used algorithms. Split the dataset into training and testing subsets for the model. Use the testing subset to assess the model's performance once it has been trained and its hyperparameters have been adjusted. Validate the performance of the model using methods like k-fold cross-validation or leave-one-out cross-validation

Hyperparameter tuning: To enhance the performance of the model, adjust its hyperparameters. Evaluation of the model: Measure the model's effectiveness using parameters like accuracy, sensitivity, specificity, and AUC-ROC. Deployment: To make sure the model is accurate and useful, deploy it in the actual world and keep an eye on how it performs. In conclusion, considerable consideration must be given to data preparation, feature selection, model selection, and hyperparameter tuning when creating a diabetes prediction model using machine learning.

III. RESULT

The early detection of diabetes using machine learning (ML) models can offer several benefits, including: Early intervention: Early detection of diabetes allows for timely interventions and treatments, which can help prevent or delay the onset of complications associated with the disease. Improved outcomes: Early detection and intervention can improve health outcomes for patients with diabetes, such as reducing the risk of developing complications like cardiovascular disease, kidney disease, and nerve damage. Personalized treatment plans: ML models can help identify patients who are at high risk of developing diabetes or its complications, and provide personalized treatment plans that take into account individual patient characteristics, such as age, sex, family history, and lifestyle factors. Reduced healthcare costs: Early detection and intervention can lead to a reduction in healthcare costs associated with diabetes, such as hospitalizations, emergency room

visits, and medication costs. Efficient use of resources: ML models can help identify patients who are at low risk of developing diabetes or its complications, which can help healthcare providers allocate resources more efficiently and effectively. Population health management: By identifying patients who are at high risk of developing diabetes or its complications, ML models can help healthcare providers implement population health management strategies that target high-risk groups and improve overall health outcomes in the community. Overall, early detection of diabetes using ML models can improve health outcomes, reduce healthcare costs, and improve the efficiency and effectiveness of healthcare delivery.

IV. DISCUSSION

There are a number of difficulties employing machine learning algorithms for diabetes detection, despite the encouraging results. Lack of high-quality data, particularly for genomic and lifestyle factors, is a significant problem. Also, there is a need for more reliable algorithms that are visible and simple for doctors to understand. The ethical and legal ramifications of applying machine learning algorithms for diabetes detection also require further study.

Artificial Intelligence in Education: Opportunities and Challenges

Roshni Pashine
Mahant Laxminarayan Das College, Raipur (C.G.)

Abstract-**Digital technologies have already become an integral part of our life. They change the way we are searching for information, how we communicate with each other, even how we behave with each other. This digital transformation applies to so many areas, including education (all levels). The main objective of this article is to identify prospective impact of artificial technologies to the imparting skills and to predict possible changes in educational landscape. In this article we considered customized educational content (videos, chats pdf etc), innovative teaching methods, technology enhanced assessment, communication between student and teacher. After the Covid -19 pandemic the significance and application of artificial intelligence practices in education sector increased all over the world. It makes possible the education to become interactive and effective in comparison to traditional tools of education. Application of Artificial intelligence in education creating new opportunities to empower students with needed skill so that they can excel in career. Chatbots, virtual reality, robots, metaverse , mobile applications creating a new era of education. Artificial intelligence will benefit students, teachers, parents and educational organizations altogether.**

Keywords – Artificial Intelligence, Education, Innovative teaching methods, Customized Educational Content.

I. INTRODUCTION

The process of using computers, software, hardware, devices and machines to mimic human perception, decision-making, and other processes to complete a task is known as Artificial intelligence. There are any ways to understand the nature of AI. Two basic types of AI include the AI which based on rules and the AI which based on machine learning. The rules based AI uses rules of decision making to produce or suggest a recommendation or a solution. An example of this is an intelligent tutor system, which can provide grammar and specific correction feedback to students.

Machine learning-based AI is much more powerful since the machines (computer oriented) can actually learn and become superior over time, particularly as they work with large, multilayered datasets. In education, machine learning-based AI tools can be used for a variety of tasks such as monitoring student activity and creating models that accurately predict student behavioral outcomes. Within AI, there is one more subfield which is natural language processing, which is the use of software to understand, predict, translate and record text content. Technique such as automated essay scoring uses natural language processing to grade written essays. There are AI systems based on voice recognition. Such systems are used in voice command tool as and Alexa and Siri . Experts have been exploring ways to use voice-based AI to diagnose reading and other academic issues. Nowadays the use of AI which is machine-based is already adopted in education. For example, several testing companies (ex. Pearson) use natural language processing for scoring essays. Massive online open courses allowing unlimited participation through the web, run by companies such as Coursera and Udamy, have also integrated AI scoring to analyze essays within their courses.

Nabiyev (2010) defines "AI as the ability of a computer-controlled device to perform tasks in a human-like manner". Here human-like qualities include mental processes like reasoning, meaning making, generalization, and learning from past experiences. Norvig and Russell (2003) define AI as a Machine Intelligence, or Computational Intelligence. AI enables to execute normal and specific tasks for ex. playing games, solving mathematical theorems, writing content, giving speech, diagnosis diseases etc. Nilsson (2014) defines AI as an algorithmic construction to copy human intelligence. In other words AI is combination of machines, software, hardware and tools which work similar or more effective than human intelligence but we cannot deny the fact that AI is also a product of Human Intelligence.

II. THE POTENTIAL BENEFITS AND USES OF ARTIFICIAL INTELLIGENCE IN EDUCATION SYSTEM

AI does not distract or keep away students from classroom but enhances the educational experience in many ways. Such as-

Personalization: AI systems adapt to each individual student's learning needs and target according to their strengths and weakness.

Tutoring: AI systems analyses and observe student's current style of learning and pre-existing abilities then deliver customized content pattern and support.

Grading: AI systems do grading not only objective answers but also on descriptive answers.

Meaningful and Real Time Feedback to students: With AI, students feel free to make mistakes which are an integral part of learning and then receive real

time feedback to do necessary correction.

Free up time: With AI the education centres can reduce time of teachers from various tedious task and use that free up time for much productive execution of course.

Adaptive Learning: Used to teach students at entry level then gradually move next stage by completing the previous one so they can become proficient.

Assistive Learning: AI can enable students to access equitable education as per need, for example by reading content to a visually impaired student.

Early Childhood Education: AI is currently used to present interactive games which teaches and develops the basic ethical and academic skills in children.

Data and Learning Analysis: Nowadays AI used by faculties and education administrators to analyse and interpret educational data.

Scheduling: In educational institutions it helps administrators to schedule classes, courses and teachers to make and plan their daily, weekly, monthly and sessional curriculum schedules.

Facilities Management: AI is very effective at monitoring the current status of various facilities in educational institutions such as power, wifi, water and staff.

Overall School Management: Currently AI is used to manage schools, records of students, vehicles, IT, time tables and budget.

Content Writing: AI applications which convert voice into text are widely used.

Different aspects through which AI empowering education system include:

- Classroom/Behaviour Management
- Lesson Planning for classes
- Classroom Audio-Visual content
- Parent-Teacher Communication
- Language Learning
- Test Prep
- Assessment of test , exams and assignments
- Learning Management Systems
- Faculty Scheduling and Substitute faculty Management
- Plagiarism Detection and removal
- Exam Integrity
- Chatbots for Enrolment and Retention of students
- Learning Management Systems
- Recording of Faculty Lectures
- Enhanced Online Discussion Boards
- Analysing Student Success Metrics
- Academic Research
- Virtual reality / animation
- Connected Campuses

III. CHALLENGES AHEAD

Along with these benefits, there are other major concerns. One major and important issue is privacy. How do these educational tools protect user privacy? How do educational institutions gain consent of both students and parents when introducing them? Should that data would be shared with researchers, companies and other external groups? Another issue is related with human experience of education .in other words AI cannot replace teachers. Experts also point out drawbacks of Artificial intelligence; it will reduce the cognitive ability of both teachers and students. Too much dependence on technology will create negative impacts also. The digital burden of content will create unnecessary pressure on students. We have to make AI supplement to teachers not the replacement of teachers. Excessive use AI should not be imposed on teachers and students.

Abstract - **Machine learning is becoming a valuable tool for predicting multiple diseases in healthcare. These systems use a variety of data sources, including medical images, demographic information, and laboratory test results, to predict the likelihood of a patient having a specific disease. The process of building such a system involves data collection and cleaning, feature engineering, model selection, training, and evaluation. The selection of a suitable machine learning model is crucial, as it determines the accuracy of the predictions. The model is trained using the engineered features and disease labels, and its performance is evaluated using various metrics.**

Multiple disease prediction systems using machine learning have the potential to transform healthcare by enabling early diagnoses and effective treatment plans. However, it is important to keep in mind the limitations of such systems, including the risk of biased data and the need for ongoing evaluation and improvement. Despite these challenges, the benefits of multiple disease prediction systems using machine learning make them an exciting and rapidly evolving area of research and development in healthcare.

This study was conducted as a means to develop a predictive and enhanced analysis approach for better decision making within

healthcare, ultimately reducing the risk of adverse events.

Keywords – Multiple disease prediction, Machine Learning, Healthcare, Supervised Learning, Laboratory test results, Accuracy, Precision, Limitations, Bias, Ongoing improvements

I. INTRODUCTION

The field of healthcare is constantly seeking ways to improve patient outcomes and reduce the burden on the healthcare system. One promising area for improvement is the use of machine learning for multiple disease prediction. These systems use various data sources, such as medical images, demographic information, and laboratory test results, to make predictions about a patient's health status. The use of machine learning algorithms in multiple disease prediction has several benefits over traditional methods, including increased accuracy, reduced costs, and improved patient outcomes.

In building a multiple disease prediction system using machine learning, several key steps must be taken, including data collection and cleaning, feature engineering, model selection, training, and evaluation. The choice of machine learning model is crucial as it determines the accuracy of the predictions. Common models used in multiple disease prediction include

decision trees, random forests, support vector machines, and k-means clustering. While the use of machine learning in multiple disease prediction offers many benefits, there are also challenges that must be addressed. These include the risk of biased data, the need for ongoing evaluation and improvement, and the complexity of building and maintaining such systems.

1.1 Description

In this paper, we will provide a comprehensive overview of multiple disease prediction systems using machine learning. This will include their benefits and challenges, and the key steps involved in building these systems. During a lot of analysis of existing health care systems, only one disease was considered at a time. There is no common system available that can analyse more than one disease at a time. The purpose of this is to provide accurate and timely disease predictions to users at the time they enter their symptoms. For example, article

[2] is used to analyse diabetes, article [3] is used to predict heart disease, article [4] is used to predict breast cancer. In the future, other diseases like skin diseases, fever analysis, and many others can be included. The user does not need to traverse different places in order to determine whether he/she has a particular disease or not. In the multiple diseases prediction system, the user needs to select the name of the particular disease, enter its parameters, and then click on submit. The corresponding machine learning model will be invoked and it will predict the output and display it on the screen.

1.2 Problem Statement

Many of the existing machine learning models for health care analysis focus on one disease per analysis. For example, liver analysis, cancer

analysis, lung diseases, heart disease, skin disease, etc. If a user wants to predict more than one disease, he/she has to browse through different sites. There is no common system where one analysis can perform more than one disease prediction. Some of the models have low accuracy which can seriously affect patients' health. When an organization wants to analyse their patients' health reports, they have to deploy many models. In addition to increasing the cost, it also takes longer. Some of the existing systems consider very few parameters which can yield false results.

II. LITERATURE SURVEY

2.1. INTRODUCTION

A literature survey of disease prediction models in machine learning can provide insights into the current state of the field, the most commonly used methods, and the trends and challenges in this area of research.

Machine learning techniques have been widely used for disease prediction and risk assessment in various

domains, including medical diagnosis, epidemiology, and public health. Some of the most commonly used machine learning methods in disease prediction include decision trees, random forests, support vector machines (SVM), artificial neural networks (ANN), and deep learning models such as convolutional neural networks (CNN) and recurrent neural networks (RNN).

III. RESEARCH BACKGROUND

Common Diseases

Dahiwade et al. [9] proposed a ML based system that predicts common diseases. The symptoms dataset was imported from the UCI ML depository, where it contained symptoms

of many common diseases. The system used CNN and KNN as classification techniques to achieve multiple diseases prediction. Moreover, the proposed solution was supplemented with more information that concerned the living habits of the tested patient, which proved to be helpful in understanding the level of risk attached to the predicted disease. Dahiwade et al. [9] compared the results between KNN and CNN algorithm in terms of processing time and accuracy. The accuracy and processing time of CNN were 84.5% and

11.1 seconds, respectively.

Kidney Diseases

Serek et al. [12] planned a comparative study of classifiers performance for Chronic Kidney disease (CKD) detection using The Kidney Function Test (KFT) dataset. In this study, the classifiers used are KNN, NB, and RF classifier; their performance is examined in terms of F-measure, precision, and accuracy. As per analysis, RF scored better in phrases of F-measure and accuracy, while NB yielded better precision. In consideration of this study, Vijayarani [13] aimed to detect kidney diseases using SVM and NB. The classifiers were used to identify four types of kidney diseases namely Acute Nephritic Syndrome, Acute Renal Failure, Chronic Glomerulonephritis, and CKD. Additionally, the research was focused on deter- mining the better performing classification algorithm based on the accuracy and execution time. From the results, SVM considerably achieved higher accuracy than NB, which makes it the better performing algorithm.

Heart Diseases

Marimuthu et al. [16] aimed to predict heart diseases using supervised ML techniques. The

authors structured the attributes of data as gender, age, chest pain, gender, target and slope [16]. The applied ML algorithms that were deployed are DT, KNN, LR and NB. As per analysis, the LR algorithm gave a high accuracy of 86.89%, which deemed to be the most effective compared to the other mentioned algorithms. In 2018, Dwivedi [17] attempted to add more precision to the prediction of heart diseases by accounting for additional parameters such as Resting blood pressure, Serum Cholesterol in mg/dl, and Maximum Heart Rate achieved. The used dataset was imported from the UCI ML laboratory; it was comprised with 120 samples that were heart disease positive, and 150 samples that were heart disease negative. Dwivedi attempted to evaluate the performance of Artificial Neural Networks (ANN), SVM, KNN, NB, LR and Classification Tree.

IV. METHODOLOGY

The analysis of ML models will be conducted on few diseases located at heart, kidney, breast, and brain. For the detection of the disease, numerous methodologies will be evaluated such as KNN, NB, DT, CNN, SVM, and LR. At the end of this literature, the best performing ML models in respect of each disease will be concluded.

1. Data collection: The first step is to collect relevant data that can be used to train the prediction model. This data typically includes patient information, such as demographics, medical history, lifestyle information, and diagnostic test results.

2. Data pre-processing: After collecting the data, it is important to clean and pre-process the data to remove any missing values, outliers, or irrelevant information. This step is crucial for ensuring the quality of the data and preparing it for modelling.

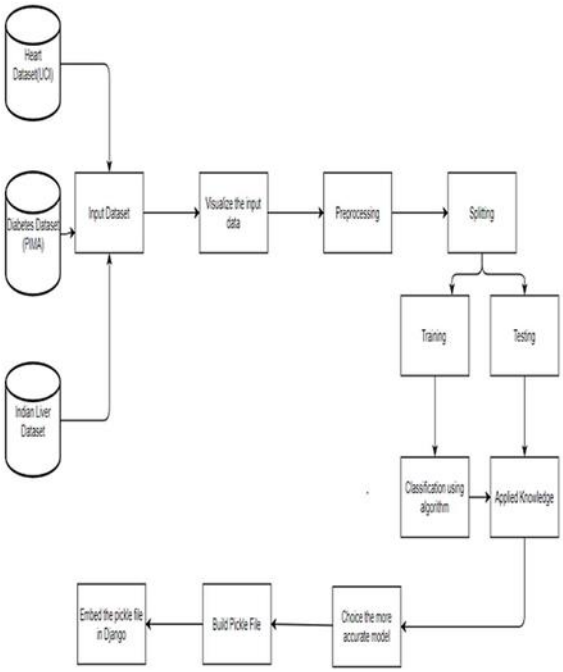
3. Feature engineering: In this step, the collected data is transformed into meaningful features that can be used as inputs to the prediction model. Feature engineering involves selecting the most relevant features, creating new features, and transforming existing features to improve the performance of the prediction model.

4. Model selection: There are several machine learning algorithms that can be used to predict diseases, including decision trees, random forests, support vector machines, and deep learning models. The choice of algorithm depends on the type of data and the problem being solved. In this step, the most appropriate algorithm is selected based on the data and the desired outcome. ANNs have been widely used in disease prediction models for their ability to handle large datasets and capture complex non- linear relationships between features. SVMs are a type of supervised machine learning algorithm that have also been used in disease prediction models. These models are useful in cases where the number of features is high compared to the number of samples. Deep learning models, such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), have been used in disease prediction models due to their ability to handle large amounts of data and capture complex relationships between features.

5. Model training: The selected machine learning algorithm is trained on the pre- processed and engineered data to learn the relationship between the features and the disease. This step is done using a training dataset, and the model is trained until it reaches an acceptable level of performance.

6. Model evaluation: After training the model, it is important to evaluate its performance on a separate dataset, known as the validation dataset. This is done to assess the model's ability to generalize to new data and to avoid overfitting, which occurs when the model is too closely fit to the training data.

7. Model deployment: Once the model has been trained and evaluated, it can be deployed for use in the real world. This can involve integrating the model into a healthcare system or using it to make predictions for individual patients.



V. RESULT

The use of different ML algorithms enabled the early detection of many diseases such as heart, kidney, breast, and brain diseases. As different types of disease prediction models are available, but individually and not properly scaled and merged into one specific interface. In this project, we will be creating the major health disease prediction models and deploy them into one single interface for the ease of medical industry as well as for the human race.

Throughout the project, SVM, RF and LR algorithms were the most widely used at

prediction, while accuracy was the most used performance metric. The CNN model proved to be the most adequate at predicting common diseases. Furthermore, SVM model showed superiority in accuracy at most times for kidney diseases and PD because of its reliability in handling high-dimensional, semi-structured and unstructured data. For Breast cancer prediction, RF showed more superiority in the probability of correct classification of the diseases because of its ability to scale well for large datasets and its susceptibility to avoid overfitting. Finally, the LR algorithm proved to be the most reliable in predicting heart diseases.

Overall, the results of multiple disease prediction systems using machine learning are very promising, and these systems have the potential to revolutionize healthcare by providing accurate and efficient predictions for multiple diseases.

VI. CONCLUSION

In conclusion, multiple disease prediction systems using machine learning can be an effective tool for healthcare providers to diagnose diseases early and improve patient outcomes. However, it is important to keep in mind the limitations of these systems, including the potential for biased data and the need for ongoing evaluation and improvement of the models.

VII. FUTURE SCOPE

- In the future we can add more diseases in the existing API.
- We can try to improve the accuracy of prediction in order to decrease the mortality rate.
- Try to make the system user-friendly and provide a chatbot for normal queries.
- Improved data integration
- Increased use of deep learning algorithms
- Personalized medicine
- Predictive maintenance
- Integration with wearable devices

Overall, the future of multiple disease prediction using machine learning is very exciting and holds great potential for improving patient outcomes and reducing the burden on the healthcare system.

Implementation of Deep Learning approaches in bioinformatics for protein deficiency- a review

Mary Margarat Valentine Neela
marym.neela@gmail.com

Abstract— **Recent advances in medical technology have resulted in the collection of large amounts of data, particularly image data. In addition, image-processing techniques aid researchers and medical professionals in diagnosis and treatment. Bioinformatics solutions provide an efficient method for image data processing to obtain information of interest and combine several data sources for knowledge extraction. Deep learning-based algorithms have been effectively used to process data in this discipline. They have displayed cutting-edge performances on high-dimensional, nonstructural, and black-box biological data. A review of the most significant recent developments in deep-learning-based design methods is presented in this article, contrasting their innovative features with traditional knowledge-based methods and demonstrating their application to notable cases. Not only do we detail the latest advancements of deep learning in structure-based protein design and direct sequence design, but we also highlight the recent uses of deep reinforcement learning in protein design. The future prospects of design objectives, difficulties, and possibilities are also thoroughly examined.**

Keywords*— *bioinformatics, Deep learning, future perspectives

I. INTRODUCTION

In many applications, including computer vision and natural language processing, deep learning has provided significant benefits. Because of its superior ability to understand complicated data structure without human involvement, it ushers in a new age for data-driven science. As a result of its widespread applicability and growing popularity, genomic researchers are starting to consider applying deep learning. Complexity and nuance characterize genomic data and their relationships with resulting outcomes (e.g., disease outcomes). However, deep learning can learn complex characteristics from the genomic data, making it a powerful tool for analyzing nonlinear and interaction effects [2]. At the same time, classical methods (such as linear regression) have typically been employed in genomic data analysis to find simple linear effects. An overview of how deep learning has been applied to genomics is presented in this study.

In the same way that supervised and unsupervised learning are subsets of machine learning, so too are these two types of approaches to what is known as deep learning. Convolutional neural networks (CNNs) have seen extensive use in solving protein structure prediction issues. Due to the complexity and difficulty of the full prediction in three-dimensional space, some research has relied on more simplified methodologies, such as predicting proteins' secondary structure or torsion angle. [3]. For the purpose of predicting the secondary structure, torsion angle, and accessible surface area of proteins, SAE was used in Heffernan et al. where DBN was used to predict the secondary structure of proteins from amino acid sequences in conjunction with the Protein Secondary Structure Prediction PSSM and FAC characteristics. When it comes to extracting knowledge from massive datasets in bioinformatics, machine learning has been one of the most popular approaches [4]. DNN has shown promising capabilities in the study of gene expression regulation, and DBN has been used to great effect in the study of splice junction prediction, one of the major research problems in the study of gene expression. In order to forecast new data, machine learning algorithms first analyze existing data (called training data) to discover hidden patterns and construct a model. Support vector machine, hidden Markov model, Bayesian networks, and Gaussian networks are just a few of the well-known algorithms that have found use in genomics, proteomics, systems biology, and other fields. Because traditional machine learning algorithms struggle with the raw form of data, researchers exert a great deal of work into translating the raw form into suitable high abstraction level features, which often requires a deep understanding of the underlying subject. Yet, a new sort of machine learning algorithm called deep learning has arisen in recent years thanks to massive data, the strength of parallel and distributed computing, and advanced algorithms. Formerly limiting factors have been removed, allowing deep learning algorithms to make significant strides in many areas, including but not limited to image recognition, audio recognition, and natural language processing. Naturally, the use of deep learning has spread to other fields, including bioinformatics.

II. BIOINFORMATICS AND MEDICAL APPLICATIONS

The application of computational methods and state-of-the-art technologies in the context of big data analysis with Deep Learning Algorithms enhances the capability of capturing and interpreting biological data. This book provides the reader with various bioinformatics computational approaches used for early disease detection by compiling state-of-the-art resources into a single collection aimed at educating the reader on issues focused on computer science, mathematics, and biology. Bioinformatics serves as an indispensable tool for managing biological and medical data in the present day. Studying how bioinformaticians interpret biological data and further our understanding of the disease, this book details the total amounts of resources.

III. LITERATURE REVIEW

The design, which includes confirming clinical execution prediction patterns, is only the first step toward the usual acquisition of forecasts for real-time point-of-care. It is assumed that healthcare analytics can be initiated at various stages, including tracking and delaying healthcare failures, assimilating new knowledge, doing an immediate evaluation, and developing a customized model. Whereas promising developments and publicity have resulted from considering data science and thought, more research and experimentation are still needed [5]. Data Mining Methods generate practical

approaches to discovering desired patterns in large datasets and establishing correlations between them to apply knowledge commentary to problem-solving. When it comes to analytics and reporting needs, healthcare organizations are increasingly turning to Big Data.

Many methods exist for analyzing healthcare data for valuable insights, including data mining, predictive analytics, and prescriptive analytics [6]. The device would be able to obtain real-time relevant information that supports decision-making and medicinal tracking through novel approaches and therapeutic data mining. In healthcare, big data input technology improves the quality of life for patients who have suffered devastating losses [7]. The rate tag for future pharmaceutical judgment is a data recovery that is acceptable and beneficial in the current age of information technology. In light of this, the unexpected rise of data analytics tools has revealed the fruitful outcomes of locked-down pattern databases. The evolution of health information technology has opened the door to investigations that would have been impossible in the past, which could lead to novel insights into health and illness [8]. Whether or not novel approaches are favored depends on how they are implemented. The therapeutic evaluation calls for the implementation of new systems on real-world data. New avenues of inquiry into health and illness are becoming possible due to health informatics developments, which are causing a sea change in health research [9]. The extent to which novel methods are adopted depends on how useful they prove to be. It is essential to put forward-thinking methods through their paces utilizing actual data from medical studies. More attention should be paid to the practical aspects of analysis and presentation of findings. Scientific statisticians have presented cutting-edge data summarization techniques throughout the past few decades, inspired by the exponential growth in computing power and storage capabilities. Networks that combine machine learning and deep learning are one example. Multiple computational approaches persist at the intersection of mathematical, analytical, and computational constraints. It is common practice for statistical procedures to employ methods that aggregate potential from various, comprehensive data sets [10]. Complex computational algorithms can be developed to produce reliable forecasting models. Unfortunately, it is not apparent how pervasive these techniques are in various fields of medicine. Following data that is collected inconsistently, such as drugs, therapies, and lab trials might make it easier to divine a patient's condition. Regular deep-learning methods can be applied to ongoing data for analysis. They must be revised in order to accommodate ongoing datasets that are tested sporadically. The study of healthcare records has prompted the examination of several deep-learning strategies for the hierarchical distribution of documents. The taxonomy formation and even processes-based methods are examined [11]. These techniques are evaluated on publicly available, standardized ICD-9 and ICD-10 coding datasets.

IV. Clustering algorithms used in bioinformatics

Algorithms for clustering data into clusters can be either hierarchical or partitioned. In contrast to the partitioning algorithms, which decide all clusters simultaneously, the hierarchical algorithms find consecutive clusters by building on top of previously existing clusters. Algorithms in a hierarchy can either be agglomerative (from the bottom up) or divisive (top-down). Algorithms that "agglomerate" start with a collection of individual nodes, or "clusters," then combine them into ever-larger nodes. Divisive algorithms take the complete set as input and split it up into smaller and smaller subsets [12]. Metrics on Euclidean spaces are used to determine hierarchical clustering. The most popular is the Euclidean distance, calculated by squaring each variable difference, summing the squaring results, and then taking the square root. Bioinformatics benefits greatly from hierarchical clustering algorithms like BIRCH due to their almost linear time complexity when dealing with generally large datasets. In order to partition a set of objects into manageable parts, algorithms often iteratively reassign objects between groups until convergence is reached [13]. In most cases, this approach can find all clusters simultaneously. Two common heuristics are the k-means algorithm and k-medoids, and both are widely used in software. Affinity propagation is just one example of an algorithm that can function without an initial set of groups. This approach has been utilized in a genomic context for both the clustering of biosynthetic gene clusters inside gene cluster families (GCF) and the clustering of GCF itself.

V. Use of Bioinformatics and Integrated Knowledge Environments

Bioinformatics helps clinicians answer a fundamental question: what is the optimal medicine for a given patient given their disease profile, lab results, genomic, proteomic, and metabolomic information? Because it connects the many stages of discovery, including experimental design, study execution, and bioanalytic analysis [14], bioinformatics is crucial for the growth of biomarker discovery.

The rapid advancement of bioinformatics over the past decade has made it possible for oncologic procedures to build biomarker-related drugs using the vast amounts of relevant "-omics" data and information from the human genome. There are already over a million articles on cancer research available on PubMed. The National Cancer Institute's caBIG bioinformatics infrastructure provides easy access to data from several studies to support ground-breaking investigation. This infrastructure makes it simple to access, compare, and download data on experiments, techniques, samples, and results. This initiative was developed by the NCI's Early Detection Research Network (EDRN) to provide cancer centers with the bioinformatics data they require for their own independent research.

Today's EDRN is a result of bioinformatics-driven enhancements to the cancer research community over the previous decade [15]. The bioinformatic analysis of large-scale experimental datasets is of critical importance, and it has altered the way research are approached. Nonetheless, many experts in the field of cancer research are not yet acclimated to

employing bioinformatics, thus they are not yet taking advantage of these benefits in their studies. This is likely to change as scientists learn to appreciate the interplay between bioinformatics and other fields of cancer study when it comes to deciphering large amounts of data.

Bioinformatics has aided translational research by providing essential tools for converting data into medical practice, which in turn has led to advances in biomarker discovery and drug development. By using biomarkers that have been proven effective in clinical settings, researchers will be able to develop less expensive and less invasive diagnostic tools for doctors and their patients [16]. Nevertheless, without access to high-quality, curated patient clinical data, correlating the biomarker data will be impossible. Clinical data and patient history such as treatment, physician notes, pathology reports, and symptoms are essential for interpreting bioinformatic results [17]..

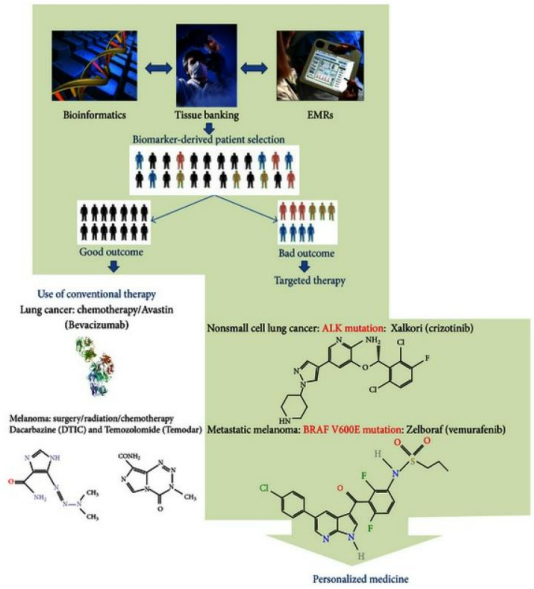

Fig. 1 data resulting from the combination of bioinformatics, tissue banking and EMRs

Many hospitals and clinics still utilize paper records despite the fact that the inability to adopt EMRs is a major factor delaying integration of patient data with experimental outcomes [18]. Clinicians and other hospital staff may not be aware of the benefits of bioinformatics, and they may not have the time or motivation to learn more about it. No one should be surprised by this, given doctors and nurses have much more pressing responsibilities than entering clinical data into a computer and have no financial incentive to do so. Clinical staff involvement in bioinformatics research is, nonetheless, crucial and should be actively developed.

Table 1: bioinformatics and medical data processing of Hypothetical protein and ligands

Author	Year	Description
Rabbi MF [19]	(2021)	This study investigated structural and functional aspects comprehensively. In order to predict the solubility, stability, and extracellular location of this hypothetical protein, physicochemical parameters and subcellular localization were used.
Imam N et al [20]	(2019)	Bush typhus, also known as scrub typhus, is a viral disease with symptoms similar to Chikungunya infection. Oriental tsutsugamushi, a gram-negative bacterium, causes this disease in vertebrates. In this investigation, we aimed to deduce the possible roles played by 344 of these putative proteins (HPs).
Umairah et al [21]	(2019)	The rise of bacterial infections that are resistant to antibiotics is a major cause for concern, as it threatens to usher in a new era of "antibiotic apocalypse." The rising death toll from these antibiotic-resistant superbugs emphasizes the pressing need for the development of novel treatments for these diseases.
Kiarash et al [22]	(2019)	The purpose of this study is to determine the functions of the proteins by using bioinformatics methods based on the traits we find in UCB-1 pistachio roots.
Khairiah Razali et al [23]	(2020)	The purpose of this study was to annotate the function and structure of these un-annotated proteins. The 39 proteins were initially screened for template availability and pathogenicity
Alariqi Reem et al [24]	(2021)	Proteomics research on Pseudomonas aeruginosa revealed that 25% of proteins are hypothetical proteins with unknown functions. This study attempts to understand the function of such a hypothetical protein, PA2373, as no experimental research has yet been conducted on it.
D. Prabhua et al [25]	(2020)	Rodlike serrations called marcescent One type of opportunistic pathogen is Gram-negative bacteria, which belongs to the Enterobacteriaceae family. As a result, humans can suffer from osteomyelitis, endocarditis, meningitis, septicemia, and infections of the urinary tract, respiratory system, ocular lens, and ear.
Muham mad	(2017)	Human adenoviruses are small DNA viruses that can cause various

Naveed et al [26]		illnesses in humans. The whole genome sequencing of human adenovirus reveals an abundance of putative proteins that are not yet assigned a cellular or metabolic function.
Cameron Bixby [27]	(2016)	Since the velocity of analysis is not able to keep up with the rate of discovery of hypothetical proteins, there are currently legions of hypothetical proteins waiting for accurate identification of their functions.
Kohda D [28]	(2018)	When it comes to many biological processes, promiscuous ligand recognition by proteins is just as important as strict recognition. Proteins in living cells contain numerous short, linear amino acid motifs that serve as targeting cues to determine the protein's final destination during transport.

VI. CONCLUSION

A bioinformatics and tissue banking education must be provided to clinicians, and electronic medical record systems must be set up to find biomarkers to guide personalized cancer treatment. Enhancing informed consent methods and delivering more information about the benefits of tissue sample contributions can provide richer data sources for determining patterns and personal differences. With these upgrades in place, researchers may focus on finding biomarkers that can forecast the course of a disease, provide more information about a specific illness, and point toward an appropriate treatment strategy. Clinicians will have the resources they need to develop designed medicine and improve patient treatment results from community-wide efforts to collect patient data, create well-controlled tissue banks, and develop novel genomic and proteomic technologies. Medical costs for patients will be lowered as a result of these initiatives. Deaths can be prevented through the integration and use of bioinformatics techniques in standard clinical practice.

Abstract-**Bioelectronics devices have shown their unprecedented potential in a wide range of biomedical applications due to their vast functionality. To fully unleash their potential, bioelectronics devices should be able to precisely respond to real-time changes in the environment to drive biological systems' response towards the desired goals. However, controlling the biological systems' response with bioelectronics devices is challenging due to the presence of uncertainties, stochasticity, unmolded dynamics, and a complex nonlinearities. Here, we demonstrate the promise of leveraging tools in synthetic biology with an online machine learning (ML)-based feedback controller to achieve a precise spatiotemporal response of biological systems using bioelectronics driven by an adaptive external "sense and respond" learning algorithm. The proposed ML-based feedback controller leverages the learning capability and low computational complexity of a class of artificial neural networks called the Radial Basis Function (RBF) network. Lyapunov analysis is provided to prove stability of the proposed controller. The satisfactory performance of the proposed method is experimentally validated by maintaining media pH using bioelectronics proton pumps**

I. INTRODUCTION

BIOELECTRONICS integrates electronic devices and materials with biological systems. The field has produced a broad range of devices with unique operating methods and functionalities and shows tremendous promise for addressing a wide range of biomedical applications including but not limited to bio sensing, neural recording and stimulation, drug delivery, and tissue engineering. In particular, there has been considerable effort in developing devices for delivery of small molecules and ions that serve an important role in biomedical applications [3]–[6]. These devices, known as ion pumps, are beneficial in that they allow for precise control over the time, location, and magnitude of delivery. Among potential ions and small molecules, protons (H^+) play a central role to many biological processes. For example, regulation of the H^+ concentration (pH) maintains healthy neuronal functioning and excitability, enzymatic activity, gene expression, and is indicative of healthy cell function. Driving biological response with spatiotemporal precision using bioelectronics devices can help advance biomedical applications for customized therapeutics. Implementation of feedback control in these devices can help achieve this but has not been widely adopted, in part, due to a limited understanding of the complexities involved. Modeling, identification, prediction, and control, which are essential to this end, are challenging due to the presence of uncertainties, stochasticity, unmolded dynamics, and complex nonlinearities. For example, bioelectronics devices are generally fabricated in parallel and, ideally, they should be identical to each other both structurally and functionally. In practice, the devices have different characteristics due to inherent variabilities in the fabrication processes. Additionally, the mechanical/electrical properties of the bioelectronics devices may change over the course of an experiment (e.g., increased resistance across electrodes in proton pump). Moreover, in biological systems, cellular response can change in different environmental conditions such as changing flow characteristics and temperature. Thus, machine learning (ML)-based techniques, which can be applied to solve different modeling and control problems when system dynamics are fully or partially unknown, may prove suitable here. Such learning methods have not been applied to the control of bioelectronics devices to the best of our knowledge. Online learning methods have been used in other related applications. For example, in, a neural network and its mathematical inverse were utilized to model a continuous stirred-tank reactor (CSTR) and control the overall process, respectively. However, most examples leverage offline training such as in, where Ławrynczuk applied artificial neural networks for modeling ´ and temperature control of a yeast fermentation biochemical reactor. Here and in most of the state-of-the-art ML-base techniques, offline training and the availability of large datasets a priori are necessary to successfully tackle modeling, identification, prediction, and control problems. Otherwise, the methods will fail in conditions previously unobserved. To accurately drive the biological systems' response towards the desired goals, the bioelectronics device should be able to adapt its response to real-time changes in measured response. Here, a real-time adaptive ML-based feedback controller is designed, in a direct control scheme, for automatic control of pH level using a bioelectronics proton pump. In order to directly apply a ML-based method to a control problem, its parameters should directly be adjusted to reduce the system's error, unlike the indirect control problem, where identification/estimation is used to approximate the system's model and then, the parameters of the ML-based controller are adjusted accordingly. We propose an adaptive ML-based feedback controller that leverages a class of artificial neural networks called the Radial Basis Function (RBF) network to achieve real-time online control without a priori knowledge of the dynamical model of the system, no dependency on large-scale datasets, and low computational complexity.

II. EXISTING SYSTEM

In Existing System, to fully unleash these potential, bioelectronics devices should be able to precisely respond to real-time changes in the environment to drive biological systems' response towards the desired goals. However, controlling the biological systems' response with bioelectronics devices is challenging due to the presence of uncertainties, stochasticity, unmolded dynamics, and complex nonlinearities.

III. LITERATURE SURVEY

"Professional chat application based on natural language processing.

There has been an emerging trend of a vast number of chat applications which are present in the recent years to help people to connect with each other across different mediums, like Hike, WhatsApp, Telegram, etc. The proposed network-based android chat application used for chatting purpose with remote clients or users connected to the internet, and it will not let the user send inappropriate messages. This paper proposes the mechanism of creating professional chat application that will not permit the user to send inappropriate or improper messages to the participants by incorporating base level implementation of natural language processing (NLP). Before sending the messages to the user, the typed message evaluated to find any inappropriate terms in the message that may include vulgar words, etc., using natural language processing. The user can build an own dictionary which contains vulgar or irrelevant terms. After pre-processing steps of removal of punctuations, numbers, conversion of text to lower case and NLP concepts of removing stop words, stemming, tokenization, named entity recognition and parts of speech tagging, it gives keywords from the user typed message. These derived keywords compared with the terms in the dictionary to analyze the sentiment of the message. If the context of the message is negative, then the user not permitted to send the message

Real world smart chatbot for customer care using software as service (SaaS) architecture.

It's being very important to listen to social media streams whether it's Twitter, Facebook, Messenger, LinkedIn, email or even company own application. As many customers may be using this streams to reach out to company because they need help. The company have setup social marketing team to monitor this stream. But due to huge volumes of users it's very difficult to analyses each and every social message and take a relevant action to solve users' grievances, which lead to many unsatisfied customers or may even lose a customer. This papers proposes a system architecture which will try to overcome the above shortcoming by analyzing messages of each ejabberd users to check whether it's actionable or not. If it's actionable then an automated Chatbot will initiates conversation with that user and help the user to resolve the issue by providing a human way interactions using LUIS and cognitive services. To provide a highly robust, scalable and extensible architecture, this system is implemented on AWS public cloud.

An Overview of Artificial Intelligence Based Chabot's and an Example Chabot Application.

Chatbot can be described as software that can chat with people using artificial intelligence. These software are used to perform tasks such as quickly responding to users, informing them, helping to purchase products and providing better service to customers. In this paper, we present the general working principle and the basic concepts of artificial intelligence based chatbots and related concepts as well as their applications in various sectors such as telecommunication, banking, health, customer call centers and e-commerce. Additionally, the results of an example chatbot for donation service developed for telecommunication service provider are presented using the proposed architecture.

Intelligent travel chatbot for predictive recommendation in echo platform

Chatbot is a computer application that interacts with users using natural language in a similar way to imitate a human travel agent. A successful implementation of a chatbot system can analyze user preferences and predict collective intelligence. In most cases, it can provide better user-centric recommendations. Hence, the chatbot is becoming an integral part of the future consumer services. This paper is an implementation of an intelligent chatbot system in travel domain on Echo platform which would gather user preferences and model collective user knowledge base and recommend using the Restricted Boltzmann Machine (RBM) with Collaborative Filtering. With this chatbot based on DNN, we can improve human to machine interaction in the travel domain

Chatbot Using a Knowledge in Database Human-to-Machine Conversation Modeling

A chatterbot or chatbot aims to make a conversation between both human and machine. The machine has been embedded knowledge to identify the sentences and making a decision itself as response to answer a question. The response principle is matching the input sentence from user. From input sentence, it will be scored to get the similarity of sentences, the higher score obtained the more similar of reference sentences. The sentence similarity calculation in this paper using bigram which divides input sentence as two letters of input sentence. The knowledge of chatbot is stored in the database. The chatbot consists of core and interface that is accessing that core in relational database management systems (RDBMS). The database has been employed as knowledge storage and interpreter has been employed as stored programs of function and procedure sets for pattern-matching requirement. The interface is standalone which has been built using programing language of Pascal and Java.

IV. PROPOSED METHODOLOGY

In this chapter, various supervised machine learning approaches are used. This section provides a general description of these approaches. Abusive messages in social media is a complex phenomenon with a broad range of overlapping modes and goals [17]. Cyberbullying and hate speech are typical examples of

abusive languages that researchers have put more interest in the past few decades due to their negative impacts in our societies. Several research have been conducted to automatically detect these undesirable messages among other messages in social media. The contributions of this study are three-fold. First to equip the readers with the necessary information on the critical steps involved in hate speech detection using ML algorithms. Secondly, the weaknesses and strengths of each method is critically evaluated to guide researchers in the algorithm choice dilemma. Lastly, some research gaps and open challenges were identified. The different variants of ML techniques were reviewed which include classical ML, ensemble approach and deep learning methods. Researchers and professionals alike will benefit immensely from this study.

- Bioelectronics proton (H+) pump
- Sensing pH
- Machine Learning based Controller

- **Bioelectronics proton (H+) pump**

A proton (H+) pump is a bioelectronics device that can be used to repetitively control and maintain the pH level in biological processes. Here, the bioelectronics device consists of multiple columns of proton (H+) pumps, which are devices capable of modulating the Ph of solution, and work by transferring H+ between polymer membranes within the device and a target solution upon an applied voltage (i.e., Vb in Fig. 1–Top). We floated Va such that a positive value for Vb drives the release of H+ from the H+ cation exchange membrane into the solution (see black dotted arrow in Fig. 1–Top) thus increasing H+ of the solution and a negative value for Vb will drive H+ from the solution into the cation exchange membrane thus decreasing H+ of the solution. The proton pumps are positioned in an array and are individually accessible through a custom-designed expansion board using a microcontroller. Figure 1–Bottom, shows the top view of proton pumps distribution in the target demonstrating different columns, selected areas for measurements, and the corresponding dimensions. In this section, we highlight the methodology in three parts describing the plant, sensor, and controller. First, a brief description of the bioelectronics proton (H+) pump is provided. Second, we introduce the fluorescent dye used for imaging. Finally, the details of the proposed machine learning-based feedback controller are elaborated. Bioelectronics proton (H+) pump. Top: Schematic of the bioelectronics proton (H+) pump with applied voltages. Bottom: Top view of an array of targets for the proton pump device. Actuated columns and selected areas for measurements are indicated.

Sensing pH

Measurement of media pH on the surface of the ion pump is a challenging task due to the small volume and requires specialized instrumentation. In this work, we instead read out changes in pH using Carboxy SNARF-1 dye, a fluorescent pH indicator developed by Molecular Probes, useful for measuring pH changes between pH 7 and pH 8. Common applications of Carboxy SNARF-1 dye are in biology, where intracellular pH is generally between 6.8 and 7.4 in the cytosol. Additionally, pH inside a cell varies by only fractions of a pH unit, and such changes may be quite slow.

Since small changes in pH can have significant impact on cellular response, there is a need for tight control within this small range of pH for applications in synthetic biology. Roughly speaking, the relevant range of pH for cells corresponds to an overall 10% change in fluorescence. In this work, we demonstrate control with less than 5% error and active control over a 10% change in fluorescence.

The circuit test is carried out by means of testing the component voltage value at each connection. Based on the results of testing a series of innovative pH meter measuring devices concluded that each component is well connected.

The measured pH sensor input voltage value is 4.92 V. The measured sensor output voltage value is 2.43 V. The measurement results of the input voltage are then entered into the pH conversion formula. From the results of the analysis of correlation values that have been done it can be seen that the pH value of the test sensor output has a good correlation with standard pH measuring devices. Good correlation is an indicator of a tool capable of providing output that is close to the standard value. Linearity states the relationship between input and output where the units of the two are already in actual units, namely pH. Input is the pH value that is read by a standard pH meter and the output is the pH that is the pH read by the pH sensor. Linearity analysis aims to find out how linear the sensor readings are against the standard device. Linearity testing can provide information about the measurement point farthest by the test sensor against the linear line. Testing the pH value to determine the precision value is done by repeating the test data at least 3 times from each pH buffer used in the test. From the results of the analysis that has been done, the precision value possessed by the pH sensor in making measurements is 99.99%. This means that the pH sensor used has good repeatabilitySensor sensitivity value is measured to determine the value of the sensor's reading power. The sensitivity sought is in the form of the voltage in mV that is read for a 1pH increase (mVpH). Data collection is done by reading the output voltage and pH that is read on the sensor in each measured pH buffer solution.

Machine Learning based Controller

The architecture of the implemented online machine learning-based feedback controller designed for the bioelectronics proton (H+) pump. The system consists of the bioelectronics proton pump where “A” is a reservoir for H+ ions (e.g., water (H2O)) and “B” is a medium with appropriate dye (e.g., water with SNARF-1 dye).

The sensing system consists of the KEYENCE BZ-X710 microscope imaging system, which takes fluorescent images in real-time and sends them to a shared folder. The image analyzer reads images from the shared folder using MATLAB scripts and computes the

mean value of the selected area of the proton pumps distribution in the target.

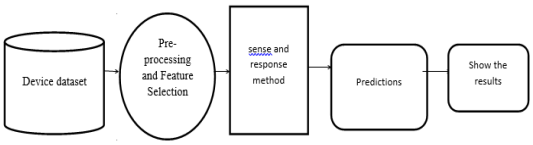
This value then is used as feedback of current states of the system to update the ML-based control output. Machine learning (ML) based controller consists of an ML-based control algorithm that is running on a PC.

The interfacing device consists of a Raspberry Pi and an expansion board which applies the commands received from the ML based controller to the bioelectronics proton pump. To design a feedback controller for the pH level control in a bioelectronics proton (H+) pump, we formulate the problem as a tracking control problem. In a tracking control problem, our interest is in a certain output variable rather than the states.

The accurate demand prediction with high efficiency and advanced demand-side controller are essential for the enhancement of energy flexibility provided by buildings, whereas the current literature fails to present the mechanism on modelling development and demand-side control. This paper aims to deal with the complexity of building demand prediction with supervised machine learning method, including the multiple linear regression, the support vector regression and the backpropagation neural network.

- The regularization, adding the sum of the weights to the learning function, is utilized to improve the training speed and to solve the overfitting by eliminating the unnecessary connections with small weights.
- The configuration of the artificial neural network was presented, and sensitivity analysis has been conducted on the learning performance regarding different training times.
- Energy flexibilities of sophisticated building energy systems (including renewable system, electric and thermal demands and building services systems) were quantitatively characterized with a series of quantifiable indicators.
- Moreover, several advanced controllers have been developed and contrasted, in regard to the flexibility utilization of building energy systems.
- Results showed that, the developed hybrid controller with short-term prediction through the cross-entropy function is more technically competitive than other controllers.
- With the implementation of the developed hybrid controller, the peak power of the grid importation can be reduced from 500.3 to 195 kW by 61%.
- This study formulates a data-driven model with an advanced machine learning algorithm for the accurate building demand prediction and a hybrid advanced controller with short-term prediction for the energy management, which are critical for the promotion of energy flexible buildings.

V. SYSTEM ARCHITECTURE



VI. RESULTS

Although we only use LSTM for developing the models in this paper, other types of models (e.g., CNN, deep neural networks, and SVM) can also be explored. It would be interesting to perform a comparative study of these models and also consider their robustness to adversarial attacks compared to our proposed fixing heuristic. Additionally, potential applications of our proposed heuristic can be explored in the speech, video, and medical domains, and in recommendation systems.

VII. CONCLUSION

A real-time adaptive external "sense and respond" machine learning-based control technique is developed in this letter to automate pH level control using a bioelectronics proton pump with unknown dynamics and unknown coupling. We demonstrated the advantages of developing online adaptive ML-based feedback control strategies with no dependency on datasets, and with low computational complexity. Furthermore, this method can be extended to control cellular systems given similar dynamical properties (e.g. monotone input/output systems. Instead of reading out fluorescent images representing relative changes in pH, we can directly read out and control other processes such as gene expression, also quantified in the form of fluorescent images using tools in synthetic biology. Future work will consider improvements to the proposed algorithm by addressing constraints on the controller output due to the device limitations.

VIII. VII. FUTURE ENHANCEMENT

In the second examination, the online adaptive ML-based feedback control algorithm was tested for automatic spatiotemporal feedback control of the pH level using a bioelectronics proton pump with unknown dynamics and unknown coupling. In order to achieve spatiotemporal control, we aim towards designing a control scheme to reliably deliver ions in different spatial locations (e.g. we would like each point in space to follow a unique reference trajectory). Here, we specify two different fluorescence intensity signals for two individual columns. The fluorescence intensities of the two columns should be kept close to the target intensities with acceptable errors. Each controller only applies the voltage Vb to its associated proton pumps. Whenever the voltage is applied to a specific proton pump, the other proton pumps are floated. Positive voltages will result in releasing ions from the proton pumps, and negative voltages will result in absorbing ions by the proton pumps. The sampling time (Ts) is divided equally for each active proton pump to be controlled.

Deep Learning Based Approach For Hate Speech Detection

Ateeqa Jabeen, Md. Ateeq Ur Rahman
Research Scholar , Department of CSE, Shadan College of Engineering and Technology, Hyderabad, Telangana, India – 500086
ateeqa.jabeen@gmail.com

Abstract-**The quality of this paper is to review man-made information (ML) estimations and techniques for scorn talk exposure in virtual redirection (SM). Scorn talk issue is routinely model as a text portrayal task. In this survey, we isolated the central check portions of scorn talk gathering using ML evaluations. There are five crucial standard parts - data strategy and appraisal, coordinate extraction, dimensionality decline, classifier attestation and organizing, and model evaluation, were explored. There have been revives in ML estimations that were used for scorn talk certification for a long time. New datasets and different execution evaluations have been proposed in the creation. To keep the experts informed concerning these models in the changed confirmation of scorn talk, it requires a total and a revived high level. The commitments of this study are three-move past. First to furnish the peruses with the fundamental information on the chief drives related with scorn talk unquestionable evidence using ML estimations. Likewise, the weaknesses and properties of each and every framework is overall evaluated to work with experts in the appraisal choice issue. In light of everything, a couple of assessment openings and open challenges were seen. The different varieties of ML systems were explored which coordinate customary ML, pack approach and basic learning procedures. Researchers and specialists, a relative will benefit enormously from this over.**

I. INTRODUCTION

Online redirection affiliations (ORAs) are the speediest technique for correspondence as messages are sent and gotten quickly [1], [2]. ORAs are the basic media for executing disdain keeps an eye out for these days. According to this, cutting edge disdain shocking way to deal with acting has filled fundamentally over the most recent several distinct years [3]. More glances at are being worked with to control with the rising events of hatred talks in virtual entertainment (SM). Various calls have been made to SM suppliers to channel each remark going before permitting it into the public space [4], [5]. The effects of disdain horrible ways to deal with acting are right currently overpowering a brief consequence of wide social gathering of SM [6] and the secret respected by the electronic clients [7]. In this season of enormous information, the doorway has seemed consuming and testing to process and depict gigantic degrees of text information in actuality. Moreover, the accuracy of the social event of manual text can without an absolutely vital stretch be impacted by human parts, like depletion and cutoff. To accomplish more specific and less reasonable outcomes, it is irreplaceable for utilize man-made mental capacity (ML) ways of managing directing robotize the text depiction processes [6]. There have been titanic sorts of progress in ML framework from obsolete ML, gathering and huge learning (DL) methodologies for disdain talk area. Considering the striking progress similarly language making due (NLP), a couple of copied data methods have accomplished inescapable results [8]. To have the decision to besides invigorate depiction of SM texts as contempt talk or non-disdain talk, scientists and experts require a restored discernment of PC based data moves close, which is speedy advancing. Astounding exertion has been spent on making new strong regions for and that better catch disdain chat on SM [9]-[11]. Slangs and new vocabularies are other than endlessly making in the SM space. New and vivified datasets are furthermore open across various locale of the world. To overcome any countering, there is a need to zero in on the plan and keep arranged specialists, old and new specialists in the loop of the streams upgrades in this evaluation region. On this note, this survey becomes essential to be shaped. The additional pieces of this article are framed in the going with ways: Inspiration and Related Works are introduced in portion II. Area III covers the perspective. Disdain talk and hatred talk showing is requested in segment IV. Disdain talk depiction, responsibility and focuses of past works, open weights in disdain talk disclosure, limit of the audit and end are battled in section V, VI, VII, VIII and IX freely.

II. RELATED WORK

Professional chat application based on natural language processing. There has been an emerging trend of a vast number of chat applications which are present in the recent years to help people to connect with each other across different mediums, like Hike, WhatsApp, Telegram, etc. The proposed network-based android chat application used for chatting purpose with remote clients or users connected to the internet, and it will not let the user send inappropriate messages. This paper proposes the mechanism of creating professional chat application that will not permit the user to send inappropriate or improper messages to the participants by incorporating base level implementation of natural language processing (NLP). Before sending the messages to the user, the typed message evaluated to find any inappropriate terms in the message that may include vulgar words, etc., using natural language processing. The user can build an own dictionary which contains vulgar or irrelevant terms. After pre-processing steps of removal of punctuations, numbers, conversion of text to lower case and NLP concepts of removing stop words, stemming, tokenization, named entity recognition and parts of speech tagging, it gives keywords from the user typed message. These derived keywords compared with the terms in the dictionary to analyze the sentiment of the message. If the context of the message is negative, then the user not permitted to send the message

Real world smart chatbot for customer care using software as service (SaaS) architecture.

It's being very important to listen to social media streams whether it's Twitter, Facebook, Messenger, LinkedIn, email or even company own application. As many customers may be using this streams to reach out to company because they need help. The company have setup social marketing team to monitor this stream. But due to huge volumes of users it's very difficult to analyses each and every social message and take a relevant action to solve users' grievances, which lead to many unsatisfied customers or may even lose a customer. This papers proposes a system architecture which will try to overcome the above shortcoming by analyzing messages of each ejabberd users to check whether it's actionable or not. If it's actionable then an automated Chatbot will initiates conversation with that user and help the user to resolve the issue by providing a human way interactions using LUIS and cognitive services. To provide a highly robust, scalable and extensible architecture, this system is implemented on AWS public cloud.

An Overview of Artificial Intelligence Based Chabot's and an Example Chabot Application.Chatbot can be described as software that can chat with people using artificial intelligence. These software are used to perform tasks such as quickly responding to users, informing them, helping to purchase products and providing better service to customers. In this paper, we present the general working principle and the basic concepts of artificial intelligence based chatbots and related concepts as well as their applications in various sectors such as telecommunication, banking, health, customer call centers and e-commerce. Additionally, the results of an example chatbot for donation service developed for telecommunication service provider are presented using the proposed architecture.

Intelligent travel chatbot for predictive recommendation in echo platform

Chatbot is a computer application that interacts with users using natural language in a similar way to imitate a human travel agent. A successful implementation of a chatbot system can analyze user preferences and predict collective intelligence. In most cases, it can provide better user-centric recommendations. Hence, the chatbot is becoming an integral part of the future consumer services. This paper is an implementation of an intelligent chatbot system in travel domain on Echo platform which would gather user preferences and model collective user knowledge base and recommend using the Restricted Boltzmann Machine (RBM) with Collaborative Filtering. With this chatbot based on DNN, we can improve human to machine interaction in the travel domain

Chatbot Using a Knowledge in Database Human-to-Machine Conversation Modeling

A chatterbot or chatbot aims to make a conversation between both human and machine. The machine has been embedded knowledge to identify the sentences and making a decision itself as response to answer a question. The response principle is matching the input sentence from user. From input sentence, it will be scored to get the similarity of sentences, the higher score obtained the more similar of reference sentences. The sentence similarity calculation in this paper using bigram which divides input sentence as two letters of input sentence. The knowledge of chatbot is stored in the database. The chatbot consists of core and interface that is accessing that core in relational database management systems (RDBMS). The database has been employed as knowledge storage and interpreter has been employed as stored programs of function and procedure sets for pattern-matching requirement. The interface is standalone which has been built using programing language of Pascal and Java.

III. METHODOLOGIES

- **A. Dataset**
- **B. Pre-Processing**
- **C. Splitting**
- **D. Apply Algorithm**
- **E. Visualization**
- **F. Accuracy**

IV. MODULE DESCRIPTION

A. Data set

A data set is an assortment of data. On account of plain data, a data set relates to at least one database tables, where each segment of a table addresses a specific variable, and each line compares to a given record of the data set being referred to.

B. Pre-Handling

Data pre-handling is a course of setting up the crude data and making it reasonable for an AI model. It is the first and significant stage while making an AI model.

While making an AI project, it isn't generally a case that we confess all and organized data. And keeping in mind that doing any activity with data, cleaning it and put in an organized way is required.

C. Splitting

Data parting is the demonstration of apportioning accessible data into. two segments, typically for cross-validatory purposes. one piece of the data is utilized to foster a prescient model. also, the other to assess the model's exhibition.

• Preparing Data: Utilized for train the model or given as contribution to the to the learning model

• Testing Data: Utilized for test the model or given as contribution to the model for expectation.

D. Apply Calculation

In this we are utilizing support vector machine calculation to foresee accuracy. It is a non-probabilistic managed AI approaches utilized for characterization and relapse. It doles out another data part to one of two potential classes. It characterizes a hyper plane that isolates n-layered data into two classes.

E. Visualization

Representation is a strategy that utilizes a variety of static and intelligent visuals inside a particular setting to help individuals comprehend and figure out a lot of data. The data is many times shown in a story design that pictures examples, patterns and relationships that may somehow slip through the cracks.

F. Accuracy

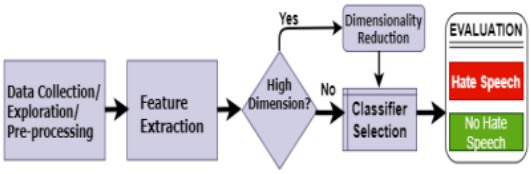
Accuracy is characterized as the level of right expectations for the test data. It very well may be determined effectively by separating the quantity of right forecasts by the quantity of all out predictionst

V. PROPOSED ALGORITHM

DEEP LEARNING TECHNIQUES, ENSEMBLE CLASSIFIER AND SUPPORT VECTOR MACHINE (SVM)

All ML calculations utilize numerical displaying as a basic piece of the calculation. Accordingly, the unstructured idea of the texts information should be changed over into organized highlight space. More scientists are currently keen on creating applications that influence text characterization techniques, particularly with late advances in NLP and text mining. By and large, disdain discourse order switch maturing ML can be gathered into five stages: Information assortment and investigation, include extraction, dimensionality decrease, classifiers determination and assessments.

VI. SYSTEM ARCHITECTURE



Over the past few decades, text classification has been researched extensively and used in many real life applications such as hate speech detection. More researchers are now interested in developing applications that leverage text classification methods, especially with recent advances in NLP and text mining. Generally, hate speech classification leveraging ML can be grouped into five phases: Data collection and exploration, feature extraction, dimensionality reduction, classifiers selection and evaluations as summarized in Figure.

VII. RESULT

Regardless of what the way that we essentially use NN for empowering the models in this paper, different sorts of models (e.g., NN, RF, SVM and so on) can similarly be analyzed. It would be enchanting to play out a near assessment of these models and besides consider their capacity to not much of composed assaults stood isolated from our proposed fixing fitting and other problems. Additionally, potential purposes behind our proposed method can be bankrupt down in the discussion, video, and clinical areas, and in thought structures.

APPLICATION

- Retail and e-commerce.
- Travel and hospitality.
- Banking, finance, and fintech.
- Healthcare.
- Media and entertainment.
- Education.

VIII. CONCLUSION

This article hated pushes made such a long ways in changed disdain talk divulgence in electronic redirection. Disdain talk as a social issue is an old evaluation locale in creative verbalization and humanities, notwithstanding, it is as of now another appraisal region in the enrolling space. Subsequently, there is a need to constantly restore specialists with the advances or advances made to keep scientists informed. We dissected the strategies for thinking from normal ML, Affiliation and enormous learning approaches specifically scorn talk in virtual redirection. This review figured out that there is more unmistakable assessment work in disdain talk affirmation utilizing standard ML than pack and fundamental learning strategies. That derives specialists can separate more on disdain talk confirmation utilizing gathering and essential learning frameworks. This appraisal similarly isolated the lacks and qualities which can be of help in orchestrating the specialists' decision of one technique over the other. This article moreover evident a couple of open difficulties in disdain talk region which include: Social groupings, pandemic or hopeless event, information sparsity, and imbalance dataset challenge and dataset accessibility concern.

IX. FUTURE ENHANCEMENT

This evaluation has figured out that exceptional characters and numeral pictures commonly utilized in Nigeria for making HS remarks have not been would in everyday by present status of-threat. For instance, the utilization of "419" to mean an unwholesome way to deal with acting is typical in Nigeria. No appraisal manages this. The doled out bunch for this evaluation audit is by and large learners in the space of disdain talk (text) gathering in the SM. This study gives each of the typical advances expected to happen in organizing text gathering errands remembering ML and two or three open inconveniences for the space.

ateeq@yahoo.com, drjothikumarr@gmail.com

Abstract-**This paper deals with the prediction of Diabetes Disease by performing an analysis of five supervised machine learning algorithms, i.e. K-Nearest Neighbours, Naive Bayes, Decision Tree Classifier, Random Forest and Support Vector Machine. Further, by incorporating all the present risk factors of the dataset, we have observed a stable accuracy after classifying and performing cross-validation. We managed to achieve a stable and highest accuracy of 76% with Random Forest classifier and remaining all other classifiers also give a stable accuracy of above 70%. We analyzed why specific Machine Learning classifiers do not yield stable and good accuracy by visualizing the training and testing accuracy and examining model over fitting and model under fitting. The main goal of this paper is to find the most optimal results in terms of accuracy and computational time for Diabetes disease prediction.**

I. INTRODUCTION

In this day and age, one of the most notorious diseases to have taken the world by storm is Diabetes, which is a disease which causes an increase in blood glucose levels as a result of the absence or low levels of insulin. Due to the many criterion to be taken into consideration for an individual to harbour this disease, it's detection and prediction might be tedious or sometimes inconclusive. Nevertheless, it isn't impossible to detect it, even at an early stage.

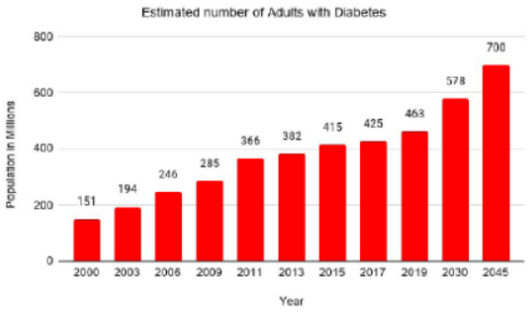

Fig. 1. Number of diabetic patients estimated with respect to year

In the year 2019, approx. 463 million adults between the age of 20-79 years had diabetes (International Diabetes Federation- IDF). 79% of the adult population were living in the countries with the low and middle-income groups. It is estimated that by the year 2045 approx. 700 million people will have diabetes (IDF). Diabetes is increasing day by day in the world because of environmental, genetic factors. The numbers are rising rapidly due to several factors which includes unhealthy foods, physical inactivity and many more. Diabetes is a hormonal disorder in which the inability of the body to produce insulin causes the metabolism of sugar in the body to be abnormal, thereby, raising the blood glucose levels in the body of a particular individual. Intense hunger, thirst and frequent urination are some of the observable characteristics. Certain risk factors such as age, BMI, Glucose Levels, Blood Pressure, etc., play an important role to the contribution of the disease.

In the Fig. 1 we can see that the number of cases is rising every year and there is not slowing down in the active cases. It is a very crucial thing to worry as diabetes has become one of the most dangerous and fastest diseases to take the lives of many individuals around the globe.

Machine Learning is very popular these days as it is used everywhere, where a large amount of data is present, and we need some knowledge from it. Generally, we can categorise the Machine Learning algorithms in two types but not limited to

- **Unsupervised Learning:** In unsupervised learning, the information is not labelled and also not trained. Here, we just put the data in action to find some patterns if possible.
- **Supervised Learning:** In supervised learning, we train the model based on the labels attached to the information and based on that we classify or test the new data with labels.

With the rise of Machine Learning and its relative algorithms, it has come to light that the significant problems and hindrances in its detection faced earlier, can now be eased with much simplicity, yet, giving a detailed and accurate outcome. As of the modern-day, it is comprehended that Machine Learning has become even more effective and helpful in collaboration with the domain of Medicine. Early determination of a disease can be made possible through machine learning by studying the characteristics of an individual. Such early tries canof permitting the disease to reach a critical degree. The work which will be described in this paper is to perform the diabetes disease prediction using machine learning algorithms for early care of an individual.

II. RELATED WORK

Saeedi, I. Petersohn, P. Salpea, B. Malanda, S. Karuranga, N. Unwin, S. Colagiuri, L. Guariguata, A. A. Motala, K. Ogurtsova, J. E. Shaw, D. Bright, and R.Williams, 2019.

Aims: To provide global estimates of diabetes prevalence for 2019 and projections for 2030 and 2045.

Methods: A total of 255 high-quality data sources, published between 1990 and 2018 and representing 138 countries were identified. For countries without high quality in-country data, estimates were extrapolated from similar countries matched by economy, ethnicity, geography and language. Logistic regression was used to generate smoothed age-specific diabetes prevalence estimates (including previously undiagnosed diabetes) in adults aged 20-79 years.

Results: The global diabetes prevalence in 2019 is estimated to be 9.3% (463 million people), rising to 10.2% (578 million) by 2030 and 10.9% (700 million) by 2045. The prevalence is higher in urban (10.8%) than rural (7.2%) areas, and in high-income (10.4%) than low-income countries (4.0%). One in two (50.1%) people living with diabetes do not know that they have diabetes. The global prevalence of impaired glucose tolerance is estimated to be 7.5% (374 million) in 2019 and projected to reach 8.0% (454 million) by 2030 and 8.6% (548 million) by 2045.
Conclusions: Just under half a billion people are living with diabetes worldwide and the number is projected to increase by 25% in 2030 and 51% in 2045.

C. R. Harris, K. J. Millman, S. J. van der Walt, R. Gommers, P. Virtanen, D. Cournapeau, E. Wieser, J. Taylor, S. Berg, N. J. Smith, R. Kern, M. Picus, S. Hoyer, M. H. van Kerkwijk, M. Brett, A. Haldane, J. F. del R'ıo, M. Wiebe, P. Peterson, P. G'erard-Marchant, K. Sheppard, T. Reddy, W. Weckesser, H. Abbasi, C. Gohlke, and T. E. Oliphant, 2020.Array programming provides a powerful, compact and expressive syntax for accessing, manipulating and operating on data in vectors, matrices and higher-dimensional arrays. NumPy is the primary array programming library for the Python language. It has an essential role in research analysis pipelines in fields as diverse as physics, chemistry, astronomy, geosciences, biology, psychology, materials science, engineering, finance and economics. For example, in astronomy, NumPy was an important part of the software stack used in the discovery of gravitational waves1 and in the first imaging of a black hole2. Here we review how a few fundamental array concepts lead to a simple and powerful programming paradigm for organizing, exploring and analyzing scientific data. NumPy is the foundation upon which the scientific Python ecosystem is constructed. It is so pervasive that several projects, targeting audiences with specialized needs, have developed their own NumPy-like interfaces and array objects. Owing to its central position in the ecosystem, NumPy increasingly acts as an interoperability layer between such array computation libraries and, together with its application programming interface (API), provides a flexible framework to support the next decade of scientific and industrial analysis.

A. Mir and S. N. Dhage, 2018. Healthcare domain is a very prominent research field with rapid technological advancement and increasing data day by day. In order to deal with large volume of healthcare data we need Big Data Analytics which is an emerging approach in Healthcare domain. Millions of patients seek treatments around the globe with various procedure. Analyzing the trends in treatment of patients for diagnosis of a particular disease will help in making informed and efficient decisions to improve the overall quality of healthcare. Machine Learning is a very promising approach which helps in early diagnosis of disease and might help the practitioners in decision making for diagnosis. This paper aims at building a classifier model using WEKA tool to predict diabetes disease by employing Naive Bayes, Support Vector Machine, Random Forest and Simple CART algorithm. The research hopes to recommend the best algorithm based on efficient performance result for the prediction of diabetes disease. Experimental results of each algorithm used on the dataset was evaluated. It is observed that Support Vector Machine performed best in prediction of the disease having maximum accuracy.

D. Sisodia and D. S. Sisodia, 2018. Diabetes is considered as one of the deadliest and chronic diseases which causes an increase in blood sugar. Many complications occur if diabetes remains untreated and unidentified. The tedious identifying process results in visiting of a patient to a diagnostic center and consulting doctor. But the rise in machine learning approaches solves this critical problem. The motive of this study is to design a model which can prognosticate the likelihood of diabetes in patients with maximum accuracy. Therefore, three machine learning classification algorithms namely Decision Tree, SVM and Naive Bayes are used in this experiment to detect diabetes at an early stage. Experiments are performed on Pima Indians Diabetes Database (PIDD) which is sourced from UCI machine learning repository. The performances of all the three algorithms are evaluated on various measures like Precision, Accuracy, F-Measure, and Recall. Accuracy is measured over correctly and incorrectly classified instances. Results obtained show Naive Bayes outperforms with the highest accuracy of 76.30% comparatively other algorithms. These results are verified using Receiver Operating Characteristic (ROC) curves in a proper and systematic manner.

P. S. Kohli and S. Arora, 2018. The application of machine learning in the field of medical diagnosis is increasing gradually. This can be contributed primarily to the improvement in the classification and recognition systems used in disease diagnosis which is able to provide data that aids medical experts in early detection of fatal diseases and therefore, increase the survival rate of patients significantly. In this paper, we apply different classification algorithms, each with its own advantage on three separate databases of disease (Heart, Breast cancer, Diabetes) available in UCI repository for disease prediction. The feature selection for each dataset was accomplished by backward modeling using the p-value test. The results of the study strengthen the idea of the application of machine learning in early detection of diseases.
The authors proposed the neural network-baseddiabetes disease prediction on Indians Pima DiabetesDataset. They have used several hidden layers to findpatterns in the data, and with the help of those patterns,they predicted the outcome. They name their proposedalgorithms as ADAP, which is a custom neural networkwith multiple partitions and with the set of associationweights and units. They managed to achieve a crossoverpoint for sensitivity, and specificity at 0.76 and are tryingto precise their result in future.

The authors in [5] used a diverse genera of machinelearning algorithms like support vector machine, randomforest, logistic regression, Decision tree and many moreand various types of disease dataset to show the applicabilityof Machine Learning in disease prediction

andanalysis. They also accompanied the traditional way ofconducting the analysis by using the data pre-processing,feature extraction and selection, classifiers training andtesting for producing the end results. They used featureselection for reducing the computational expenses. Also, toget the most optimal outcome, they divided every datasetinto 90% training set and remaining 10% testing set. Alongwith the accuracy measure, they did the cross-validationfor everyalgorithm and showed different results based ondifferent k values for k-fold cross-validation.

III. METHODOLOGIES

In this paper, we have shown the relation of different symptoms and diseases that cause diabetes so that we can help a person to diagnose diabetes at an early stage. Nowadays, machine learning classification approaches are well accepted by researchers for developing disease risk prediction models. Therefore eleven machine learning classification algorithms such as Logistic Regression (LR), Gaussian Process (GP), Adaptive Boosting (AdaBoost), Decision Tree (DT), K-Nearest Neighbors (KNN), Multilayer Perceptron (MLP), Support Vector Machine (SVM), Bernoulli Naive Bayes (BNB), Bagging Classifier (BC), Random Forest (RF), and Quadratic Discriminant Analysis (QDA) have been used in this study. Among all these machine learning classifiers, Random Forest (RF) classifier has showed the best accuracy of 98%. And its Area Under Curve (AUC) is also the highest.

The main goal of this paper is to find the most optimal results in terms of accuracy and computational time for Diabetes disease prediction. One of the significant impediments with the progression of technology and medicine is the early detection of a disease, which is in this case, diabetes. However, in this study, systematic efforts were made into designing a model which is accurate enough in determining the onset of the disease. With the experiments conducted on the Pima Indians Diabetes Database, we have readily predicted this disease. Moreover, the results achieved proved the adequacy of the system, with an accuracy of 76% using the K-Nearest Neighbours classifiers. With this being said, itis hopeful that we can implement this model into a system to predict other deadly diseases as well. There can be room for further improvement for the automation of the analysis of diabetes or any other disease in the future.

To perform our experiment, we have used a publiclyavailable dataset named as Pima Indians DiabetesDatabase [4]. This dataset includes a various diagnosticmeasure of diabetes disease. The dataset was originallyfrom the National Institute of Diabetes and Digestive andKidney Diseases. All the recorded instances are of thepatients whose age are above 21 years old. Our proposedmodel exists of 5 phases which are shown in the Fig. 2.

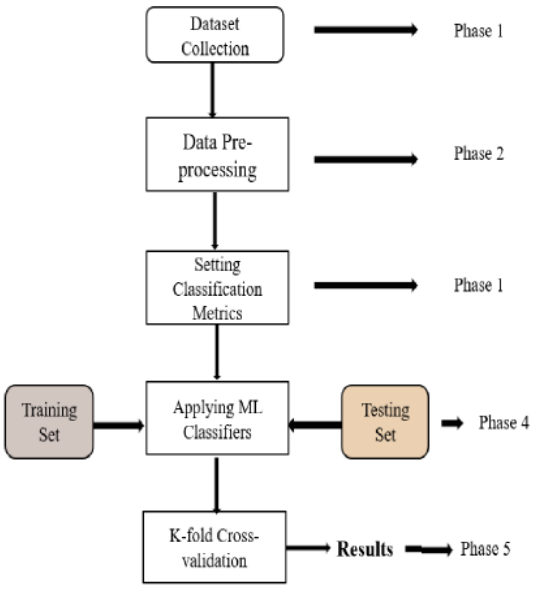

Fig. 2: Different phases of our experiment.

1. Proposed Algorithm

A. Data Collection

The dataset mentioned above [4] has eight features which are defined in Table I.

TABLE I
LIST OF FEATURES PRESENT IN THE DATASET

Features	Description
Pregnancies	Number of Pregnancies patients had earlier.
Glucose	Glucose level present in the patient.
Blood Pressure	Recorded blood pressure level at that particular time.
Skin Thickness	Skin thickness level of the patient.
Insulin	Amount of Insulin present in the body.
BMI	Body Mass Index of the individual.
Diabetes Pedigree Function	Family history of Diabetes disease.
Age	Age of an individual.

Along with the feature, the dataset also has 2 label(0- No and 1- Yes) which is the outcome of the diabetesdisease. The detailed information about each attribute orfeatures is discussed below.

- **Pregnancies**: Those who develop gestational diabetesare at higher risk of developing type 2 diabetes laterin life. The subjects with more number of pregnancieshave a higher risk of developing diabetes.
- **Glucose:** The subjects were given an oral glucosetest, whereby, they were administered glucose anda reading of their plasma glucose concentration wastaken after 2 hours. The subjects with higher levelsof glucose concentration after 2 hours have a higherrisk of developing diabetes.
- **Blood Pressure:** Having blood pressure over 140/90mmHg of Mercury are linked to having increasedrisk of developing diabetes. Although, certain subjectshaving diastolic blood pressure ¿70 mmHg maydevelop diabetes.
- **Skin Thickness:** Skin thickness is primarily determinedby collagen content and is increased in the

caseof insulin dependent diabetic patients. The subjects'tricep skin fold were measured and results showedthat having a skin thickness of 30mm of greater areat a higher risk.

• **Insulin:** Normal insulin levels after 2 hours of glucoseadministration is 16-166 mlU/L. Subjects havinglower or higher levels than said value are at a higherrisk.

• **Body Mass Index (BMI):** Subjects having a BMIover 25 have a relatively high risk in having diabetes.

• **Diabetes Pedigree Function:** The diabetes pedigreefunction provides "a synthesis of the diabetes mellitushistory in relatives and the genetic relationship ofthose relatives to the subject." The higher the DPF,the more likely it is for a subject to be diabetic.

• **Age:** Diabetes is prevalent in any age group, but iscommonly found in middle aged adults (45 onwards).Taking that into consideration, subjects with in thehigher age group have a higher expectancy of diabetes.

B. Data Pre-process

The dataset, which is quoted above, has lapsed and haveshed data. To make the dataset serviceable and obtainthe knowledge from it, we have performed data preprocessing.In order to handle erroneous data, we haveanalyzed the dataset for the unusual entries and fixed themmanually. Missing values are handled with the help ofcalculating the standard deviation of that particular featureand allotting it to the missing spaces. To make the datasetuseful, we have used Pandas [6] and NumPy [7] libraryfor handling the dataset efficiently and easy data handlingthroughout the experiment.

C. Setting Classification Metrics

To classify disease and get a prediction result, we needto set a few metrics which will help us in predicting theDiabetes disease. Since we are using scikit-learn (Sklearn)machine learning library [8] for our experiment, we haveused confusion matrix as the classification measure metrics.All the used metrics, i.e. Precision, Recall, F1-Scoreand Accuracy in our analysis, are listed below.

• **Precision (P)** is defined as the number of true positives(Tp) over the number of true positives plus thenumber of false positives (Fp). Mathematically,

$$P = \frac{T_p}{T_p + F_p} \qquad (1)$$

• **Recall (R)**is defined as the number of true positives(Tp) over the number of true positives plus thenumber of false negatives (Fn).

$$R = \frac{T_p}{T_p + F_n} \qquad (2)$$

• **F1-Score (F1)** is defined as the harmonic mean ofprecision and recall.

$$F1 = 2 * \frac{P * R}{P + R} \qquad (3)$$

• **Accuracy (A)** is defined as follows.

$$A = \frac{T_p + T_n}{T_p + T_n + F_p + F_n} \qquad (4)$$

D. Applying Machine Learning Algorithms

For our experiment, we will perform 5 supervisedmachine algorithms on the pre-processed dataset. Thealgorithms which we used are as follows-

1) K-Nearest Neighbor (KNN) with K=10
2) Naive Bayes (NB)
3) Decision Tree (DT)
4) Random Forest (RF)
5) Support Vector Machine (SVM)

E. K-Fold Cross Validation

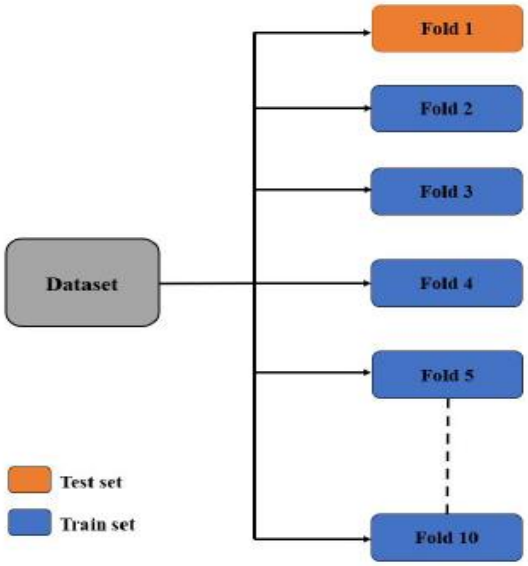

Fig. 3. 10- Fold Cross- Validation

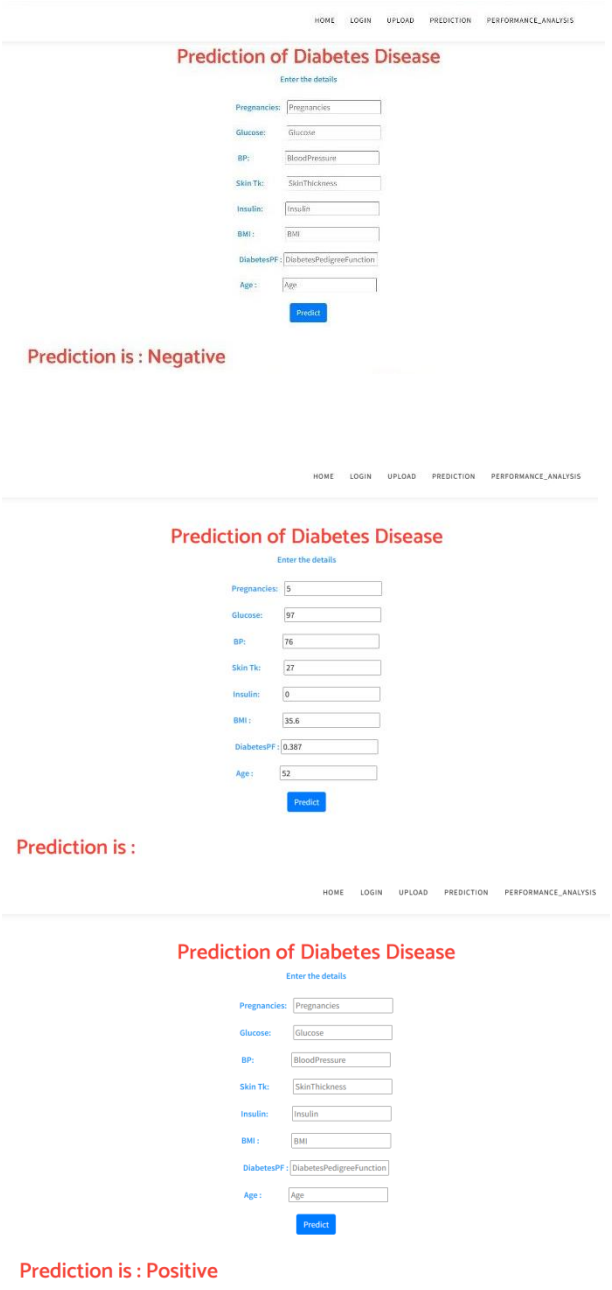
Lastly, we have used another evaluation method, namelyK- Fold cross-validation for precise use of dataset and alsofor calculating most optimal accuracy results [9]. In Kfoldcross-validation the dataset is partitioned into K-differentfolds (in our case K= 10) and then in each cycle oneof the fold (say Fold-1) is examined with the remaining(k-1) folds. This process is going to recur continuously tillall the folds get examined. For a better understanding ofK- Fold Cross-validation, we have pictorial representationof this evaluation metrics in Fig. 3.

IV. RESULT



V. CONCLUSION AND FUTURE ENHANCEMENT

One of the significant impediments with the progressionof technology and medicine is the early detection of disease, which is in this case, diabetes. However, inthis study, systematic efforts were made into designing amodel which is accurate enough in determining the onsetof the disease. With the experiments conducted on thePima Indians Diabetes Database, we have readily predictedthis disease. Moreover, the results achieved proved theadequacy of the system, with an accuracy of 76% using theK-Nearest Neighbours classifiers. With this being said, itis hopeful that we can implement this model into a systemto predict other deadly diseases as well. There can be roomfor further improvement for the automation of the analysisof diabetes or any other disease in the future.

Future Work: In future, we will try to create a diabetes dataset incollaboration with a hospital or a medical institute and willtry to achieve better results. We will be incorporating moreMachine Learning and Deep learning models for achievingbetter results as well.

Abstract—**Due to the widespread use of social media, scammers attempt to deploy malicious social bots that produce fake tweets, attempt to build relationships with other users by pretending to be followers or attempt to create several fake accounts that engage in malicious actions. Additionally, they frequently post malicious URLs that direct real people to malicious web servers. Therefore, it is crucial to distinguish between legitimate accounts and bot accounts. It has been found that profile-based features and URL features, such as redirected URLs, spam data, frequency of URL sharing, etc., are better indicators of bots than social factors. In this study, we propose a novel method that exposes malicious bots on social networks by utilizing profile-based attributes and Deep Learning algorithms. We apply the aforementioned model to the Twitter data set and see that it performs better than other methods. We also made an effort to create a web application that might demonstrate that the aforementioned strategy performs better than other models that are already in use.**

Keywords—Learning automata (LA), malicious social bots, online social networks (OSNs), trust.

I. INTRODUCTION

Social media platforms have a large number of accounts where users can post and share material. Since there are millions of profiles, it is impossible to personally verify that an account is legitimate and not a fraudulent account because of this[1]. As a result, users may unknowingly share their personal information and it may be used for other illegal activities. Over time, many fake accounts have been created, acting like malevolent bots that may harm legitimate users by spamming, posting, and sharing URLs that direct users to malicious servers, etc. Therefore, it is absolutely necessary[3]. To monitor and, if necessary, remove all bot accounts, one must be able to determine whether a Twitter account is one or not. The majority of currently used strategies make use of social activity-related traits, but it has been noted that profile-based features and URL features play a significant part in identifying malicious bots[2]. Therefore, in this research, we develop a novel method that can recognize a bot utilizing features from a profile. We fed the proposed model, which was created using cutting-edge machine learning techniques, the Twitter data set, and saw that it performed better than the existing systems.

II. RESEARCH BACKGROUND

A. Problem Statement

Due to the widespread use of social media, there has been a significant increase in cybercrimes such as phishing, spamming, and other forms of abuse by nefarious social bots that attempt to post malicious content to users and direct them to websites where the user's personal information can be obtained and used inappropriatel[4]y. To prevent cybercrimes from happening, it is imperative that these malicious bots are found. In this project, we suggest a cutting-edge method for locating malicious bots based on the user's profile features[5]

B. Aim Of The Project

The primary goal of the project is to locate harmful bots in Twitter accounts using aspects of the user's profile. We have incorporated the Twitter data set into the proposed model, which was created utilizing cutting-edge machine-learning methodologies.

C. Scope Of The Project

The project's objectives are restricted to calculating the proposed model's accuracy and identifying harmful bots. The system administrator uses test data to test the proposed model and training data to train the model. The "results.csv" file contains the test data's results. The project does not include deactivating bots, monitoring user accounts, or maintaining user accounts. Although malicious bots can be exposed using URL-based features, this method has not been used in this study because the BOT Prediction algorithm has an accuracy of roughly 93% for the given dataset..

D. Technical Approach

The technological strategy to solve the issue is listed below:

1. Dataset identification
2. Exploratory data analysis
3. Dataset preparation and NLP approaches
4. Running the dataset through many algorithms to see which one best fits the situation.
5. Developing a final classifier model and training the final classifier
6. Validating the ultimate classifier and recording the outcomes.

III. SYSTEM ANALYSIS

A. Research Gap

Due to the widespread usage of social media sites like Facebook, Twitter, etc., malicious individuals attempt to utilize bots to create phony accounts, control users' attitudes, and send them to malicious websites by spamming. Because they rely on qualities that search bots employ to build relationships with real consumers, traditional techniques to identify search bots are ineffective. It is impossible to tell manually if the account is a bot or not. Numerous social feature-based

techniques have been developed, but they are not particularly useful.

B. Proposed System

The "BOT PREDICTION ALGORITHM" is a revolutionary technique used by the proposed system to recognize bots utilizing URL data and relationship features. The profile-based elements listed in the table below would assist in spotting malicious social bots and determining whether users were being forwarded to bogus websites where they may enter their personal information. The features listed below have made it possible to recognize bots with great accuracy.

Below are the features that are being used in the project:

Feature Name	Description
Id	Twitter Id of the twitter account
followers_count'	No. of followers for the user
friends_count	No. of friends for the user
verified	Boolean value which describes if a user is verified or not
name	Name of the user in the twitter account
description	Description of the user
screen_name	Displayed screen name on the twitter account
status	Latest status of the user
listed_count	No of users who really want to follow the user.

BOT Prediction algorithm

The Bot Prediction Algorithm's steps are as follows:

1. Download the dataset.
2. Applying feature engineering to the verified and id columns.
3. Changing id to an integer.
4. Changing verified to a vector.
5. Verify whether the screen name or name contains the character "b0t"
6. Verify if the user is authentic
7. See if the description includes BuzzFeed.
8. See if the listed count exceeds 16000

Advantages:

- High precision
- Extendable to real-time settings..

IV. PROJECT IMPLIMENTATION

Proposed Modular Implementation

Below is the proposed modular implementation of the project. It consists the below Admin modules:

Admin Module:

The admin of the system is responsible for the activities like:

1. Uploading the dataset
2. An examination of Twitter user data.
3. Evaluation of several machine learning methods using the Twitter bot dataset.
4. Create a model for detecting malicious bots.
5. Examine how well the algorithms performed on the provided dataset.
6. Using test data, check the model for harmful bot prediction.

A. SYSTEM DESIGN

1. Data Flow Diagram: Admin

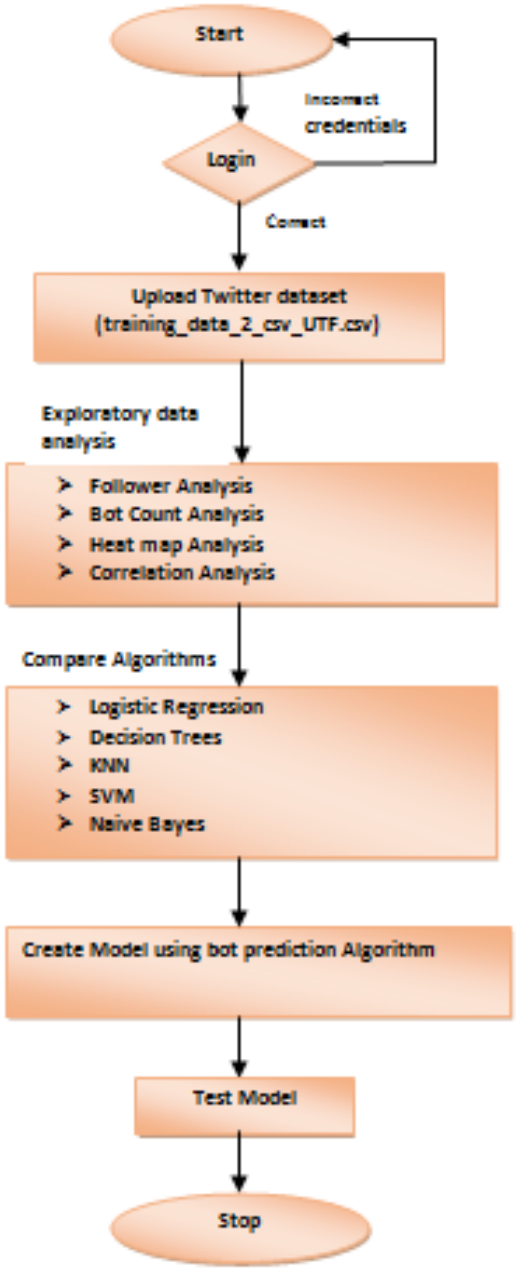

Figure 1: A Data Flow Diagram for Admin

V. IMPLEMENTATION AND RESULT ANALYSIS

A. Project execution process:

1. Upload Dataset

The system administrator can upload datasets that are used to train machine learning models on this page. To upload a file to a server, an administrator must first choose the file by clicking the Choose file button, then click the Upload button. A success message indicating that the file was successfully uploaded would be shown once the upload was finished. We are utilising the datasets test data 4 students and training data 2 csv UTF reviews for this project.

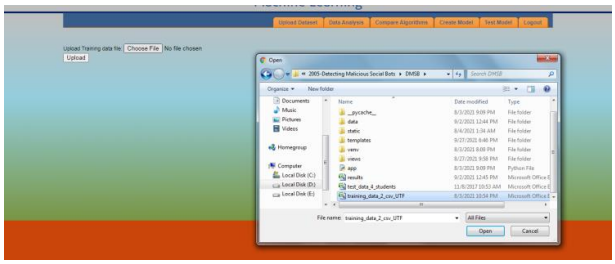

Figure 3: Upload Dataset

2. Data Analysis

Exploratory data analysis is done on the dataset to uncover patterns, find missing data, and establish links between different output characteristics using graphs, statistics, etc.

a) Follower Analysis:

The follower analysis is displayed in the graph below.

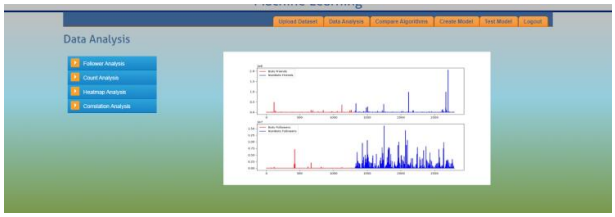

Figure 5: Follower Analysis

b) CountAnalysis:

The below graph shows the Count analysis.

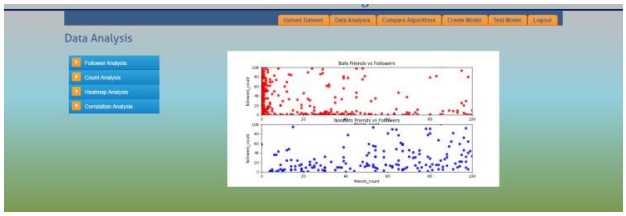

Figure 6: Count Analysis

3. Compare Algorithms

The administrator can use this page to train several algorithms on a dataset and determine each algorithm's test accuracy.

a) Logistic Regression

The test accuracy is 0.86 when the dataset is fed into the logistic regression algorithm, as we see.

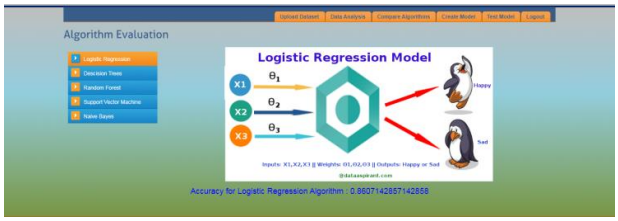

Figure 7: Logistic Regression

b) Decision Trees

The test accuracy is 0.8785714285714286 when the dataset is fed into the decision tree method, as we can see.

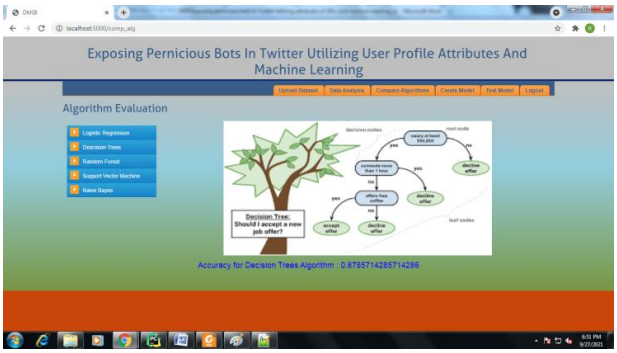

Figure 8: Decision Trees

c) Support Vector Machine

The test accuracy is 0.6178571428571429 when the dataset is fed to the Support Vector Machine method.

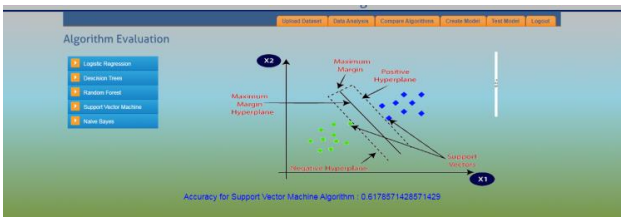

Figure 9: Support Vector Machine Algorithm

4. Create Model

The Create Model button can be used to create the Bot Prediction Model. After pressing the button, a success message is presented and the model is built. BOT Prediction is 96.94% accurate.

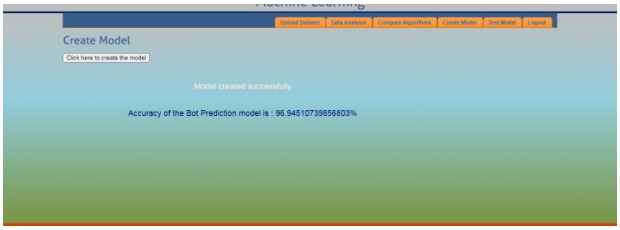

Figure 10: Create Model

5. Test Model:

The model can be tested using the below screen.

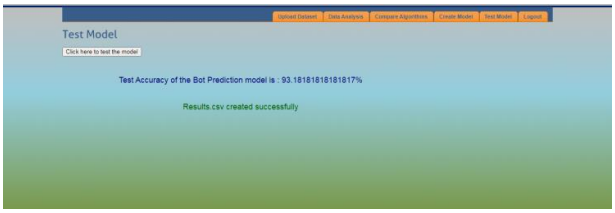

Figure 11: Test model

B. Metrics Evaluation :

Accuracy- One parameter for assessing classification models is accuracy. Informally, accuracy is the percentage of accurate predictions made by our model.

Macro avg - The macro average, also known as the precision, memory, and f1 score, is the arithmetic mean of each individual class. When all classes must be

treated equally, macro average scores are used to assess the classifier's overall performance in comparison to the most popular class labels.

Weighted avg- A calculation that accounts for the varied levels of significance of the numbers in a data set is known as a weighted average.

Metrics for Algorithms in CompAlg.py

Classification report contains the complete metric information of the evaluated algorithm. They are Precision, Recall, F1-Score, Support

Precision – What percent of your predictions were correct?

Precision is the capacity of a classifier to avoid classifying as positive anything that is in fact negative. It is described for each class as the proportion of true positives to the total of true and false positives.
TP – True Positives
FP – False Positives
Precision – Accuracy of positive predictions.
Precision = TP/(TP + FP)

1) Recall – What percent of the positive cases did you catch?

The capacity of a classifier to locate every successful instance is known as recall. It is described as the proportion of true positives to the total of true positives and false negatives for each class.

FN – False Negatives

Recall: Fraction of positives that were correctly identified.

Recall = TP/(TP+FN)

2) F1 score – What percent of positive predictions were correct?

The F1 score is a weighted harmonic mean of recall and precision, with 1.0 representing the best result and 0.0 the lowest. F1 scores typically perform worse than accuracy measures because they incorporate precision and recall into their computation. It is often recommended to compare classifier models using the weighted average of F1, rather than overall accuracy.

F1 Score = 2*(Recall * Precision) / (Recall + Precision)

The amount of real instances of the class in the given dataset is known as support. The requirement for stratified sampling or rebalancing may be indicated by unbalanced support in the training data, which may point to structural flaws in the classifier's reported scores.

VI. CONCLUSION

Conclusion : In this research, we attempt to put into practice a deep learning model that exposes harmful bots on the Twitter network by using profile-based features. One could determine whether or not the account is used to upload content is a bot based on the aforementioned characteristics. In this research, the profile-based features-based Bot Prediction model was built and trained using the Twitter data set. Additionally, we tried to produce test outputs by inputting test data and testing the accuracy of it. The results of the experiments demonstrate that the suggested method provides the maximum accuracy. This methodology, which employs profile-based characteristics to expose malicious bots and URL-based features to identify spammed content, will eventually be expanded to larger datasets and real-time situations

Sophisticated Loan Endorsement System Based On Machine Learning Techniques

Mohammed Riyaz, Mohammed Sirajuddin, Md. Ateeq Ur Rahman
Shadan college of Engineering and Technology, Hyderabad, Telangana, India
mohammedriyaz7555@gmail.com, siraj1978@gmail.com

Abstract— **Humankind's survival and standard of living have been enhanced through technology. The proposal aims to produce new and original content every day. In the banking sector, the candidate receives proofs/backup prior to the loan being approved, therefore technology supports our lives and helps in making them better. The system's use of the individual's or entity's historical data determines whether a loan would be sanctioned or not. Numerous individuals apply for loans in either banks or financial institutions each day, yet the banking sector or financial institution resources are constrained. Using a classes-function algorithm in this situation would be quite advantageous. Several instances include support vector machine (SVM) classification, logistic regression, and random forest classifiers. The quantity of loans a bank makes or loses depends on how much the client or candidate pays back the loan. The most crucial task for commercial banks is loan recovery. The process of improvement is crucial in the banking industry. Utilizing several categorization techniques, a computational model was developed with historical information about the candidates. The major goal of this study is to use models of machine learning trained on historical information to forecast whether a new application will be approved for a loan.**

Keywords—Machine learning, Data, Loan, Training, Testing, Prediction.

I. INTRODUCTION

The proposed system can determine whether a loan will be approved or not using the prediction of a modernized loan approval system that is based on a machine learning technique. Information is collected from the user for this system, such as his monthly salary, family status, moneylending, tenure, etc. The bank will then determine if the client will receive the loan based on its criteria. Therefore, there exists a classification scheme. In this framework, a training set is used to create the model, and the classifier is able to place the data objects into the correct class[2]. In order to train the data and provide the correct outcome, which is the client's potential and ability to repay the loan, a testing dataset is constructed. For banks and customers alike, the prediction of a modernized credit approval system is quite helpful[1]. This method evaluates each candidate based on their priority. The client can register his application form to the bank, in which case the bank will handle the entire procedure without interference from a third party or stockholder[3]. Finally, based on its priority system, the bank will determine if the applicant is deserving or not. This study paper's sole goal is to ensure that the worthy applicant receives straightforward answers right away

II. RESEARCH BACKGROUND

A. Problem Statement

A significant issue is that many individuals are unable to repay bank debts. Additionally, banks are losing money. Every day, banks receive many loan applications, but not all of them are approved. The majority of banks or financial institutions use their own risk estimation & assessment methods and credit scoring systems to determine whether to sanction the loan. In a matter of minutes, the predicament of why there is a loan difficulty will be answered. The primary purpose of acquiring a loan would be to meet a need[4]. A loan is necessary for a businessman if they want to grow their company or if they need to recover from a loss. People in the middle class want to meet their demands so people would like to apply for credit leading. Therefore, the fundamental goal of this is to satisfy someone's or something's wants. Once more, the issue of what issues are developing in credit provision is raised. The response to this inquiry is that not everyone qualifies for loans because if the borrower is unable to repay the loan, either they themselves or the business or bank that provided it would suffer a loss[5]. Therefore, the person granting the loan must first confirm or establish some criteria as to whether the person receiving it is capable of paying back it or not. Like with banks, we do have a Credit lending bank card option, but not everyone qualifies for one. To determine eligibility for just that, a credit history is available. To be eligible for a loan, a person needs to have a decent credit score. A source of earnings and other requirements should be present to obtain a credit card. Banks offer loans, but the borrower must submit documentation and undergo verification. For example, when a company is unable to offer loans, banks suffer losses, and they are referred to as NBFCs.

B. Aim Of The Project

In this project, I aim to come up with an effective and efficient machine-learning model that can predict whether an individual can repay a loan. This system will help banks or financial institutions to make appropriate decisions and help in the process of approving loans faster. As every individual applicant's information would contain multiple patterns, machine learning models are the best way to predict their eligibility and their capacity to repay loan amounts specific to their capacity and tenure. This would be of immense help as banks or other financial institutions can process loans faster and have a better percentage of the recovery.

C. Scope Of The Project

Background verification should be high so that we can expect a return of the loan at the perfect time. So, we

analyze several factors and these are called our input variables.

This proposed model will characterize the behavior of customers based on their records. These records are taken from the customers to create a data set. With the help of these data sets and training machine learning models, we predict whether the customer's loan will be approved or not. This Machine algorithms predict the possibility of whether a customer would be able to repay the loan or not

A. Technical Approach

The technological strategy to solve the issue is listed below:

1. Dataset identification
2. Analysis of Exploratory Data
3. Dataset preparation
4. Running the dataset through many algorithms to see which one best fits the situation.
5. Developing a final classifier model and training the final classifier
6. Validating the ultimate classifier and recording the outcomes.

III. SYSTEM ANALYSIS

A. Research Gap

In the banking industry, the candidate receives proofs/backup prior to acceptance of the loan amount. Folks utilize gadgets to assist our existence and make us more or less complete. The system's historical data about the candidate determines whether or not the application is granted. Numerous people ask for credit lending every day in the banking industry, yet the bank's resources are constrained. The people who truly deposit in a bank would be impacted if the credit lending's not retrieved, which could result in losses for the institutions. The current conventional processes are unable to determine whether or not the sanctioned credit lending may be properly retrieved.

B. Proposed System

The suggested model focuses on forecasting client repayment reliability for loans by examining their behavior. The client behavior that was gathered serves as the model's input. One can decide whether one should accept or decline the customer request based on the classifier's output. Loan prediction and severity can be predicted using various data analytics technologies. In order to anticipate the type of loan, it is essential to train this data using various algorithms before comparing it to user data. to identify commonalities in a dataset of often authorized loans, and then to create a predictive model focusing on these identified patterns. The test data is now sent to the machine learning model, and the model is built using this data set. Each new applicant's application form information serves as just a test data set.

The question of how we evaluate whether or not to grant the loan emerges. We supply the credit to our consumers based on two goal criteria. We must verify all the requirements, including evidence of income, address, and identification. The applicant is then given the loan, whether they are eligible to return it or not. The middle class has a significant need for loans because parents need them for their children's education as well as for their businesses. Some people have abrupt financial crises, while others attempt to defraud banks of their money. As a result, we must double-check everything just because lenders are not experiencing NPA loans. Higher possibilities of loan repayment are associated with better customers. Background checks should be thorough therefore that we can anticipate receiving the loan back at the ideal moment. We analyze data on a variety of bases, and these are referred to as our target variables.

This suggested approach will evaluate consumer behavior based on their past conduct. These client records are collected to form a data set. We make predictions about whether or not the customer's loan will be approved using these data sets and a machine learning model that has been trained. These computer algorithms forecast the likelihood that a consumer will be able to pay back the lending credit or not.

After testing, the model determines whether the new application is a good candidate for loan approval or not based on the inference it draws from the training sets of data to determine if a client would indeed be capable of repaying his loan or not

Advantages Of Proposed System

- High precision
- Extendable to real-time settings.

IV. ALGORITHMIC PROCESS

A. Creating Model

The algorithm used: Decision Tree algorithm

Below is the technical approach used for the Loan recommendation system using the Loan review dataset

1. Data cleaning and visualization
2. Feature Extraction
3. Data Preparation
4. Splitting the data set into test data and training data
5. Data modeling using Sequential and Decision Tree algorithm classifier
6. Data Evaluation and prediction
7. Building the prediction of a modernized loan approval system

1)Feature extraction:

Below are the features present in the dataset:

Feature Name	Type
Loan_ID	String
Gender	String
Married	String
Dependents	Int
Education	String
Self_Employed	String

ApplicantIncome	Int
CoapplicantIncome	Int
LoanAmount	Int
Loan_Amount_Term	Int
Credit_History	Int
Property_Area	String

Feature Extraction Details:

A. Imputing Missing Values

When no information is given for one or more elements, a whole unit, or both, this is known as missing data. Missing data is a major issue in real-world situations. In pandas, missing data can also refer to NA (Not Available) values. Many datasets in DataFrame occasionally arrive with missing data, either because the data was never collected or because it was present but was not captured. We can use the fillna(), replace(), and interpolate() functions to fill in any null values in a dataset by replacing NaN values with one of their own. Each of these functions aids in filling in null values in a data frame's datasets. Interpolate() function is basically used to fill NA values in the data frame but it uses various interpolation techniques to fill the missing values rather than hard-coding the value. Although it uses a variety of interpolation algorithms rather than hard-coding the value, the Interpolate() function is mostly used to fill NA values in data frames.

```
for the column in ['Gender', 'Dependents', 'Married', 'Education'
'Self_Employed', 'Loan_Amount_Term',
                'Credit_History']:
    dataset[column].fillna(dataset[column].mode()[0], inplace=True

dataset['LoanAmount']
dataset['LoanAmount'].fillna(np.nanmedian(dataset['LoanAmount'])
```

B. Label Encoding

In machine learning, we usually deal with datasets that contain multiple labels in one or more than one column. These labels can be in the form of words or numbers. To make the data understandable or in human-readable form, the training data is often labeled in words.

Label Encoding refers to converting the labels into a numeric form so as to convert them into a machine-readable form. Machine learning algorithms can then decide in a better way how those labels must be operated. It is an important pre-processing step for the structured dataset in supervised learning.

```
for column in ['Gender', 'Dependents', 'Married', 'Education',
'Self_Employed', 'Credit_History']:S
    encoder = LabelEncoder()
    dataset[column] = encoder.fit_transform(dataset[column])

encoder = LabelEncoder()
dataset['Loan_Status'] =
encoder.fit_transform(dataset['Loan_Status'])
```

C. One Hot Encoding

Most Machine Learning algorithms cannot work with categorical data and needs to be converted into numerical data. Sometimes in datasets, we encounter columns that contain categorical features (string values) for example parameter Gender will have categorical parameters like Male, Female. These labels have no specific order of preference and also since the data is string labels, machine learning models misinterpreted that there is some sort of hierarchy in them.

One approach to solve this problem can be label encoding where we will assign a numerical value to these labels for example Male and Female mapped to 0 and 1. But this can add bias in our model as it will start giving higher preference to the Female parameter as 1>0 and ideally both labels are equally important in the dataset. To deal with this issue we will use the One Hot Encoding technique.

One Hot Encoding:

In this technique, the categorical parameters will prepare separate columns for both Male and Female labels. So, wherever there is a Male, the value will be 1 in the Male column and 0 in the Female column, and vice-versa.

```
dummy_data = pd.get_dummies(dataset['Property_Area'])
dataset = pd.concat([dataset, dummy_data], axis=1)
dataset.drop(['Property_Area'], axis=1, inplace=True)
dataset.drop(['Loan_ID'], axis=1, inplace=True)

X = dataset.drop(['Loan_Status'], axis=1)
y = dataset['Loan_Status']
```

D. Defining features and Labels

```
X_train, X_test, y_train, y_test = train_test_split(X, y,
test_size=0.2, random_state=300)
```

E. Generating Synthetic Samples

Imbalanced Data Distribution is a phrase used frequently in machine learning and data science and refers to situations where observations in one class are significantly greater or lower than those in the other classes. Machine learning algorithms do not take the class distribution into account since they prefer to improve accuracy by decreasing the error.

SMOTE (Synthetic Minority Oversampling Technique) – Oversampling

One of the most popular oversampling techniques to address the imbalance issue is SMOTE (synthetic minority oversampling technique).

By increasing minority class samples at random and duplicating them, it seeks to balance the distribution of classes.

SMOTE combines already existing minority instances to create new minority instances. For the minority class, it creates virtual training records using linear interpolation. For each example in the minority class, one or more of the k-nearest neighbours are randomly chosen to serve as these synthetic training records. Following the oversampling procedure, the data is rebuilt and can be subjected to several categorization models.

```
sm = SMOTE(random_state=300)
X_train, y_train = sm.fit_resample(X_train, y_t
```

F. Scaling the data

Data Scaling is a data preprocessing step for numerical features. Many machine learning algorithms like Gradient descent methods, KNN algorithm, linear and logistic regression, etc. require data scaling to produce good results.

MinMax Scaler shrinks the data within the given range, usually from 0 to 1. It transforms data by scaling features to a given range. It scales the values to a specific value range without changing the shape of the original distribution.

```
scaler = MinMaxScaler()
X_train = scaler.fit_transform(X_tra
X_test = scaler.transform(X_test)
```

V. PROJECT IMPLIMENTATION

A. *Proposed Modular Implementation*

Below is the proposed modular implementation of the project. It consists of modules:

1. Admin
2. User

1. Admin Module:

The admin of the system is responsible for the activities like:

a) Uploading the dataset
b) The dataset's data analysis
c) Divvying up the dataset into training and test halves
d) Developing the model with several algorithms
e) Examine how well the algorithms performed on the provided dataset.
f) Use the Decision Tree approach to create the model.

2. User Module:

The system's user may take advantage of the following available machine learning services: logging in and entering fresh applicant loan information to forecast future trends

.

B. *SYSTEM DESIGN*

1. Data Flow Diagram: Admin

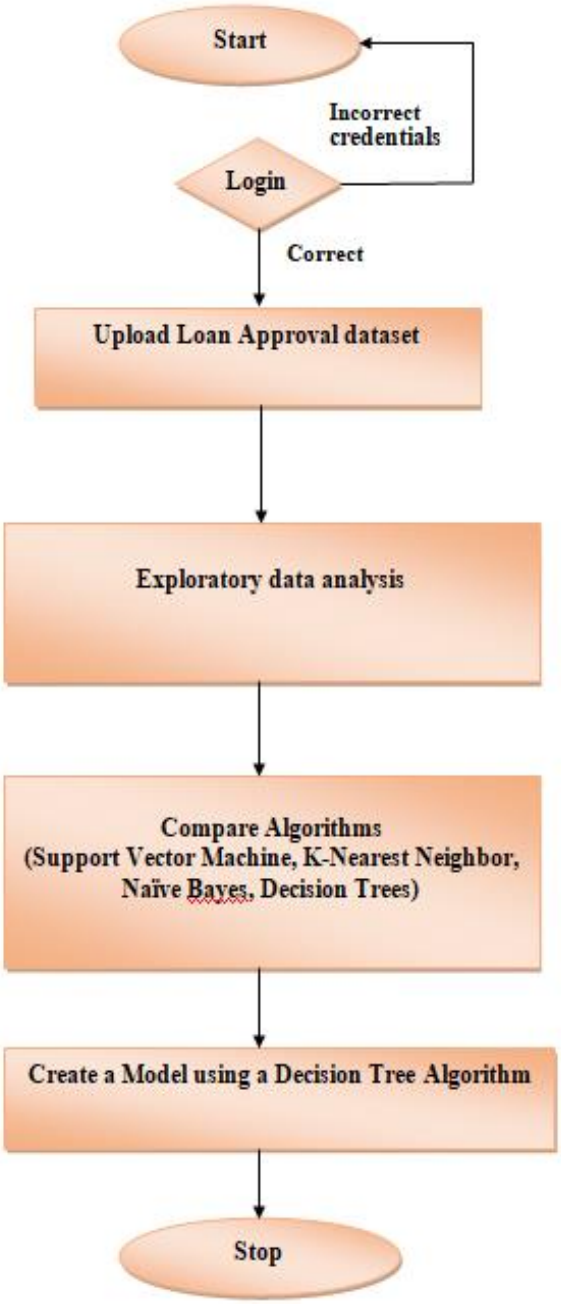

Figure 1: A Data Flow Diagram for Admin

2. Data Flow Diagram: User

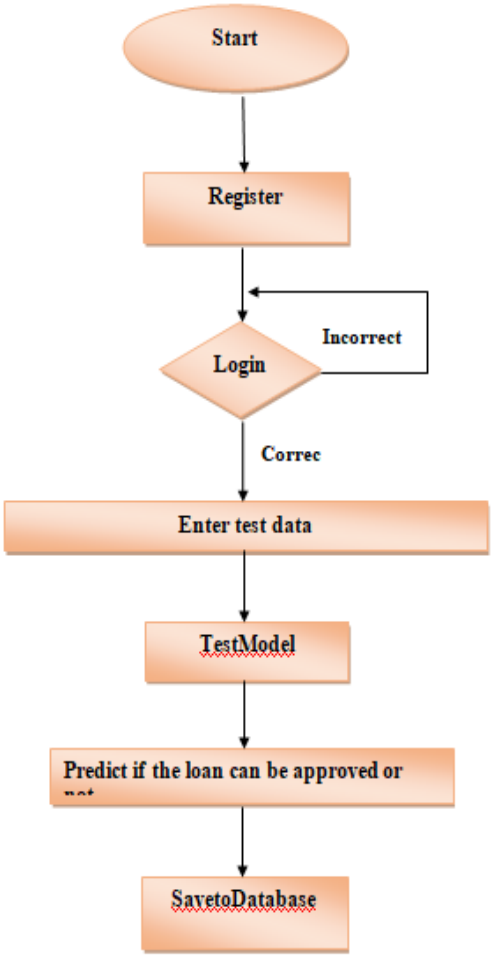

Figure 2: A Data Flow Diagram for Admin

VI. IMPLEMENTATION AND RESULT ANALYSIS

A. Project execution process:

1. Upload Dataset

On this page, the administrator of the system can upload datasets that are used for training the machine learning models. The admin has to select the file by clicking on the Choose file button and clicking on the upload button to upload the file to the server. Once the upload is complete, a success message would be displayed that the file is successfully uploaded. For this project, we are using Loan_Train.csv as a dataset.

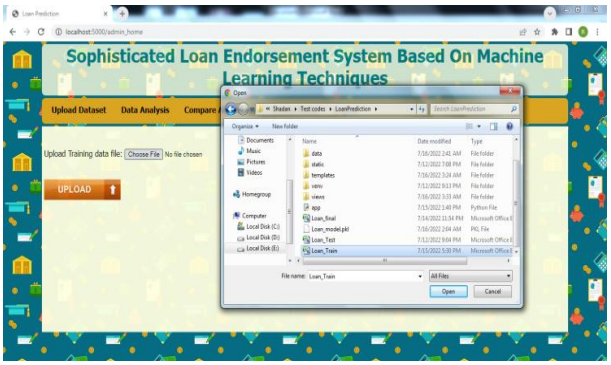

Figure 3: Upload Dataset

Figure 4: File uploaded

2. Data Analysis

Exploratory Data Analysis is performed on the dataset in order to clean the dataset for any missing data, identify patterns, and identify the relationships of various parameters of the outputs with the help of graphs, statistics, etc. so that Data Analysis can be performed.

a) Education Analysis:

The below graph shows the Education Analysis of an individual from the Training dataset Loan_Train.csv File.

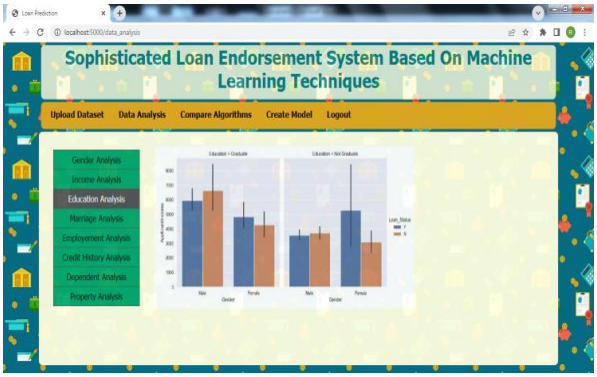

Figure 5: Education Analysis

3. Compare Algorithms

On this page, the admin can feed the dataset to various Algorithms to train them and get the test accuracy for each algorithm.

a) K-Nearest Neighbour:

When the dataset is fed to K-Nearest Neighbour algorithm we observe that the test accuracy is 85.36%

Figure 7: KNN

b) Decision Trees

The test accuracy is 86.99% when the dataset is fed to the decision tree method.

Figure 8: Comment Analysis

a) Support Vector Machine

The test accuracy is 86.99% when the dataset is fed into the support vector machine method, as we can see..

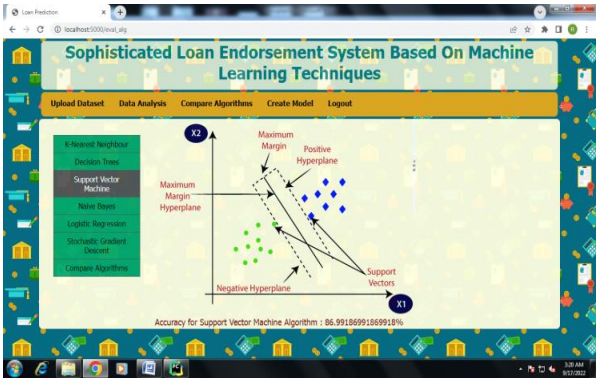

Figure 9: Support Vector Machine Algorithm

4. Create Model

The Generate Model button can be used to create the Model. After pressing the button, a success message is presented and the model is built. Our model's precision is 86.99%.

Figure 10: Create Model

5. Test Model:

This is in User Home Page for the user module. The user need to login into the system with his credentials in order to facilitate prediction over a of new applicant Loan data over dataset.

Figure 11: Test model

B. Metrics Evaluation :

Accuracy- One parameter for assessing classification models is accuracy. Informally, accuracy is the percentage of accurate predictions made by our model.

Macro avg - The macro average, also known as the precision, memory, and f1 score, is the arithmetic mean of each individual class. When all classes must be treated equally, macro average scores are used to assess the classifier's overall performance in comparison to the most popular class labels.

Weighted avg- A calculation that accounts for the varied levels of significance of the numbers in a data set is known as a weighted average.

Metrics for Algorithms in CompAlg.py

Classification report contains the complete metric information of the evaluated algorithm. They are Precision, Recall, F1-Score, Support

Precision – What percent of your predictions were correct?

Precision is the capacity of a classifier to avoid classifying as positive anything that is in fact negative. It is described for each class as the proportion of true positives to the total of true and false positives.

TP – True Positives
FP – False Positives

Precision – Accuracy of positive predictions.
Precision = TP/(TP + FP)

1) **Recall – What percent of the positive cases did you catch?**

The capacity of a classifier to locate every successful instance is known as recall. It is described as the proportion of true positives to the total of true positives and false negatives for each class.

FN – False Negatives

Recall: Fraction of positives that were correctly identified.

Recall = TP/(TP+FN)

2) **F1 score – What percent of positive predictions were correct?**

The F1 score is a weighted harmonic mean of recall and precision, with 1.0 representing the best result and 0.0 the lowest. F1 scores typically perform worse than accuracy measures because they incorporate precision and recall into their computation. It is often recommended to compare classifier models using the weighted average of F1, rather than overall accuracy.

F1 Score = 2*(Recall * Precision) / (Recall + Precision)

The amount of real instances of the class in the given dataset is known as support. The requirement for stratified sampling or rebalancing may be indicated by unbalanced support in the training data, which may point to structural flaws in the classifier's reported scores.

1) Metrics using Decision Tree Algorithm:
Decision Trees accuracy: 0.8699186991869918

Decision Trees Classification Report:

	precision	recall	f1-score	support
0	0.90	0.56	0.69	32
1	0.86	0.98	0.92	91
accuracy			0.87	123
macro avg	0.88	0.77	0.80	123
weighted avg	0.87	0.87	0.86	123

2) Metrics using K-Nearest Neighbour Algorithm:
KNN accuracy: 0.8536585365853658

KNN Classification Report:

	precision	recall	f1-score	support
0	0.89	0.50	0.64	32
1	0.85	0.98	0.91	91
accuracy			0.85	123
macro avg	0.87	0.74	0.77	123
weighted avg	0.86	0.85	0.84	123

3) Metrics using Logistic Regression Algorithm:
Logistic Regression accuracy: 0.8536585365853658

Logistic Regression Classification Report:

	precision	recall	f1-score	support
0	0.85	0.53	0.65	32
1	0.85	0.97	0.91	91
accuracy			0.85	123
macro avg	0.85	0.75	0.78	123
weighted avg	0.85	0.85	0.84	123

4) Metrics using Support Vector Machine Algorithm:
SVM accuracy: 0.8699186991869918

SVM Classification Report:

	precision	recall	f1-score	support
0	0.94	0.53	0.68	32
1	0.86	0.99	0.92	91
accuracy			0.87	123
macro avg	0.90	0.76	0.80	123
weighted avg	0.88	0.87	0.86	123

VII. CONCLUSION AND FUTURE SCOPE

B. Conclusion : This project can determine whether the customer is likely to return the loan, as well as the accuracy is decent. Age, income, loan length, and loan amount are the most crucial variables when determining (whether the applicant would have been). Zip code and credit history are the two most crucial variables in determining the loan applicant's category. The standard of living for humans has improved thanks to technology. We intend to provide something fresh and unique every day. In the banking industry, the candidate receives proofs/backup prior to acceptance of the loan amount. Humans need gadgets to support our life and to make us somewhat complete.The system's historical data about the candidate determines whether or not the application is granted. Numerous people ask for loans every day in the banking industry, yet the bank's resources are constrained. A classes-function algorithm would be very helpful in this situation if the proper prediction could be made. Examples include support vector machine, logistic regression, and random forest classifiers. The quantity of loans a bank makes or loses depends upon whether the customer or the client pays back the loan. The most crucial task for the financial system is loan recovery. The process of improvement is crucial in the banking industry.Utilizing several categorization techniques, a computational model was constructed using the available information of the candidates. The major goal of this study is to use machine learning algorithms trained on historical information to determine whether a new application will be approved for a loan or not.

Detecting Self Destructive Intentions From Twitter Posts Using NLP Techniques

Mohd Siddiq Ali, Sridhar Gummalla, Mohammed Sirajuddin
Shadan college of Engineering and Technology, Hyderabad, Telangana, India
siddiqali626@gmail.com, sridhar_gummalla@yahoo.com, siraj1978@gmail.com

Abstract— **Everyone is busy with their work, schedules, and hobbies in the quickly changing world. Relationships are no longer a priority. As a result, a lot of people are expressing their emotions on social media and yearning for emotional support. Self-destruction could be avoided if the tweets or posts could be examined and prompt assistance provided. Self-harm is a troubling general medical problem that kills more people every year all around the world. Through this investigation, inactive subjects were naturally removed from Twitter and online social networks that promoted self-destructive thoughts. Customers have welcomed these platforms as long-distance interpersonal connection sites have become more common, using them to discuss extremely intimate topics like their concerns about self-destruction. The tweets are important for research since calculations that process them must do so under extremely strict capacity and time constraints because information appears in them with a high frequency. In this project, we leverage Twitter's API to gather a variety of tweets for use as a dataset and train our machine-learning model to recognize tweets that have self-destructive intent. Once the dataset has been downloaded, it is analyzed using n-gram analysis before being fed into a variety of machine learning algorithms, including Logistic Regression, Support Vector Machine, Naive Bayes, Decision Trees, and Random Forest classifier, in order to assess the accuracy of each algorithm. To construct the ideal model for this issue, the top-performing algorithm is chosen and further optimized. After pre-processing with NLP methods, we see that the Random Forest algorithm performs well, with an accuracy of 93.3%. We also host a web program that analyses tweets to determine whether they contain suicidal intent.**

Keywords—Suicide, social media (SM), social networks (SNs), machine learning techniques, reviews, twitter posts.

I. INTRODUCTION

Suicide, which is the act of intentionally bringing about one's own death, is the tenth leading cause of death in the United States and is estimated to cost $44.6 billion annually[2]. This downplays how serious the problem is with each attempted suicide. Self-destructive ideation encompasses a wide range of thoughts, from passing thoughts to extensive planning or unsuccessful actions. Taking care of this emotional wellness issue is necessary for overall well-being due to its severity and effects[1]. Many people frequently refer to common manifestations when discussing their ideas: feeling helpless, feeling lonely, being too exhausted, being insecure, having the impression that one's brain is working overtime, or placing an excessive amount of focus on ineffective goals Understanding the common themes in self-destructive ideation will help us better comprehend the reasons behind such thoughts, which can eventually lead to treatment and remedial action[3]. Several danger factors have been identified in clinical studies aimed at understanding suicide. Mental illnesses including melancholy, schizophrenia, alcoholism and drug abuse all anticipate a contributing factor[6]. Additionally, the emotional stress[5] brought on by suffering, interpersonal ties, and other factors is also important. In any event, a therapeutic viewpoint is frequently captured in these representations of self-destructive ideation. People considering suicide have increasingly expressed their suicidal thoughts through online chats, tweets, and other social media due to the intricacy and recognition of online informal organizations[4]. The result is a fantastic synergistic portrayal of suicide-related thoughts and motivations.

The approaches to extract casual inert themes from this information are currently being demonstrated in this article. This model is an AI method for extracting information from a variety of data[9]. Using this research, one can find common themes like discouragement, drug use, or brutality that are evident in internet posts. Several words that are closely connected to "sadness," such as "torment," "emotions," "dread," "stress," and "languishing," may also be used to describe it[7]. The model used in this study is based on both online and offline tweets that were connected to suicidal ideation and were gathered using the tweeter API

II. RESEARCH BACKGROUND

A. Problem Statement

Suicide, which is the act of intentionally bringing about one's own death, is the tenth leading cause of death in the United States and is estimated to cost $44.6 billion annually[8].

This downplays how serious the problem is with each attempted suicide. Self-destructive ideation encompasses a wide range of thoughts, from passing thoughts to extensive planning or unsuccessful actions. Taking care of this emotional wellness issue is necessary for overall well-being due to its severity and effects. Many people frequently mention common manifestations when discussing their ideas, such as feeling helpless or alone, being too exhausted, having low self-esteem, having the impression that their brain is working overtime, or placing an excessive amount of focus on pointless goals[10]. Understanding the common themes in self-destructive ideation might help us better comprehend the motivations underlying such thoughts, leading to eventual treatment and retaliation.

B. Aim Of The Project

The primary goal of the research is to use Twitter data to predict suicide intentions from tweets. We made advantage of the open-source Twitter Suicide dataset from Kaggle. This corpus, which was created using sophisticated machine learning algorithms, is made up of tweets containing both suicidal and non-suicidal intentions.

C. Scope Of The Project

The project's scope is restricted to calculating the proposed model's accuracy and determining whether or not the tweet's goal is suicidal. The system administrator uses training data to develop the suggested model. To determine whether or not a tweet's aim is suicidal, test data can be provided to the algorithm. The project's scope does not include user account maintenance.

a. Technical Approach

The technological strategy to solve the issue is listed below:

1. Dataset identification
2. Analysis of Exploratory Data
3. Dataset preparation and NLP approaches
4. Running the dataset through many algorithms to see which one best fits the situation.
5. Developing a final classifier model and training the final classifier
6. Validating the ultimate classifier and recording the outcomes.

III. System Analysis

A. Research Gap

Existing methods for identifying self-destructive tweets on Twitter posts used machine learning techniques like SVM and decision trees, however they are insufficient. Many of the current systems do not make use of natural language processing.

B. Proposed System

In the suggested approach, we classify self-destructive ideation from tweets using a cutting-edge algorithm. the following process is described:

1. Preparing and processing data:
    a. the project's use of the Twitter Suicide Dataset after downloading it
    b. removal of tweets written in tongues other than English.
    c. Making all of the tweets in the collection lower case.
    d. Eliminate all strings that represent connections or hyperlinks introduced in the tweets; this includes URLs.
    e. Changing any username that is introduced in the tweets to @username, removing the username, and taking into account that these are not taken into account for estimates.
    f. Transforming the hash labels into common terms because hash marks might sometimes provide some helpful information, it's vital to replace them with the identical word without the hash. For instance, Happy instead of #Happy.
    g. Eliminating any unnecessary characters, extra spaces, etc
2. N-gram analysis
    a. Positive and negative bigrams and trigrams are utilised to assess the frequently used terms in both suicidal and non-suicidal circumstances.Comparison of algorithms:
    b. A variety of machine learning techniques, including SVM, Logistic Regression, Naive Bayes, decision trees, and random forest algorithm, among others, are applied to the dataset, and their accuracy results are compared.
3. Creation of model:

    The pre-processed data is taken and below NLP techniques are applied:
    a. Bag of words
    b. Added TFIDF feature
    c. Removed stop words
    d. Added n-grams

Advantages Of Proposed System

- High precision
- Extendable to real-time settings.

IV. Algorithmic Process

A. Creating Model

This project assists in identifying users' self-destructive intentions from their tweets and their emotional health through their posts. Early intervention can prevent suicides and save lives. Therefore, in this study, we eliminated inactive, sporadic participants from tweeters propagating self-destructive ideas. We evaluated the dormant subjects in an abstract manner first, and then we compared them to chance components.

The urgency of the posts is also predicted using the proposed models.

1. Dataset division
2. Text cleaning and preparation
3. Utilizing Tfidf to vectorize
4. Classification with Random Forest
5. Hyper parameter tweaking
6. Evaluation of the Test and Validation Set
7. The most important characteristics for prediction.

92.5% accuracy is what the results show for the Random Forest Classifier with TFIDF and N-gram Feature.

1)Feature extraction:

Below are the features present in the dataset:

Feature Name	Type
ID	String
Content	String
Sentiment	String

2)Loading the datase:

Datasets for training the machine learning models can be uploaded by the system administrator. To upload a file to a server, an administrator must first choose the file by clicking the Choose file button, then click the Upload button.

A success message indicating that the file was successfully uploaded would be shown once the upload was finished. We are utilising the dataset twitter-suicide-data.csv for this study..

```
data = pd.read_csv('Twitter_Suicide_Data_new.csv')

# we will use 80% of data as training, 20% as validation data
training_samples = int(303 * .8)
validation_samples = int(303 - training_samples)
# sanity1 check
print(len(texts) == (training_samples + validation_samples))
print("The number of training {0}, validation {1} ".format(training_samples
validation_samples))
```

3)Bag of words

Transform texts into a bag-of-words matrix (number of rows = total set, number of columns = number of unique words). Check out Bag-of-words model in computer vision for more information. The bag-of-words model is a condensing representation used in information retrieval and natural language processing (IR). This paradigm ignores syntax and even word order while maintaining multiplicity and represents a text (such as a sentence or document) as the bag (multiset) of its words. Computer vision has also made use of the bag-of-words approach. The bag-of-words model is frequently employed in document classification techniques in which the (frequency of) occurrence of each word is used as a feature for instructing a classifier.

```
# transform document into a matrix(the number
indicates the number of words showing up in the
document)
bag_of_words = vect.transform(toy_samples)
print("Transformed sparse matrix is: ")
print(bag_of_words.toarray())
```

4)GridSearchCV

```
grid = GridSearchCV(logreg, param_grid, cv=5)
logreg_train = grid.fit(X_train, y_train)
#remove stopwords
from sklearn.feature_extraction.text import ENGLISH_STOP_WORDS
print("Number of stop words is :", len(ENGLISH_STOP_WORDS), "\n")
print("Examples: ", list(ENGLISH_STOP_WORDS)[::10])
# logreg = LogisticRegression(C=0.1).fit(X_train, y_train)
pred_logreg = logreg_train.predict(texts_test)
print("accuracy is: ", grid.score(texts_test, y_test))
confusion = confusion_matrix(y_test, pred_logreg)
print("confusion matrix \n", confusion)
```

5)TFIDF vectorizer

Unlike a bag of words, tfidf assigns higher weights to terms that are used less frequently in a manuscript. In other words, it recognises such terms as being crucial when they appear in a particular paper (since these are the s features of the specific documents)

Here is a brief introduction to the TF-IDF vectorizer. The majority of machine learning algorithms rely on mathematical concepts from areas like statistics, algebra, calculus, and other areas. They anticipate the information to be numerical, perhaps in the form of a two-dimensional array with rows serving as instances and columns as features. Natural language presents a challenge because the data is in the form of raw text, which necessitates its transformation into a vector. Text vectorization is the term used to describe the process of turning text into a vector. It's a key step in natural language processing because no machine learning method, not even computers, can comprehend a text. Text can be converted into vectors with the aid of the text vectorization technique TF-IDF vectorizer, which is a well-liked method for conventional machine learning methods.

Text is converted into a vector form using the text vectorizer term frequency-inverse document frequency. Term Frequency (TF) and Document Frequency are two ideas that are combined (DF). The term frequency is the quantity of times a particular phrase appears in a document. The frequency of a term in a document reveals its importance.

Each text from the data is represented by term frequency as a matrix, where the rows correspond to the number of documents and the columns to the number of unique terms used in each document.

The quantity of documents that use a particular term is known as the document frequency. The frequency of documents reveals the term's usage frequency. The weight of a term is determined by its inverse document frequency (IDF), which attempts to lessen the weight of a term if its occurrences are dispersed over all the documents.

```
# Check which words are considered to be low tfidf (widely used words across many tweet
and high tfidf (used only in a few tweets)
vectorizer = grid.best_estimator_.named_steps["tfidfvectorizer"]
X_train = vectorizer.transform(texts_train)
max_value = X_train.max(axis=0).toarray().ravel()
sorted_by_tfidf = max_value.argsort()

feature_names = np.array(vectorizer.get_feature_names())

print("features with lowest tfidf")
print(feature_names[sorted_by_tfidf[:20]], "\n")

print("featues with hightest tfidf")
print(feature_names[sorted_by_tfidf[-20:]])
```

Text must be represented as a numerical feature in order to be processed as natural language. Text vectorization is the process of converting text into a numerical feature. One of the most widely used text vectorizers is TF-IDF; the computation is relatively straightforward and simple to comprehend. Both the usual word low weight and the uncommon term large weight are given.

6)Ngrams

Single words are frequently inaccurate predictors. Like and dislike, for instance, are the polar opposites. Only word counts matter in the Bag-of-words model, which represents documents with less order.

For instance, in the earlier illustration "John enjoys watching movies. Mary enjoys watching movies as well, but the depiction in a bag of words hides the fact that the verb "likes "always appears in this text after a person's name. The n-gram model can instead store this geographical information.

```
feature_names =
np.array(grid.best_estimator_.named_steps['tfidfvectorizer'].get_feature_names
coef = grid.best_estimator_.named_steps['logisticregression'].coef_
mglearn.tools.visualize_coefficients(coef,feature_names, n_top_features=40)
plt.title("tfidf-cofficient")
```

7)Hyper parameter tuning with gridsearchCV

In virtually every machine learning project, we train various models on the dataset and choose the one that performs the best. We cannot be certain that this specific model is the best one for the issue at hand, so there is potential for improvement. Therefore, our goal is to make the model better in whatever manner we can. These models' hyperparameters play a crucial role in how well they function; once the right values are chosen for these hyperparameters, a model's performance can advance considerably. In this post, we'll learn how to use GridSearchCV to identify a model's hyperparameters' ideal values.

```
logreg = LogisticRegression()
  pipe = make_pipeline(TfidfVectorizer(min_df=3, norm=None, stop_words='english'),
logreg)
  param_grid = {'logisticregression__C': [0.001, 0.01, 0.1, 1, 10]}
  grid = GridSearchCV(pipe, param_grid, cv=5)
  logreg_train = grid.fit(texts_train, y_train)
```

8)Pseudo Code Of Proposed System Model

1) Load the dataset first.
2) Divide the data into training and validation portions, respectively.
3) Use the bag of words technique to convert texts into bag of words matrices (number of rows = total set, number of columns = number of unique terms).
4) Use the TFIDF method. Unlike a bag of words, tfidf assigns higher weights to terms that are used less frequently in a manuscript. In other words, it recognises such terms as being crucial when they appear in a particular paper (since these are the s features of the specific documents)
5) Use Pipeline to generate the final model by feeding the Logistic Regression into GridSearchCV for hyperparameter tuning.

V. PROJECT IMPLIMENTATION

A. Proposed Modular Implementation

Below is the proposed modular implementation of the project. It consists of modules:

1. Admin
2. User

1. Admin Module:

The admin of the system is responsible for the activities like:

a. Submitting the data
b. N-gram analysis of a dataset of suicidal tweets
c. Evaluation of several machine learning techniques using the Tweets Dataset.
d. Examine how well the algorithms performed on the provided dataset.
e. Create a model to predict suicidal intent.
f. Using test data, test the model's ability to identify tweeting intentions.

2. User Module:

By inputting the tweet, the user can log in and test the model. The model receives the tweet as input and must determine whether the message's goal is suicidal or normal.

B. SYSTEM DESIGN

1. Data Flow Diagram: Admin

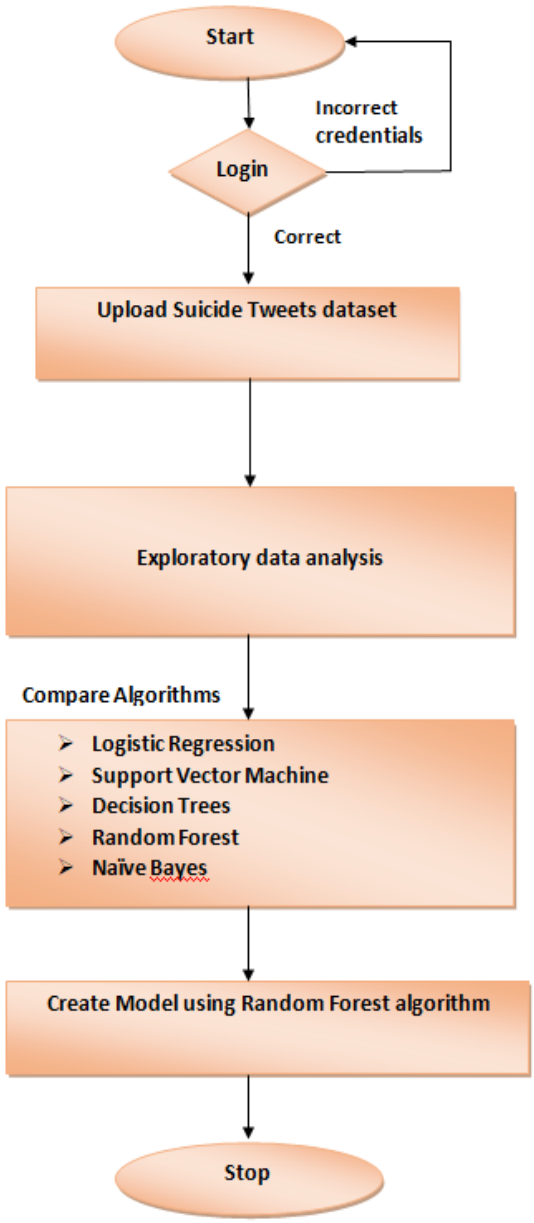

Figure 1: A Data Flow Diagram for Admin

2. Data Flow Diagram: User

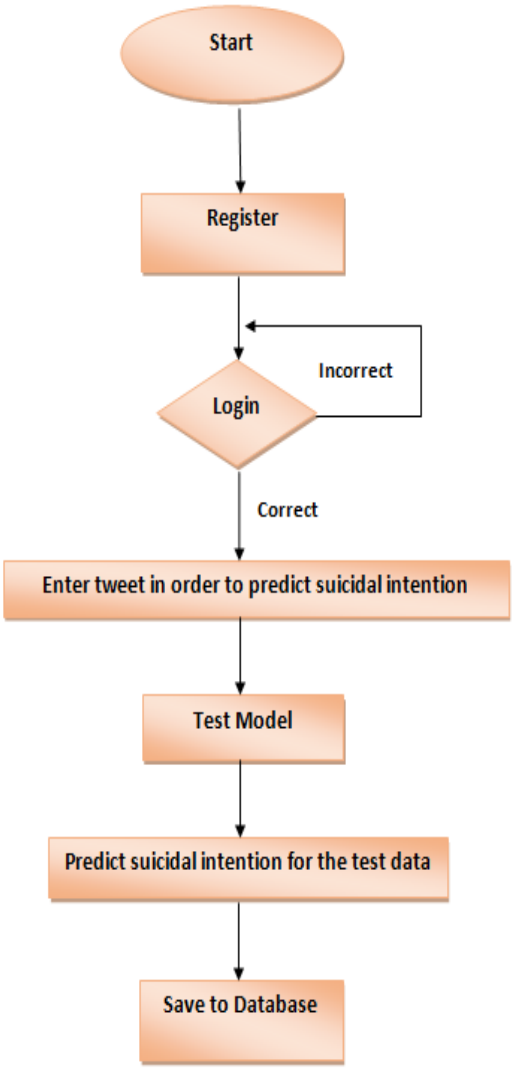

Figure 2: A Data Flow Diagram for Admin

VI. IMPLEMENTATION AND RESULT ANALYSIS

A. Project execution process:

1. Upload Dataset

The system administrator can upload datasets that are used to train machine learning models on this page. To upload a file to a server, an administrator must first choose the file by clicking the Choose file button, then click the Upload button. A success message indicating that the file was successfully uploaded would be shown once the upload was finished. We are utilising the dataset twitter-suicide-data.csv for this study.

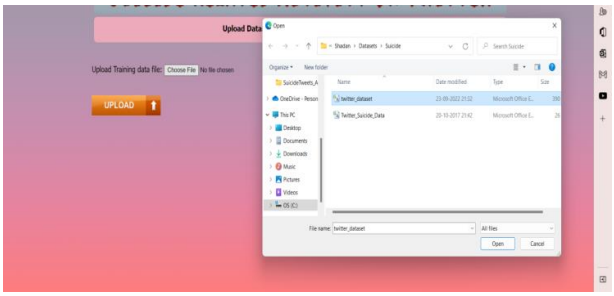

Figure 3: Upload Dataset

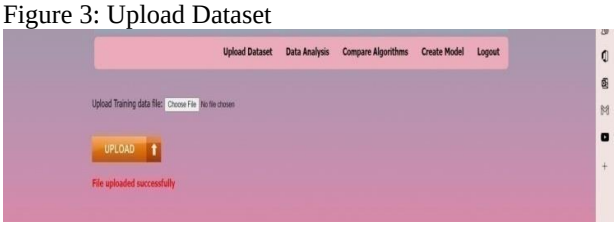

Figure 4: File uploaded

2. Data Analysis

Exploratory data analysis is used to examine the dataset for any missing data, spot trends, and establish connections between different output characteristics using graphs, statistics, and other visual aids.

a) Cause Analysis:

The below graph shows the distribution of causes of suicide for each gender.

Figure 5: Cause Analysis

3. Compare Algorithms

The administrator can use this page to train several algorithms on a dataset and determine each algorithm's test accuracy.

a) Logistic Regression

We see that the test accuracy is 79% when the dataset is fed to the logistic regression algorithm.

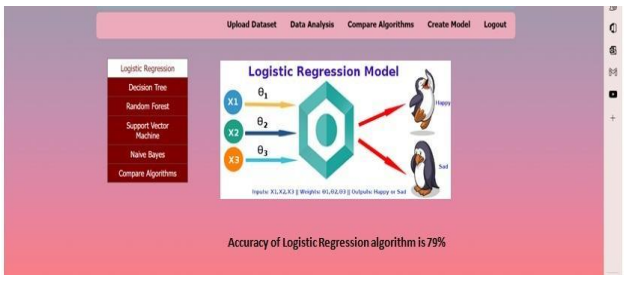

Figure 7: Logistic Regression

b) Decision Trees

The test accuracy is 70.5% when the dataset is fed to the decision tree method.

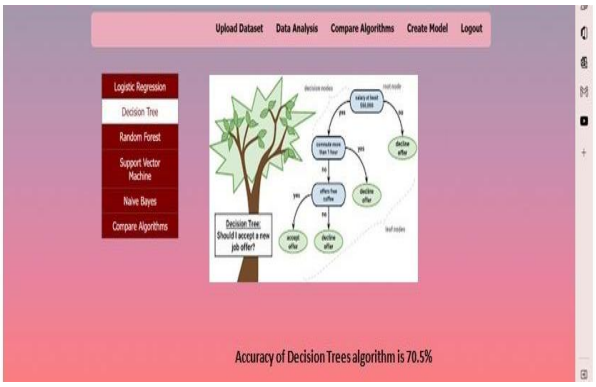

Figure 8: Comment Analysis

c) Support Vector Machine

The test accuracy is 87.5% when the dataset is fed into the support vector machine method, as we can see..

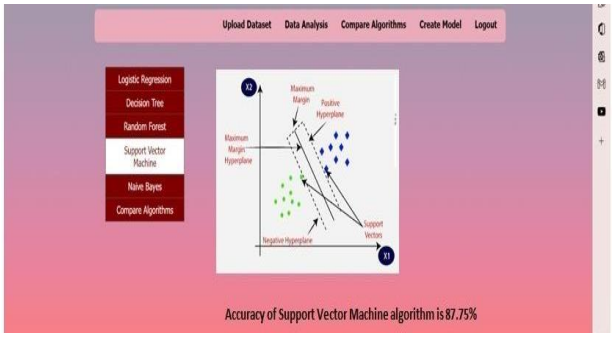

Figure 9: Support Vector Machine Algorithm

4. Create Model

The Generate Model button can be used to create the Model. After pressing the button, a success message is presented and the model is built. Our model's precision is 89.75%.

Figure 10: Create Model

5. Test Model:

The model can be tested using the below screen.

Figure 11: Test model

B. Metrics Evaluation :

Accuracy- One parameter for assessing classification models is accuracy. Informally, accuracy is the percentage of accurate predictions made by our model.

Macro avg - The macro average, also known as the precision, memory, and f1 score, is the arithmetic mean of each individual class. When all classes must be treated equally, macro average scores are used to assess the classifier's overall performance in comparison to the most popular class labels.

Weighted avg- A calculation that accounts for the varied levels of significance of the numbers in a data set is known as a weighted average.

Metrics for Algorithms in CompAlg.py

Classification report contains the complete metric information of the evaluated algorithm. They are Precision, Recall, F1-Score, Support

Precision – What percent of your predictions were correct?

Precision is the capacity of a classifier to avoid classifying as positive anything that is in fact negative. It is described for each class as the proportion of true positives to the total of true and false positives.
TP – True Positives
FP – False Positives

Precision – Accuracy of positive predictions.
Precision = TP/(TP + FP)

1) **Recall – What percent of the positive cases did you catch?**

The capacity of a classifier to locate every successful instance is known as recall. It is described as the proportion of true positives to the total of true positives and false negatives for each class.

FN – False Negatives

Recall: Fraction of positives that were correctly identified.

Recall = TP/(TP+FN)

2) **F1 score – What percent of positive predictions were correct?**

The F1 score is a weighted harmonic mean of recall and precision, with 1.0 representing the best result and 0.0 the lowest. F1 scores typically perform worse than accuracy measures because they incorporate precision and recall into their computation. It is often recommended to compare classifier models using the weighted average of F1, rather than overall accuracy.

F1 Score = 2*(Recall * Precision) / (Recall + Precision)

The amount of real instances of the class in the given dataset is known as support. The requirement for stratified sampling or rebalancing may be indicated by unbalanced support in the training data, which may point to structural flaws in the classifier's reported scores.

1) Metrics using Decision Tree Algorithm:

Decision Trees accuracy is: 0.8688524590163934

Decision Trees Classification Report:

	precision	recall	f1-score	support
0	0.81	1.00	0.89	34
1	1.00	0.70	0.83	27
accuracy				0.87 61
macro avg	0.90	0.85	0.86	61
weighted avg	0.89	0.87	0.86	61

2) Metrics using K-Nearest Neighbour Algorithm:

KNN accuracy is: 0.7049180327868853

K-Nearest Neighbour Classification Report:

VII. CONCLUSION AND FUTURE SCOPE

b. *Conclusion :* This project assists in identifying users' self-destructive intentions from their tweets and their emotional health through their posts. Early intervention can prevent suicides and save lives. In this work, inactive, non-essential subjects who were tweeting potentially damaging thoughts were deleted. We evaluated the dormant subjects in an abstract manner first, and then we compared them to chance components. The findings show that the Random Forest Classifier with TFIDF and N-gram Feature provides accuracy of 93.33%. The urgency of the posts is also predicted using the proposed models.

c. *Future Scope :* In the future, we will expand our research to include other mental wellness difficulties, such as post-horrific pressure problems and dejection. The suicide prediction system employs various machine learning algorithms to foretell posts expressing suicidal thoughts on social media and avoid such occurrences. Our model's results are quite accurate because we are applying many machine learning techniques. As a part of this work, we describe our approach for leveraging the social network Twitter as a preventive tool in the struggle against suicide, which may be based on various machine learning techniques.

d. In order to increase the precision of our process, we intend to continue to develop and improve our techniques. In order to understand more about the pattern of the user's posting time and how it ties with suicidal thoughts, it is intended to divide the day into various time intervals.

e. The ability to detect suicidal thoughts more accurately may be improved by adding more feature sets, such as timely information and word embedding. Future research in this field is expected to build on the findings of this study.

Forecasting Polling Results Utilizing Social Media Posts

Gajapathi Kishore Kumar Varma, Sridhar Gummalla, Mohammed Waheeduddin Hussain
Shadan college of Engineering and Technology, Hyderabad, Telangana, India
gadiraju.kishore@gmail.com, gummalla@yahoo.com, mwaheeduddinhussain@gmail.com

Abstract—**Modern social media (SM), such as social networks like Facebook, Twitter, and Instagram, was introduced and has become widely used, changing how politicians communicate with the public and run political campaigns (SNs). A new field of research has emerged that focuses on using SM data to predict election results because of the inherent advantages of SM, particularly the large volume of data that can be accessed in real-time. Even though there has been a lot of research in the last ten years, the results are usually contested. In this regard, this paper makes an effort to analyze, describe, and lay out the state of the art and state of the practice in election prediction utilizing SM data from its beginnings, as well as to identify future research directions in this area. In terms of methodology, we carried out a methodical review of the literature, assessing the volume and quality of publications, the electoral context of studies, the key approaches and characteristics of successful studies, as well as their main advantages and disadvantages, and compared our findings with those of previous reviews.**

The project's primary goal is to forecast election outcomes using information from Twitter. The project's scope is restricted to determining who has an advantage over others and calculating the correctness of the suggested model. The system administrator uses training data to develop the suggested model. To determine whether a tweet has a favorable or negative sentiment, test data can be provided to the model. The project's scope does not include user account maintenance.

The most important findings are the poor performance of the most popular method, namely volume and sentiment analysis on Twitter, and the better outcomes with novel methods, including regression techniques trained with conventional polls. The implementation of cutting-edge machine learning techniques has to be properly researched, among other things, and is mentioned in a vision of future research on integrating advancements in process definitions, modeling, and evaluation.

Keywords—Regional Elections, social media (SM), social networks (SNs), machine learning techniques, reviews.

I. INTRODUCTION

This decade has seen a significant impact of social media (SM) on elections and politics[9]. Politicians today run ongoing campaigns that are not time or place-bound, and new information about them can be accessed not just by the press but also straight from their profiles on social networks (SNs) and by other users sharing and amplifying their views on SM[6]. A new age is being mediated through SM. In this new environment, electoral campaigns heavily utilize social media [1], and the success of an online campaign can even influence elections. Recent examples of SM engagement and electoral success include the 2016 U.S. presidential election, in which Donald Trump focused his campaign on free-media marketing [2], and the 2018 Brazilian presidential election, in which the candidate with more SM engagement but less emphasis on traditional media won [3].

Furthermore, it is possible to assess the manner in which a politician's message is being spread on social media and make an educated prediction as to how much interest or how many people are talking about a certain candidate[5]. As a result, a brand-new field of study has been established with the goal of forecasting election results using SM data. This area of research is made possible by the abundance of data that is accessible in real-time, the low cost of acquiring it, and the development of systems for analyzing it[4].

Even the same study may yield favorable results in one situation and negative results in another, as several studies showed overwhelmingly positive results while others cast doubt on the usefulness of SM as a predictor. As a result, there are currently no established methods, processes, or tools for forecasting election results using SM data. Furthermore, over time, even the SM context has changed[8]. For instance, Facebook currently surpasses Twitter in terms of active members, and new SN has emerged like Instagram.

The purpose of this paper is to present a thorough analysis and examination of the current state of the art and practice of predicting election results using SM data in this context, as well as to highlight the key research challenges and opportunities in this area[7]. After performing a rigorous examination of 83 investigations from 2008 to 2019, we thoroughly examined potential directions. We outlined the context of the studies, important models, the advantages and disadvantages of this new subject, as well as the essential characteristics of effective studies[10].

II. RESEARCH BACKGROUND

A. Problem Statement

It has been discovered that the current methods for predicting election outcomes based on the number and sentiment of tweets are worthless. Research is being done in 28 countries across six distinct continents, and the number of publications in this sector is on the rise. Yet, no renowned individuals, groups, or clusters have been found to be engaged in sustainable research in the area. Additionally, no specific well-known forum for publication on this topic was identified, so the results were dispersed throughout several forums. We discovered that, despite being the most popular strategy, volume/sentiment does not exhibit high success rates, which is consistent with the findings of other surveys,

by integrating the characteristics and success of the studies.

B. Aim Of The Project

The primary goal of the research is to forecast election outcomes using information from Twitter. We made advantage of the open-source US Presidential Election 2020 Tweets dataset from Kaggle. All of Donald Trump's and Joe Biden's tweets make up this corpus, which was used to build the suggested model using sophisticated machine learning methods.

C. Scope Of The Project

The project's scope is restricted to determining who has an advantage over others and calculating the correctness of the suggested model. The system administrator uses training data to develop the suggested model. To determine whether a tweet has a favorable or negative sentiment, test data can be provided to the model. The project's scope does not include user account maintenance.

D. Technical Approach

Below is the technical approach to address the problem:

1. Identification of dataset
2. Explorative Data Analysis
3. Cleaning the dataset and applying NLP techniques
4. Feeding the dataset to multiple algorithms and finding the best algorithm that suits the scenario
5. Training the final classifier and creating a model for the final classifier
6. Testing the final classifier and saving the results.

III. System Analysis

A. Research Gap

The introduction and widespread use of modern social media (SM), including social networks like Facebook, Twitter, and Instagram, has changed how politicians interact with the public and conduct political campaigns (SNs). Due to the inherent strengths of SM, namely the vast amount of data that can be accessed in real time, a new area of study has formed that focuses on using SM data to forecast election results. Despite the fact that numerous research have been done in the last ten years, the findings are frequently disputed.

B. Proposed System

This paper explores and reviews the development of research on election prediction using SM data since its inception, presents the state of the art and the state of the art in practise, and highlights future directions for this study. In terms of methodology, we conducted a methodical review of the literature, evaluating the quantity and calibre of publications, the electoral context of studies, the main approaches and traits of successful studies, as well as their main advantages and disadvantages, and compared our findings with those of previous reviews. We found and examined 83 pertinent studies, and problems with methodology, sample, modelling, performance assessment, and scientific rigour were found in numerous areas.The main conclusions include the least successful strategy, which is volume and sentiment analysis on Twitter, and the better outcomes using new methods, including regression techniques trained with conventional polls.

Technical process involved in proposed model:

1. Identification of Dataset
2. Data preprocessing
3. Tweet analysis
4. Feature extraction
5. Creation of Model
6. Testing the model.

Advantages Of Proposed System

- High accuracy
- Can be extended to real time environments.

IV. Algorithmic Process

A. Creating Model

We concentrated on the task of forecasting election outcomes using tweets and postings from social media. We suggest a novel algorithm that can determine the sentiment of the tweet after evaluating the tweets in the datasets. On the electoral tweets dataset, we used NLP techniques, performed the necessary exploratory data analysis, and then fed the processed information to various machine learning algorithms to test their performance. Finally, we developed a machine learning model with an accuracy of roughly 93% that can determine the sentiment of each tweet and compute the aggregate sentiment for Trump and Biden.

This includes the following:

1. Loading the dataset:
2. We will use 80% of data as training, 20% as validation data
3. Bag of words
4. Sanity check
5. Removing duplicates
6. Cleaning tweets
7. Removing punctuatuons
8. Cleaning tweets
9. Removing punctuatuons
10. Transforming the vectorizer
11. Converting to DataFrame
12. Final Classifier Creation

As from the results, Random Forest Classifier with TFIDF and N-gram Feature gives 92.5% accuracy

1)Loading the dataset:

Datasets for training the machine learning models can be uploaded by the system administrator. To upload a file to a server, an administrator must first choose the file by clicking the Choose file button, then click the Upload button. A success message indicating that the file was successfully uploaded would be shown once the upload was finished. We are utilising the dataset Biden No Retweet Full Text.csv for this study.

```
df =
pd.read_csv("../Biden_No_Retweet_Full_Text.csv")

# We will use 80% of data as training, 20% as validation data

training_samples = int(303 * .8)
validation_samples = int(303 - training_samples
```

2)Bag of words

Transform texts into a bag-of-words matrix (number of rows = total set, number of columns = number of unique words). Check out Bag-of-words model in computer vision for more information. The bag-of-words model is a condensing representation used in information retrieval and natural language processing (IR). This paradigm ignores syntax and even word order while maintaining multiplicity and represents a text (such as a sentence or document) as the bag (multiset) of its words. Computer vision has also made use of the bag-of-words approach. The bag-of-words model is frequently employed in document classification techniques in which the (frequency of) occurrence of each word is used as a feature for instructing a classifier.

```
# transform document into a matrix(the number
indicates the number of words showing up in the
document)
bag_of_words = vect.transform(toy_samples)
print("Transformed sparse matrix is: ")
print(bag_of_words.toarray())
```

3)Sanity check

```
print(len(texts) == (training_samples +
validation_samples))
print("The number of training {0}, validation
".format(training_samples, validation_samples)
```

4)Removing duplicates

Eliminate Duplicate record in order to contribute accuracte prediction system

```
df.drop_duplicates(subset="Tweet", keep="first"
inplace=True, ignore_index=True)
```

5)Cleaning tweets

Removes URLs, Hashtags, Mentions, Reserved Words (RT,FAV) Emojis, Smileys and appending to a list

```
tweet_list = [re.sub('[^a-zA-Z]', ' ', i) for i
in tweet_list]
```

6)Removing punctuatuons

```
clean_tweets = []
for tweet in tweet_list:
    for word in set(stopwords.words("english")):
        token = " " + word + " "
        tweet = tweet.replace(token, " ")
    clean_tweets.append(tweet)
```

7)Transforming the vectorizer

```
df_vect = pd.DataFrame(trans.toarray(),
columns=vector.get_feature_names())
```

8)Converting to DataFrame

```
pol = []

for tweet in df["Processed"]:
    blob = TextBlob(tweet)
    pol.append(blob.sentiment.polarity)
df['Polarity'] = pol

# One hot encoding for training set
    integer_encoded_train =
train_labels.reshape(len(train_labels), 1)
    onehot_encoded_train =
onehot_encoder.fit_transform(integer_encoded_train)

    # One hot encoding for validation set
    integer_encoded_val =
validation_labels.reshape(len(validation_labels), 1)
    onehot_encoded_val =
onehot_encoder.fit_transform(integer_encoded_val)
```

9)Final Classifier Creation

Using machine learning and deep learning approaches, we were able to create a machine learning model that can finally determine the sentiment of each tweet. We also computed the total sentiment for Trump and Biden, and its accuracy was created using bidirectional long-short term memory (bi-lstm)

```
model = tf.keras.Sequential([

        Embedding(vocab_size, embedding_dim,
input_length=max_length),
        Bidirectional(LSTM(256)),
```

V. PROJECT IMPLIMENTATION

A. Proposed Modular Implementation

Below is the proposed modular implementation of the project. It consists of modules:

1. Admin
2. User

1. Admin Module:

The admin of the system is responsible for the activities like:

1. Submitting the data
2. Examining the dataset of electoral tweets.
3. Evaluation of several machine learning techniques using the Tweets Dataset.
4. Examine how well the algorithms performed on the provided dataset.
5. Create a model to forecast election outcomes.
6. Use test data to assess the model's ability to identify tweet sentiment and compute total sentiment using the complete dataset.

2. User Module:

By inputting the tweet, the user can log in and test the model. The model receives the tweet as input and is tasked with determining whether the review will be favorable or unfavorable.

B. SYSTEM DESIGN

1. Data Flow Diagram: Admin

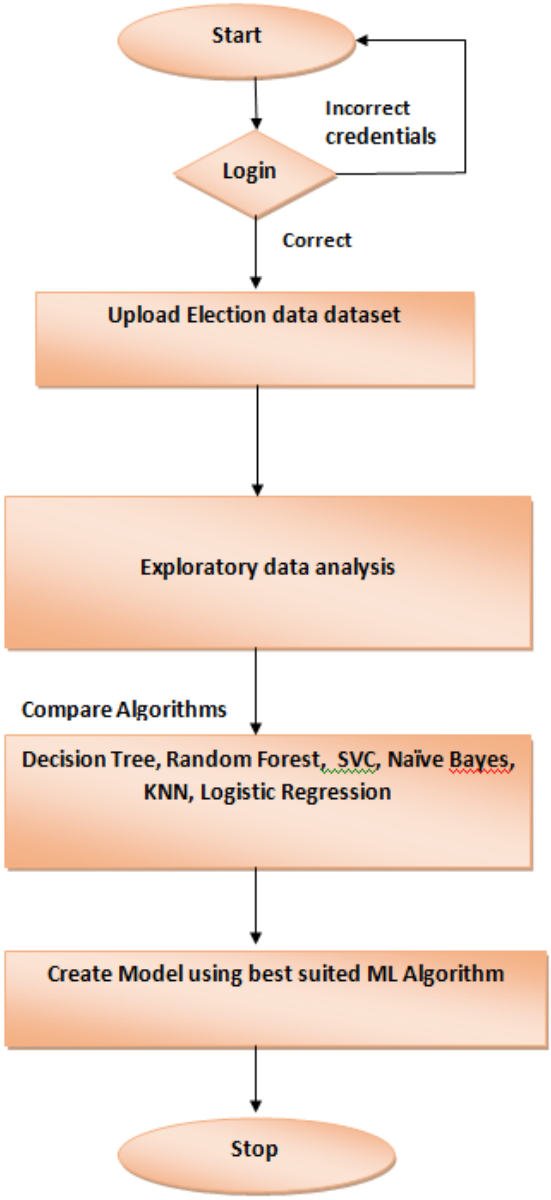

Figure 1: A Data Flow Diagram for Admin

2. Data Flow Diagram: User

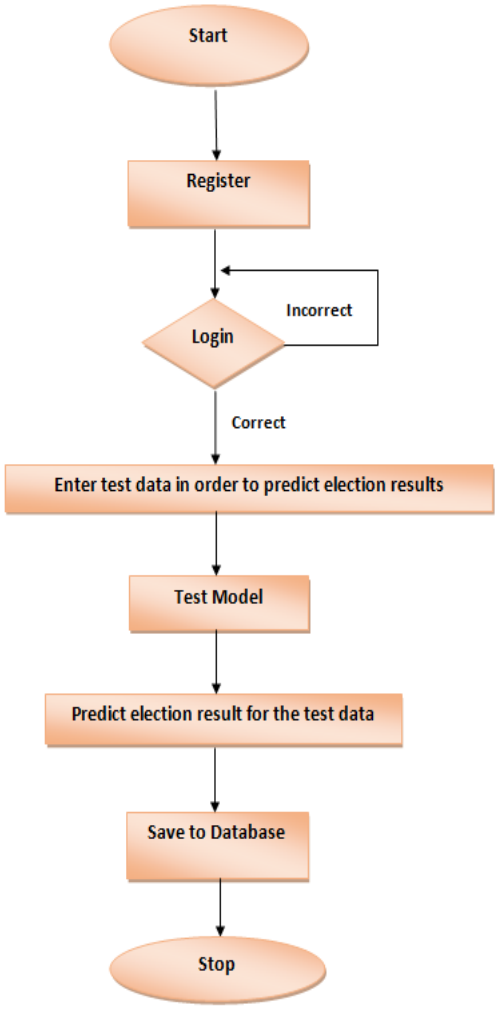

Figure 2: A Data Flow Diagram for Admin

VI. IMPLEMENTATION AND RESULT ANALYSIS

A. Project execution process:

1. Upload Dataset

The system administrator can upload datasets that are used to train machine learning models on this page. To upload a file to a server, an administrator must first choose the file by clicking the Choose file button, then click the Upload button. A success message indicating that the file was successfully uploaded would be shown once the upload was finished. We are using the datasets biden.csv and trump.csv for this research.

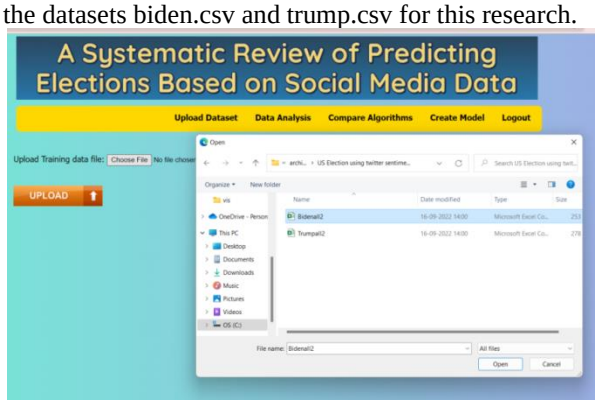

Figure 3: Upload Dataset

Figure 4: File uploaded

2. Data Analysis

Exploratory data analysis is done on the dataset to uncover patterns, find missing data, and establish links between different output characteristics using graphs, statistics, etc.

a) Trump Polarity Analysis:

The sentiment polarity of tweets made in support of Trump is depicted in the graph below.

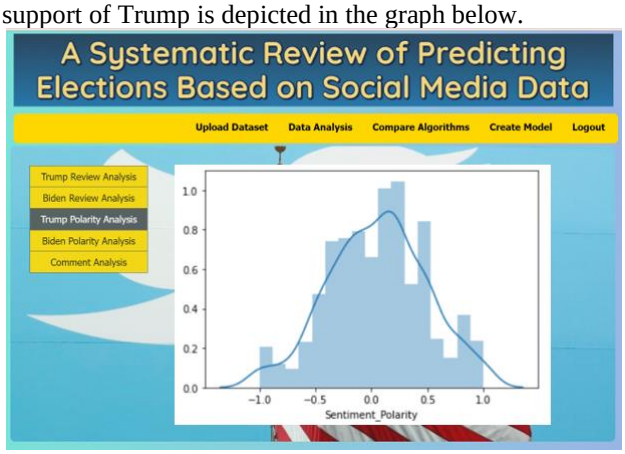

Figure 5: Trump Polarity Analysis

b) Biden PolarityAnalysis:

The sentiment polarity of tweets received for Biden is depicted in the graph below.

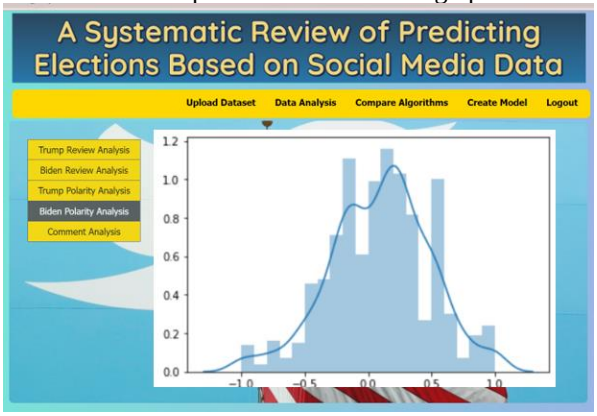

Figure 6: Biden Polarity Analysis

3. Compare Algorithms

The administrator can use this page to train several algorithms on a dataset and determine each algorithm's test accuracy.

a) Logistic Regression

The test accuracy is 86% when the dataset is fed into the logistic regression algorithm, as we can see.

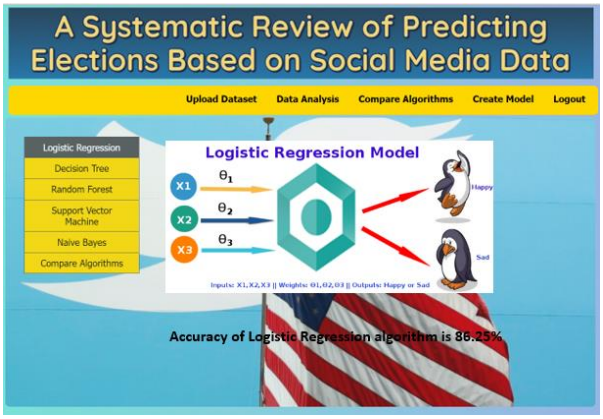

Figure 7: Logistic Regression

b) Decision Trees

The test accuracy is 66.5% when the dataset is fed into the decision tree method, as we can see.

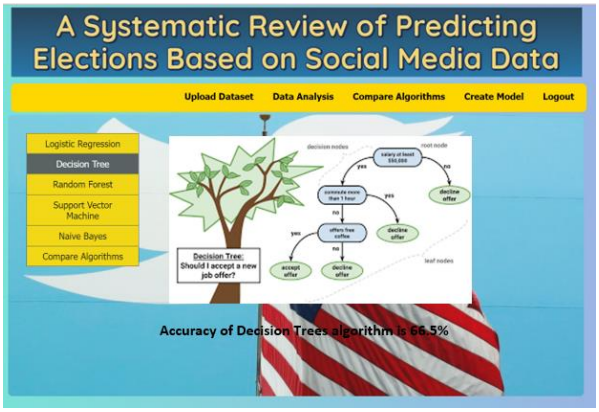

Figure 8: Comment Analysis

c) Support Vector Machine

The test accuracy is 84.75% when the dataset is fed to the Support Vector Machine method.

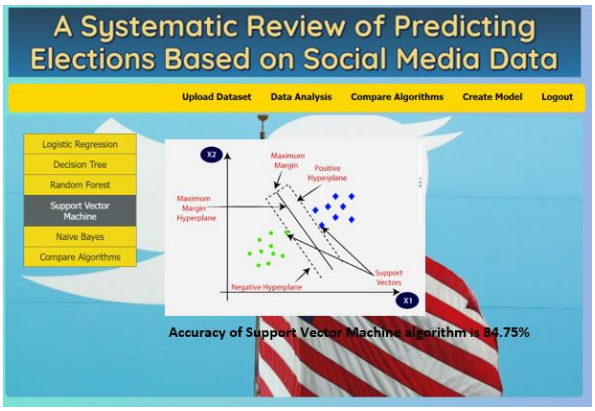

Figure 9: Support Vector Machine Algorithm

4. Create Model

The Generate Model button can be used to create the Model. After pressing the button, a success message is presented and the model is built. Our model's precision is 93.75%.

Figure 10: Create Model

5. Test Model:

The model can be tested using the below screen.

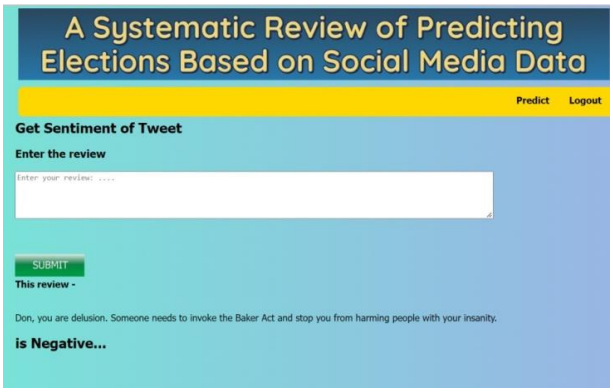

Figure 11: Test model

B. Metrics Evaluation :

Accuracy- One parameter for assessing classification models is accuracy. Informally, accuracy is the percentage of accurate predictions made by our model.

Macro avg - The macro average, also known as the precision, memory, and f1 score, is the arithmetic mean of each individual class. When all classes must be treated equally, macro average scores are used to assess the classifier's overall performance in comparison to the most popular class labels.

Weighted avg- A calculation that accounts for the varied levels of significance of the numbers in a data set is known as a weighted average.

Metrics for Algorithms in CompAlg.py

Classification report contains the complete metric information of the evaluated algorithm. They are Precision, Recall, F1-Score, Support

Precision – What percent of your predictions were correct?

Precision is the capacity of a classifier to avoid classifying as positive anything that is in fact negative. It is described for each class as the proportion of true positives to the total of true and false positives.
TP – True Positives
FP – False Positives

Precision – Accuracy of positive predictions.
Precision = TP/(TP + FP)

1) Recall – What percent of the positive cases did you catch?

The capacity of a classifier to locate every successful instance is known as recall. It is described as the proportion of true positives to the total of true positives and false negatives for each class.

FN – False Negatives

Recall: Fraction of positives that were correctly identified.

Recall = TP/(TP+FN)

2) F1 score – What percent of positive predictions were correct?

The F1 score is a weighted harmonic mean of recall and precision, with 1.0 representing the best result and 0.0 the lowest. F1 scores typically perform worse than accuracy measures because they incorporate precision and recall into their computation. It is often recommended to compare classifier models using the weighted average of F1, rather than overall accuracy.

F1 Score = 2*(Recall * Precision) / (Recall + Precision)

The amount of real instances of the class in the given dataset is known as support. The requirement for stratified sampling or rebalancing may be indicated by unbalanced support in the training data, which may point to structural flaws in the classifier's reported scores.

VII. CONCLUSION AND FUTURE SCOPE

Conclusion : In this work, we concentrated on the task of forecasting election outcomes based on tweets and posts on social media. We suggest a novel algorithm that can determine the sentiment of the tweet after evaluating the tweets in the datasets. On the electoral tweets dataset, we used NLP techniques, performed the necessary exploratory data analysis, and then fed the processed information to various machine learning algorithms to test their performance. Finally, we developed a machine learning model with an accuracy of roughly 94% that can determine the sentiment of each tweet and compute the aggregate sentiment for Trump and Biden.

Future Scope : In our study, we predicted the outcome of the election using Twitter data. In the future, we plan to look at data from Facebook as well as data from other social media platforms and integrate them to forecast election outcomes broadly. We could also have dialogues using images, sounds, and video.

Abstract-**Persuading screening as for Corona virus cases has been turning out to be crucial for dial down and stop the quick spread of the disease during the steady time of Corona virus pandemic beginning with one side of the world then onto the following. In this article, we consider radiology assessment of utilizing chest X-bar pictures, which is among the steady examining up approaches for Corona virus case affirmation. Given basic learning is a persuading gadget and development for picture assessment, there have been piles of assessments for Corona virus case region through preparing huge learning models with X-shaft pictures. In any case, some of them report astounding measure results, their proposed key getting models could experience the shaky effects of overfitting, high change, and speculation messes up accomplished by commotion and a destined number of datasets. Taking into account gathering learning can beat the nonappearances of titanic advancing by making figures with different models instead of a solitary model, we propose EDL-Coronavirus, a party essential learning model utilizing significant learning and outfit learning. The EDL-Coronavirus model is made by joining different depiction models of Coronavirus Net, which has driven in a uninhibitedly conveyed Coronavirus case certification strategy with enormous frontal cortex network controlled chest X-shaft pictures, by utilizing a proposed weighted averaging gathering structure that has an immense information on various responsive qualities of basic learning models on various classes' sorts. Key results show that EDL-Coronavirus offers promising outcomes for Coronavirus case irrefutable interest with a precision of 95%, better than Coronavirus Net of 93.3%.**

I. INTRODUCTION

THE first Coronavirus Disease 2019 (Covid), as a remarkable compelling and hazardous disorder all around the planet, is achieved by SARS-CoV-2, a serious extreme respiratory condition Coronavirus 2, which has not been anytime found in individuals before Dec 2019 [1]. There is a speedy individual to individual transmission between two people in close contact through sprayers or little drops made by talking, hacking, and wheezing. Once polluted, people will for the most part have the going with typical incidental effects following a couple of days, including fever, hack, taste/little mishap, and shortness of breath. As of 10th January 2020, there are even more than 90 million powerful debased cases, and 1.94 million people have passed on around the world. To stop the speedy spread of Covid, a huge task is to sort out debased people through convincing screening so much that they can be disconnected and sought brief treatment. Up until this point, the most by and large included assessing approach for Covid case ID is to take a contrary record polymerase chain reaction (RT-PCR) test over an illustration of nasopharyngeal exudate accumulated from suspectable people for the emotional acknowledgment of nucleic destructive from SARS-CoV-2 credits to its advantages as a fundamental anyway unambiguous abstract measure [6], [30]. Despite the way that RT-PCR testing has been seen as a "greatest level" for spoiled case disclosure of the disorder, there are at this point a couple of issues about it. In any case, the responsiveness of its recognizable proof outcomes is significantly factor, which can deliver misdirecting negative and fake positive results according to another report by Tahamtan et al. [34]. Second, in light of the fast spread of Covid, there are not sufficient PCR reagent packs to satisfy the stunning screening demand especially in poor and energetically affected locales [35]. Despite RT-PCR, radiography evaluation is a choice fruitful assessing method for fast area of Covid, where the chest X-bar (CXR) and CT pictures are performed and taken apart by radiologists to choose whether or not a suspect competent individual has been spoiled by SARS-CoV-2 [3], [36]. Continuous assessments have seen the surprising features in radiography pictures of Covid cases and it has been comprehensively used in China at the past period of the overall eruption [15], [16], [38]. Regardless of the way that CT check has a higher repugnance for pneumonic sicknesses, there are a couple of limitations for its conventional purposes in Covid case ID at a greater extension, including nonprobability, long haul looking at, and the bet of uncovering the clinical facility staff. Conversely, with CT looks at, CXR imaging is helpful, faster, more immediately open, and can be performed inside a separated room while offering a good accuracy in Covid case revelation [29]. In light of these benefits, various new assessments [7], [18], [29], [36] have now revolved around CXR picture examination for COVID19 case area. Particularly, there are a couple of examinations [25] proposing to take helpful CXR imaging as a reliance system for Covid case acknowledgment with the quick spread of the pandemic. While CXR imaging is especially speedy, it needs ace radiologists to make judgment for Covid case disclosure genuinely, which requires capable data and is a dreary cycle. Meanwhile, the amount of radiologists is a lot not exactly that of people under revelation. An electronic thinking (man-made knowledge)- upheld suggestive structure is in this way expected to assist radiologists with making screening of Covid cases in an all the more fast and precise way, regardless it is leaned to happen that polluted people can't be perceived and confined immediately and subsequently can't seek treatment helpful.

II. EXISTING SYSTEM

In Existing System, to fully unleash these potential, bioelectronics devices should be able to precisely respond to real-time changes in the environment to drive biological systems' response towards the desired goals. However, controlling the biological systems' response with bioelectronics devices is challenging due to the presence of uncertainties, stochasticity, unmolded dynamics, and complex nonlinearities.

III. LITERATURE SURVEY

"Professional chat application based on natural language processing.

There has been an emerging trend of a vast number of chat applications which are present in the recent years to help people to connect with each other across different mediums, like Hike, WhatsApp, Telegram, etc. The proposed network-based android chat application used for chatting purpose with remote clients or users connected to the internet, and it will not let the user send inappropriate messages. This paper proposes the mechanism of creating professional chat application that will not permit the user to send inappropriate or improper messages to the participants by incorporating base level implementation of natural language processing (NLP). Before sending the messages to the user, the typed message evaluated to find any inappropriate terms in the message that may include vulgar words, etc., using natural language processing. The user can build an own dictionary which contains vulgar or irrelevant terms. After pre-processing steps of removal of punctuations, numbers, conversion of text to lower case and NLP concepts of removing stop words, stemming, tokenization, named entity recognition and parts of speech tagging, it gives keywords from the user typed message. These derived keywords compared with the terms in the dictionary to analyze the sentiment of the message. If the context of the message is negative, then the user not permitted to send the message

Real world smart chatbot for customer care using software as service (SaaS) architecture.

It's being very important to listen to social media streams whether it's Twitter, Facebook, Messenger, LinkedIn, email or even company own application. As many customers may be using this streams to reach out to company because they need help. The company have setup social marketing team to monitor this stream. But due to huge volumes of users it's very difficult to analyses each and every social message and take a relevant action to solve users' grievances, which lead to many unsatisfied customers or may even lose a customer. This papers proposes a system architecture which will try to overcome the above shortcoming by analyzing messages of each ejabberd users to check whether it's actionable or not. If it's actionable then an automated Chatbot will initiates conversation with that user and help the user to resolve the issue by providing a human way interactions using LUIS and cognitive services. To provide a highly robust, scalable and extensible architecture, this system is implemented on AWS public cloud.

An Overview of Artificial Intelligence Based Chabot's and an Example Chabot Application.

Chatbot can be described as software that can chat with people using artificial intelligence. These software are used to perform tasks such as quickly responding to users, informing them, helping to purchase products and providing better service to customers. In this paper, we present the general working principle and the basic concepts of artificial intelligence based chatbots and related concepts as well as their applications in various sectors such as telecommunication, banking, health, customer call centers and e-commerce. Additionally, the results of an example chatbot for donation service developed for telecommunication service provider are presented using the proposed architecture.

Intelligent travel chatbot for predictive recommendation in echo platform

Chatbot is a computer application that interacts with users using natural language in a similar way to imitate a human travel agent. A successful implementation of a chatbot system can analyze user preferences and predict collective intelligence. In most cases, it can provide better user-centric recommendations. Hence, the chatbot is becoming an integral part of the future consumer services. This paper is an implementation of an intelligent chatbot system in travel domain on Echo platform which would gather user preferences and model collective user knowledge base and recommend using the Restricted Boltzmann Machine (RBM) with Collaborative Filtering. With this chatbot based on DNN, we can improve human to machine interaction in the travel domain

Chatbot Using a Knowledge in Database Human-to-Machine Conversation Modeling

A chatterbot or chatbot aims to make a conversation between both human and machine. The machine has been embedded knowledge to identify the sentences and making a decision itself as response to answer a question. The response principle is matching the input sentence from user. From input sentence, it will be scored to get the similarity of sentences, the higher score obtained the more similar of reference sentences. The sentence similarity calculation in this paper using bigram which divides input sentence as two letters of input sentence. The knowledge of chatbotis stored in the database. The chatbot consists of core and interface that is accessing that core in relational database management systems (RDBMS). The database has been employed as knowledge storage and interpreter has been employed as stored programs of function and procedure sets for pattern-matching requirement. The interface is standalone which has been built using programing language of Pascal and Java.

IV. PROPOSED METHODOLOGY

In this chapter, various supervised machine learning approaches are used. This section provides a general description of these approaches. Abusive messages in

social media is a complex phenomenon with a broad range of overlapping modes and goals [17]. Cyberbullying and hate speech are typical examples of abusive languages that researchers have put more interest in the past few decades due to their negative impacts in our societies. Several research have been conducted to automatically detect these undesirable messages among other messages in social media. The contributions of this study are three-fold. First to equip the readers with the necessary information on the critical steps involved in hate speech detection using ML algorithms. Secondly, the weaknesses and strengths of each method is critically evaluated to guide researchers in the algorithm choice dilemma. Lastly, some research gaps and open challenges were identified. The different variants of ML techniques were reviewed which include classical ML, ensemble approach and deep learning methods. Researchers and professionals alike will benefit immensely from this study.

- Snapshot Model Training
- Model Ensembling
- EDL-COVID Evaluation Results

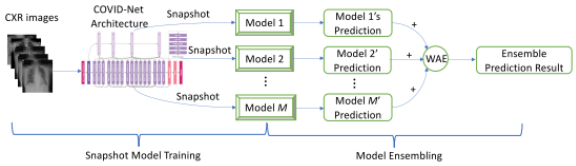
Snapshot Model Training

After generating multiple model snapshots in the first phase, we now come to the model ensembling phase for building EDLCOVID by combining these models as illustrated in Fig. 3. As we discussed in Section II-A, there are many ensembling strategies for model ensemble. For snapshot ensemble learning, averaging is a popular ensembling strategy [17]. For an input sample, it simply averages the class probabilities for each class from all models, respectively. Let be the number of classifiers (i.e., deep learning models). Let(di) be the class probability of the kth class output by the mth classifier with respect to the input sample di. Then the average class probability is M m=1 pm, (di) M, fork∈ [1, K] of the input sample di, with K denoting the number of classes. The traditional averaging ensembling strategy is implicitly based on the assumption that all models have the same weights. However, there are two key observations as follows. 1) For a deep learning model, the testing accuracies for different classes are generally different. 2) Different deep learning models tend to have different accuracies for each class. It indicates that we cannot simply treat each model equally during the model ensembling. Based on the two observations above, we instead propose a WAE approach for snapshot model ensemble as depicted in Algorithm 1. Let ai, j be the test accuracy of the it model for the jth class over the test data of the CXR images dataset. Let w, jdenote the normalized weight of the ith model for the jth class. Then we have WI, j= ai, M m=1 am, j (Line 7). For each input sample di, we first get the output of every class probability pm, k (di) from the mth model for ∀m ∈ M (Line 10–12). Then we can estimate the class probability of EDL-COVID by summing up the weighted class probabilities of all models (Line 13–14) for ∀k ∈ K. Finally, we can get the predicted class by returning the class index with the maximum class probability for each input sample**.**

EDL-COVID Evaluation Results

In this section, we evaluate the EDL-COVID model from the following perspectives. Weights Estimation forWAE. Recall in Section IV-B that we proposed a model ensembling strategy called WAE to combine multiple deep learning models with the awareness of different accuracies on different class types for different models. We first need to obtain weights for all deep learning models on each class type for WAE. Fig. 6 illustrates the estimated class-level weights for all deep learning models, which is based on the estimated sensitivity result on each class type as shown inTable I. We can see that different classes tend to have different weights for different deep learning models. For example, for COVIDNet-M6, it has the largest weight for the COVID-19 class but relatively low weight for the Pneumonia class. Predicted Results. The confusion matrix for the proposed EDL-COVID is presented as in Fig. 7, which analyzes the COVIDx dataset, including CXR images of 100 COVID-19 cases, 594 pneumonia cases, and 885 normal cases. For COVID19 testing, only four out of 100 CXR images of COVID-19 are not screened out, and six out of 1579 CXR images are mistakenly.

V. SYSTEM ARCHITECTURE



VI. RESULTS

Although we only use LSTM for developing the models in this paper, other types of models (e.g., CNN, deep neural networks, and SVM) can also be explored. It would be interesting to perform a comparative study of these models and also consider their robustness to adversarial attacks compared to our proposed fixing heuristic. Additionally, potential applications of our proposed heuristic can be explored in the speech, video, and medical domains, and in recommendation systems.

VII. CONCLUSION

In this article, to beat a couple of issues of overfitting, high variance, and hypothesis missteps of a particular significant learning model for additional created execution on Covid case ID, we proposed EDL-Covid, a social event significant acquiring model called for Covid case acknowledgment from CXR pictures in light of the openly delivered network designing called Covid Net. We initially made different model reviews through setting up the Covid Net association on top of COVIDx CXR datasets, followed by ensembling these models with a proposed WAE ensembling approach that is familiar with different responsive characteristics for different significant learning models on different classes' types. Tests a COVIDx test data of 1579 CXR pictures exhibit the way that EDL-Covid can recognize Covid cases with extraordinary promising results of 96% responsiveness and 94.1% PPVs, beating each individual significant learning model. We trust our reenacted knowledge based screening approach can assist radiologists with accelerating the screening of Covid cases while guaranteeing a high accuracy in the continuous Covid pandemic all around the planet.

VIII. VII. FUTURE ENHANCEMENT

However, current work is vigorously subject to work by Wang et al. [36] on Coronavirus Net organization engineering and COVIDx dataset. There are a few future work that should be possible to upgrade EDL-Coronavirus for commonsense use. In the first place, the quantity of Coronavirus CXR pictures is still somewhat little contrasted with CXR pictures of different classes for the COVIDx dataset, demonstrating that we can't just make a judgment that the as of now prepared model previews from Coronavirus Net engineering keep on functioning admirably with a high exactness for concealed Coronavirus CXR pictures. To further develop EDL-Coronavirus, we want to retrain model previews of Coronavirus Net at whatever point new CXR pictures are accessible. Other than depiction models, we can likewise integrate some other openly accessible great profound learning models into EDL-Coronavirus for better execution. Second, we would want to expand EDL-Coronavirus for other Coronavirus applications, for example, risk definition for Coronavirus cases endurance investigation, risk status examination of Coronavirus cases, which are significant for patient hospitalization and care arranging.

Sales Prediction Analysis In Stop Store Based On Machine Learning Algorithms

Mohammed Jaser Ali Talha, Ganesh Mani, Syed Shujath Ali
Shadan college of Engineering and Technology, Hyderabad, Telangana, India
tahatalhatariq@gmail.com, ganesh.mecse@gmail.com, Shujath.syed@yahoo.com

Abstract— **Large supermarket run-centers, also known as Big Marts, now keep track of the sales volume and revenue figures for each individual product in order to estimate potential domestic demand and update inventory management. Inconsistencies and wide trends are frequently discovered by examining the data warehouse's database server. Businesses like Big Mart may use analytics to anticipate possible product sales using several machine learning techniques. To predict the sales of the products in the Big Mart, we used a variety of machine learning algorithms in this project, including Linear Regression, Ridge Regression, Lasso Regression, Decision Tree Regression, Random Forest Regression, Support Vector Regressor, Adaboost Regressor, and XGBoost Regression. We find that, of the methods described, XGBoost Regression performs the best in forecasting sales volume. In order to further increase the accuracy, we built a model using XGBoost Regression and fine-tuned it. This model is available on a flask application, where users may log in, enter the details of a product, and receive accurate forecasts of its sales.**

Keywords—Linear Regression, Polynomial Regression, Ridge Regression, Xgboost Regression.

I. INTRODUCTION

The competition between various retail stores and huge supermarkets is growing more ferocious and fierce on a daily basis as a result of the quick expansion of international retailers and online purchases[1]. In order to manage inventory, shipping, and operational tasks for the business, it must be able to pull in a sizable number of clients in a brief period of time and predict the amount of income for each product. In order to outperform low-cost methods used for prediction, the current machine learning technology is highly advanced and offers approaches for estimating or forecasting sales patterns for just about any type of firm[3]. Always more precise forecasting is helpful for developing and improving the business plan, which is also very advantageous.

There has been a lot of work done up to this point that was specifically intended for the field of transaction forecasting[2]. The substantial research on big-mart agreements that has been done is briefly summarised in this section. Several other Measurable approaches, including regression, auto-regressive integrated moving average (ARIMA), and auto-regressive moving average (ARMA), have been used to build a few deals prediction standards. A. S. Weigend et al. [6]suggested combining the occasional quantum relapse strategy with the (ARIMA) Auto-Regressive Integrated Moving Average method to manage daily food deals anticipating. Predicting transactions is a difficult problem that is affected by both internal and external factors.

II. RESEARCH BACKGROUND

A. Problem Statement

Individuals' purchasing power has been rapidly increasing in both offline and online settings in recent years[4]. Large supermarkets occasionally offer a variety of deals during holidays like Christmas and the New Year. Since it is clear that sales will be quite strong during this time, it is crucial for management to accurately forecast product sales and maintain proper inventory management[5]. The superstore should purchase sufficient product inventory and sell it off within the time. If it fails to do so and its projections prove to be inaccurate, the mart will incur significant losses. There are currently no methods available that can correctly forecast product sales based on historical data. It is only carried out by managers, who carefully examine historical data and attempt to gauge sales volume in light of several events and other pertinent facts[7]. This activity cannot be completed by an automated system; instead, human assistance is required.

B. Aim Of The Project

This project's main goal is to forecast how many things will be sold at a superstore. For this, we used the Big Mart sales data set from Kaggle. The R2 score of this data set is compared after preprocessing, analysis, and feeding it to many regression algorithms. Stock booking and inventory maintenance are outside the purview of this project.

Technical Approach

The technological strategy to solve the issue is listed below:

1. Dataset identification
2. Exploratory Analysis of Data
3. Dataset preparation
4. Running the dataset through many algorithms to see which one best fits the situation.
5. Developing a final classifier model and training the final classifier
6. Validating the ultimate classifier and recording the outcomes.

III. SYSTEM ANALYSIS

A. Research Gap

It goes without saying that sales would be quite strong during special days of the year like new year's, Christmas, etc. Therefore, it is crucial for management to accurately anticipate product sales and manage their inventory without any problems. The superstore should purchase sufficient product inventory and sell it off within the time. If it fails to do so and its projections prove to be inaccurate, the mart will incur significant

losses. There are currently no methods available that can correctly forecast product sales based on historical data. It is solely carried out by managers who carefully examine historical data and attempt to anticipate the sales volume based on several events and other pertinent information. Predictions require human effort.

B. Proposed System

In this project, we suggest using a variety of machine learning algorithms, such as Linear Regression, Ridge Regression, Lasso Regression, Decision Tree Regression, Random Forest Regression, Support Vector Regressor, Adaboost Regressor, and XGBoost Regression, to predict the sales of the products in the Big Mart. We then use the algorithm that performs best to build a model to predict sales volume. We want to host this model on a flask application where users can log in, enter the details of the product, and receive the pertinent forecasts regarding the product's sales.

This suggested approach will evaluate consumer behavior based on their past conduct. These client records are collected to form a data set. We make predictions about whether or not the customer's loan will be approved using these data sets and a machine learning model that has been trained. These computer algorithms forecast the likelihood that a consumer will be able to pay back the lending credit or not.

After testing, the model determines whether the new application is a good candidate for loan approval or not based on the inference it draws from the training sets of data to determine if a client would indeed be capable of repaying his loan or not

Advantages of Proposed System:

- High precision
- Extendable to real-time settings.

IV. ALGORITHMIC PROCESS

A. Creating Model

The algorithm used: XGBoost Regressor

Below is the technical approach used for the Loan recommendation system using the Loan review dataset

1. Data cleaning and visualization
2. Feature Extraction
3. Data Preparation
4. Splitting the data set into test data and training data
5. Data modeling using Sequential and Decision Tree algorithm classifier
6. Data Evaluation and prediction
7. Prediction of a sales in big marts systems

1)Feature extraction:

Below are the features present in the dataset:

Feature Name	**Type**
Item_Identifier	String
Item_Weight	String
Item_Fat_Content	String
Item_Visibility	String
Item_Type	String
Item_MRP	String
Outlet_Identifier	String
Outlet_Establishment_Year	String
Outlet_Size	String
Outlet_Location_Type	String
Outlet_Type	String
Item_Outlet_Sales	String

Feature Extraction Details:

A. Imputing Missing Values

When no information is given for one or more elements, a whole unit, or both, this is known as missing data. Missing data is a major issue in real-world situations. In pandas, missing data can also refer to NA (Not Available) values. Many datasets in DataFrame occasionally arrive with missing data, either because the data was never collected or because it was present but was not captured. We can use the fillna(), replace(), and interpolate() functions to fill in any null values in a dataset by replacing NaN values with one of their own. Each of these functions aids in filling in null values in a data frame's datasets. Interpolate() function is basically used to fill NA values in the data frame but it uses various interpolation techniques to fill the missing values rather than hard-coding the value. Although it uses a variety of interpolation algorithms rather than hard-coding the value, the Interpolate() function is mostly used to fill NA values in data frames.

```
# Read files:
    train = pd.read_csv("train.csv")
    test = pd.read_csv("test.csv")

    data = pd.concat([train, test])

# imputing missing values

    data['Item_Weight'] =
data['Item_Weight'].replace(0, np.NaN)

data['Item_Weight'].fillna(data['Item_Weight'].mean()
, inplace=True)

data['Outlet_Size'].fillna(data['Outlet_Size'].mode()
[0], inplace=True)

    data['Item_Outlet_Sales'] =
data['Item_Outlet_Sales'].replace(0, np.NaN)

data['Item_Outlet_Sales'].fillna(data['Item_Outlet_Sa
les'].mode()[0], inplace=True)
```

B. Label Encoding

In machine learning, we usually deal with datasets that contain multiple labels in one or more than one column. These labels can be in the form of words or numbers. To make the data understandable or in human-readable form, the training data is often labeled in words. Label Encoding refers to converting the labels into a numeric form so as to convert them into a machine-readable form. Machine learning algorithms can then decide in a better way how those labels must be operated. It is an important pre-processing step for the structured dataset in supervised learning.

```
# label encoding

    data.apply(LabelEncoder().fit_transform)
```

C. One Hot Encoding

Most Machine Learning algorithms cannot work with categorical data and needs to be converted into numerical data. Sometimes in datasets, we encounter columns that contain categorical features (string values) for example parameter Gender will have categorical parameters like Male, Female. These labels have no specific order of preference and also since the data is string labels, machine learning models misinterpreted that there is some sort of hierarchy in them.

One approach to solve this problem can be label encoding where we will assign a numerical value to these labels for example Male and Female mapped to 0 and 1. But this can add bias in our model as it will start giving higher preference to the Female parameter as 1>0 and ideally both labels are equally important in the dataset. To deal with this issue we will use the One Hot Encoding technique.

One Hot Encoding:
In this technique, the categorical parameters will prepare separate columns for both Male and Female labels. So, wherever there is a Male, the value will be 1 in the Male column and 0 in the Female column, and vice-versa.

```
# one hot encoding
    data = pd.get_dummies(data)
```

D. Defining features and Labels

```
X_train, X_test, y_train, y_test =
train_test_split(X, y, test_size=0.2
random_state=300)
```

E. Generating Synthetic Samples

Imbalanced Data Distribution is a phrase used frequently in machine learning and data science and refers to situations where observations in one class are significantly greater or lower than those in the other classes. Machine learning algorithms do not take the class distribution into account since they prefer to improve accuracy by decreasing the error.

SMOTE (Synthetic Minority Oversampling Technique) – Oversampling

One of the most popular oversampling techniques to address the imbalance issue is SMOTE (synthetic minority oversampling technique).
By increasing minority class samples at random and duplicating them, it seeks to balance the distribution of classes.

SMOTE combines already existing minority instances to create new minority instances. For the minority class, it creates virtual training records using linear interpolation. For each example in the minority class, one or more of the k-nearest neighbours are randomly chosen to serve as these synthetic training records. Following the oversampling procedure, the data is rebuilt and can be subjected to several categorization models.

```
sm = SMOTE(random_state=300)
X_train, y_train = sm.fit_resample(X_train, y_train)
```

F. Scaling the data

A data preparation technique for numerical features is called data scaling. Data scaling is necessary for the success of many machine learning techniques, including the KNN algorithm, linear and logistic regression, and gradient descent approaches.

The MinMax Scaler reduces the data inside the specified range, often between 0 and 1. By scaling features to a predetermined range, it changes data. It scales the values to a particular value range while preserving the original distribution's shape.

V. PROJECT IMPLIMENTATION

A. Proposed Modular Implementation

Below is the proposed modular implementation of the project. It consists of modules:

1. Admin
2. User

1. Admin Module:

The admin of the system is responsible for the activities like:

1. Uploading the dataset
2. The dataset's data analysis
3. Data Preparation
4. Divvying up the dataset into training and test portions
5. Conditioning the model for various regression techniques
6. Examine how well the algorithms performed on the provided dataset.
7. Use the XGBoost regressor algorithm to build the model.

2. User Module:

The system's user may take advantage of the following available machine learning services:
logging in and entering item/product information to forecast future sales

.

B. SYSTEM DESIGN

1. Data Flow Diagram: Admin

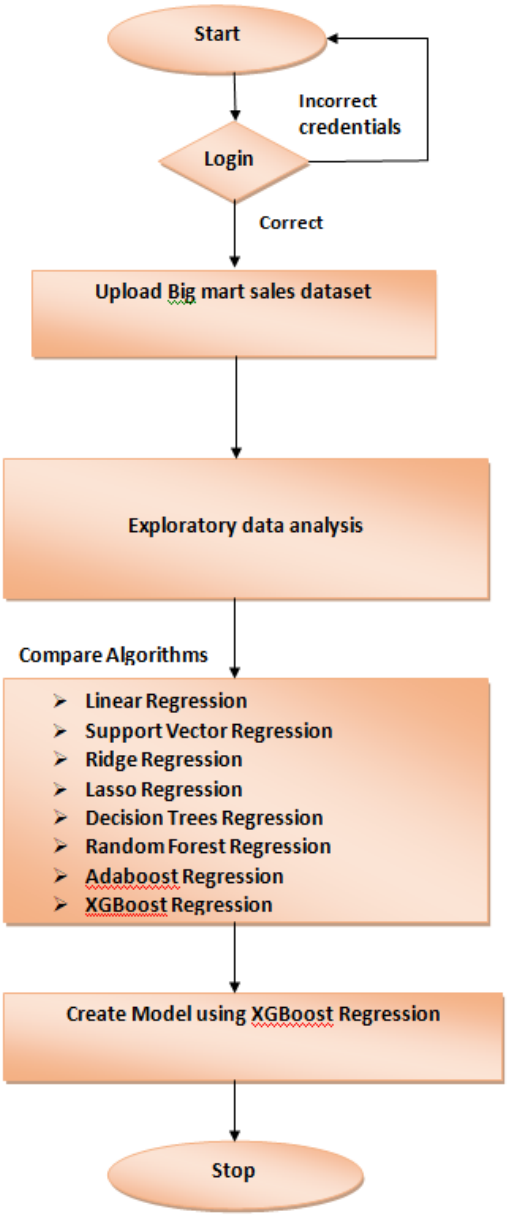

Figure 1: A Data Flow Diagram for Admin

2. Data Flow Diagram: User

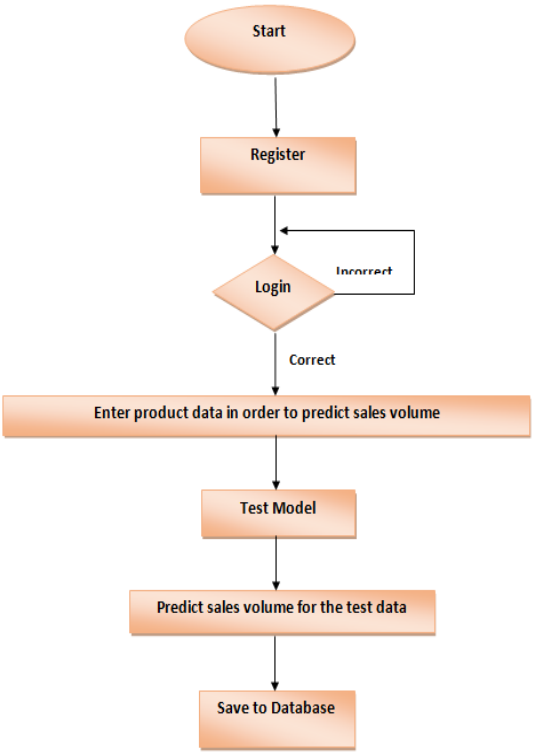

Figure 2: A Data Flow Diagram for Admin

VI. IMPLEMENTATION AND RESULT ANALYSIS

A. Project execution process:

1. Upload Dataset

The system administrator can upload datasets that are used to train machine learning models on this page. To upload a file to a server, an administrator must first choose the file by clicking the Choose file button, then click the Upload button. A success message indicating that the file was successfully uploaded would be shown once the upload was finished. We are utilising the dataset train.csv for this project.

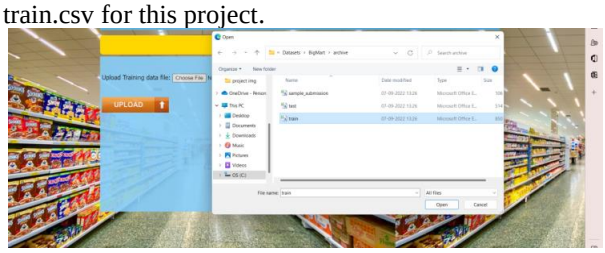

Figure 3: Upload Dataset

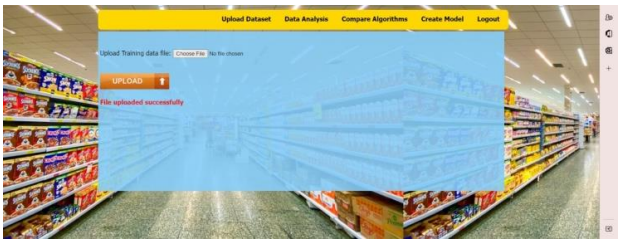

Figure 4: File uploaded

2. Data Analysis

Exploratory Data Analysis is performed on the dataset in order to clean the dataset for any missing data, identify patterns, and identify the relationships of various parameters of the outputs with the help of graphs, statistics, etc. so that Data Analysis can be performed.

a) Item Type Analysis:

The below graph shows the Education Analysis of an individual from the Training dataset Loan_Train.csv File.

Figure 5: Item Type Analysis

3. Compare Algorithms

On this page, the admin can feed the dataset to various Algorithms to train them and get the test accuracy for each algorithm.

a) Linear Regression:

When the dataset is fed to Linear Regression algorithm we observe that the variance is 0.27

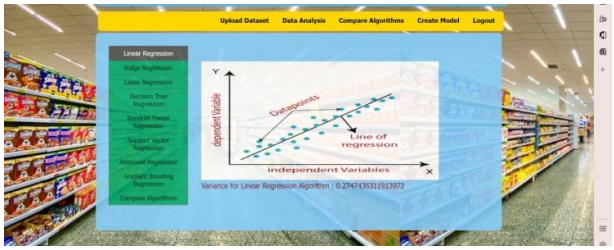

Figure 7: Linear Regression

b) Decision Trees Regression

We see that the variance is -0.4 when the dataset is fed into the Decision Trees Regression algorithm.

Figure 8: DT Regressor

c) XGBoost Regressor

We see that the dataset's XGBoost Regression algorithm's variance is 0.29.

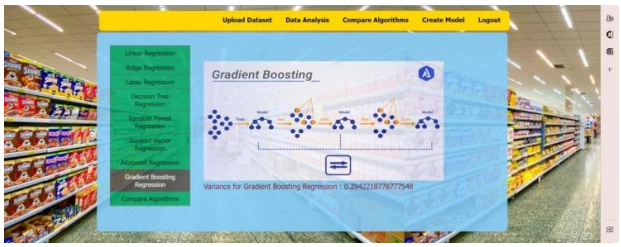

Figure 9: XGBoost Regression Algorithm

4. Create Model

The Generate Model button can be used to create the Model. After pressing the button, a success message is presented and the model is built. Our model's precision is 98.85%.

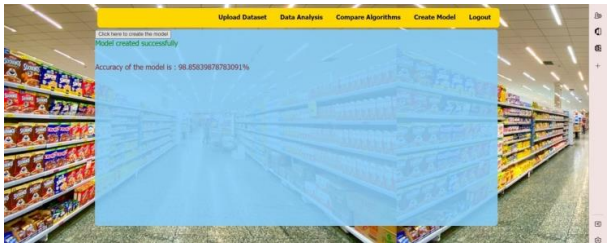

Figure 10: Create Model

5. Test Model:

This is in User Home Page for the user module. The user need to login into the system with his credentials in order to facilitate prediction over a of new applicant Loan data over dataset.

Figure 11: Test model

B. Metrics Evaluation :

Mean Squared Error (MSE):

The term Mean Squared Error (MSE) refers to the square of the difference between actual and estimated values in statistics. You may determine how closely a regression line resembles a set of points using the mean squared error (MSE). This is accomplished by squaring the distances between the points and the regression line (also known as the "errors"). The squaring is required to eliminate any unfavourable indications. Additionally, it emphasises bigger discrepancies. Since you're averaging

a collection of errors, this error type is known as the mean squared error. The forecast is more accurate the lower the MSE. A crucial component of the estimation of the statistics is the mean-squared error. Through the use of a special method to determine the square of the mistakes and their average, it aids in calculating the differences between the estimated value and the actual value and provides insight. The value of the MSE is determined by the square and the average. The difference between the value being estimated and the estimated value is the basis for calculating mistakes. It is a risk function because it predicts the amount of the loss. This quantification aids in determining the loss's cause, which might also be the estimator. MSE is largely favourable. There are several methods for determining MSE. For instance, the variance and mean-squared error will be equal if the estimator is not biassed. The unit changes depending on how the quantity is primarily measured.

What is variance?

In terms of linear regression, variance is a measure of how much the mean of the predicted values and the observed values vary from one another. The objective is to have a low value. The r2 score measures what low implies (explained below).

****

Linear Regression variance score: 0.2898929014039604

Linear Regression accuracy score: 0.2898929014039604

****

VII. CONCLUSION

We were successful in creating and implementing a machine learning model for this project that forecasts sales of various products in a superstore. We have used the Big Mart sales data set from kaggle.com, an open source data set, in order to accomplish this. The data has been cleaned and preprocessed, divided into training and test data, and fed to a variety of regression algorithms, including Linear regression, Support vector regression, Ridge regression, Lasso regression, Decision Trees regression, Random Forest regression, Adaboost regression, and Xgboost regression. That transaction, which we have seen, provides the highest level of accuracy. As a result, we improved the xG boost regressor, which now provides an accuracy of roughly 98%. For this data set, our model performs better than any other machine learning models we have used. Future plans call for expanding this research to include time series analysis using ARIMA.

Text Summarization Using Zero-Shot Model

Dr. Ajay B Gadicha, Dr. V B Kute, Prof Zeeshan I Khan, Prof M K Nichat
Head-Artificial Intelligence and Data Science, Computer Sci. & Engg, Computer Science & Engineering
hodai@prpotepatilengg.ac.in, hodcse@prpotepatilengg.ac.in, zikhan@prpotepatilengg.ac.in, mknichat @prpotepatilengg.ac.in

Abstract-**Automatic text summarization comprises a set of techniques that use algorithms to condense a large body of text, while at the same time preserving the important information included in the text. It is an area of computer automation that has seen steady development and improvement, although it does not get as much press as other machine learning approach. This is not to say that text summarization is of little importance, quite the contrary. A large amount of the information we create and exchange is in written form. Therefore, systems that can extract the core ideas from text and preserve the overall meaning stand to revolutionize entire industries, from health care to law, to finance, by allowing you to share information faster and more efficiently. Automatic summarization as a field is not limited to text. In fact, you can "summarize" images and videos as well as text. Automatic summarization as "the process of shortening a set of data computationally, to create a subset (a summary) that represents the most important or relevant information within the original content". The end goal, whether we summarize text, images or videos, is to reduce the amount of resources required to transmit and process data.**

I. INTRODUCTION

In recent years, this area has become a particular point of interest due to the explosion of written content available online. Everything from tweets, to news articles, to blog posts includes text. This text may contain vital information for businesses, brands, financial asset traders, etc. but the amount of text generated far outpaces our ability to process it. The positive side of the explosion of written content available online is that we now have more training data we can use to create advanced summarization models. In fact, while early summarization algorithms were never really very good, newer models based on deep-learning techniques and trained on vast amounts of data can produce impressive results.

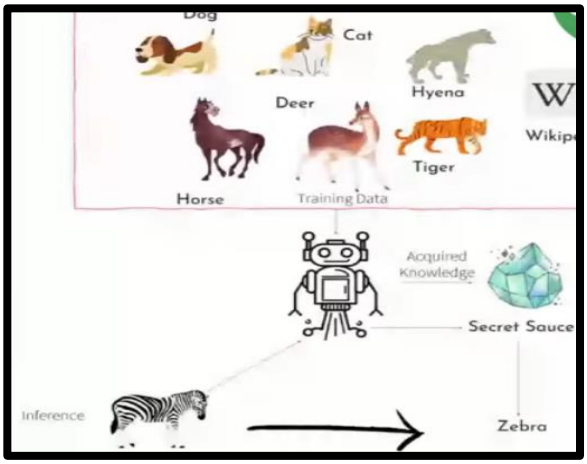

Figure1: Generalized Model of text Summarization [1]

Fine-tune Model:

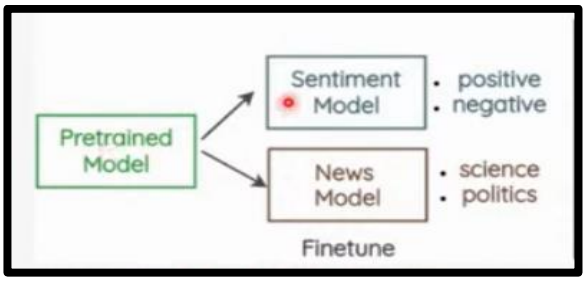

Figure2: Fine-tune Model [2]

Types of Text Summarization

There are two main types of Text Summarization:

II. EXTRACTIVE:

Extractive summarization methods work just like that. It takes the text, ranks all the sentences according to the understanding and relevance of the text, and presents you with the most important sentences.This method does not create new words or phrases; it just takes the already existing words and phrases and presents only that. You can imagine this as taking a page of text and marking the most important sentences using a highlighter.

III. ABSTRACTIVE:

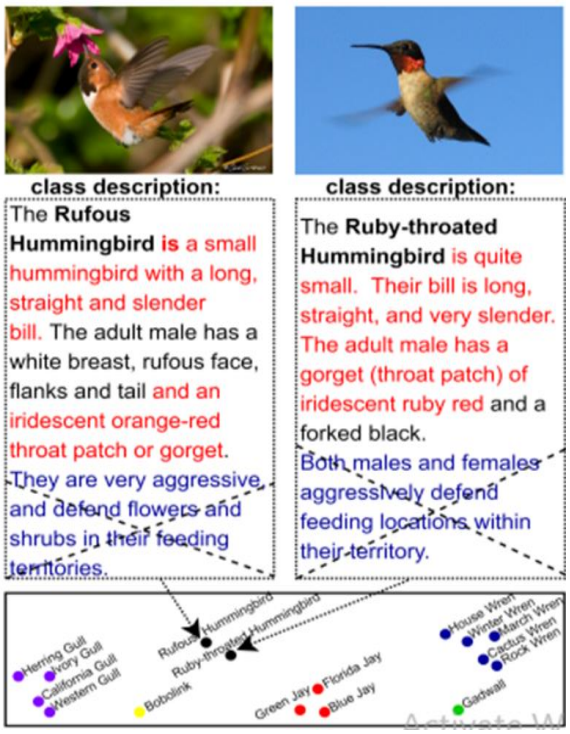
Abstractive summarization, on the other hand, tries to guess the meaning of the whole text and presents the meaning to human.It creates words and phrases, puts them together in a meaningful way, and along with that, adds the most important facts found in the text. This way, abstractive summarization techniques are more complex than extractive summarization techniques and are also computationally more expensive.

Summarization using Two Approaches

1. On the basis of Textual Similarity & Visual Description

   In computer vision, zero shot-learning (ZSL) for image classification is the problem of classifying images given auxiliary information. An image classification model is trained to classify images from a pre-defined set of classes. At test time, images from new classes are given, and the task is to transfer knowledge learned from seen classes during training to unseen test classes.

   Fiqure 3: Summarization of Wikipedia articles [3]

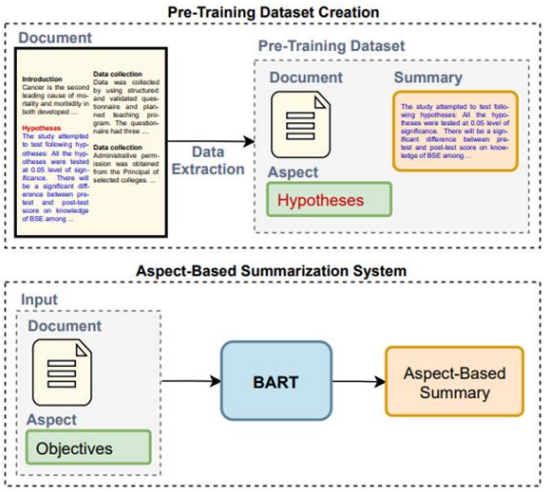


2. Scientific Document Summarization

Scientific document summarization aims to summarize research papers, and it is usually considered as generating paper abstracts Compared to the news summarization datasets like CNN/Daily Mail, scientific papers are significantly longer, follow a standard structure, and contain more technical terms and complex concepts. Recently, there have been remarkable improvements in the area of scientific document summarization due to the availability of large-scale datasets such as arXiv and PubMed and pre-trained sequence to sequence models such as BART and PEGASUS. However, little research has been conducted on aspect-based scientific document summarization.

Aspect-based summarization is the task of summarizing a document with respect to a specificpoint of interest. Aspect-based scientific document summarization has several advantages for readers to explore retrieved articles quickly and facilitates document assistance systems. It can be particularly helpful to assist readers in critical reviewing of articles.

Collecting a largescale dataset for this task is extremely costly. Meng et al. (2021) introduce FacetSum, an aspect-based document summarization dataset. They employ structured abstracts from the Emerald database to create summaries from four perspectives (purpose, method, findings, and value). However, in real applications, readers may be interested in new aspects that go beyond proposed annotations.



Fiqure 4: Summarization of Scientific Unlabeled Documents

Scientific document summarization falls under the problem of long document summarization. Different approaches have been proposed to alleviate models struggle with long inputs, such as applying a hierarchical encoder together with a decoder attending to discourse-level information or summarizing papers sections separately.

V. CONCLUSION

In this paper, we studied the problem of zero-shot aspect-based summarization of scientific documents. We established various experimental setups to investigate the effect of additional pre-training and intermediate training on the zero-shot performance with respect to domain-shift and unseen aspects. We proposed a self-supervised approach to pre-train the model using unlabeled target datasets. Results indicate that additional pre-training on the target dataset followed by intermediate training results in the best zero-shot performance. This paper also aims to establish a better way to represent the language modality in text-based ZSL for image classification. Our approach only relies on semantic information about visual features, and not on the visual features themselves.

Route Optimization for Police

Atul Pal, Ravinarayan Panda, Anshu Pandey
Thakur College of Engineering and Technology, Mumbai, India

Abstract-**Finding the fastest path for cars to take between two points is a process known as route optimization. Police cars can use this idea to increase the patrol coverage and response time of their vehicles. In order to reduce travel time and distance while still making sure that all of the important locations are covered, police routes are optimised. This results in improved resource management and elevated public safety. Police cars need to be able to respond to situations quickly, so route optimization is essential. They can go to the site and deal with the matter more quickly if the route is more effective. Police departments may now choose the most practical routes to follow thanks to modern mapping technology and GPS tracking. Real-time traffic patterns, road conditions, and other variables that may affect journey time are all taken into account by the optimization programme. In conclusion, route optimization is a crucial tool for police to use to increase the efficacy and efficiency of their operations. It helps shorten reaction times, use less gasoline, and guarantee coverage of the entire city. As a result, there is an improvement in public safety and resource efficiency. Police agencies may now choose the most effective routes to travel with the use of cutting-edge mapping technologies and GPS tracking, making it simpler for them to respond to emergencies and keep the community safe.**

Keywords – road segment classification, smart city management, patrol routing optimization

I. INTRODUCTION

Route optimization for police patrols is an important area of study that aims to improve the effectiveness and efficiency of law enforcement operations. The goal of route optimization is to determine the best path or sequence of locations for police officers to patrol in order to accomplish specific objectives, such as reducing crime, improving response times, and maximizing coverage.

Route optimization for police patrol is a complex problem that involves a variety of factors, including crime patterns, real-time information, limited resources, and other constraints. To address these challenges, researchers have developed a range of optimization algorithms, including linear programming, integer programming, and heuristics, that take into account different aspects of the problem.

Despite advances in the field, many challenges remain in developing effective route optimization algorithms for police patrol. These include the need to incorporate real-time information, deal with dynamic and uncertain crime data, balance competing objectives, manage limited resources, and integrate with other systems and processes.

This research aims to contribute to the development of effective route optimization algorithms for police patrol by addressing some of the remaining challenges in the field. By providing a comprehensive overview of the current state of the art and identifying areas for further improvement, this research will support the development of more effective and efficient police patrol operations.

II. LITERATURE SURVEY

Mathematical optimization methods for route optimization in policing have been widely researched in the literature. One common approach is linear programming, which involves formulating the optimization problem as a linear function subject to constraints. Linear programming has been used to optimize police routes with various objectives, such as minimizing response times, reducing fuel consumption, and maximizing officer safety.

Dynamic programming is another optimization method that has been used for route optimization in policing. This method involves breaking down a complex optimization problem into a series of smaller subproblems, which can then be solved individually. Dynamic programming has been used to optimize police routes with a variety of objectives, including minimizing response times, reducing fuel consumption, and enhancing officer safety.

Metaheuristics are a family of optimization algorithms that are designed to be applied to complex problems. These algorithms are often used for problems that are difficult to solve using traditional optimization methods. Some common metaheuristics for route optimization include genetic algorithms, simulated annealing, and ant colony optimization. These methods have been used to optimize police routes with various objectives, including minimizing response times, reducing fuel consumption, and maximizing officer safety.

Empirical studies on the application of route optimization methods in policing have shown mixed results. Some studies have found that optimized routes can significantly improve response times and reduce fuel consumption, while others have found that the benefits are more modest or that the effects depend on the specific policing environment. A few studies have investigated the impact of route optimization on officer safety, and have found that optimized routes can reduce the risk of officers being involved in accidents or other dangerous situations.

However, the literature also highlights the importance of considering the specific needs and constraints of each policing organization when optimizing police routes. Factors such as traffic patterns, crime patterns, and resource availability can greatly impact the effectiveness of route optimization methods. Additionally, the choice of optimization method may also impact the results, as each method has its own strengths and weaknesses.

In conclusion, the literature suggests that route optimization can be a valuable tool for improving policing outcomes, but that the specific benefits depend on the needs and constraints of each organization and the methods used to optimize the routes. Further research is needed to better understand the impact of route optimization on policing outcomes and to develop more effective and efficient methods for optimizing police routes.

III. METHODOLOGY

The methodology for road optimization for police can vary depending on the specific problem being addressed and the approach taken by the researchers. However, some common methods include:

Mathematical modelling: Researchers may use mathematical optimization techniques, such as linear programming, mixed integer linear programming, or non-linear programming, to model the problem of road optimization for police. These models consider various factors, such as patrol vehicle availability, patrol schedules, patrol durations, travel time, and crime hotspots, to optimize the allocation of patrol routes.

Algorithm-based approach: Researchers may use algorithms, such as particle swarm optimization (PSO), genetic algorithms (GA), or simulated annealing (SA), to solve the problem of road optimization for police. These algorithms iteratively improve a set of solutions, based on predefined objective functions and constraints, to find the optimal solution.

Case study approach: Researchers may also use case studies to analyse the effectiveness of road optimization for police in real-world scenarios. This approach involves collecting data from a specific case, such as a city or a neighbourhood, and applying optimization techniques to analyse the results.

Regardless of the approach taken, the goal of road optimization for police is to improve the efficiency and effectiveness of patrols, while also considering factors such as cost and resource constraints.

Certainly! Here are a few more points that could be included in the methodology of road optimization for police:

Crime data analysis: Researchers may use crime data to identify crime hotspots and high-risk areas that require increased police presence. This information can then be incorporated into the optimization models or algorithms to ensure that patrol routes are optimized in these areas.

Geographical Information System (GIS) mapping: Researchers may use GIS mapping tools to visualize the patrol routes, crime hotspots, and other relevant information on a map. This helps to better understand the geographical distribution of crimes and the impact of patrol routes on crime reduction.

Multi-objective optimization: Researchers may consider multiple objectives, such as crime reduction, patrol efficiency, and cost, when optimizing the patrol routes. This approach takes into account trade-offs between different objectives and ensures that the final solution is a compromise that balances these objectives.

Real-time optimization: In some cases, researchers may develop algorithms or models that can be applied in real-time, allowing police departments to optimize patrol routes in response to changing crime patterns or resource constraints.

Evaluation and assessment: Researchers may also evaluate and assess the effectiveness of the road optimization methods using metrics such as crime reduction, patrol efficiency, and cost. This helps to understand the impact of the optimization methods on police operations and inform future improvements.

These points further highlight the importance of considering various factors and approaches when developing road optimization methods for police.

IV. PROBLEM STATEMENT

One of the unresolved problems in the field of route optimization for police patrols is the challenge of incorporating real-time information into route optimization algorithms. Police patrol operations are dynamic and require real-time adjustments to account for changing circumstances, such as traffic conditions and emergency calls. However, many existing route optimization algorithms do not take real-time information into account, which can lead to suboptimal patrol routes that do not effectively respond to changing circumstances.

To address this challenge, researchers are working on developing algorithms that can incorporate real-time information into route optimization models. This may involve using techniques such as online optimization, which adjusts the solution in real-time based on new information, or using predictive models that estimate the impact of real-time information on patrol routes.

Another unresolved challenge is the need to balance competing objectives in police patrol routing. Police patrols must balance a variety of objectives, such as maximizing coverage, reducing response times, and minimizing travel distances, which can be conflicting. As a result, it is important to develop algorithms that can effectively balance these competing objectives to generate patrol routes that are both efficient and effective.

Finally, there is a need to integrate route optimization algorithms with other systems and processes to effectively support the work of law enforcement. This may involve integrating with dispatch and communications systems, or developing algorithms that take into account the capabilities and limitations of specific police departments.

These are some of the unresolved challenges in the field of route optimization for police patrols that present opportunities for further research and development. Addressing these challenges will help to develop more effective and efficient police patrol operations, improving public safety and supporting the work of law enforcement.

V. RESULT AND DISCUSSION

The result of the problem statement I stated earlier, which is the integration of community policing strategies into route optimization algorithms for police patrols, could be the development of algorithms that effectively balance the conflicting objectives of maximizing coverage, reducing response times, and minimizing travel distances, while taking into account the priorities and concerns of local communities.

The result of such research could lead to improved police-community relations and better alignment of patrol routes

with community priorities. This could result in more efficient and effective police operations that better serve the needs of both police and the communities they serve.

Additionally, the result of this research may also provide insights into the trade-offs involved in balancing the objectives of community policing and route optimization, and the impact of these trade-offs on patrol routes and police-community relations. This information could be useful in informing policy decisions and the development of community policing strategies and programs.

In conclusion, the result of addressing the challenge of integrating community policing strategies into route optimization algorithms for police patrols could lead to the development of more effective and efficient police operations that better serve the needs of both police and the communities they serve.

VI. FUTURE SCOPE

One aspect that may not have been fully addressed in previous research on route optimization for police patrols is the integration of community policing strategies. Community policing is a philosophy and strategy of law enforcement that emphasizes the importance of partnerships between police and the communities they serve. In community policing, police officers are encouraged to engage with community members to identify and address public safety concerns, and to work together to find solutions.

Integrating community policing strategies into route optimization algorithms can help to ensure that patrol routes are aligned with the priorities and concerns of local communities. For example, algorithms could be designed to prioritize patrol in areas identified as high-risk or to allocate resources to communities that have expressed specific public safety concerns.

Additionally, integrating community policing strategies into route optimization algorithms could also help to improve police-community relations by demonstrating a commitment to community engagement and ensuring that police resources are being used to address the concerns of local communities.

In conclusion, the integration of community policing strategies into route optimization algorithms for police patrols is an aspect that has not been fully addressed in previous research, and presents an opportunity for further exploration. By taking into account the perspectives and priorities of local communities, it may be possible to develop more effective and efficient patrol operations that better serve the needs of both police and the communities they serve.

VII. CONCLUSION

In conclusion, route optimization for police patrols is a complex and challenging problem that requires a multi-disciplinary approach to effectively balance the conflicting objectives of maximizing coverage, reducing response times, and minimizing travel distances. Over the years, researchers have developed a range of algorithms and methodologies for route optimization for police patrols, but the integration of community policing strategies has not been fully addressed.

Integrating community policing strategies into route optimization algorithms can help to ensure that patrol routes are aligned with the priorities and concerns of local communities, and can improve police-community relations. The result of such research could lead to the development of algorithms that effectively balance the objectives of community policing and route optimization, and to the development of more effective and efficient police operations that better serve the needs of both police and the communities they serve.

Overall, route optimization for police patrols is an important area of research with the potential to inform policy decisions and improve public safety. By continuing to explore and address the challenges of route optimization for police patrols, researchers and practitioners can help to ensure that police resources are being used in the most effective and efficient manner possible.

Sarcasm Detection

Riti Moradiya, Krishna Desai, Rohit Gupta
Thakur College of Engineering and Technology Mumbai, India
ritimoradiya1102@gmail.com,desaikrishna322@gmail.com, rohitgupta9769@gmail.com

Abstract— **Sarcasm identification is one of the difficult tasks for the opinion mining assignment, and we want to review it in this work. We want to discuss sarcasm identification in this work because it is one of the challenging jobs for the opinion mining assignment. Many researchers have made an effort to explore the sarcasm's different properties in order to accomplish this, including its theories, syntactical traits, psycholingsssuistic traits, lexical features, semantic properties, etc. Semantic features and machine learning-based analysis techniques have both advanced as a result of research over the past 15 years. The most popular technique for sarcasm detection will be covered in this article. In light of our findings, we will offer a conclusion that could help other researchers produce more useful findings in the**

Keywords—opinion mining, sarcasm detection, syntactics, lexicon, psycholinguistic, semantic, machine learning

I. INTRODUCTION

Sentiment analysis is a method used in natural language processing (NLP) to ascertain the emotional undertone of a

document. It is often referred to as opinion mining. Organizations frequently utilise this technique to find and collect thoughts on a certain product, service, or idea. With the aid of data mining, machine learning, and artificial intelligence, text is mined for sentiment and subjective information (AI).

Systems for sentiment analysis help organisations extract information from unstructured, disorganised language included in online sources such as emails, blog posts, support tickets, web chats, social media channels, forums, and comments. To replace manual data processing, algorithms use rule-based, automatic, or hybrid procedures. Rule-based systems do sentiment analysis using predetermined, lexiconbased rules, whereas automatic systems employ machine learning to learn from data. A hybrid sentiment analysis is the result of combining the two techniques.

Sarcasm identification, a particular application of sentiment analysis where the emphasis is on sarcasm rather than detecting a sentiment throughout the entire spectrum, is a somewhat specialised area of NLP research. To ascertain if a specific text is satirical or not is the aim of this area.

Microblogging websites are the main platforms for expressing one's ideas, thoughts, and opinions on a range of topics and events. Sarcasm is a sophisticated form of irony that is widely utilised on social media and microblogging websites since they frequently encourage trolling and/or the criticism of others.

Twitter is one of the most well-known platforms for users to express their thoughts, discuss their perspectives, and report events in real time. Twitter has significantly increased its content over the past few years, making it a prime example of what is commonly referred to as big data. According to its official website, Twitter now boasts more than 288 million active users and receives more than 500 million tweets every day. Numerous organisations and corporations are curious about the public's impressions of current events, well-liked products, and films in light of these figures.

However, it might be challenging to grasp user sentiments and do such analysis due to the casual language used on Twitter and the character constraint (140 characters per tweet).

In the online Oxford dictionary, sarcasm is defined as "the use of irony to make or transmit contempt." The Collins dictionary defines it as "mocking, contemptuous, or sarcastic language designed to communicate scorn or abuse." The deeper concept of sarcasm, on the other hand, is directly related to language and common knowledge.

Although sarcasm varies in strength from person to person, it is typically very common and difficult to detect. Sarcasm is frequently used in daily life to criticise ideas, individuals, or events in addition to making jokes and being funny. It thus regularly occurs on social media sites, especially on microblogging services like Twitter.

II. LITERATURE SURVEY

Recent publications have focused on the categorization of tweets as researchers have become more interested in Twitter sentiment analysis. However, many classification techniques and qualities are used depending on the objective. Sriram et al. employed non-contextual criteria, such as the presence of slang, time-event words, opinionated expressions, and Twitter user information, to classify tweets into a pre-defined set of generic classes, such as events, opinions, deals, and private conversations.

The majority of studies, however, focused on the content of tweets and attempted to classify tweets according to the users' sentiments about specific problems. There were several recommended features. They also contain non-textual components like slang and emoticons, which are keyboard symbols that simulate facial emotions like a smile or frown and are generally used to reflect the writer's attitude, emotion, or intended tone. They go beyond just the frequency and presence of adjectives, bigrams, and unigrams. According to context and grammatical structure, Dong et al. suggested a target-

dependent categorization framework that learns to spread the sentiments of words towards the target.

Many more such researchers like Burfoot and Baldwin, Campbell and Katz, Davidov et al. and Tsur et al., etc., proposed their theories and their works can be classified into 3 categories which are:

Code	Classification	Description
S	Study purpose	Studies focusing on sarcasm detection
P	Platform	Twitter platform
C	Class labeling	The labeling mechanism of the target features (i.e., class) such as polarity
M	Machine learning algorithm	The type of machine learning algorithm used (supervised or unsupervised or semi-supervised)
E	Evaluation metrics	The utilized metrics to evaluate the performance of the classifier
L	Language	The language of the study and the data were in English

i. Rule-based approach

ii. Semi-supervised approach

iii. Supervised approach

III. . PROPOSED WORK

Following are the characteristics of the project which are mainly focused in this paper.

We extract a collection of features, consult a training set, and utilise machine learning algorithms to do the classification in order to determine if a tweet is sarcastic or not. Several tweet components are used in the algorithm used to extract the features, which also takes into account different subgenres of sarcasm. Our research uses a set of tweets that have been manually inspected and annotated

A. Data

For a few months, tweets with the hashtag "#sarcasm" were collected using Twitter's streaming API, and they were then divided into three sets. The first batch, often known as the "training set," is checked and categorised manually by individuals. The second batch has a lot of noise because it is not manually verified. However, by deleting non-English tweets and tweets with URLs, some noise is eliminated. The term "optimization set" is used to describe this set. Third set is carefully examined and designated as "test set." Each of the three groups contains a mixture of sarcastic and nonsarcastic tweets

B. Tools

To complete the numerous Natural Language Processing (NLP) tasks, we employed Apache Open NLP (such as tokenization, lemmatization, etc.). Due to the irrelevant content and the use of slangs, etc., Open NLP PoS tagger does not perform well when used with the provided model to tag tweets, thus we used Gate Twitter part-of-speech tagger instead. This PoS-tagger gets a 90.5% accuracy rate when used with Twitter data To perform the classification, we used the toolkit weka which presents a variety of classifiers. We used libsvm to perform the classification using Support Vector Machine (SVM).

C. Features Extraction

While annotating the data, the annotators concluded that these purposes fall mostly, but not totally, in three categories: sarcasm as wit, sarcasm as whimper and sarcasm as avoidance.

exclamation and question marks, as well as some sarcasm-related emoticons

• Sarcasm as whimper: when used as whimper, sarcasm is employed to show how annoyed or angry the person is. Therefore, it tempts to show how bad the situation is by using exaggeration or by employing very positive expressions to describe a negative situation.

• Sarcasm as wit: when used as a wit, sarcasm is used with the purpose of being funny; the person employs some special forms of speeches, tends to exaggerate, or uses a tone that is different from that when he talks usually to make it easy to recognize. In social networks, voice tones are converted into special forms of writing: use of capital letter words

• Sarcasm as evasion: it refers to the situation when the person wants to avoid giving a clear answer, thus, makes use of sarcasm. In this case, the person employs complicated sentences, uncommon words and some unusual expressions

Other main features that are extracted from the tweets are lexical features, Part-Of-Speech taggers, synonyms, sentiment-related features, punctuation-related features, syntactic and semantic features, pattern features and pragmatic features

i. Lexical feature

The most typical feature type in text mining is lexical features. The distinctive words, phrases, noun phrases, or named entities that are connected to a score to reveal its level of polarity are known as lexical characteristics. It may be possible to gauge the text's emotional intensity by using these qualities for emotion-mining (Yadollahi et al., 2017). According to Gonzalez-Ibanez et al. (2011), the lexical features can be divided into unigrams- and dictionary-based features. Dictionary-based features are derived from a dictionary-sampling method that includes four general classes, according to Ghosh et al. (2015) and GonzálezIbanez et al. (2011): (a) linguistic processes (e.g., adverbs and pronouns), (b) psychological processes (e.g., positive and negative emotions), (c) personal concerns (e.g., work and achievement), and (d) spoken categories (e.g., assent and non-fluencies). Additionally, the majority of dictionarybased features are drawn from a list of punctuation and interjections, such as ah, oh, and yes.

These findings show that the lexical features have more distinguishing cues that are connected to user polarity scores. The degree of polarity must therefore be estimated with a high degree of precision utilising a variety of methods. Several methods are typically used in the sarcasm detection task to determine the polarity of words. However, Signhaniya et al. (2015) discovered that the

miningtechnique can perform better when the lexical structure from a dependency tree is used. In conclusion, lexical traits are crucial components for resolving text mining issues. Lexical traits can be utilised to determine a statement's polarity, making it feasible to identify sarcastic tweets

ii. Part-Of-Speech taggers

To categorise words according to their POS forms, POS taggers were created. Due to the following factors, sentiment analysis frequently uses it: (A) Expressions devoid of sentiment typically include nouns and pronouns. With the use of a POS tagger, it may exclude words like these: (b) To identify words that can be used in various POS, a POS tagger can also be utilised. Researchers are using POS tagger to analyse sarcastic tweets because of its benefits. For instance, Ghosh et al(2015) .'s use of POS as a method to describe contextual information for co-training algorithms assisted in the development of a reliable corpus and precise predictions.

Barbieri et al. (2015) employed POS in a different study to incorporate specific elements intended to capture the structure of both positive and negative tweets. As a result, researchers have consistently used POS tagging in statement annotation due to its significant contribution to the categorization challenge. Before beginning the classification process, it is required to apply POS tagging in challenging jobs like sarcasm detection to determine whether the statement can be classified as sardonic or not.

iii. Synonyms

The technique of extracting features that share words with the same meaning is referred to as the extraction of synonyms-related features. This method appears to be effective in sarcasm detection when expressing a particular opinion in various contexts. Barbieri et al. (2015) described the method of selecting synonyms in the sarcasm detection task by collecting the list of synonyms for each word and then calculating (across all the terms of the tweet) the greatest/lowest number of synonyms with frequency higher than the one present in the tweet.

Additionally, they calculated the average number of synonyms for terms with frequencies higher or lower than the one in the tweet, as well as the greatest/lowest number of synonyms for those phrases (gap feature). Along with all the words that include POS features, the collection of synonym features must also be computed. Based on this, the usage of synonyms would improve the classifier's performance by analysing several features that are pertinent to the goal of detecting sarcasm. Synonyms can also improve the training set that will be utilised to train the classifier for the detection task

iv. Sentiment-related feature

This feature identifies and detects sarcasm when a positive statement, usually a verb or a phrasal verb, is collocated with a negative situation (e.g., “I love being ignored all the time”). In our work, we opt for a more straight-forward, yet more general approach. We consider any kind of inconsistency between sentiments of words as well as other components within the tweet. Therefore, to identify and quantify such inconsistency, we extract sentimental components of the tweet and count them. For this purpose, we maintain two lists of words qualified as “positive words” and “negative words”. The two lists contain respectively words that have positive emotional content (e.g., “love”, “happy”, etc.) and negative emotional content (e.g., “hate”, “sad”, etc.). The two lists of words are created using SentiStrength database.

We first calculate the ratio of emotional words ρ(t) defined as

$$\rho(t) = \frac{(\delta \cdot PW + pw) - (\delta \cdot NW + nw)}{(\delta \cdot PW + pw) + (\delta \cdot NW + nw)}$$

In case the tweet does not contain any emotional word, ρ is set to 0. In the rest of this work, δ is set to 3.

v. Punctuation-related feature

As previously said, sarcasm is a sophisticated kind of discourse that uses low tones, exaggeration, and facial gestures in addition to manipulating words and their meanings. When writing a message, these factors translate into certain punctuation choices or vowel repetitions. We extract a group of properties that we categorise as punctuation-related features in order to recognise these elements. For each tweet, we calculate certain values like Number of exclamation marks number of question marks, number of dots number of all-capital words and number of quotes.

We also add a sixth feature by checking if any of the words contains a vowel that is repeated more than twice (e.g., “looooove”). If such a word exists, the feature is set to “true”, otherwise, it is set to “false”. vi. Syntactic and Semantic features

In addition to the punctuation-related elements, sarcasm is frequently expressed using some common idioms. It is possible to determine whether or not something is being stated is sarcastic by comparing these terms with the punctuation. In addition, it's normal for people to use unusual words or construct complex statements while trying to avoid giving the reader or listener a clear answer. This happens frequently when sarcasm is employed as a form of "evasion," or when a person wants to conceal their true feelings or opinions. The use of unusual words, the quantity of uncommon words, the presence of typical sarcastic phrases, the frequency of interjections, and the number of laughing expressions are some features that we extract to portray these qualities

vii. Pattern-related features

In particular, spoken English frequently employs the "popular sarcastic expression" patterns that were selected

in the previous subsection. But in both our training and test sets, they are unusual, limited in number, and absent from the bulk of tweets. We dig deeper and extract a different set of features in light of this. We conceptualised our patternrelated attributes using concepts from Davidov et al. The author grouped terms into two categories: high-frequency words and content words based on how frequently they appeared in his data collection, and described a pattern as a "ordered sequence of high frequency words and slots for content words." viii. Pragmatic features

Pragmatic characteristics are texts that use symbols and metaphors (e.g., smiles and other emoti - cons). Because of the restrictions on tweet length, these characteristics are widely employed in tweets. A strong sign for sarcasm in Twitter is the pragmatic traits. As a result, numerous academics have taken pragmatic aspects and applied them to the classification of sarcasm. On the basis of this, it is clear how crucial it is toextract pragmatic aspects from social media posts. These characteristics are linked to consumers' attitudes towards a particular topic. In order to create a rich lexicon of users' emotions in relation to their opinions, previous studies extracted pragmatic elements from tweets containing sarcasm and linked them with the latent emotion encoded in such tweets

IV. RESULTS AND DISCUSSION

After extracting the features, we performed the experiments and formulated the results based on 3 main parameters:

- Precision: Precision denotes the percentage of sarcastic news reports that were accurately identified among classified posts, messages, and news records. It describes how effectively the suggested methods work. The values for precision can be calculated in the following manner.

$$\text{Precision} = \frac{\mathbf{TP}}{\mathbf{TP+FP}}$$

- Recall: Recall displays the percentage of correctly identified sarcastic postings, news, and messages. The recall is also acknowledged as sensitive. The values of recall can be calculated by the following manner

$$\text{Recall} = \frac{\mathbf{TP}}{\mathbf{TP+FN}}$$

- F-measure: F-measure denotes assessing all performance based on recall and precision measurements. The values of f-measure can be calculated by the following manner

$$\text{F} - \text{Measure} = \frac{\mathbf{2\times pre\times Rcall}}{\mathbf{pre+Rcall}}$$

A. Random Forest Classifier:

It is well known that the Random Forest classifier lessens bias brought on by overfitting and class imbalances between tweets. The method that was used the most frequently to identify sarcastic tweets was the polarity method. This approach was used by Bouazizi and Ohtsuki (2016) to categorise their data as either positive or negative. Later research by Bouazizi and Ohtsuki (2018) classified tweets as positive, negative, or neutral using the polarity method. Previous studies revealed performance ranging from 45.9% to 83.1%.

A. SVM:

Due to its effectiveness in streamlining the sentiment classification process, SVM is the most widely used algorithm for identifying sarcasm on Twitter in the literature (González- Ibanez et al., 2011). The gathered tweets were labelled using a variety of labelling techniques before being sent to the SVM classifier. Sarcasm can be detected, for instance, using the polarity approach, a natural language processing (NLP) application that was used to classify text sentiment. As part of this, it is possible to identify prospective changes in user emotion based on the traits of their tweets.

B. K-nearest neighbor

It is an ML framework with examples. The KNN of each sample is what determines the class label for each instance in this algorithm. As a result, the nearby example uses the concept of majority vote to select the class label. The overall accuracy of k-NN was 81.5% with the precision score of 72.0% and F1 score of 79.6%

C. Maximum Entropy:

Ptáek et al. (2014) employed Maximum Entropy (MaxEnt) to describe sarcasm in two languages (English and Czech). Ptáek et al. (2014) employed the major labels sarcastic and non-sarcastic to carry out the sarcasm detection process. MaxEnt's performance score was 77.4%. The character n-gram, skip-bigram, and pointedness in its structure are responsible for its great performance

Hence, the overall accuracy obtained reaches 83.1% using the classifier Random Forest for an F1-score equal to 81.3%. SVM, on the other hand, offers a low F1-score of 33.8% for a precision of 98.1%. This confirms that the majority of the tweets that were identified as being sarcastic actually are. Only a tiny fraction of the caustic tweets (almost

20%) were found, though. In other words, SVM can accurately recognise sarcasm and the result can be used to improve sentiment analysis, but it does not capture all sarcastic tweets.

Because there are significantly less sarcastic tweets in a real stream of tweets than there were in the dataset used, the results reveal that just one out of every five sarcastic tweets will be found. Random Forest performs the best, even when classifiers like k-NN and Maximum Entropy

show high accuracy and F1-scores. Both the preliminary experiments (i.e., parameter optimization) and the remainder of our inquiry use the classifier Random Forest's results

TABLE I. ACCURACY, PRECISION, RECALL AND F1-SCORE OF CLASSIFICATION USING DIFFERENT CLASSIFIERS

	Overall Acc.	Precision	Recall	F1-Sc
Rand. Forest	83.1%	91.1%	73.4%	81.3
SVM	60.0%	98.1%	20.4%	33.8
k-NN	81.5%	88.9%	72.0%	79.6
Max. Ent.	77.4%	84.6%	67.0%	74.8

V. CONCLUSION

Irony with a sophisticated twist, sarcasm, was widely used on the Twitter platform. Identifying sarcastic tweets is crucial for text classification and has numerous ramifications. In order to classify the sarcastic tweets in Twitter, this study examined a number of machine learning techniques. In this case, sarcasm detection on Twitter was performed using classification methods, and the PRISMA statement was used to provide a detailed guideline of the preferred reporting style.

31 papers were included after a thorough database search that was divided into the AMLA and CMLA groups. Our findings demonstrated that the SVM algorithm was the AMLA group's preferred technique for identifying sarcasm on the Twitter network. Additionally, it was discovered that CNN and SVM had a high prediction performance. Different text processing and categorization features, however, were used by other CMLAs. CMLAs' design parameters could vary, which led to various performance outcomes.

SVM and CNN-SVM were the most effective machine learning algorithms for predicting sarcasm on Twitter, according to the classification findings. The effectiveness of lexical, pragmatic, frequency, and POS tagging in enhancing SVM performance was also demonstrated by our findings. Using CNN-SVM, we also discovered that the primary predictors of sarcasm were both lexical and personal variables. These findings support the use of specific lexical, pragmatic, frequency, POS tagging, and personal factors in the identification of sarcasm on microblogs.

Additionally, this study advises using two target labels to identify sarcastic tweets. Such a labelling technique (such as negative/positive or sarcastic/non-sarcastic) could greatly aid the machine learning algorithm's learning process and hence improve the classification task. The published research on sarcasm recognition in the context of the Twitter platform, however, was the only restriction on the current study.

Additionally, we disregarded research that concentrated on irony identification because sarcasm is one sort of irony. Additionally, this review omitted talking about essential algorithmic aspects like the kernel type as well as data-related problems like the quantity of words used and the features of the normalized instances technique. Future research may take into account the potential impact that such factors may have on how well AMLAs and CMLAs perform in terms of detecting sarcasm on the Twitter platform

VI. ACKNOWLEDGMENT

The research results have been achieved by

“Cognitive Security: A New Approach to Securing Future

Large Scale and Distributed Mobile Applications,” the Commissioned Research of National Institute of Information and Communications Technology, Japan

We suggest that you use a text box to insert a graphic (which is ideally a 300 dpi TIFF or EPS file, with all fonts embedded) because, in an MSW document, this method is somewhat more stable than directly inserting a picture.

To have non-visible rules on your frame, use the

MSWord “Format” pull-down menu, select Text Box > Colors and Lines to choose No Fill and No Line.

Food Grains Distribution Sytem Using Machine Learning and Data Analysis

Sunil Gupta, Nikit Gupta, Ankit Mishra
Thakur Collage Of Engineering and
Technology Mumbai ,India
sunilgupta48@gmail.com, nikitg200@gmail.com, ankitm8421@gmail.com

Abstract— **In India a lot of people have low wages due to which for their food needs they are mostly dependent on government rations. Most of the Ration Distributors take advantage of the current loop holes in this scenario which results in increasing pockets of distributors and lowering the rations of needy people. In this scenario we're using latest technologies such as machine learning by which we aimed to make this system more flexible and more transparent as well as reduce the current corrupt loopholes. The proposed system.**

Keywords— Food, Distribution, Public, Grains

I. INTRODUCTION

The Ration Distribution System in India is a government initiative aimed at providing food grains like wheat, rice, sugar, and kerosene to those who cannot afford high-cost food options. The system is currently run manually and has several shortcomings that need to be addressed. One of the major problems with the manual process is the potential for corruption, where shopkeepers may sell the rationed food at higher prices or not provide enough to customers. Another problem is the manual process itself, which can be time- consuming and prone to inaccuracies in measuring the amount of food provided. To overcome these problems, a proposal has been made to automate the Ration Distribution System using machine learning algorithms. Automating the process would not only make it more efficient, but it would also reduce the potential for human error and control corruption. For instance, customers could be given a password to access information about their ration allocation, including the number of people it is intended for, the amount that will be provided, and the distribution schedule. This would create a more transparent and accountable system, reducing the potential for corruption and improving the distribution of food to those in need. The proposed solution would also address another issue with the manual process, which is that people are often not aware of the availability of ration in their local shops.

With the automated system, customers would have access to up-to-date information about the availability of ration and the distribution schedule, reducing the need for them to travel long distances to obtain their food. This would not only save time, but it would also increase access to food for those in remote areas.

In addition to improving the distribution of food to those in need, the automated Ration Distribution System would also benefit the government by providing a more efficient and cost-effective process. By reducing manual labor and increasing the accuracy of the process, the government could save money and allocate those resources to other areas that need it. Furthermore, the government could use the data collected by the automated system to better understand the needs of those who rely on the Ration Distribution System, allowing them to make informed decisions about how to improve the program in the future.

In conclusion, the proposed use of machine learning to automate the Ration Distribution System in India has the potential to make a significant impact on the lives of those who rely on the program for their food. By reducing corruption and improving the efficiency of the process, the government could ensure that more people have access to the food they need to survive. Additionally, automating the system would benefit the government by providing a more cost-effective and data-driven approach to distributing food to those in need.

II. LITERATURE SURVEY

A literature survey of recent research on the use of machine learning (ML) and databases, including face recognition technology, for proper ration distribution systems reveals a growing interest in using these technologies to improve the efficiency and accuracy of food distribution programs.

One application of face recognition in ration distribution systems is to verify the identities of individuals who are receiving food rations. This helps to prevent fraud and ensure that only eligible individuals receive food. For example, some programs use face recognition technology to compare the face of an individual receiving food with a database of eligible recipients, thereby reducing the risk of fraudulent or unauthorized distributions. In addition to face recognition, ML algorithms are being used to analyze food distribution data to make predictions about food distribution needs. For instance, researchers have used ML to predict food demand in disaster relief efforts by analyzing data on population demographics, weather patterns, and the availability of food and other resources.

Databases also play a crucial role in proper ration distribution systems. For example, some programs use databases to store information on food inventory, distribution routes, and delivery schedules. This information can be used to optimize food distribution by reducing waste and ensuring that food is delivered to areas with the greatest need. However, there are also challenges that must be addressed when using ML and databases, including face recognition technology, for proper ration distribution. One challenge is ensuring the privacy and security of personal information, as the use of databases and face recognition technology can raise concerns about data protection and the misuse of personal information.

Another challenge is the accuracy and reliability of face recognition technology, as the technology is not always able to accurately identify individuals, particularly those from marginalized communities who may be underrepresented in the data used to train the technology.

The Public Distribution System (PDS) is a government-run food security system in India that aims to provide food grains and other essential commodities to the economically weaker sections of the population at subsidised prices.

The literature regarding the PDS in India can be broadly categorised into three types: evaluations of the effectiveness of the PDS in meeting its goals, analyses of the underlying causes of its inefficiencies, and studies on the impact of PDS reforms. Studies have shown that the PDS has had limited success in meeting its goals of providing food security to the needy. Leakages and diversions in the supply chain, coupled with poor targeting of beneficiaries, have resulted in a significant proportion of the subsidised food grains not reaching the intended recipients. Some of the factors contributing to these inefficiencies include corruption, weak implementation, and lack of transparency in the system.

Reforms to the PDS, such as the introduction of the targeted public distribution system (TPDS) and the use of digital technologies, have shown some promise in improving the effectiveness of the system. For example, the use of digitisation has been found to reduce corruption and increase transparency in the supply chain. However, the implementation of these reforms has been uneven across states, and their impact on the overall functioning of the PDS is still being studied.

In conclusion, the literature suggests that the PDS has had limited success in meeting its goals of providing food security to the economically weaker sections of the population in India. The underlying causes of its inefficiencies are multi-faceted and include corruption, weak implementation, and lack of transparency in the system. Reforms to the PDS, including the use of digital technologies, have shown some promise but their impact on the overall functioning of the system is still being studied.

The use of ML, databases, and face recognition technology has the potential to improve the efficiency and accuracy of proper ration distribution systems. However, it is important to address the challenges associated with these technologies, such as privacy and security concerns, and ensure that food distribution systems are transparent, accountable, and equitable for all individuals in need.

III. WORKING STRUCTURE:

A proper ration distribution system using machine learning (ML) and databases, including face recognition technology, can be structured as follows:

1. Data Collection: The first step in building a proper ration distribution system is to gather and store data on food inventory, distribution routes, and delivery schedules. This data can be used to make predictions about food distribution needs and to optimize food distribution.

2. Data Analysis: Once the data has been collected, it can be analyzed using ML algorithms, such as neural networks, decision trees, and support vector machines, to identify patterns and make predictions about food distribution needs.

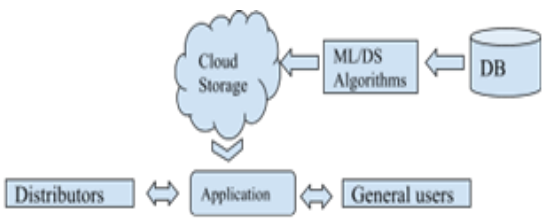
3. Face Recognition: To verify the identities of individuals who are receiving food rations, face recognition technology can be used to compare the face of an individual with a database of eligible recipients. This helps to prevent fraud and ensure that only eligible individuals receive food.

4. Optimization: Using the information generated from the data analysis and face recognition, the system can optimize food distribution by reducing waste and ensuring that food is delivered to areas with the greatest need.

5. Monitoring and Evaluation: The system should also include mechanisms for monitoring and evaluating its performance, including monitoring food inventory levels, distribution routes, and delivery schedules. This information can be used to make improvements to the system and ensure that it is functioning effectively.

6. Privacy and Security: To ensure the privacy and security of personal information, the system

A. Flowchart of process:



should include measures to protect the data, such as encryption and secure storage, and to prevent the misuse of personal information.

In conclusion, a proper ration distribution system using ML and databases, including face recognition technology, can be structured as a multi-step process that includes data collection and analysis, face recognition, optimization, monitoring and evaluation, and privacy and security measures. By implementing these steps, the system can improve the efficiency and accuracy of food distribution programs and ensure that food is distributed equitably to all individuals in need.

IV. PROBLEM STATEMENT

The problem with the current public distribution system (PDS) in India is that it lacks transparency in the distribution of food grains and other essential commodities to the economically weaker sections of the population. This leads to a number of challenges and issues, including:

1. Leakages and diversions in the supply chain, resulting in a significant proportion of subsidised food grains not reaching the intended recipients.
2. Corruption and mismanagement, which undermines the effectiveness of the system and results in a waste of public resources.
3. Poor targeting of beneficiaries, leading to subsidies being availed by those who are not in need.
4. Lack of accountability and transparency in the supply chain, making it difficult to monitor and improve the functioning of the system.
5. Inefficient distribution and storage systems, which result in food grains being wasted or being of poor quality.

V. FUTURE SCOPE:

The use of machine learning (ML) and databases, including face recognition technology, for proper ration distribution systems has significant potential for further development and growth in the future.

Here are a few possible future directions:

1. Improved Face Recognition Technology: As face recognition technology continues to improve, it is likely that it will become more accurate and reliable for use in ration distribution systems. This will enable the technology to better identify individuals and prevent fraud and unauthorized distributions.
2. Integration with Other Technologies: The integration of ML and databases, including face recognition technology, with other technologies, such as block chain and the Internet of Things (IoT), has the potential to further improve the efficiency and accuracy of ration distribution systems. For example, blockchain can provide a secure and decentralized database for storing food distribution information, and IoT devices can be used to track food inventory levels and delivery schedules in real-time.
3. Personalized Recommendations: ML algorithms can be used to provide personalized recommendations to individuals on their food needs and preferences. For example, by analyzing data on individual dietary restrictions, food preferences, and health conditions, the system could provide recommendations for food items that are most appropriate for each individual.
4. Predictive Maintenance: ML algorithms can be used to predict when food items are likely to run out and to schedule preventive maintenance for food storage and distribution equipment. This will help to reduce food waste and ensure that food is always available when it is needed.
5. Social Impact Analysis: ML algorithms can be used to analyze the social impact of food distribution programs and to make recommendations for improving the equitable distribution of food. For example, by analyzing data on food distribution patterns and socioeconomic indicators, the system could identify areas where food distribution programs are having the greatest impact and areas where additional resources are needed.

VI. CONCLUSION:

In conclusion, the use of machine learning (ML) and databases, including face recognition technology, for proper ration distribution systems has the potential to greatly improve the efficiency and accuracy of food distribution programs. By utilizing these technologies, it is possible to identify individuals accurately and prevent fraud and unauthorized distributions. Additionally, by integrating these technologies with other systems, such as blockchain and the Internet of Things (IoT), it is possible to create a more secure, efficient, and equitable food distribution system. Furthermore, ML algorithms can be used to provide personalized recommendations, predictive maintenance, and social impact analysis, which can further improve the distribution of food. Overall, the use of ML and databases, including face recognition technology, for proper ration distribution systems holds great promise for the future and has the potential to greatly benefit those in need of food assistance.

VII. ACKNOWLEDGMENT

We would like to express my special thanks of gratitude to our guide Mr. Namdeo Badhe, who gave us the opportunity to do this wonderful research work on the topic fertilizer

sssalgorithms which also helped me in doing lots of research and i came to know many things i am really thankful to himand even my friends

Sentiment Analysis for Code-Mixed Languages using Deep Learning

Preet Desai, Somil Doshi, Ronak Dhakad
Thakur College of Engineering and Technology Mumbai, India
desaipreetfore.ever@gmail.com , somil12doshi@gmail.com, dhakadronak9967@gmail.com

Abstract—**This paper presents a deep learning approach for Sentiment Analysis in Code-Mixed language, which combines two or more languages in a single sentence, making it a challenging task. A dataset of Code-Mixed language tweets was collected from Twitter and used to train a deep learning model. The model was evaluated using metrics such as accuracy, F1 score, precision, and recall, and the results showed that it outperformed existing methods for Sentiment Analysis in Code-Mixed language. The study also presents a unique contrastive learning-based method, known as Sentiment Analysis of Code-Mixed Text (SACMT), that categorizes sentences into positive, negative, or neutral connotations by mapping the sentences of code-mixed and standard languages to a single sentiment space using shared parameters of Siamese networks. Additionally, a clustering-based preprocessing technique is offered to identify word variants using code-mixed transliteration. The difficulties encountered in this task and potential future directions for improvement are also discussed.**

Keywords—Sentiment Analysis, Siamese Networks, Code-Mixed Text

I. INTRODUCTION

Social media platforms have become widely popular in multilingual societies with a substantial internet penetration rate. This has led to an increase in the use of code-mixed text, which is a combination of two or more languages in a single sentence. The use of code-mixed text is especially prevalent in social media, where people express their thoughts, opinions, and feelings about various subjects. This makes sentiment analysis of code-mixed data from social media platforms an important area of research. However, sentiment analysis of code-mixed text is a challenging task due to the unique structures and vocabularies that develop from the mixing of different languages. Standard approaches to semantic analysis are not equipped to capture the meaning of code-mixed sentences, making sentiment analysis even more difficult. The lack of annotated data for sentiment analysis is another hindrance to the development of this field. To address these challenges, a new approach called SACMT (Shared Attention Code-Mixed Text) has been proposed. This approach involves reducing the energy function connecting twin networks, which allows SACMT to learn the shared model parameters and the similarity measure.

The sentiment similarity of sentences is modeled into a shared sentiment space by the learned similarity metric. If the sentiment of phrases on both individual Bi-LSTM networks is the same, parameter sharing, and the Similarity Metric ensure that they are closer to each other in the sentiment space. On the other hand, if the sentiments are different, the networks are farther apart. This allows SACMT to effectively differentiate between phrases with similar sentiments, such as "India match jit gayi (India won the match)" and "Diwali ke shubh kamnaye sabko (Happy Diwali to everyone)," and phrases with different sentiments, such as "India match jit gayi (India won the match)" and "Bhai ki movie flop gayi (Bhai's movie was a fiasco)." Another challenge in sentiment analysis of codemixed text is the multiple spellings of the same word that are produced when phonetic languages like Hindi are transliterated into roman script. For example, the word "" (more) can be written as bahut, bohot, or bohut. To overcome this difficulty, SACMT implements a preprocessing phase that groups together various word variations using an empirical similarity measure. In conclusion, the remainder of the essay will provide a comprehensive overview of the field of sentiment analysis of code-mixed text, including a discussion of prior methods, datasets, SACMT's architecture, baselines, experimental design, findings, and future directions.

II. LITERATURE SURVEY

The distributional semantics technique is a method of capturing the meaning of words by analyzing the context in which they appear. While this approach is effective in determining the semantic meaning of individual words, it lacks the ability to capture the information about the order of words in a sentence. This means that it cannot accurately understand the relationships between words and their meanings within a sentence, which can lead to inaccurate sentiment analysis.

In addition to this limitation, the approach also assumes that words are unchangeable and cannot handle spelling mistakes or words that are not present in the lexicon. This can result in a failure to correctly classify a word's sentiment, even if the word itself is well understood

To address these limitations, the technique of using polarity scores for individual words has been developed. The sentiment of the entire sentence is determined by summing the sentiment scores of all individual words. However, this approach still suffers from the loss of information about the words' order and relationship, which can result in inaccurate classification.

One way to overcome this limitation is by using Ngrams, which consider the context of a word by looking at the words surrounding it. However, this approach is not a

complete cure and still may not accurately capture the meaning of a sentence.

Another related technique used in this field is Siamese Networks. Siamese Networks are a type of neural network that aid in the contrastive learning of a similarity metric. This type of network was developed to address the issue of signature verification, but has since been adapted for use in other fields, including sentiment analysis. The key advantage of Siamese Networks is that they do not rely heavily on the attributes of the input, allowing them to be more flexible and generalizable.

It is important to note that abbreviations and acronyms can present challenges in sentiment analysis, as they often carry a different sentiment than the full form of the word. Siamese Networks and character level LSTMs can help to overcome this challenge by analyzing the text at the subword level, which can provide a more detailed understanding of the text, including abbreviations and acronyms.

A. Research, character level LSTMs are used to analyze social media text at the subword level, which allows for a more in-depth analysis of the text. This approach utilizes an annotated corpus to gather information about the text, which is then used to classify the sentences. The use of character level LSTMs also offers a useful strategy for embedding sentences, which is an important aspect of sentiment analysis.

The discriminative loss function architecture is a type of architecture used in computer vision tasks, such as face verification. This architecture has proven to be effective in raising the standard of visual search. In recent years, Siamese networks have also been used to address the issue of community question answering. A Siamese network is a type of neural network that seeks to find a value for a parameter W, such that the similarity metric between two inputs X1 and X2 is small if they are members of the same category and large if they are members of different categories. This is achieved by representing the relationship between the inputs as a scalar energy function S(C, R), which can be written as ||F(C)F(R)||. Here, F(X) represents the family of functions with parameters X, and || represents the Euclidean distance between the inputs.

In the context of sentiment analysis, the scalar energy function can be used to represent the sentimentrelatedness between tweets written in code-mixed text (C) and resource-rich language (R). This allows the Siamese network to determine the similarity of sentiments between the two inputs and provide a score that reflects the sentiment-relatedness of the tweets. The Siamese network is differentiable with respect to the parameter W, which allows for the use of gradientbased optimization algorithms to find the optimal value of W.

III. METHODOLOGY

The dataset used in this study is crucial in evaluating the architecture on code-mixed (Hindi-English) data as well as text from social media in a standard language (English). A total of 3879 annotated Hindi-English code-mixed utterances make up the dataset, which was proposed in an earlier study. The annotations provide valuable insights into the complexity of code-mixed data and the difficulties that arise in processing this type of data. Additionally, the study used 103035 annotated English tweets, which were collected from social media platforms. These annotated tweets provide a comprehensive understanding of the challenges faced in processing text from social media in a standard language.

The study also used the dataset for Task 2B1 of SemEval 2013, which is made up of the Architecture of SACMT. The use of this dataset helps to evaluate the performance of the architecture on a widely used benchmark in the field of sentiment analysis. The SemEval 2013 dataset provides a comprehensive evaluation of the ability of the architecture to handle sentiment analysis tasks in a real-world setting.

Overall, the use of these datasets provides a

comprehensive evaluation of the architecture on a wide range of data types, including code-mixed data, standard language text from social media, and a widely used benchmark in sentiment analysis. The results of the study will provide valuable insights into the strengths and limitations of the architecture in processing different types of data and its potential for future applications in the field of natural language processing.

A siamese network is employed in this study, where a completely connected layer is placed on top of the network, utilizing twin character-level Bi-LSTM networks. The sentences are projected into a common sentiment space using bi-LSTMs, which allows the linking of sentiment vectors produced by the two subnetworks. This sentiment space is then fed into a layer that computes the similarity between the two sentiment vectors. This similarity measurement, combined with the corresponding label, is then utilized in the contrastive loss function. The gradient of the loss function is computed with respect to the weights and biases shared by the sub-networks through backpropagation across time.

One of the challenges in handling code-mixed word variations is transliteration from languages with phonetic scripts, such as Hindi. This can lead to variations in words depending on the user. To solve this issue, the study utilizes clustering of skip-gram vectors, which provides a representation of a word in the semantic space based on its context. The word variations, which have similar functions and contexts, are then clustered based on a similarity metric that captures both the semantic and consonant properties of the words. The similarity metric is defined as a function that compares the overall similarity between two variations and returns the closest word variations. The most frequent word in the cluster is

then selected as the representative of the cluster, based on the assumption that the most frequent word is also the most likely to be the correct one.

The use of primary embeddings in sentiment analysis of code-mixed text has proven to be effective in overcoming challenges posed by the informal nature of such text. This is because code-mixed text often contains spelling mistakes and vocabulary word shortages, which can impact the sentiment expressed in the text. For example, the word "Heeey" might express a positive emotion, while the word "Hey" might be neutral. To address this, the authors suggest treating character trigrams as units instead of words, as there are more words than character trigrams. This reduces the computational complexity of the analysis.

The authors use the SACMT twin networks, which are fed with two character-based term vectors representing the tweet and a label. The label indicates the sentiment space proximity of the samples, where positive samples are closer in the sentiment space. By providing the twin networks with the same information for positive samples, the authors aim to improve the accuracy of sentiment analysis.

The use of primary embeddings in the form of character trigrams helps overcome challenges posed by the informal nature of code-mixed text and enables more accurate sentiment analysis. The authors recommend using the SACMT twin networks for this purpose. Additionally, for science writers, the authors suggest consulting an excellent style manual, such as [7].

IV. METHODS

A. Once the editing of the text is finished, the next step is to prepare the paper for formatting. To do this, the author should duplicate the template file by using the "Save As" command and rename the file according to the naming convention prescribed by the conference. In the newly created file, the author should select all of the contents and import the edited text file.

The final step is to style the paper. The author should use the formatting toolbar on the left side of the MS Word window to apply the desired format and styling to the text. The scroll down window on the left of the MS Word Formatting toolbar provides access to various formatting options, such as font size, font style, and text alignment. By using these tools, the author can create a well-designed and visually appealing paper that meets the requirements of the conference.

A classification exercise is being carried out with the focus on Hindi-English CodeMixed (HECM) sentences. To perform the classification, the HECM sentences are aligned with English sentences from Twitter datasets that have the same mood, which are designated as positive samples and assigned the number 1. Furthermore, an equal number of English sentences with different moods, which are designated as negative samples, are randomly selected and assigned the number -1.

The purpose of this exercise is to examine the benefits of training the model, SACMT(HE-Eng), with both Hindi-English CodeMixed and English phrases. The objective is to evaluate the effectiveness of using this model for the classification of HECM sentences, and to determine whether the performance of the model can be improved by training it with a combination of HECM and English sentences. The results of this study will provide insight into the impact of language mix on the performance of machine learning models, and help in developing better methods for handling code-mixed text.

The aim of this study is to evaluate the performance of a sentiment analysis model, SACMT(HE-Eng), when trained using both Hindi-English CodeMixed (HECM) sentences and English phrases. By including HECM sentences in the training data, we aim to improve the model's ability to accurately classify the sentiment of HECM statements. The experiment will provide insight into whether incorporating HECM sentences into the training data can improve the overall performance of the sentiment analysis model for code-mixed text.

V. FUTURE SCOPE

Expanding the scope of the study to cover multiple language pairs in code-mixed text, including multilingual code-mixed text. Incorporating other deep learning techniques, such as attention-based models, to enhance the performance of the sentiment analysis system. Evaluating the system on code-mixed data from other domains, such as customer reviews and product descriptions. Investigating the performance of the system in cross-lingual sentiment analysis, where the code-mixed text is translated into a resource-rich language before analysis. Developing methods to improve the interpretability of the system, such as visualizing the sentiment space and the similarity metrics used in the system. Incorporating the system into real-world applications, such as sentiment analysis of customer feedback and opinion mining of social media data. Investigating the generalization capability of the system to unseen code-mixed text and new variations in the code-mixed language. Using transfer learning techniques to fine-tune the system on a specific domain or language pair to improve its performance. Overall, the future scope for this research paper is to continue improving the performance and versatility of the system for sentiment analysis of code-mixed text and to expand its application in various domains and languages.

VI. CONCLUSION

In this study, we aim to tackle the issue of sentiment analysis for code-mixed text by proposing a new method called SACMT (Sentiment Analysis for Code-Mixed Text). SACMT takes advantage of the power of bidirectional LSTM networks, which are deep learning models that are capable of capturing the context of words

in a sentence. In our method, we use twin bidirectional LSTM networks with shared parameters to project the sentences into a shared sentiment space. This sentiment-based representation is then used to group together sentences with similar sentiment and measure their similarity.

We evaluated SACMT on several datasets and compared its performance with other state-of-the-art techniques. The results showed that SACMT outperforms these techniques and provides a noticeable improvement in sentiment analysis for code-mixed text. In addition to using bidirectional LSTMs, SACMT also makes use of resources from various languages to enhance sentiment analysis. This is achieved by incorporating an emoji-based strategy, which improves the performance of the overall sentiment analysis. The management of word variants was also found to be effective in enhancing the performance of all trained models, including the baseline models. SACMT is a novel approach to sentiment analysis for code-mixed text and provides a promising solution to this challenging problem. Our method can be easily applied to different domains and languages, making it a valuable tool for researchers and practitioners alike. Future work will focus on exploring additional strategies to improve the performance of SACMT and extending its application to other areas of natural language processing.

Sentiment analysis for code-mixed languages is a

rapidly growing field that utilizes deep learning techniques such as Bidirectional LSTMs and siamese networks to project sentences into a shared sentiment space. The use of these models and techniques has shown to significantly improve the accuracy of sentiment analysis for code-mixed text. Utilizing resources from multiple languages and managing word variants have also been found to further improve the performance of these models

Clinical Decision Support System

Riya Agrawal, Riya Gour, Aanchal Pandey
Information Technology Thakur college of Engineerring and Technology Mumbai,India

Abstract— **In this chapter, we are presenting theoretical background, proposed machine learning tools and modern research trends required for Clinical decision support system. A two-layer knowledge base paradigm (disease-symptom) of rule reasoning is frequently used in clinical decision support systems. Since it just assumes that a disease exists based on the presence of specific symptoms, this model frequently does not effectively represent information. In order to leverage more helpful information in inference, we suggest a three-layer knowledge base model (disease-symptom-property) in this study. Based on a multisymptom naive Bayes algorithm, the system iteratively predicts the likelihood that a patient will have a disease. The specificity of these illness symptoms is weighted by the estimated degree to which they contribute to the diagnosis of the condition. To better implement the naive Bayes algorithm, the dependencies between attributes are greatly reduced. The inference engine's parameter optimization stage of the online learning process was then completed. Our technology can give clinicians useful clinical suggestions by comparing prediction findings with clinical outcomes. Additionally, we discovered that the three-layer model can increase prediction accuracy in comparison to the two-layer model.**

Keywords— Clinical decision support system, three layer model, naïve

I. INTRODUCTION

There is a upward trend in the AI research to patient care, clinical decisions and healthcare. ML and DL research has significantly helped in dermatology, oncology and radiology. The most common specialty represented in the review was oncology. Similar to cardiology, AI and ML research in oncology has shown good prediction performances over the years. Currently, most organisations are aiming to use machine learning for mundane CDS tasks for now. It is the workflow and administrative kinds of models- the ones that help with things like patient scheduling or predicting patient no-shows – that are already making an impact. For now, we focus on a number of things that are not necessarily difficult diagnostic problems, but they are things that might improve the workflow in some way. Machine learning and CDS tools are most effective when they are trained on data that is accurate, clean, and complete. After all, an algorithm's output is only as good as its input, and in the high-stakes industry of healthcare, the input has to be pretty precise. The availability of healthcare data has increased with electronic health record systems and the rise of connected devices. In this study, we combined Extensible Markup Language (XML) technology with a professional medical knowledge base and constructed a three-layer model of a professional medical knowledge base. This model expands the knowledge base and utilizes more useful information. Doctors can communicate with patients online, get information about their symptoms and physical characteristics, and feed that data into our system, which then determines the condition and the likelihood that the patient will be affected. The system's decision-making outcomes are then compared to actual clinical outcomes for online learning of the inference engine's parameter optimization.

The rest of this essay is structured as follows. A three-layer approach for a medical knowledge base is introduced in Section 2 of this document. We describe our three-layer model's inference engine in Section 3. The specificity weighted for online learning parameters are introduced in Section 4. The system design and its execution are displayed in Section 5. The system is assessed in Section 6, and the findings are discussed. Section 7 provides conclusions.

II. RELATED WORK

The proposed machine learning structure includes two stages. Stage I applies online learning using hierarchical temporal memory (HTM) to enable real time stream processing and provides unsupervised predictions. Stage II is a long short-term memory (LSTM) classifier that forecasts the status of the patient's MAP ahead of time based on Stage I stream predictions. Maintaining the Integrity of the Specifications

The proposed system saves extensive offline modelling, uncertainty, and delays associated with conventional systems. In this model, HTM provides unsupervised predictions in real time, and LSTM provides the classification, it is used to analyse and train on predicted streams. The average prediction time per patient was 150 seconds and the delayed predictions were 75 seconds on average.

III. DESIGN & METHODOLOGY

A. Medical Knowledge Base

A CDSS must have some level of medical knowledge, and this information must follow the inference engine design principles, in order for it to function . The medical knowledge base of our system is constructed using XML, which is widely used for Web transport and offers a standardised approach to describe and communicate structured data that is independent of the application.

With the use of expertise from knowledgeable specialists and medical literature, we constructed our medical knowledge foundation for this investigation. Data, information, and knowledge are arranged and displayed in a way that both people and machines can comprehend what they imply. Different labels are used by XML to define various types of data, each of which has been specially created by developers to allow for future extension, modification, or improvement. In this system, a disease knowledge base and a symptom knowledge base for common diseases are combined to form a three-layer model medical knowledge base.

B. Three Layer Model

There are numerous syndromes for an illness, including symptoms and vital signs. Furthermore, different diseases can occur with the same symptoms. As an illustration, patients with primary bronchial lung cancer and tuberculosis (TB) would exhibit the same symptoms, such as coughing and hemoptysis. As seen in Figure 1, we refer to the disease-symptom model as a two-layer model. The CDSS is built on a two-layer paradigm of rule reasoning, which is common in many existing systems. In other words, the existence of specific symptoms implies the presence of the disease. This straightforward method makes it challenging to effectively represent information when translating it into machine language.

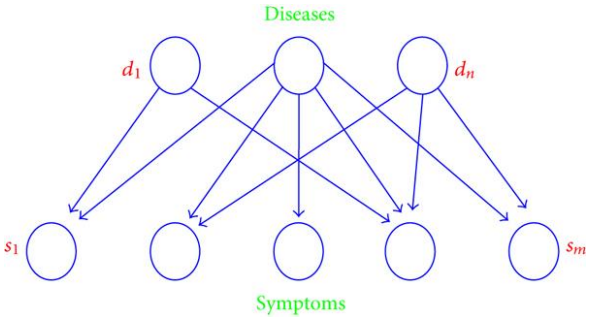

Figure 1: Schematic of disease-symptom model

By adding a "property" to the two-layer knowledge base, we propose a three-layer model of "disease-symptom-property" that is inspired by the two-layer model and Collins' theory of the decision tree for disease diagnosis. Coughing is one symptom of TB, for instance, and it can have a variety of distinct characteristics, such as length of time it lasts or how severe it is. Based on this finding, we enlarge the medical knowledge database to add more information and more precisely convey the knowledge. Figure 2 shows the three-layer model.

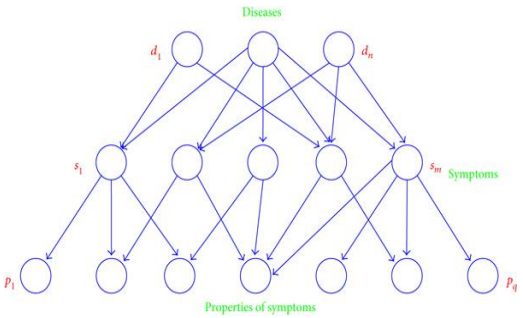

Figure 2: Schematic of disease-symptom-property model

We require prior probability knowledge for the inference engine. The disease knowledge base includes the properties of symptoms in addition to the presence of symptoms as a prior possibility. Utilizing clinical data and expert clinical experience, we provide these prior probabilities to the knowledge base of our three-layer model. Experts also assign the starting probability value of the emergence of certain symptoms and characteristics of the disease. For a disease, the prior probability of this condition is given an initial probability value. When a certain symptom and attribute combination occurs for a specific disease, the risk that the disease will occur is increased; the "specificity" is then applied to the symptom weighting in the inference engine to determine the disease.

We constructed a three-layer model of an XML medical knowledge base for common respiratory diseases compiled by doctors at the Anhui University of Chinese Medicine. This medical knowledge base primarily contains 380 three-layer model pieces of information, including prior probability knowledge and specificity value, and 11 different types of respiratory disorders.

C. Inference Engine: Multisymptom Naive Bayes Algorithm and Symptom Specificity Weighting

a) Inference Engine:

Data processing is carried out by the inference engine, which also uses knowledge and an inference strategy to manage and coordinate the complete expert system. The representation of internal information serves as the foundation for the inference engine. Model-based reasoning, rule-based reasoning, and case-based reasoning (CBR) are the three types of inference engines that may be found in CDSSs. Model-based systems replicate the composition and operation of the system under investigation. Rule-based reasoning is primarily defined as reasoning that is based on a set of rules. Excelicare CBR, a UK commercial clinical decision system that uses electronic medical records as case data for real-time aid in helping, is an example of such a system. CBR refers primarily to the utilization of prior case experience to reason.

Belief networks and the probability based on the Bayesian theorem approach are frequently used to make decisions. The inference engine's purpose is to make choices and predictions by applying medical knowledge to patient data, and developing it is a crucial step in building a CDSS. The system employs the probability to represent the relationship between sickness and symptom based on prior knowledge of the Bayes theorem.

b) Naïve Bayesian Algorithm

Using Bayes' theorem as its foundation, the broad Bayesian classifier is a type of classification algorithm. A very basic and uncomplicated classification algorithm is the naïve Bayes (NB) algorithm [14]. Naive Bayes classifiers are a family of straightforward probabilistic classifiers used in machine learning that are based on the application of Bayes' theorem and strong (naive) independence assumptions between the features.

The NB classifier works as follows:

1) As usual, for an *n*-dimensional attribute vector, $X = (a_1, a_2, \ldots\ldots a_m)$, depicting it for 'm' attributes, respectively, $a_1, a_2, \ldots\ldots a_m$.

2) Suppose that there are n classes: $C = (y_1, y_2, \ldots.y_n)$. Given a tuple, X, the naïve Bayes algorithm predicts that tuple X belongs to class y_i, if and only if $P(y_i \mid X) > P(j \mid X)$ $(1 \leq j \leq n, j \neq i)$. This is the maximum probable hypothesis and may formally be called the maximum a posteriori hypothesis.

3) Thus, using Bayes' theorem, the conditional probability can be decomposed as

$$P(y_i|X) = \frac{P(X|y_i)P(y_i)}{P(X)} = \frac{P(X|y_i)P(y_i)}{\sum_{i=1}^{n} P(X|y_i)P(y_i)}$$

(1)

4) This presumes that the values of the attributes are conditionally independent of one another, given the class label of the tuple. This means that

$$P(X|y_i) = P(a_1|y_i)P(a_2|y_i)\cdots P(a_m|y_i) = \prod_{j=1}^{m} P(a_j|y_i)$$

(2)

5) Therefore, formula (1) becomes

$$P(y_i|X) == \frac{P(X|y_i)P(y_i)}{\sum_{i=1}^{n} P(X|y_i)P(y_i)} = \frac{P(y_i)\prod_{j=1}^{m} P(a_j|y_i)}{\sum_{i=1}^{n} P(y_i)\prod_{j=1}^{m} P(a_j|y_i)}$$

(3)

c) Multisymptom Naive Bayes Algorithm

The multisymptomatic naive Bayes formula is as follows:

$$P(D_i \mid S_1, S_2, \ldots, S_m) = \frac{P(D_i)\prod_{k=1}^{m} P(S_k|D_i)}{\sum_{i=1}^{n} P(D_i)\prod_{k=1}^{m} P(S_k|D_i)}$$

where,

(1) D_1, D_2, ….D_n represent kinds of mutually exclusive diseases, with "*i*" representing the sequence number of the disease;
(2) $P(D_i)$ is the prior probability of D_i, (the prior probability of occurrence of disease);
(3) S_1, S_2,…..,S_m are the symptom properties, where "*m*" represents the number of the property;
(4) $P(S_k|D_i)$ is the probability of the occurrence of symptom S_k under disease D_i.
(5) P (Di | S1, S2,…., Sm) is the posteriori probability of disease D_i under the condition of the symptoms presented by the patient.

The system first filters out some susceptibility factors from the patient's information (like gender and age), then it combines the remaining data with susceptibility factors from the medical knowledge base (like common diseases in men or elderly people who are susceptible to disease), and it reports back to the doctor so they can ask about related symptoms. The patient's symptoms are entered into the system as a result of the interaction between the doctor and the patient. The multisymptom naive Bayes algorithm determines the posterior probability of the patient's potential disease under the known condition of prior probabilities. The next step is to perform the specificity weighting of the symptom.

d) Symptom Specificity Weighting

An evaluation of the degree of contribution to disease diagnosis weighs the specificity of certain disease symptoms. The weighting greatly minimizes the dependencies between specificities, allowing for improved application of the NB algorithm. A novel model that provided a partial weight rather than a normal variable weight value was proposed in 2001 to enhance the NB algorithm [15]. A multisymptomatic naive Bayes algorithm's inference engine, as previously said, infers potential diseases and their associated probabilities, and the current input symptom information decides if it is specific for the inferred disease. Thus, the following weighting is applied to the appropriate a posteriori probability:

$P(D_i \mid S_1, S_2, \ldots, S_m)' = P(D_i \mid S_1, S_2, \ldots, S_m) + P(D_i \mid S_m) \times (1 + \text{specificity weight})$, (5)

Where P (Di | S1, S2, …., Sm) are the possible diseases and their corresponding probabilities found by using the multisymptomatic naive Bayes algorithm, $P(D_i \mid S_m)$ is the specificity of the current input symptom to the disease, and specify weight ϵ [0,1) is the specificity weighting value for online learning, whose initial value is 0.6.

P (Di | S1, S2, …., Sm)' are the calculated disease and the corresponding probability.

D. Online Learning Process

More and more industries in the big data era require quick data processing. Particularly for the more conventional batch machine learning techniques, learning and training neural networks require a significant amount of data as input. Online learning must handle the data stream in real time and strike a compromise between speed and accuracy because, in practise, the limited training data frequently arrives in real time. Regular upkeep and upgrades to the medical knowledge base are required. Consequently, our online learning system offers a benefit in this regard.

a) Perceptron Learning Algorithm

The perceptron is a supervised learning technique for binary classifiers in machine learning (functions that can decide whether or not an input, represented by a vector of numbers, belongs to some specific class). Many machine learning algorithms have made extensive use of the "reward-punishment" notion. If the input was successfully classified, the weighting vector stays the same. If the input was improperly classified, the weight vector will be changed to point in the right direction.

The algorithm is as follows:

(1) Choose *n* points belonging to the positive or negative instance, in the case of a binary classification problem, as shown in the following type:

$\{(x_1, y_1), (x_2, y_2) \ldots (x_n, y_n)\}$,

$X_i = R^{d+1}, y_i \epsilon \{-1,+1\}$,

where x_i are the corresponding eigenvectors of samples, y_i are the classifications of corresponding sample labels, d is the characteristic number, and n is the total sample training set. Take the weight vector of the initial value, w_0 , beginning at iteration t=1.

(2) Train samples iteratively online, and calculate the values of the weights and the correct vector:

$$\omega_t = \begin{cases} \omega_{t-1}, \omega_{t-1}^T x_i \geq 0 \\ \omega_{t-1} + \sigma x_1, \omega_{t-1}^T x_i < 0 \end{cases}$$

Here, $\boldsymbol{\sigma}(\boldsymbol{\sigma}>0)$ is an adjustment of the step length.

(3) As long as an error classification remains, return to step 2 until the correct classification for all samples has been achieved.

b) Online Learning System

The system initially s The "reward-punishment" notion and the perceptron theory are used in this system to create specialized weighting factors for online learning. The highest probability inference results, D′, and the clinical results of disease diagnosis were compared; if the clinical results do not agree with the system's results, we know that the particular weighting parameter has a certain contribution to the algorithm in the inference engine. The online learning method is used to adjust it, and the result will gradually move towards the actual value:

Specificity weight

$$\begin{cases} specificity\ weight, D = D', \\ specificity\ weight + \delta\ x\ specificity\ weight, D \neq D', \end{cases} \quad (8)$$

Where $\boldsymbol{\delta}$(=0.1) is the parameter used for studying; if specificity weight > 1, we assign specificity weight = 0.99.

E. System Design and Its Implementation

The mechanism: Our system was created in the C# programming language. Additionally, the Web, a SQL Server database, and an IIS server were employed. Users first need to register. Common users, managers, and doctors are the three different categories of users in the system. The system can be used mostly by clicking on Web pages, and during the interaction process, advice, justifications, and diagnoses can be given.

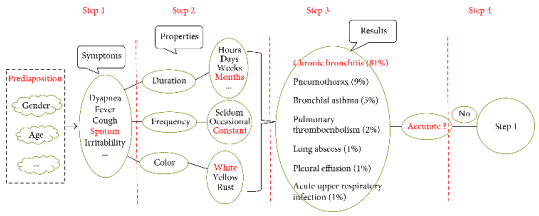

Figure 3: System Framework Design

Figure 3 illustrates the four essential components of our framework: a user module, a built-in inference engine, medical knowledge, and online learning.

Identify applicable funding agency here. If none, delete this text box.

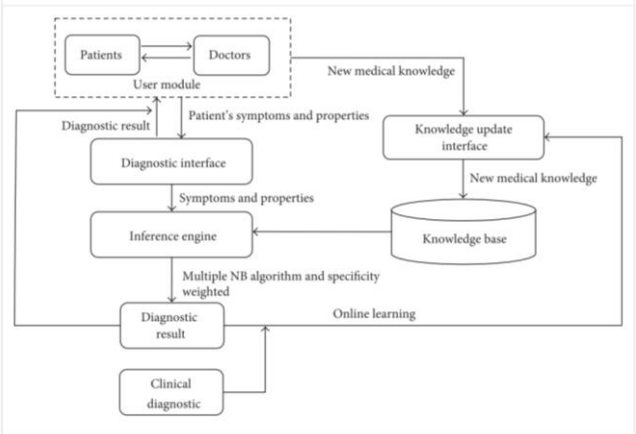

Figure 4: System Framework

A doctor chooses the patient's symptoms and characteristics in the user module, and the system uses its own inference engine to determine the patient's potential diseases and their probabilities. A knowledge update interface is also part of the system, allowing the clinician to directly edit the knowledge base. The clinician can add to, remove from, or change the three-layer medical knowledge base using this graphical interface. The knowledge update interface is crucial since the physician could gradually pick up new diagnostic expertise. The other three sections were thoroughly explained in the section before it.

a) Interaction Process

The doctor can obtain some very basic information from the system page such as name, age and sex of the patient. The system separates a variety of susceptible elements, including initial feedback regarding potential disease symptoms and common disease alternatives, gender-susceptible factors (common diseases for men or women), age-susceptible factors (age-related disease, etc.), and so on. Information from outpatient departments will be included in susceptibility variables in the future. The page will asynchronously enter the symptoms into our internal reasoning algorithm and compute the patient's potential disease information and likelihood when the doctor selects the symptoms and properties. A new symptomatic issue will be displayed on the page along with a chart that shows the doctor how likely it is that the condition is present. The explanation module will present information on the potential illness. Iteratively repeating the process, doctors and patients are still interacting.

An interactive process flowchart is shown in Figure 4. Step 1 displays a list of symptoms that were discovered as a result of several vulnerable conditions. Step 2 displays the attributes and associated alternatives under the relevant symptoms list. Step 3 displays the potential illnesses and the associated probability determined by the inference engine algorithm; if the results are unreliable, step 1 is repeated.

F. System Evaluation and Results

Utilizing actual testing scenarios, our system is evaluated for clinical efficacy and contrasted with a two-layer method. First, two top specialist doctors tested the system's functionality and provided feedback on the

front-end page that allowed us to improve the system and make it simpler to use. Second, doctors employed 50 clinical cases, covering 10 different types of respiratory diseases, to evaluate the clinical efficacy. These cases are frequently used to test knowledge-based systems to show whether a system exhibits a performance level equivalent to that attained by human specialists. To compare with the three-layer approach, we lastly constructed a knowledge base based on a two-layer model.

a) Clinical efficiancy and results

Doctors practised interacting with patients by selecting the patient's symptoms and characteristics from the website and entering them into the internal inference engine. We investigated the system inference findings and clinical diagnosis outcomes, and we employed five measurements—deterministic, recommended, indicated, possible, and recall—to separate the results in our clinical efficacy study. The deterministic type gauges the system's power and has a focus on diagnostic success. It states that there is an 80% to 100% chance that the system will correctly identify the ailment. The probability for the recommended and suggested kinds are between 0.6 and 0.8 and 0.4 and 0.6, respectively; these two types represent the fraction of a gold standard diagnostic (which may include several components) that has been accurately proposed by the system. For the recollection type, the likelihood of sickness is less than 0.1, while the probability for the potential type is between 0.1 and 0.4. Table 1 provides a summary of the findings.

Table 1: Summary of clinical efficacy evaluation results

	Deterministic	Recommended	Suggested	Possible	Recall	Sum
Probability distribution	0.8–1	0.6–0.8	0.4–0.6	0.1–0.4	<0.1	
Test case	7	13	24	5	1	50
Overall performance	0.14	0.26	0.48	0.10	0.12	1.00

The system's recall-type results don't provide doctors with any guidance on how to make decisions. A clinical misdiagnosis proportion is defined as:

"misdiagnosis proportion(%) = $\frac{N_{recall}}{N_{test}} \times 100\%$"

From table 1, we can calculate misdiagnosis proportion hence, correct proportion(%)=1–misdiagnosis proportion(%)=98% Otherwise, we discovered that the majority of the results are distributed in the range of recommended and suggested types; this is consistent with the reality because the system detects the disease through patient interaction and offers some recommendations and suggestions to aid the clinician in making clinical decisions, but additional examinations, such as imaging tests and blood tests, are also necessary to detect the disease. Naturally, the likelihood of having a certain symptom associated with a particular disease in our three-layer model knowledge base will be relatively high, hence the system will produce a deterministic outcome similar to a deterministic type.

b) Results

Due to the limitations of a two-layer model for the medical knowledge base, it is not always possible to infer disease just from the presence of symptoms. For instance, symptoms like coughing, sputum production, fever, and others are used to determine whether a person has tuberculosis (TB), but they can also indicate an acute upper respiratory infection or bronchiectasis disease. To better identify between these comparable diseases, we added a "property" (such as length and severity) to this two-layer model. These qualities have their own specificity for specific diseases. Doctors extracted the symptom data from clinical cases using a two-layer model, and then they entered it into the internal inference engine.

Table 2: Correct Proportion and Misdiagnosis proportion

	Correct proportion	Misdiagnosis proportion
Three-layer model	98%	2%
Two-layer model	88%	12%

As a result, using Table 3, we discovered that the majority of the results are distributed according to the two-layer model's possible types, meaning that this model is unable to give doctors clinical recommendations that are effective. Additionally, the two-layer model has a lower proportion of correct diagnoses and a higher proportion of misdiagnoses than the three-layer model.

G. Conclusion

In this research, we offer a method for computing the posterior probability of the patient's potential disease based on a three-layer model. By adding "property" to the two-layer knowledge base, the three-layer model knowledge base successfully addresses the expression inaccuracy of the knowledge and uses more meaningful information in inference. To train the inference engine's parameters for online learning, the decision outcomes of our three-layer model were contrasted with actual clinical outcomes. We conducted an evaluation and discovered that our approach can offer doctors useful clinical recommendations.

We need to enhance our present system to include vital signs, laboratory and radiographic expertise, and other factors because it is currently only capable of treating common respiratory disorders. The NB classifier, one of the best classification models, is dependent on the premise of attribute independence, which is frequently broken in practical data mining applications. The accuracy of the NB classifier can be increased by lowering the assumption of attribute independence using a variety of optimization strategies.

Disaster Management of Flood and Landslides Using Machine Learning

Aniruddha Bhoir, Atharva Dalvi, Chitvan Nagaich
Information technology TCET, Mumbai, India

Abstract **-Disaster management is a crucial aspect of ensuring the safety and well-being of communities in the event of natural calamities such as floods and landslides. Effective disaster management strategies involve early warning systems, evacuation plans, and effective communication systems to minimize the impact of these disasters on the lives and property of individuals. The development of infrastructure such as embankments, dams, and retaining walls can also play a critical role in reducing the damage caused by floods. On the other hand, proper land use planning and management, as well as deforestation control measures, can help prevent landslides. A multidisciplinary approach involving government agencies, non-government organizations, and local communities is essential for an effective disaster management plan for floods and landslides.**

Disaster management refers to the systematic process of preparing for, responding to, and recovering from natural or man-made disasters. Floods and landslides are two common types of disasters that can cause significant damage and loss of life. Effective disaster management strategies must be in place to minimize the impact of these events on communities. Floods occur when water levels rise above normal due to heavy rain, melting snow, or other factors. They can cause significant damage to homes, roads, and infrastructure, as well as result in loss of life.

Effective disaster management strategies for floods include early warning systems, evacuation plans, and temporary shelter arrangements. The restoration of essential services such as electricity, water supply, and healthcare facilities should also be a priority. Landslides occur when soil or rockslides down a slope due to gravity, often caused by heavy rain or earthquakes. They can cause widespread damage to infrastructure and homes, and result in loss of life. Effective disaster management strategies for landslides include early warning systems, risk assessment and mapping, and proper land use planning. In areas prone to landslides, the construction of retaining walls, stabilizing slopes, and planting vegetation can also help mitigate the impact of landslides.

In conclusion, effective disaster management is critical for minimizing the impact of floods and landslides on communities. This requires a multi-disciplinary approach that involves early warning systems, risk assessment, evacuation plans, and the restoration of essential services. Effective disaster management strategies can help to reduce the loss of life and property and ensure a quicker recovery for affected communities.

Keywords—disaster management, landslides, flood, strategies, safety and well-being.

I. INTRODUCTION

Disaster Management with Machine Learning: An Introduction

Natural disasters such as floods and landslides have the potential to cause significant damage to communities, resulting in loss of life, property, and infrastructure. Effective disaster management is critical to minimize the impact of such events and ensure the safety of those affected. Machine learning has emerged as a promising tool in the field of disaster management, offering the potential to improve early warning systems, risk assessments, and post-disaster response efforts.

Floods

Floods are one of the most common and destructive natural disasters, causing significant damage to communities every year. Machine learning algorithms can be used to improve flood prediction and early warning systems, allowing for more effective evacuation and rescue efforts. For example, machine learning algorithms can analyze vast amounts of data such as rainfall patterns, river levels, and soil moisture to make accurate predictions about the likelihood and severity of a flood event. This information can then be used to alert communities and emergency response teams, enabling them to take appropriate actions to minimize the impact of the disaster.

Landslides

Landslides are another common natural disaster, often resulting from intense rainfall, earthquakes, or volcanic activity. Machine learning algorithms can be used to identify areas at risk of landslides and predict the likelihood of a landslide occurring in a specific location. This information can be used to develop targeted evacuation and mitigation plans, reducing the risk of injury and damage to property. Additionally, machine learning algorithms can be used to analyze satellite imagery and aerial photographs to detect and monitor the extent of a landslide in real-time, providing valuable information for post-disaster response efforts.

Machine learning is a rapidly developing field with the potential to revolutionize disaster management. By leveraging the power of data analysis, machine learning algorithms can improve our understanding of natural disasters and help communities better prepare for and respond to such events. As technology continues to evolve, it is likely that machine learning will play an increasingly important role in disaster management efforts, helping to reduce the impact of natural disasters and ensure the safety of those affected.

II. NEED OF DISASTER MANAGEMENT USING MACHINE LEARNING

Natural and man-made disasters affect the lives of millions.

Of people around the world each year. It is not uncommon for lives to be lost in these events. In addition to human loss, disasters have a significant impact on infrastructure. and property.

Disaster management measures are implemented before, during and after a disaster to prevent human loss, protect people and infrastructure, reduce economic impact and restore normalcy. The complexity of disasters and the criticality and complexity of disaster response requires robust decision-making enhanced by information technology, especially AI. Managing the scale and impact of

disasters requires informed and effective disaster management, encouraged in recent years.
by advances in ML and DL. Application areas include disasters such as hurricanes, earthquakes, floods, forest fires and landslides. Dealing with man-made disasters such as the refugee crisis can also benefit from recent technological developments. However, there is no clear definition of disaster. In the terms of the United Nations Office for Disaster Risk Reduction (UNISDR), a disaster is "a serious disruption to the functioning of a community or society, resulting in human, material, economic or environmental loss and impact. It is beyond the capacity of the community." 'Coping power' for affected communities and societies to deal with themselves. Based on EM-DAT terminology, disasters can be divided into two main groups: natural disasters and technological disasters Using another classification, disasters are divided into natural and man-made disasters. Additionally, climate-related disasters in 2020 were the leading cause of the 389 recorded disasters in the year. Statistics show that 2020 saw a higher-than-average number of recorded disasters, with a 26% increase in storms, a 23% increase in floods, and an increase in average annual economic losses.

Disaster management deals with disasters over time Four phases are widely accepted: mitigation, preparedness, response and recovery. Mitigation refers to activities that prevent a disaster from occurring or reduce the effects of a disaster. Preparedness includes activities that prepare communities to act in response to disasters. B. Emergency planning, stockpiling, training, and community education for better response to or mitigation of disaster impacts. Response includes operations to implement plans to protect life and property, the environment, and the socio-economic structure of communities. Disaster relief and response also includes activities such as implementing emergency plans, emergency relief and medical supplies, establishing and managing emergency shelters, distributing relief supplies, and assessing damage. This phase is one of the most studied as people and infrastructure need the most urgent support. Time is of the essence at this stage, so technology focuses not only on highly accurate results, but also on streamlined methods that work quickly. Recovery (reconstruction) involves long-term actions aimed at bringing a normal state to the community.

Activities in this phase include, but are not limited to, financial assistance and reconstruction/reconstruction (such as buildings and major infrastructure). In addition, active involvement of local communities in disaster management can lead to community resilience AI techniques used to support disaster management in all phases consist of several ML and DL methods. ML methods include Support Vector Machines (SVM), Naive Bayes (NB) methods, Decision Trees (DT), Random Forest (RF), Logistic Regression (LR), and K-Nearest Neighbors (KNN) clustering algorithms. DL methods, on the other hand, include various architectures of artificial neural networks (ANNs) such as: LSTM), Transformer Architecture, Generative Adversarial Networks (GAN) ML and DL have enabled the development of systems capable of predicting, responding to, and recovering from disasters using large and complex data sets, resulting in practical decision support tools. These techniques leverage the ability to manipulate different types of data from multiple sources and determine patterns that can provide information that cannot otherwise be disclosed. Big data is available from sources such as satellite imagery, unmanned aerial vehicles (UAVs), social media, crowdsourcing, geographic information systems (GIS), and wireless sensor networks. A recent review in disaster management focuses on the application of AI in disaster management and the use and potential of big data in natural disaster management San et al. provides an overview of exemplary AI applications in various application areas of disaster management, such as hazard assessment, vulnerability assessment, early warning systems, disaster detection, event mapping, damage assessment, disaster relief and assistance, and resource allocation. showed. There is a growing trend to use AI to analyze and process big data from various data sources to make informed disaster management decisions. A total of 26 AI methods were used for 17 application areas of disaster management in the studies included in. Yura. provided a systematic overview of the role of big data in disaster management. This review included journal articles published between 2011 and 2018. The authors recogniz e ML, including DL, as both an evolutionary technology and an emerging technology theme to facilitate disaster management.

Considering the increasing trend in developing ML-based methods for disaster management and the rapid progress of DL, a comprehensive review focusing on the progress of ML and DL in disaster management is needed. Therefore, a review of the literature survey using ML and DL since 2017, covering different phases of disaster management using different types of techniques and data, was performed in this paper. The purpose of this study is to provide a comprehensive analysis of ML and DL techniques developed for disaster management and to indicate future trends. Also included are recently developed ML and DL based applications for disaster management. The methodology is described in the next section. Below is the theoretical background for some important ML and DL methods used in disaster management. It then analyzes recent research since 2017 and categorizes it into sub-phases: Hazard and Hazard Forecasting, Risk and Vulnerability Assessment, Disaster Detection, Early Warning Systems, Disaster Surveillance, Damage Assessment, and Aftercare. A disaster management case study and a section detailing the technical application of ML/DL techniques to disaster management follow. A discussion of the results is presented next. Finally, a conclusion is drawn.

III. METHODOLOGY

For the purposes of this study, a search of Google Scholar and relevant journal databases was conducted for articles published between 2017 and 2021 (September). The keywords used in the search were 'natural disaster', 'disaster management', 'prediction', 'assessment', 'mitigation', 'preparedness', 'response', 'assistance', 'post-disaster analysis', "Case study" "Application" "Machine learning" "Deep learning". The initial search returned 1,210 items with no reviews.

Based
othe author's research experience, further searches
were conducted in the top his journal archives in each target database. Databases examined primarily included IEEE, Elsevier, Springer, Taylor and Francis, Scopus, Web of Science, and Wiley. A manual search was also performed to exclude irrelevant studies or studies outside the scope of this study. Therefore, 55 papers were ultimately included in this review shows the percentage distribution of research articles included in this review by database shows the keyword combinations used to collect the works included in this study.

I. An overview of the machine learning Mehtods

ML effectively addresses the elimination of irrelevant data, provides faster processing and analysis of disaster event information,
and effectively supports all stages of disaster management [10]. However, traditional ML methods cannot learn representations of complex systems directly from raw data. DL is a subclass of ML that can automatically learn representations of complex systems for the purposes of
prediction, detection, or classification. DL uses long causal chains of neural network layers (NN) that enable more advanced and abstract computational models of real systems [11,12]. DL techniques allow representation with many levels of abstraction afforded by simple non-linear modules, with each level transforming the representation into something higher and more abstract, ultimately leading to immutable functions and highly complex functions are learned [12]. Advances in DL enable new approaches to disaster management. CNN dominates computer vision tasks, making satellite and aerial imagery systems essential for disaster response and damage assessment [13]. ANNs are widely used as powerful tools for big data analysis [10,14]. On the other hand, text-based NNs, namely Long Short-Term Memories (LSTM) and recently Transformer, use their architecture to perform natural language processing tasks [15]. These types of NNs are used for damage assessment studies on social media datasets. Then, we present two DL and one ML architectures commonly used in disaster management, namely CNN and LSTM and SVM, to provide theoretical background.
CNN
CNN architecture is based on convolutional layers (CL). In these layers, data is propagated and applied in tabular multiplication by n*m tabular filters, also called kernels. In most cases n is equal to m. This process produces different representations of the input data based on the applied filters. Each representation reveals a different feature, which is projected onto
a feature map that quantifies the stimulus produced by each convolutional layer filter [11,12]. The convolution results in some unique transformation of the input data. The number and size of kernels used in convolution are critical to the overall network performance. After the convolution step, the data passes through a pooling layer (PL) that groups the results of the convolution by keeping the maximum, minimum, or average of each part of the data and retains only the most significant ones in the network. To do. Depending on the depth of the mesh, this entire process is repeated multiple times before the data is flattened in one-dimensional space and fed to a fully connected layer (FL) for classification. SoftMax layers transform data into probability distributions. Figure 2 shows the CNN architecture. Note that each CL in the network provides some level of abstraction in the feature extraction process.
LSTM
LSTM is a NN commonly used for text classification in disaster management of social media datasets. LSTM is a type of recurrent neural network (RNN). An RNN is a network that repeatedly applies the same computation to each element of a set of sequential data, passing some information to the next iteration. As a result, at each time step, predictions are made about the input data, which influence future predictions. This operation allows the network to understand complex text data and extract meaning based on word positional data in sentences. LSTMs differ from regular RNNs due to their internal cell architecture. LSTM uses a storage cell called constant error carousel (CEC) that determines at each time step how much information about the current state is passed along with the new input data at the next time step [11]. The predictions that an LSTM can provide are varied. Network outputs can be used with probabilistic classifiers for classification purposes, as element predictions for the next element in a sequence, or even to predict entirely new element sequences. The most important hyperparameters to fine-tune in LSTM are learning rate and network size. LSTMs can tune hyperparameters independently, which saves a lot of time in training and experimentation [16]. Figure 3 shows the LSTM
architecture. Accurate and thorough analysis of textual data is crucial in various stages of disaster management, and LSTM has proven to be efficient and effective, as described in the next section.

II. ML/DL Methods in Developed Applications for Disaster Management

With the advent of 5G technology, many innovations are happening in various industries due to its low latency. Decentralized edge
computing combined with his 5G technology is
gaining momentum in automation processes across many industries. His one such example is reported in Ardiansyah et al. [69], 5G DIVE. In this article, the author used this his 5G-DIVE on autonomous drones

for real-time navigation, surveillance, and emergency detection. The authors also used edge computing ML models for real-time detection of this emergency.

The system he called EagleEYE was basically an aerial system for disaster relief operations. The system reused existing datasets and created an object fusion mechanism to reduce the time required for training. The system also worked in parallel on both detection and response tasks. A new algorithm, Merged Object Detection (MOD), was proposed by the authors, and CNN and YOLO V3 were also used. For evaluation purposes, the authors tested this system in real-time on two datasets, including the COCO and Google Open Images datasets, and achieved 87% accuracy and 90% reduction in inference latency for detection purposes.

strung. [70] processed the application for the damage assessment phase.

Many applications including AI and DL-based deep NN approaches have been previously proposed by various researchers. These applications used post-disaster imagery to assess the severity of damage and impacts in disaster-affected areas.

However, the black-box nature of AI algorithms makes it difficult to achieve high accuracy. To this end, the focus of research has changed and new avenues have been explored to address this issue. In this paper, the authors also incorporated crowdsourced information obtained from social media data into AI-based algorithms. Before machine intelligence, crowdsourced information was used to tune, improve, and debug the black-box nature of AI algorithms. Then, within the system, this crowdsourced information worked closely with machine intelligence. A damage assessment application based on the DL model called CrowdLearn has been developed: a Crowd-AI hybrid application. CrowdLearn is based on a crowdsourcing platform and used a combination of cloud intelligence and machine intelligence to perform damage assessment. The system was assessed in real time and proved capable of providing a timely and accurate assessment of the disaster. It outperformed existing AI algorithms such as VGG-16, achieving a classification accuracy of 0.877 and his F1 score of 0.894.

Alamet al. [71] worked to solve the problems encountered during the relief work by applyin g image processing techniques to the images. This system was called Image4Act. The system used image data from social media posts to help humanitarian organizations conduct relief efforts.

The system collected data, denoised it, and classified it during natural disasters. Perceptual hashing and deep NN techniques were used to remove noisy data. A real-time cyclonic natural disaster case was used to assess the damage to infrastructure caused by the disaster. Evaluation of existing disaster datasets and the system in real-time has proven that the system can be used very effectively and reliably in real-time natural disasters.

Sung et al. [72] developed a disaster management system called DeepMob to predict and simulate evacuation behavior and human movement and evacuation routes after various types of earthquakes. DeepMob used disparate big data sources, including GPS recordings, transportation network data, and Japanese earthquake data. The system achieved an accuracy of 87.8% in predicting people's evacuation behavior.

IV. vi. LIMITATIONS

According to the results of this white paper, no research studies focused on ML/DL approaches to (long-term) disaster recovery were identified. The keyword "disaster recovery" was not included in the search, but the keyword "disaster management" may have returned results related to disaster recovery. Disaster recovery encompasses a wide range of activities aimed at returning communities to normal, building community resilience and designing efficient policies, but has been poorly studied in the literature. . Therefore, future research should focus on long-term disaster recovery facilitated or driven by advances in both ML and DL. Some research articles may not have been included in this review due to manual filtering after the initial keyword search.

V. FUTURE RESEACRH TRENDS

Bottlenecks in DL that need to be addressed in future studies, in order to enhance the robustness of DL-based methods for effective disaster management, include the limited amount of available labeled training data and the human labeling of the datasets [44,45]. DL overcomes the manual feature engineering process by automatically learning complex structures, yet with the expense of requiring very large amount of labeled data manually annotated in order to automatically learn the features. Moreover, social media data contain high levels of noise [50], therefore, more methods should be developed to effectively differentiate signal from noise in the above data.

According to the results of this paper, the prevalence and importance of Twitter has been shown as a tool to extract both qualitative and quantitative information valuable to emergency responders and other decision makers in all phases of disaster management. Considering that Twitter contains geospatial information, in contrast to other social media platforms, the extracted information can provide answers not only to what happened but also to where it happened. Since Twitter users may not be representative of the entire affected population, cross-validation with information collected by other methods such as B. Emergency calls were extracted, and the performance of the developed methods improved [53].

Crowdsourcing platforms like Amazon Mechanical Turk have been shown to help develop new ways to improve the performance of AI algorithms for disaster management tasks [70]. Combining cloud intelligence with machine intelligence can increase the accuracy of the developed ML/DL techniques and reduce the labor cost of hiring domain experts for data

labeling. More research is needed in different areas of disaster management to realize the benefits of crowdsourcing combined with ML/DL-based methods. Online news data has proven to be a reliable source of disaster-related information compared to social media data [39]. The process of extracting the right information at the right time from wireless sensor networks and other related technologies deployed in disaster-affected areas uses web crawling or web scraping for effective preparedness and response operations. can be strengthened by
In addition, as already mentioned in previous reviews, all stages and areas of disaster management should be focused [3]. ML/DL-based methods of disaster recovery management have not been well studied. Long-term disaster recovery includes sustainable development efforts that ultimately lead to building resilience in communities. The resilience of key infrastructure influences the effectiveness and progress of disaster recovery efforts

VI. Conclusion

Natural disasters are a leading cause of loss of life and damage to infrastructure and property. Advances in ML and DL are increasingly being used to deal with complex disasters. In this paper, review studies are conducted to examine how his ML and DL techniques are used in different areas of disaster management to support disaster management operations and improve their performance. I was. For this purpose, works published since 2017 were displayed and grouped into categories covering various phases and sub-phases of catastrophe events. Within these categories, different ML and DL techniques have been used for different types of disasters such as floods, lava flows, earthquakes, typhoons, hurricanes, and landslides.
Evaluated research focuses on the areas of hazard and hazard forecasting, risk and vulnerability assessment, disaster detection, early warning systems, disaster monitoring, damage assessment, post-disaster response, and case studies and applications. Issues and future research directions were discussed. Future research should be directed towards leveraging ML and DL to improve the performance of disaster recovery operations. Disaster recovery operations must be sustainable. Research should therefore focus on using ML and DL to improve defenses, mitigate vulnerabilities, and assess resilience, including key infrastructure.
The importance and complexity of disaster response require robust and validated ML and DL solutions. Disaster response affects lives. Therefore, the models developed must be explainable so that they can be understood by domain experts and decision makers [73]. In addition, research should focus on improving data quality and developing new data collection techniques and using crowdsourcing to improve the performance of ML/DL-based methods for disaster management interventions.

Abstract—**Diabetes is a major global health concern caused by elevated blood glucose levels. This condition is characterized by frequent urination, increased thirst, and increased appetite, andis a leading cause of serious health issues including stroke, renal failure, heart failure, amputations, blindness, and kidney failure. This** study aims to investigate the relationship between diabetes and **lifestyle factors such as caloric intake, junk food consumption, and stress. A predictive model will be developed to estimate the likelihood of developing diabetes and provide remediation strategies including diet and exercise plans. The results of this study will provide valuable insights into the impact of lifestyle on diabetes and inform the development of preventative measures to reduce the burden of this chronic condition.**

Keywords— Machine Learning, Diabetes Prediction, SVM, weighted Algorithm

I. INTRODUCTION

Every year, millions of individuals are diagnosed with diabetes, a chronic ailment that is spreading alarmingly throughout the world. An array of symptoms, including frequent urination, increased thirst, and increased appetite, are brought on by high blood glucose levels, which are the underlying cause of it. Amputations, kidney failure, a stroke, renal failure, heart failure, blindness, and kidney failure are all frequently brought on by diabetes.

This research aims to create a prediction model that can forecast the likelihood of a person suffering from diabetes in the upcoming years. The model will consider various parameters such as calories consumed every day, junk food consumption every week, and stress levels to make the prediction. The model will be developed using deep learning algorithms such as weighted algorithms, which will separate the users into groups according to the number of years in which they would be likely to suffer from diabetes.ly to have diabetes in the future.

1.2 Machine learning

Machine learning may be an area of research devoted to comprehending and developing "learning" processes, that is, processes that use data to improve performance on a given set of tasks. It is considered a component of computing. Machine learning is highly complicated, and how it functions depends on the task at hand and the technique used to complete it. However, a machine learning model could fundamentally be an algorithm that analyses data, spots patterns, and then uses that knowledge to carry out the task at hand moreefficiently. Machine learning can automate any operation that depends on a set of data points or rules, even more difficult tasks like taking customer service calls and looking over resumes.

We've created a system employing data processing that has the ability to forecast whether the patient has diabetes or not, which gives us the flexibility to look for a solution to the current problem. Additionally, early disease prediction allows for the treatment of people before their condition deteriorates. The versatility of data processing allows for the extraction of hidden knowledge from a significant volume of diabetes-related data. As a result, it currently plays a significant role in diabetes research. The goal of this research is to create a system that can accurately estimate a patient's level of diabetic risk. The goal of this project was to create a system that supported the three classification techniques— Support Vector Machine, Random Forest, Linear Regression Algorithm.

1.3 DATA PREPROCESSING:

The most crucial stage in creating a prediction model is preprocessing the data. The usefulness of data pertaining to healthcare is sometimes hampered by missing values and contamination. To increase the effectiveness and calibre of the outcomes, data preparation is done. Missing values will be removed from the data and the data will be split in two for this project's data pre-processing.

Missing Values removal: All instances having a value of 0 (zero) will be removed in this stage. This is due to the fact that zero is an impractical value, and the process of feature subset selection, which lowers the dimensionality of the data by deleting unused features and instances, is what is known as. Additionally, it expedites the work.

Splitting of data: Data cleaning will be followed by model training and testing using the cleaned data. The training data set and the test data set will be divided into two groups. While the test data set is placed aside, the algorithm will be trainedon the training data set. A training model will be developed through the training process based on thereasoning, procedures, and values of the features in the training data. Putting all features on the same scale is the main objective of normalization.

The goal of this research, in summary, is to develop a prediction model that can precisely forecast a person's likelihood of developing diabetes in the next years. The projection will be based on the model's consideration of a number of variables, including calorie intake, junk food consumption, and stress

levels. Data pre-processing will bedone to enhance the quality of the findings while the model is constructed using deep learning methods. This effort makes a substantial contribution to the field of diabetes research by providing early disease prediction, which is essential for the treatment of patients before their condition worsens.

II. METHODOLOGY

For Prediction we will be using following machine learning algorithm:

1.) Support Vector Machine: Support Vector Machine (SVM) is a potent and popular machine learning technique used to solve both classification and regression issues. Numerous applications, such as text categorization, bioinformatics, and picture classification, all make use of it. As diabetes is a significant issue in today's society, this research study will concentrate on how SVM can be used to predict diabetes.

Chronic health issues like diabetes are brought on by an unhealthy lifestyle, a high caloric consumption, and a lot of stress. Predicting this condition is an important stage in the healing process because an early diagnosis and course of therapy can stop the patient's health from declining. The objective of this study is to create a system that can correctly forecast a patient's likelihood of developing diabetes and aid in problem solving.

Because the SVM algorithm is a supervised machine learning technique, it uses training data to discover correlations between the input and output variables. Finding a hyperplane that divides the input data into various classes is how the algorithm operates. In the case of diabetes prediction, the various parameters, such as calorie consumption and stress levels, would serve as the input data, and the output would be the prediction of the patient's likelihood of having diabetes.

Due to its ability to create hyperplanes in high-dimensional space, the SVM algorithm is particularly well suited for high dimensional data. This is significant in the prediction of diabetes because the disease may be caused by a variety of different variables. These associations can be found and used by the SVM algorithm to generate precise predictions.

The SVM algorithm's capacity to classify samples without data support is one of its main features. Therefore, even if there is insufficient data to justify a prediction, it can nevertheless generate predictions. As there may not always be sufficient information to establish a firm prognosis, this is significant in the case of diabetes. By making predictions based on the closest training point for each class, the SVM method helps to reduce the impact of missing data.

For its prediction procedure, the SVM algorithm employs a technique known as hyperplane separation. Finding the hyperplane that optimizes the margin between the various classes is the first step in this approach. The margin is the separation between the nearest representatives of each class and the hyperplane. Finding a hyperplane that divides the data into distinct groups while simultaneously maximizing the margin is the objective.

It is crucial for diabetes prediction that the SVM algorithm be able to handle non-linear data. A linear model might not be able to adequately reflect the interactions between many of the non-linear elements that cause diabetes. By translating the nonlinear data into a higher-dimensional space where it can be divided by a hyperplane, the kernel trick is a method used by the SVM algorithm to handle non-linear data.

The requirement for data preparation makes utilizing SVM for diabetes prediction difficult. The accuracy of the predictions can be impacted by the frequent presence of missing values and other impurities in healthcare-related data. To solve this problem, the data must be cleaned, and any instances with missing values must be removed. In order to equalize the scale of all the features, the data must also be standardized.

An input dataset is used to train the SVM algorithm, while an output dataset is used to assess the method's performance. A training dataset and a test dataset are created from the data, and the training dataset is used to train the algorithm. The effectiveness of the algorithm is then assessed using the test dataset, enabling a comparison of the predicted values and the actual values.

Finally, it can be said that the Support Vector Machine (SVM) algorithm is a potent instrument for diabetes prediction.

Algorithm: Choose the hyperplane that divides the class more

Effectively Calculating the Margin, the distance between the planes and the data will help you choose the best hyperplane.

Low distances between courses increase the likelihood of missed conception, and vice versa. So, we must

Choose the class with the largest margin. Margin is equal to the sum of the distances to the positive and negative points.

2. Random Forest: - Popular machine learning algorithm, Random Forest is a part of the supervised learning methodology. In machine learning, it is applied to classification and regression issues. This strategy is built on the idea of ensemble learning, which is a technique for combining many classifiers to address a challenging issue and enhance the model's performance.

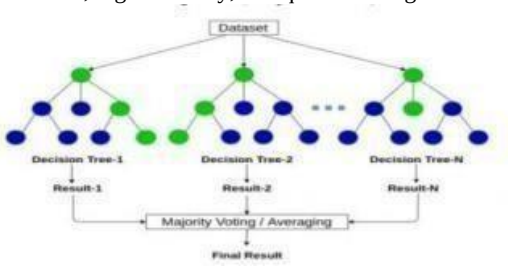
In order to avoid the overfitting issue that frequently arises while using decision trees, Random Forest was developed. An over fitted decision tree model performs poorly when making predictions on fresh, untainted data because it fits the training data too closely. The Random Forest approach uses numerous decision trees, each constructed using a different randomly chosen subset of the data, to solve this problem. The decision tree with the highest frequency of occurrence is chosen as the projected label for a particular data point in the final prediction, which is reached by casting a vote among all the decision trees.

In comparison to other algorithms, Random Forest is a quick and effective method. Even for massive datasets, it can accurately anticipate the outcome. Furthermore, Random Forest is resilient to missing data, preserving accuracy even when a sizable amount of data is absent.

It is crucial to remember that, although being a strong and successful algorithm, Random Forest might not be the ideal option for all tasks. The algorithm selected will rely on the particular specifications of the task and the kind of data being used. Other methods, such support.

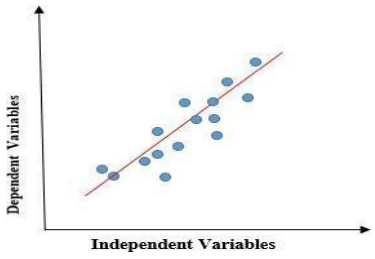
vector machines or neural networks, could be better appropriate in some circumstances.

All things considered, Random Forest is a popular and efficient machine learning technique that works well for a variety of pr prediction is made by taking a weighted average of the predictions of the individual models, where the weights are determined by theiraccuracy ediction issues. Data scientists and machine learning professionals frequently use it because of its capacity to manage missing data, high accuracy, and quick trainingtime.



2. Linear Regression Algorithm: - One of the most often used machine learning methods for prediction is linear regression. Based on one or more independent variables, it is used to forecast a continuous dependent variable. The relationship between the independent and dependent variables is assumed to be linear, which indicates that a change in the dependent variable will result in a change in the independent variables that will be proportional. The idea behind the linear regression algorithm is that a linear equation may adequately describe the connection between the dependent and independent variables. Y is the dependent variable in this equation, while the other variables are X1, X2, the coefficients of the equation are b0, b1, b2, bn, and Xn are the independent variables. The link between the dependent and independent variables is represented by the coefficients, which are computed using the training data.

The least squares approach is used by the linear regression algorithm to estimate the coefficients. By minimizing the sum of the squared differences between the dependent variable's observed and predicted values, the method of least squares is a statistical technique. The training data is used to generate the predicted values of the dependent variable, while the observed values are the actual values of the dependent variable. Finding the coefficients that reduce the sum of the squared differences is the goal of the linear regression algorithm.



A variable's value can be predicted using linear regression analysis based on the value of another variable. The dependent variable is the one you want to be able to forecast. The independent variable is the one you're using to make a prediction about the value of the other variable. Numerous uses of the linear regression technique include forecasting stock prices, sales, and demand, among others. It is a popular option for many data scientists because it is straightforward to use and simple to comprehend. It does have some restrictions, though. Its assumption that the connection between the dependent and independent variables is linear, which may not always be the case, is one of its fundamental drawbacks. Other regression procedures, like polynomial regression, may be more appropriate when the relationship is not linear.

The assumption that the relationship between the dependent and independent variables is independent, meaning that the presence or absence of one independent variable has no bearing on the other independent variables, is another drawback of linear regression. Multicollinearity can occur when there is a correlation between the independent variables, which is not always the case. Other regression techniques, like ridge regression or lasso regression, may be better appropriate under these circumstances because the linear regression process may yield incorrect results.

In conclusion, linear regression is a popular algorithm used in machine learning for prediction. It is simple to implement, easy to understand, and has a wide range of applications. However, it has limitations, including its assumption of a linear relationship between the dependent and independent variables, its sensitivity to outliers, and its assumption of independence between the independent variables. These limitations may be addressed by using other regression algorithms that are more suitable for specific data sets and applications.

Now, from above three algorithms the one which has more accuracy we will be using that for our prediction.

In order to predict at what age an individual will get an diabetes we will be using weighted majority algorithm.

The weighted majority algorithm is a powerful method for combining the predictions of multiple models in order to make a final prediction. It is especially useful in cases where there is a large number of models with different levels of accuracy, and it has the ability to handle both classification and regression tasks. In this essay, we will discuss the weighted majority algorithm in detail, including its concepts, applications, and limitations.

The weighted majority algorithm works by assigning a weight to each individual model based on its accuracy. The weight of a model is determined by its performance on the training data set, and the more accurate a model is, the higher its weight will be. This means that the predictions of the more accurate models will have a greater impact on the final prediction than the predictions of the less accurate models. The final prediction is then made by taking a weighted average of the predictions of the individual models.

One of the key advantages of the weighted majority algorithm is its simplicity. Unlike other ensemble methods, such as bagging and boosting, the weighted majority algorithm does not require complex algorithms or extensive tuning. This makes it easy to implement and understand, and it is ideal for situations where there is limited computational resources or limited expertise in machine learning.

The weighted majority algorithm can be used for both classification and regression tasks. For classification, the algorithm predicts the class that is most predicted by the

individual models. For regression, the algorithm predicts the value that is most predicted by the individual models. In both cases, the final.

III. SYSTEM ARCHITECTURE

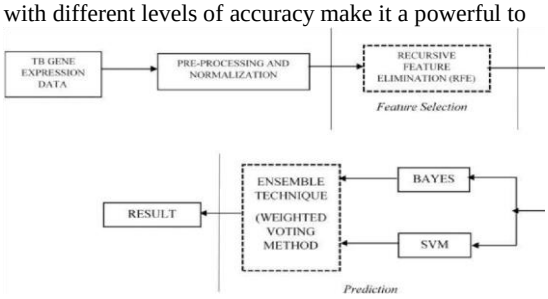
The weighted majority algorithm is particularly wellsuited to situations where there is a large number of models with different levels of accuracy. In these cases, it can effectively combine the predictions of the individual models in order to make a more accurate final prediction. For example, in the field of medical diagnosis, the weighted majority algorithm can be used to combine the predictions of multiple risk factors in order to diagnose a patient with a specific condition, such as diabetes. In this case, the weight of each individual risk factor would be determined based on its accuracy in predicting the condition, and the final prediction would be made by taking a weighted average of the predictions of all the individual risk factors.

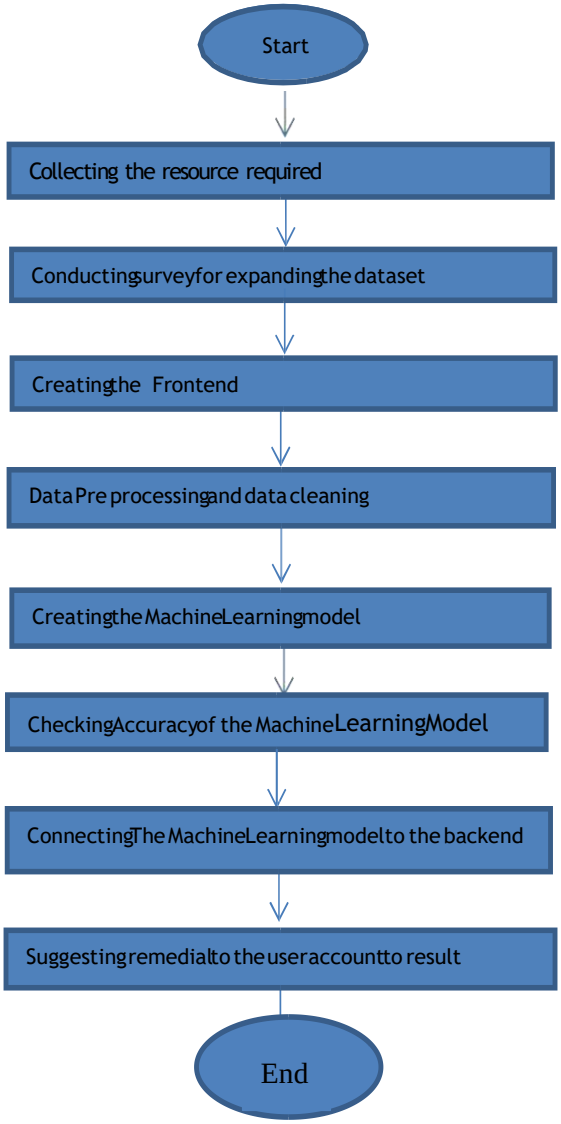
Another important application of the weighted majority algorithm is in the field of financial forecasting. In this case, the algorithm can be used to combine the predictions of multiple financial models in order to make a more accurate prediction of the future value of a stock or other financial asset. The weights of the individual models would be determined based on their accuracy in predicting the future value of the asset, and the final prediction would be made by taking a weighted average of the predictions of the individual models.

There are, however, some limitations to the weighted majority algorithm. One of the main limitations is that it assumes that the individual models are independent, meaning that they do not interact with each other. This assumption may not hold in all cases, and in some situations it may be necessary to modify the algorithm in order to account for the interdependence of the models.

Another limitation of the weighted majority algorithm is that it assumes that the accuracy of the individual models does not change over time. This may not be the case in some situations, and in these cases it may be necessary to periodically re-evaluate the weights of the individual models in order to ensure that they continue to reflect their accuracy.

In conclusion, the weighted majority algorithm is a simple and effective way to combine the predictions of multiple models in order to make a final prediction. Its simplicity, ability to handle both classification and regression tasks, and suitability to situations with a large number of models with different levels of accuracy make it a powerful to





IV REVIEWOFLITERATURE

A review of earlier research on the connection between undergraduate students' success and their prior academic accomplishment was done. The data from this evaluation provided a foundation for comparing the results ofthe current study to those discovered in the earlier.

In this research, Deepti Sisodia and Dlip Singh Sisodia[1] try to predict diabetes at an early stage. To makepredictions, decision trees, SVM, and Naive Bayes classification algorithms are employed. The WEKA tool is used to assess accuracy. According to Xue-hui Menget alstudy's [2], which compared three algorithms for predicting diabetes or prediabetes using common risk indicators, the Nave Bayes method had the highest accuracy. We compare the logistic algorithm, ANN, and decision tree algorithms. 735 patients were tested, and they came from two Guangzhou, China, areas. The classification algorithm achieves the maximum level of accuracy (77.87%)

Different classifiers are employed in machine learning by Monisha.A et al. in [3] to predict and diagnose diabetes. like logistic regression, extreme gradient boosting, and naive Bayes statistical modelling. Diabetes databases for Pima Indians are tested. The Extreme Gradient Boosting algorithm has an accuracy of 81%, which is higher than the accuracy of the other two algorithms. The goal of this work, as stated by B. Tamilvanan et al. in [4], is to predict diabetes more accurately. The accuracy rates of the three classification algorithms—Naive Bayes, Random Forest, and NB-Tree—are compared. application of the Weka tool. As a result, Naive Bayes has the highest accuracy rate (7 6 3%) and lowest error rate (23 . 7 %), giving it the strongest predictive capacity. In [5], VeenaVijayan.V et al. It is obvious that selecting proper algorithms for categorization improves the system's accuracy and effectiveness. The major goal of this work is to evaluate the advantages of various pre-processing methods for diabetes

prediction decision support systems based on Support Vector Machine (SVM), Naive Bayes classifier, and

DecisionTree. Principal Component Analysis and

Discretization are the pre-processing techniques that are the subject of this study. The variation in accuracy assessed both with and without pre-processing methods. This study makes use of the Weka tool. The University of California, Irvine (UCI) machine learning repository served as the source of the dataset. This paper by Veena Vijayan V et al. [6] focused on diabetes mellitus prediction with minimal error rate. Datasets are retrieved from the machine learning repository at UC Irvine. Verification of accuracy using the Matlab and Weka tools.

Using AdaBoost-decision stump classifiers, which have an 80 . 729 % accuracy rate and a low amount of error, diabetes maybe predicted.

This work by Ayan Mir et al. [7] concentrated on diabetes forecasting. Diabetes databases for Pima Indians are used. The Weka interface uses the Naive Bayes, SVM, Random Forest, and Simple CART algorithms for categorization. As a result, SVM offers greater accuracy than the competition. According to Aakansha Rathore et al. Diabetic disease detection and prediction. Diabetes dataset for Pima Indians was used experimentally, andR Studio was used to assess the performance measurements. The SVM and Decision Tree machine learning methods are employed. The SVM yields accuracy of 82%.

According to Aiswarya Iyar et al. in [9] diabetes affects 246 million persons globally. The WHO estimates that there will be over 3 80 million of them in 2025. The purpose of this study is to identify a method for disease diagnosis. utilizing Naive Bayes and decision tree methods. Implementation is done using the Weka tool. The accuracy of the naive Bayes algorithm is 79.5652%.

Amina Azar et al. in [10] hereditary disease affected among young peoples and ancient peoples. These units raised day by day and it does not curable. processing is used to early stage prediction. This paper in main aim is provides the differentiation and advocate best rule. The PID datasets unit used. the selection tree, Naive man of science and K-Nearest neighbor algorithms unit compared and used for predict the hereditary disease designation at early stage with highest accuracy and efficiency. The weak is used for testing and validation exploitation speedy manual laborer. the result is the selection tree is that the simplest prediction rule. It provides the accuracy level is seventy 5.6 5

V ACKNOWLEDGMENT

We are grateful for the support and guidance provided by our supervisor, Mrs. Kamal Shah, during the course of this research. Her invaluable contributions and expertise have been instrumental in the successful completion of this paper. Mrs. Shah has provided us with insightful feedback and suggestions, which have helped us to improve the quality of our research. Her support and encouragement have been a constant source of motivation for us throughout the entire research process.

We would also like to extend our gratitude to the Thakur College of Engineering and Technology for supporting our research. This support has enabled us to conduct a comprehensive and in-depth study of linear regression in machine learning for prediction. We are grateful for the resources, facilities, and opportunities provided by the institution, which have been critical in ensuring the success of our research.

Moreover, we would like to acknowledge the role played by our faculty members from our institution in the successful completion of this research. They have provided us with valuable feedback and insights, which have helped us to improve our understanding of linear regression in machine learning for prediction. Their expertise and knowledge have been instrumental in guiding us in the right direction and ensuring that our research was on the right track.

In conclusion, we would like to express our heartfelt gratitude to all those who have supported us in this research journey. Their contributions have been invaluable, and we could not have completed this research without their support. We are grateful for the opportunities, guidance, and encouragement provided by our supervisor, the institution, and our faculty members. Their contributions have been instrumental in the successful completion of this research, and we look forward to continuing our association with them in the future.

VI CONCLUSION

Diabetes is a chronic condition that has spread around the world and is now a serious public health issue. It is characterised by elevated blood glucose levels and, if unchecked, can result in major health issues like heart disease, blindness, renal failure, and amputations. In order to avoid severe problems, diabetes must be properly diagnosed and managed. Therefore, the creation of a system that can properly anticipate the onset of diabetes, particularly in its early stages, is crucial.

The major goal of this project was to develop and put into use a machine learning-based diabetes prediction system. The technique seeks to foretell whether a person has diabetes or not, and if so, when they will become diabetic. The experiment was successful, and the suggested approach used a number of ensemble learning and classification algorithms, including Support Vector Machines (SVM), Random Forest, and the Weighted Majority Algorithm. The system was created to use

user data, such as age, sex, BMI, calories and carbohydrates ingested daily, amount of sleep, and junk food consumed weekly, to estimate when diabetes will start to develop. These inputs were utilised by the system to train the machine learning algorithms, who then learned from the data and could anticipate outcomes based on fresh data inputs. A sizable dataset of people with and without diabetes was used to train the algorithms. The data were divided into two groups, diabetes and non-diabetic, using the SVM method. The approach is known to work effectively with high-dimensional datasets and divides the data into two groups using a hyperplane. The forecasts of various decision trees were combined using the Random Forest technique to provide a more precise prediction. Based on the results of the other two algorithms and accounting for each algorithm's accuracy, predictions were made using the weighted majority algorithm. According to the experimental findings, the system could typically anticipate the beginning of diabetes properly. The algorithm was able to separate those with a high risk of getting diabetes from those without one. The system's predictions were then verified using a different dataset, and the findings showed that they were accurate.

Since they can utilize the system to make early predictions and judgements to cure diabetes and save lives, the project's findings are highly pertinent to healthcare professionals. The technology can make it easier for medical professionals to spot patients who are at a greater risk of getting diabetes and treat them accordingly. By doing so, patients' quality of life can be improved and significant health consequences related to diabetes can be avoided. The method can assist in locating those who are at a high risk of contracting diabetes and offering them early treatment. The conclusions of this project show how machine learning approaches can enhance healthcare and even save lives. The method can be further enhanced and expanded to incorporate additional variables, such family history, that are known to increase diabetes risk.

Tracking Impact of PM Poshan Scheme on Children's Nutritional Status and Well-Being

Ritika Kanojia, Gauri Kudalkar, Anusha Kulal
Information Technology Department, Thakur College of Engineering & Technology, Mumbai
Kanojiaritika723@gmail.com, gaurikudalkar29@gmail.com, anushakulal36@gmail.com

Abstract—**The following section provides an overview about tracking of children nutritional status. According to PM Poshan scheme, children from std I to std VIII are served one hot meal every day. This scheme was proposed due to rise of malnutrition among kids. As the scheme was proposed, but there was no tracking of the improvement in student. To make it easier to know how much improvement is made in child's the tracking of nutritional status this is recommended. The tracking system contains parameters like height, weight, it would calculate the body mass index and produce a graph. The data would be entered on weekly basis and the graph would be to make it to understand better and which would be easier to compare.**

Keywords— PM Poshan, mid-day meal, malnutrition, weight, height, bmi

I.INTRODUCTION

PM Poshan scheme is the largest lunch programme aimed at improving the nutritional wellbeing of students studying in government aided school. With a view of increasing enrolment, retention and attendance along with simultaneously improving nutritional levels among the children. The Cabinet Committee on Economic Affairs (CCEA) chaired by Prime Minister Narendra Modi on September 29, 2021, approved a new meal scheme known as 'Pradhan Mantri Poshan Shakti Nirman' scheme (PM Poshan Scheme) for government and government-aided schools for the next five years (from 2021-22 to 2025-26) with the financial outlay of Rs 1.31 trillion, and the existing 'Mid-Day Meal' scheme will also be included in this programme. The central government will bear an additional cost of nearly Rs 45,000 crore on providing subsidised food grains from the food ministry over the years amounting to a total outlay of Rs 1.31 trillion. PM Poshan Scheme provides school meals, which act as a strong incentive for parents to send their children to schools. So under this scheme every child in government and government aided school from std I to std VIII is serve with hot midday meal a minimum content of 450 calories of energy and 20 grams' protein per day for primary children and 700 calories of energy and 40 grams' protein per day for Upper primary children.

II. NUTRITION AND FOOD NORMS UNDER THISSCHEME

PM POSHAN is one of the leading rights-based central assistance programs under the National Food Security Act of 2013 (NFSA). The main goal of this program is to improve the nutritional status of children studying in grades I-VIII in targeted schools. The nutrition and food standards under the program are: H. INR 1/kg for coarse grains, INR 2/kg for wheat and INR 3/kg for rice.

Cooking fee: Including material cost.

Legumes, vegetables, cooking oil, other spices and fuel. His daily cooking cost per child is 4.97 rupees in elementary school and 7rupees.

45 for High School 01.04.2020

Cook and helper fee: Rs 1000 per month for 1 year and 10 months.

Transportation Assistance: Follows PDS rate schedule for transportation of grain from FCI house to school door. Up to ₹1500 per MT for transporting grain from FCI godowns in NER and states other than 2 Himalayas and 2 states other than UT to school doors.

Management, Monitoring and Evaluation (MME): 3% of the total cost of cereals, cooking costs, cook and attendant costs, and transportation costs.

Provision of meals during summer vacation in drought- and disasterstricken areas.

Shop Kitchen: Based on base area standards and state tariffs. 20 m² for a school with 100 students. Additional 4m² for each additional student up to 100.

Kitchen utensils: Associated with enrollment.

Repair of shop kitchens: Rs. 10,000 per shop kitchen built 10 years ago.

Food Fortification: Systematic food fortification by Food Corporation of India (FCI).

Innovation/Flexibility Component without Separate Budgetary Support: 5% of the total cost of is grain, cooking costs, transportation support, cooking and helper fees, and MME, without separate additional budgetary support for this component. The funding requirements for this component will be covered from available funding and will

be implemented in accordance with OM No. 55(5)/PF-II/2011 of the Ministry of Expenditure of 6 September 2016.

Provision of preparatory classes or

Balvatika (i.e. before Class I) meals in primary

schools covered by Samagra Shiksha as stipulated in the National Education Policy.

III.PROBLEM STATEMENT

PM Poshan scheme is providing hot meal for children's from std I to std VIII which will help to the children's nutritional status. Poshan Tracker is an important governance tool. Poshan Tracker is a mobile application launched by the Department of Women and Child Development, Government of India through the National e-Governance Division (NeGD) on March 1, 2021. Aim is to design an online system which will be tracking the impact of the PM poshan scheme on children and compatible enough for users to handle it from any device.

IV.EXISTING SYSTEM

There exist an system to track the impact PM Poshan scheme called Poshan Tracker. Poshan Tracker is a mobile application launched by the Department of Women and Child Development, Government of India through the National e-Governance Division (NeGD) on March 1, 2021. Poshan Tracker is an important governance tool. Use Poshan Tracker technology to dynamically identify child stunting, wasting and underweight and track nutrition service delivery over the last mile. But this app does not provide on how this scheme is impacting children's wellbeing.

The PM-POSHAN Tracker is a system that allows you to track the performance of your PMs on a daily basis. It also provides you with an overview of how each employee is performing in comparison to their peers. pm poshan tracker is a powerful yet easy to use product tracker, it allows you to set reminders and alarms for each task. It also provides an extremely easy-to-use interface for creating and managing your tasks. Its powerful calendar integration makes it easy for you to keep track of all important dates

V. LITERATURE SURVEY

PM Poshan Scheme is a government program which helps to provide food, good healthcare and education to people who are living in poverty. In terms of nutritional status, the study shows that total yin intake was significantly higher in children who benefited from the scheme. Additionally, the number of children with low energy and protein intakes was less than expected at baseline but increased significantly during the period when they received PM Poshan.In terms of nutritional status, the study shows that total yin intake was significantly higher in children who benefited from the scheme. The tracking impact of PM

Poshan Scheme on children's nutritional status and wellbeing has started. During period 1, we found that the scheme had a significant positive impact on child nutritional status, which is evident from the improved weight-for-height z-score ($p=0.02$). We also examined how PM Poshan Scheme affected a child's health and wellbeing by examining two outcomes: (i) stunting prevalence and height for age levels, as well as (ii) health care seeking behaviors such as doctor visits and immunizations after age 10. When the programme began, there were no data on its impact on children's nutritional status and well-being. However, by using several recent monitoring surveys, we found that it significantly improved the nutritional status of both girls and boys in terms of height-for-age z-scores (HAZ), micronutrient sufficiency (measured as PEM), and weight z-score (WZ). Children under 5 years old who benefited from the scheme gained an average of 3.47 cm in HAZ and 0.35 mg per day in PEM over 2 years.

VI. SYSTEM ARCHITECTURE

To develop the system which will be flexible enough to track the impact of scheme for users. Using this system would make it easy to track the nutritional status of children under the PM Poshan Scheme.

VII. TOOLS & TECHNOLOGY

A. Tools

- Python Idle
- Web Tool
- Microsoft Excel
- Power BI

B. Technologies

- Data Analytics
- DBMS
- Machine Learning
- Python
- Data Science
- Web Technologies

VIII.TECHNOLOGY

A. The Importance of Impact Tracking:

Tracking your organization's goals ensures that all efforts are focused on achieving the same high-level goals, ensuring that everyone is contributing to the company's growth and development. Additional benefits include:

1) Clarity of purpose

2) Greater unity and camaraderie

3) Increased productivity

4) Fewer errors

5) Improved skills

6) More opportunities for future projects

7) Increased likelihood of meeting budget targets

8) Increase Satisfaction

B. Technologies Used in Tracking: The two main technologies that help develop tracking are data analysis and database management systems. p.

Data Analytics

1) Data analytics is the process of analyzing raw data in order to draw out meaningful, actionable insights, which are then used to inform and drive smart business decisions.

2) A data analyst will extract raw data, organize it, and then analyze it, transforming it from incomprehensible numbers into coherent, intelligible information. Having interpreted the data, the data analyst will then pass on their findings in the form of suggestions or recommendations about what the company's next steps should be.

3) You can think of data analytics as a form of business intelligence, used to solve specific problems and challenges within an organization. It's all about finding patterns in a dataset which can tell you something useful and relevant about a particular area of the business—how certain customer groups behave, for example, or how employees engage with a particular tool.

4) Data analytics helps you to make sense of the past and to predict future trends and behaviors; rather than basing your decisions and strategies on guesswork, you're making informed choices based on what the data is telling you. Armed with the insights drawn from the data, businesses and organizations are able to develop a much deeper understanding of their audience, their industry, and their company as a whole—and, as a result, are much better equipped to make decisions and plan ahead. 5) Difference between data analytics and data science The terms "data science" and "data analytics" tend to be used interchangeably. However, they are two different fields and denote two distinct career paths. What's more, they each have a very different impact on the business or organization.

One of the key differences between data scientists and data analysts is what they do with data and what results they achieve. Data analysts want to answer specific questions or address specific problems that have already been identified and known to the business. To do this, we study large data sets to identify trends and patterns. The results are then "visualized" in the form of charts, graphs, and dashboards. These visualizations are shared with key stakeholders and used to make informed strategic decisions based on the data.

A data scientist, on the other hand, considers what questions the business should or could be asking. They design new processes for data modeling, write algorithms, devise predictive models, and run custom analyses. For example: They might build a machine to leverage a dataset and automate certain actions based on that data—and, with continuous monitoring and testing, and as new patterns and trends emerge, improve and optimize that machine wherever possible.

In short: data analysts tackle and solve discrete questions about data, often on request, revealing insights that can be acted upon by other stakeholders, while data scientists build systems to automate and optimize the overall functioning of the business.

Another main difference lies in the tools and skills required for each role.

Data analysts are typically expected to be proficient in software like Excel and, in some cases, querying and programming languages like SQL, R, SAS, and Python. Analysts need to be comfortable using such tools and languages to carry out data mining, statistical analysis, database management and reporting.

6) Data scientists, on the other hand, might be expected to be proficient in Hadoop, Java, Python, machine learning, and object-oriented programming, together with software development, data mining, and data analysis.

7) Different types of data analysis:

8) Descriptive analytics

9) Descriptive analytics is a simple, surface-level type of analysis that looks at what has happened in the past. The two main techniques used in descriptive analytics are data aggregation and data mining—so, the data analyst first gathers the data and presents it in a summarized format (that's the aggregation part) and then "mines" the data to discover patterns.

10) The data is then presented in a way that can be easily understood by a wide audience (not just data experts). It's important to note that descriptive analytics doesn't try to explain the historical data or establish cause-and-effect relationships; at this stage, it's simply a case of determining and describing the "what". Descriptive analytics draws on descriptive statistics, which you can learn about here. Diagnostic analytics

11) While descriptive analytics looks at the "what", diagnostic analytics explores the "why". When running diagnostic analytics, data analysts will first seek to identify

anomalies within the data—that is, anything that cannot be explained by the data in front of them.

For example: If the data shows that there was a sudden drop in sales for the month of March, the data analyst will need to investigate the cause.

12) To do this, they'll embark on what's known as the discovery phase, identifying any additional data sources that might tell them more about why such anomalies arose. Finally, the data analyst will try to uncover causal relationships—for example, looking at any events that may correlate or correspond with the decrease in sales. At this stage, data analysts may use probability theory, regression analysis, filtering, and time-series data analytics.

Predictive analytics

13) Just as the name suggests, predictive analytics tries to predict what is likely to happen in the future. This is where data analysts start to come up with actionable, data-driven insights that the company can use to inform their next steps. Predictive analytics estimates the likelihood of a future outcome based on historical data and probability theory, and while it can never be completely accurate, it does eliminate much of the guesswork from key business decisions.

14) Predictive analytics can be used to forecast all sorts of outcomes—from what products will be most popular at a certain time, to how much the company revenue is likely to increase or decrease in a given period. Ultimately, predictive analytics is used to increase the business's chances of "hitting the mark" and taking the most appropriate action.

Prescriptive analytics

15) Building on predictive analytics, prescriptive analytics advises on the actions and decisions that should be taken.

In other words, prescriptive analysis shows how predicted outcomes can be exploited. When conducting prescriptive analysis, data analysts consider multiple possible scenarios and evaluate different actions a company can take.

16) Prescriptive analysis is one of the most complex types of analysis and can involve tasks involving algorithms, machine learning, and computational modeling procedures. However, effective use of prescriptive analytics can have a profound impact on a company's decision-making process and ultimately its bottom line.

17) The type of analysis you perform depends on the type of data you are working with.

If you're not already familiar with it, it's worth learning about the four levels of data measurement: Nominal, Ordinal, Interval, and Relative.

D. Database Management System

Database Management System (DBMS) is system software for creating and managing databases. A DBMS allows end users to create, protect, read, update and delete data in databases. The most common type of data management platform, a DBMS essentially acts as an interface between a database and a user or application, ensuring that data is consistently organized and easily accessible.

What does a DBMS do?

The DBMS manages the data; the database engine allows data to be accessed, locked and modified; and the database schema defines the database's logical structure. These three foundational elements help provide concurrency, security, data integrity and uniform data administration procedures. The DBMS supports many typical database administration tasks, including change management, performance monitoring and tuning, security, and backup and recovery. Most database management systems are also responsible for automated rollbacks and restarts as well as logging and auditing of activity in databases and the applications that access them.

1) The DBMS provides a centralized view of data that can be accessed by multiple users from multiple locations in a controlled manner. A DBMS can limit what data end users see and how they view the data, providing many views of a single database schema. End users and software programs are free from having to understand where the data is physically located or on what type of storage medium it resides because the DBMS handles all requests.

2) The DBMS can offer both logical and physical data independence to protect users and applications from having to know where data is stored or from being concerned about changes to the physical structure of data. So long as programs use the application programming interface (API) for the database that the DBMS provides, developers won't have to modify programs just because changes have been made to the database.

What is included in the DBMS?

3) A DBMS is a complex system software consisting of several integrated components that provide a consistent and manageable environment for creating, accessing and modifying data in a database. These components include:

4) Storage Engine

This basic DBMS element is used to store data. A DBMS needs to interact with the file system at the operating system (OS) level to store data. Additional components can be used to store data or interact with actual data at the file system level.

5) Metadata catalogue

Sometimes called a system catalog or database dictionary, a metadata catalog functions as a repository for all the database objects that have been created. When databases and other objects are created, the DBMS automatically registers information about them in the metadata catalog. The DBMS uses this catalog to verify user requests for data, and users can query the catalog for information about the database structures that exist in the DBMS. The metadata catalog can include information about database objects, schemas, programs, security, performance, communication and other environmental details about the databases it manages.

6) Database access language

The DBMS also must provide an API to access the data, typically in the form of a database access language to access and modify data but may also be used to create database objects and secure and authorize access to the data.

SQL is an example of a database access language and encompasses several sets of commands, including Data Control Language for authorizing data access, Data Definition Language for defining database structures and Data Manipulation Language for reading and modifying data. 7) Optimization engine

A DBMS may also provide an optimization engine, which is used to parse database access language requests and turn them into actionable commands for accessing and modifying data.

8) Query processor

After a query is optimized, the DBMS must provide a means for running the query and returning the results.

9) Lock manager

This crucial component of the DBMS manages concurrent access to the same data. Locks are required to ensure multiple users aren't trying to modify the same data simultaneously.

10) Log manager

The DBMS records all changes made to data managed by the DBMS. The record of changes is known as the log, and the log manager component of the DBMS is used to ensure that log records are made efficiently and accurately. The DBMS uses the log manager during shutdown and startup to ensure data integrity, and it interfaces with database utilities to create backups and run recoveries.

11) Data utilities

A DBMS also provides a set of utilities for managing and controlling database activities. Examples of database utilities include reorganization, runstats, backup and copy, recover, integrity check, load data, unload data and repair database.

IX. Working

The first page of the online system would be a login page. Through this the information of each and every student's data would be saved. It would take a particular student's height, weight and age. And would return the body mass per index. The system would be fed with information of each student every week, then at the end of the month it will generate a graph, so that it would be easy to analyse the growth in the nutritional status and the benefit that a student received by this scheme.

X.RESULTS

The results of this study show that PM Poshan therapy had a positive effect on children with improved nutrition and wellbeing. The results of the PM Poshan plan showed that children from grades 1 to 6 showed significant improvements in nutritional status and IQ. The PM Poshan plan has been found to be beneficial in improving children's health and well-being by increasing intake of nutritious foods and increasing the frequency of physical activity. The PM Poshan program was launched to improve children's nutrition and well-being. Results so far have observed that nearly 70% of children have benefited from the scheme. The children were found to have taken nutritional supplements, and most were well covered, allowing them to visit the polyclinic regularly. Nutritional status of children under 5 years of age has improved over the past 3 years. Children get adequate amounts of calories, protein and fat.

XI. CONCLUSION

PM Poshan Scheme is a scheme where children from std IVIII are given one hot cooked meal every day. This scheme was founded to curb rising malnutrition and hunger among children. In order to track the progress of this scheme we will be building a software that will take data as input and give results as output that can be in the form of graph. This will be done using DBMS and Data Analytics. XII. **Reference**

Land Use Land Cover Change Detection using Machine Learning

Kiarah Patel, Devansh Pathak, Nandita Patra
Thakur college of engineering and technology Mumbai, India
hempatel263@gmail.com, devanshpathak2002@gmail.com, nanditap580@gmail.com

Abstract— **Despite the fact that the phrases "land use" and "land cover" are sometimes used synonymously, they are not the same. Land-use change refers to a change in how a particular area of land is utilised or managed by humans. Two of the most well-known land use types are urban and agricultural land uses. Land-cover change can be defined as change in some continuous characteristics of the land, such as vegetation type, soil conditions, etc. Using satellite remote sensing data, a huge region of land cover can be quickly recognised and mapped. Planners and managers can use these maps to comprehend the existing environment, which will enable them to assess previous management choices and gain perspective on the outcomes of their current choices before they are put into action. For instance, coastal managers utilise maps and data on land cover to comprehend how natural occurrences and human usage of the terrain affect each other. Maps can assist managers in assessing urban growth, simulating problems with water quality, predicting and evaluating the effects of floods and storm surges, tracking the loss of wetlands and potential effects from sea level rise, prioritising areas for conservation efforts, and comparing changes in land cover to environmental effects or to connections with socioeconomic changes like population growth. Unsupervised or supervised methodologies, or a combination of the two, can be used to create a straightforward land cover and use map. The spectral, spatial, and radiometric resolution of the picture data set determines the resulting map. The fundamental requirements for an image**

classification are a general understanding of the research area's landscape, post classification field verification, and accuracy assessment.

Keywords— Land Cover Change, Land Use change, Climate Change, LULC Change, Classification Algorithms, Deforestation

I. INTRODUCTION

Future investigations into a number of global phenomena, such as droughts, floods, erosion, migration, and climate change, will be aided by an understanding of land use and land cover at different scales. The activities conducted for sustainable development in any given area must include ongoing, precise LULC analysis. A wide range of research investigations on the effects of climate change on stream-flow and water budgets, geomorphology, groundwater management, social knowledge management of natural resources, and agricultural land monitoring all benefit from detailed LC maps. LULC maps can be used to identify the types of areas that are best suited for agriculture and those that are generally helpful for managing watersheds. The most popular technique for mapping land cover and monitoring changes over time is remote sensing photography. The hydro-logic and water resources modelling community is eager to incorporate and assess changing land use and its impact on the water budget due to population growth and the need to develop new regions to meet the need for food production, energy generation, and water security. Large-scale low-resolution land cover mapping requires a vast amount of data. As a result, enormous storage capabilities, powerful processing, and the ability to use a variety of techniques are all necessary.

According to a number of studies, the LULC classification using medium- and low-resolution satellite images has a number of spectral and spatial constraints that reduce its accuracy. Therefore, in order to overcome the aforementioned constraints and produce high-precision LULC pictures, researchers have been using machine-learning techniques [1,2]. Furthermore, because successful outcomes depend on the machine-learning model setup, training data, and input parameters, not all machine-learning techniques always result in a high-precision LULC map. Numerous studies have been done on land-use classification using machine-learning algorithms up to this point, but the effectiveness of the models has not been thoroughly assessed [3,4]. Six machine-learning algorithms were used in this research to determine which methodology, based on accuracy statistics, can build a high-precision LULC map.

II. Review of Literature

The majority of the terrestrial biosphere has been altered by human populations and land usage into anthropogenic biomes. A number of novel ecological patterns and processes have emerged as a result of this transition, which has been significant for more than 8000 years (Ellis, 2011). Many different types of scholars have recently become interested in issues with LULC transformation, from those who prefer studying spatio-temporal patterns of land conversion to others who attempt to understand the origins, implications, and consequences (Verburg et al. 1999; Brown et al. 2000; Theobald, 2001) [5,7]. Despite being constrained by physical limitations, human activities that are primarily driven by socioeconomic factors result in changes in both undeveloped and developed land (Long et al. 2007) [10]. A significant amount of the earth's land surface has been changed via land use change, including land conversion from one type to another and land cover modification through land use management. The objective is to meet the urgent needs of humans in terms of natural resources (Meyer and Turner, 1992; Vitousek et al. 1997) [8]. In a research conducted in the Shurugwi district of Zimbabwe's Midlands Province in 2010, Mark and Kudakwashe noted a rise in cropland. He credited the Land Reform and Resettlement Program for this rise. For many agricultural purposes, such as creating new farming plots, obtaining wood for fuel, and erecting poles for among other things, construction of both houses and cow enclosures. In Davangere city, Karnataka, India, the built-up area has nearly doubled between 1970 and 2005 at the expense of agricultural and scrub land (Begum et al. 2010) [9].

III. Need for the study

A society's social and economic development is completely correlated with its rate of expansion. This is the main justification behind socioeconomic surveys. Datasets from both spatial and non-spatial sources are used in this kind of survey. The planning, management, and monitoring of programmes at the local, regional, and national levels heavily relies on LULC maps. On the one hand, this type of information aids in a better understanding of land utilisation issues, and on the other, it is crucial in the establishment of the policies and programmes needed for development planning. Monitoring the ongoing pattern of land use/land cover through time is essential for ensuring sustainable development. Authorities involved in urban development must create these planning models so that every available piece of land can be used in the most logical and effective way in order to ensure sustainable urban development and prevent the haphazard growth of towns and cities. Information about the area's past and present land usage and land cover is necessary for this. We may study the changes in our ecology and surroundings with the aid of LULC maps. We can create regulations and start programmes to safeguard our environment if we have inch-by-inch data on the Land Use/Land Cover of the study unit.

IV. RELATED Work

Rao & Narendra (2006) and Boakye et al (2008) have done the mapping of land use and land cover changes using unsupervised classification methodology. To classify data and prepare final maps, they used ERDAS envision software. Researchers and scientists have utilised the ERDAS Imagine software for classification purposes in a number of projects [12].

Studies on sustainable watershed management have been conducted in places where resources are best used for the welfare of the populace and the overall growth of a region. Studies were conducted to decide on different land use alternatives in a watershed by visual interpretation techniques employing GIS in order to achieve the best possible resource usage. Similar research was done in the National Capital Region (NCR) of Delhi, where Mohan (2005) conducted urban LULC change detection as part of planning for rural and urban communities [13].

For use in their Maryland Geographic Information (MAGI) database, the State of Maryland Health Resources Planning Commission created a land cover data set using Landsat TM information. The U.S. Geological Survey also conducted research in 1985 to create 1:250,000 scale land cover maps for Alaska using data from the Landsat MSS satellite (Fitzpatrick et al. 1987). A 21-class land cover map was produced using all seven TM bands (EOSAT, 1992).

In 1992, the Georgia Department of Natural Resources mapped the whole State of Georgia using Landsat Thematic Mapper data to locate and quantify wetlands and other land cover types (ERDAS, 1992). Similarly, using TM multi-temporal and multi-spectral data, the State of southern Carolina Lands Resources Conservation Commission created a thorough land cover map with 19 classes (EOSAT, 1994).

For the investigation of land use/land cover patterns in Indonesia, a mix of MSS Landsat and land use maps was used (Dimyati, 1995). Remote sensing techniques were used to generate the index of changes. This was accomplished by superimposing land use/land cover pictures from 1972, 1984, and 1990 on top of each other[16]. Remote sensing and GIS techniques were utilised by Adeniyi and Omojola (1999)[15] in their land use and land cover change evaluation in the Sokoto-Rima Basin of north-western Nigeria to examine changes in the two dams (Sokoto and Guronyo) between 1962 and 1986. The study showed that although land use/land cover category varied, settlement remained the dominant one.

Many researchers, including Rao and Narendra (2006), Remi et al (2007), Chaudhary et al (2008), and Kim et al (2008), have used supervised classification in their investigations as opposed to unsupervised classification. They stated that the Maximum Likelihood Classification

(MLC) decision rule was used to classify land use and land cover with the highest classification accuracy possible [14].

According to the State Forest Report Maharashtra (2005), Maharashtra has a total area of 30,771,000 hectares, of which 19.27% is unsuitable for agriculture, 2.94% is occupied by cultural waste, 3.81% by fallow lands other than current fallows, and 3.87% by current fallows.

V. Study Area

The selected study area for the land use and land cover analysis is the Mumbai Metropolitan Region (MMR). Mumbai Metropolitan Region is a metropolitan area made up of Mumbai (Bombay) and its surrounding communities in the western Indian state of Maharashtra's northern Konkan division. With a population of over 26 million and a total area of 6,355 square kilometres (2,454 sq mi), the region is one of the most populated metropolitan areas in the world. Rapid urbanisation has caused issues with unplanned and illegal development in the area. Some of the largest warehousing areas in India may be found in the villages along the NH 3 in Bhiwandi, which are examples of haphazard growth in the MMR. Governmental organisations like the Thane Collector and Town Planner have had to deal with unorganised growth.

Figure 1: Mumbai Metropolitan Region (MMR)

The exact latitude and longitude coordinates of MMR are: 19.076090, 72.877426. The area of Mumbai Metropolitan region is around 8,500 km2. Population of MMR region is 22,885,000 according to 2016 Census.

VI. Data Set

The LANDSAT 5 and LANDSAT 8 time series spatial data for three years (different decades 2000, 2011 and 2020) were used. L-8 and Landsat 8 (30 mts) (OLI). The USGS website was used to get the georeferenced data. The results would also depend on the meteorological conditions in the MMR regions if the photographs were from the same month.

This work has been divided into two stages for evaluation and prediction of LULC: (2) Future LULC map prediction using historical LULC data to simulate the future changes in LULC pattern and urban growth. (1) Spatiotemporal LULC maps are created from satellite photos.

USGS website was used to get the georeferenced data. Having photos from almost the same month would also produce outcomes according to the MMR regions' air conditions.

VII. Proposed Methodology

Figure 2 represents the methodology used. Supervised algorithms are used for LULC Detection. Supervised algorithms are predicated on the notion that a user can choose sample pixels from an image that are characteristic of particular classes, instructing the image processing software to utilise these training sites as references for the categorization of all other pixels in the image. The user's knowledge is taken into consideration while choosing training sites, sometimes referred to as testing sets or input classes. The threshold for how similar other pixels must be to be grouped together is likewise chosen by the user. These limits are frequently established using the training area's spectral properties, plus or minus a certain increment (often based on "brightness" or strength of reflection in specific spectral bands). Additionally, the user specifies how many classifications the image will fall under.

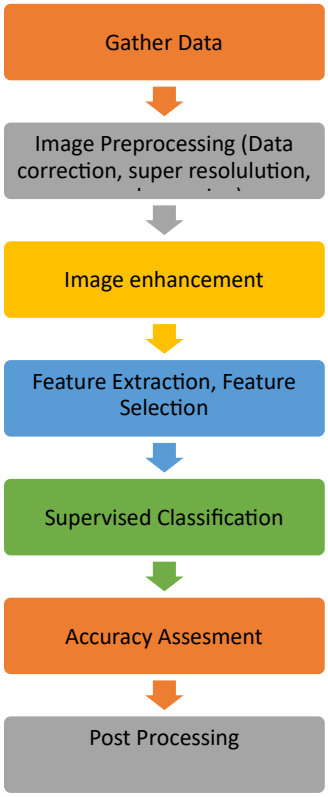

Figure 2: Methodology

Machine learning algorithms, such as RF, CART, and SVM, and deep learning algorithms such as ANN, were used to train the classifiers for both Landsat-5 and Landsat-8 images.

Classification and Regression Tree (CART)

The CART algorithm, which is used in machine learning, shows how the values of the target variable can be predicted based on other factors. Each fork of the decision tree is divided into a predictor variable, and at the conclusion of each node is a prediction for the target variable. Depending on the threshold value of an attribute, nodes in the decision tree are divided into sub-nodes. The training set is the root node, which is divided into two by taking the best attribute and threshold value into account. Additionally, the subsets are divided according to the same rationale. This continues until the tree has either produced all of its potential leaves or found its last pure sub-set.

Random Forest Classification

Popular machine learning algorithm Random Forest is a part of the supervised learning methodology. It can be applied to ML issues involving both classification and regression. It is built on the idea of ensemble learning, which is a method of integrating various classifiers to address difficult issues and enhance model performance. Random Forest, as the name implies, is a classifier that uses a number of decision trees on different subsets of the provided dataset and averages them to increase the dataset's predictive accuracy. Instead than depending on a single decision tree, the random forest uses forecasts from each tree and predicts the result based on the votes of the majority of predictions.

Support Vector Machine

One of the most well-liked supervised learning algorithms, Support Vector Machine, or SVM, is used to solve Classification and Regression problems. However, it is largely employed in Machine Learning Classification issues. The SVM algorithm's objective is to establish the best line or decision boundary that can divide n-dimensional space into classes, allowing us to quickly classify fresh data points in the future. A hyperplane is the name given to this optimal decision boundary. SVM selects the extreme vectors and points that aid in the creation of the hyperplane. Support vectors, which are used to represent these extreme instances, form the basis for the SVM method.

Artificial Neural Networks

Artificial Neural Networks contain artificial neurons which are called units. These units are arranged in a series of layers that together constitute the whole Artificial Neural Networks in a system. A layer can have only a dozen units or millions of units as this depends on the complexity of the system. Commonly, Artificial Neural Network has an input layer, output layer as well as hidden layers. The input layer receives data from the outside world which the neural network needs to analyze or learn about. Then this data passes through one or multiple hidden layers that transform the input into data that is valuable for the output layer. Finally, the output layer provides an output in the form of a response of the Artificial Neural Networks to input data provided. In the majority of neural networks, units are interconnected from one layer to another. Each of these connections has weights that determine the influence of one unit on another unit. As the data transfers from one unit to another, the neural network learns more and more about the data which eventually results in an output from the output layer.

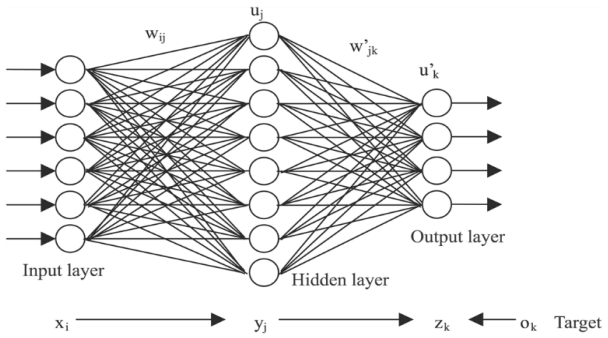

Figure 3: Artificial Neural Networks

VIII. Conclusion

The study aims to generate Land Use/ Land Cover (LULC) maps for Mumbai Metropolitan Region (MMR) which will provide important information such as dynamics of agricultural ecosystems, forest conversions, surface water bodies, etc. on annual basis and classify land into agriculture, bare soil, bushland, forest, grassland, built-up, water, and wetland which will help in land conservation, sustainable development, and management of water resources. This will also help in the formation of policies and programme required for development planning, achieve sustainable urban development and to check the haphazard development of towns and cities.

Acknowledgement

Without the outstanding assistance of our teacher and project advisor, Mr. Vijay Yele, this report and the research behind it would not have been feasible. The Thakur College of Engineering and Technology provided funding for this study. We are grateful to our institution's faculty members who offered knowledge and insight that were extremely helpful to the research. Additionally, we would like to express our gratitude to Mr. Vijay Yele for lending us his perspective and ideas during this project.

Abstract— **The aim of this study is to develop systems to track the performance of a student at ABC University. System development is necessary because different sources and separate data are not always available when the Department of Information Systems wants to track student performance. Furthermore, the data is not provided in a timely manner, which hinders the tracking process, thereby affecting student learning outcomes. Therefore, the system also aims to make it easier for users of the system to see student learning outcomes in line with the data required for monitoring.**

Keywords—student, academics, marks, performance monitoring, marks prediction, machine learning

I.INTRODUCTION

Future changing agents must be intelligent and capable of critical thought. According to this paradigm, students must participate actively in all events and activities on campus. Students are one age group that is younger in terms of potential for humanity, which includes people with higher than normal thought levels. Personal and social interests, however, may occasionally conflict. This issue will affect how well students do. The success of a student's academic endeavours is influenced by both internal and external variables, claims Slameto [1]. 1) Internal variables, broken down as 1) Physical Factor 2) Psychology Factor 3) Fatigue Factor 2) External factors divided into a) Family Factor, b) School Factors, c) Society Factors.

Predicting pupils' performance has grown more challenging due to the enormous amount of data in educational databases. Lack of a set system for assessing and monitoring success also not taken into account at the moment. There are two main causes for such types of occurring. First, there is yet inadequate study on current prediction techniques to determine the most the most suitable techniques for forecasting student performance at schools. The second is the lack of inquiry courses in question. A summary of the artificial intelligence systems that were utilised for prediction is the actual objective. Academic education. This study focuses on how to categorise the most important characteristics of students. This study also focuses on applying prediction algorithms to categorise the student data's most important characteristics. We might be able to more effectively and efficiently increase student performance and growth by using educational machine learning techniques. Academic institutions, educators, and students all stand to gain from this.

II.METHODOLOGIES:

Linear Regression:

One of the simplest and most well-liked Machine Learning algorithms is linear regression. It is a statistical technique for performing predictive analysis. For continuous/real or quantitative variables like sales, salary, age, product price, marks, etc., linear regression generates predictions.

The classification method that deals with the threshold value is logical regression. The threshold value is determined using the following factors: • Low Precision

/ High Recall • High Precision / Low Recall

B. Decision Tree:

The regression model called a decision tree classifier is displayed as a tree structure. The dataset will be divided into smaller subsets using a decision tree classifier. Decision nodes and leaf nodes make up the tree. The property that provides the most information will serve as a decision node in our suggested architecture. The root node, which is the node that makes up the majority of the decision nodes, functions as a predictor. Leaf nodes are nodes that cannot be further separated.

The decision tree's steps are listed below in detail:

• Process 1: Start the root.

• Process 2: Perform the test.

• Process 3: Follow the edges that correspond to the result.

• Process 4: go to step 2 until reaches leaf node.

• Process 5: Predict what will happen based on the leaf.

C. K-Nearest Neighbour:

One of the fundamental and fundamental classification techniques in machine learning is K-Nearest Neighbor. It is non-parametric and doesn't make any underlying predictions about how the data will be distributed.

Following is a list of the steps that the KNN took:

• The training data should be saved in a sample points array.

• The Euclidean distance measures.

• Make the least distance range available.

The categories for the logical regression can be categorized as follows:

• Binomial

• Multinomial

• Ordinal

III. RELATED WORK

To assess student success and evaluate student performance, an automated evaluation method has been proposed. Here, the author employs the tree method to accurately forecast student performance. The classification of the suggested approach uses Education Data Mining (EDM). The extensive student database is analysed using the clustering data mining technique. This method will expedite the search process and produce a more accurate classification result.

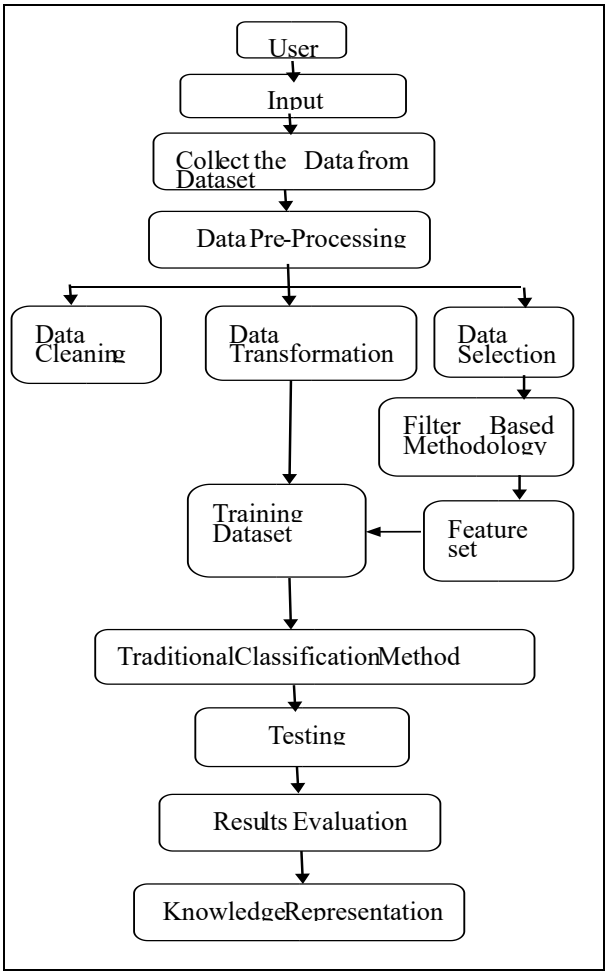
Utilizing the student data from college enrolment, a novel learning model has been presented.

The finished dataset is made available as input to machine learning (ML) algorithms that may apply and forecast student academic achievement. They chose 13 algorithms from the Naive Bayes, SVM, MLP, IBK, Rules, and tree categories of machine learning (ML).

It has been suggested to compare various supervised learning methods for student prediction. 14 feature set for classification are used by the author. KNN, Decision trees, and Navie Bayes are the tools used in classification.

Using student intellectual factors that have an impact on their studies, psychometric analysis of student behaviour has been presented. For the purpose of determining the educational data pertaining to psychological variables, many mining approaches are applied. The accuracy rate of the prior study was 89%, however by implementing the suggested system, it has increased to 90%. To attain greater precision, the author in this instance used a Radical Basis Function Kernel.

V.SYST ARCHITEC



IV. DATA PREPARATION

a) Data Consolidation

• Data Selection:

• Academic variables of interest identified

b) Data Cleaning

• Missing Values Report:

• No reported values missing

• Outlier Detection Report:

• No reported outliers

c) Data Transformation

• Dummy variable creation:

• College

• Attends-College Hours

• Accommodations Class

d) Data Reduction

• Removed variable Return

Removed 23 records that included the Return attribute

The above figure clearly explains the system architecture of the proposed system.

The suggested system's steps are as follows:

• Collecting data about users and the behavior.

• Transforming the data into features.

• Train the model.

• Deploy the trained model.

VI. REVIEW OF LITERATURE

A review of earlier research on the connection between undergraduate students' success and their prior academic accomplishment was done. The data from this evaluation provided a foundation for comparing the results of the current study to those discovered in the earlier.

A. Academic success

The academic success of university students has been the subject of a sizable body of literature (at undergraduate and postgraduate levels). Academic success is a phenomenon that includes academic success, achieving learning goals, acquiring desirable skills and competences, satisfaction, perseverance, and performance after college (York et al., 2015). Academic success has alternatively been defined as completing tasks that advance the academic performance of the student in question.

In order to meet the goals for knowledge and skill development during the learning process, academic success is crucial. Therefore, it is important to comprehend the underlying aspects that influence university students' academic achievement.

Numerous factors affect undergraduate students' academic achievement at the university level, according to academic success research This has led to the development of several ideas. Such as pedagogical theory, curricular theory, and learning theory in the realm of education a few others Empirical research has examined the effects of a wide range of variables on the University undergraduate students' academic achievement (Parker et al., 2004; Young,1989). It's important to note the use of the words "achievement" and "academic success" in literature interchangeably. Herminio (2005) identified two elements that influence academic performance. variables that are both internal and external to success. The external influences are extracurricular activities, family and work activities, as well as the class schedule, size of the class, classroom setting, lecturers' roles, technology, and kind of exam. The results of Herminio (2005) demonstrate that internal factors are far more important than external influences. Ling et al. (2010) also looked at how different teaching and learning strategies affected student performance. It was discovered that greater academic achievement is associated with the growing teaching strategy and the accomplishing motive learning approach. Similarly, research has shown that first-year university students' academic success is significantly influenced by their earlier academic performance (e.g. McKenzie and Schweitzer, 2001; Win and Miller, 2005).

B. Prior academic performance and success on undergraduate programs

Recent research has looked at the connection between prior academic success and undergraduate students' academic success in universities (see Abisuga et al., 2015; Curtis et al., 2007; Whyte et al., 2011; Shahiri and Husain, 2015). According to Curtis et al. (2007), admission standards are only marginally predictive of first-year dental students' academic success. Similar to this, Whyte et al. (2011) found that students' age and index scores are the best indicators of academic achievement for paramedic and nursing students.

Additionally, several research indicated that age maturity and academic entry requirements are the best indicators of academic achievement in undergraduate nursing and paramedic programmes (Van Rooyen et al., 2006; Whyte et al., 2011).

The studies that have been discussed thus far show that there is a link between undergraduate students' academic success and their prior academic accomplishment. The impact of this link is influenced by other circumstances, it should be mentioned.

C. Method

Using a variety of techniques, several academics have looked at the factors that affect academic performance in programmes for the built environment. In the literature, a questionnaire survey (Ling et al., 2010), simulation (Long et al., 2009), and longitudinal survey are among the research techniques used (Guillermo et al., 2014). Although a variety of research methodologies have been used in the literature, it is crucial to remember that the suitability of a certain strategy to solving a research problem is a key aspect to be taken into account when choosing a research methodology. An efficient strategy to examine the relationship between dependent and independent variables is to use the modelling research method (Fellows and Liu, 2015). Predictions can then be made using the revealed underlying pattern. Additionally, theory/hypothesis testing can benefit from prediction modelling (Shmueli, 2010).

Therefore, the academic success of undergraduate students enrolled in an architecture programme at a Nigerian university was predicted using two machine learning modelling techniques (namely, the k-NN algorithm and linear discriminant analysis).

D. Ethical consideration

Prior to data collection, permission from the relevant academic department was acquired. The administrators in charge of the database anonymized each student's academic records in order to adhere to ethical standards.

E. Data

The Olabisi Onabanjo University launched its undergraduate architecture programme in 2003. The programme incorporates pertinent courses from different built environment disciplines as well as studiobased learning methodologies. The current entrance requirements are meant to give strong academic achievers (based on prior academic accomplishment) and students from

educationally disadvantaged areas entry opportunities into the architecture programme. Additionally, the National Universities Commission has accredited the undergraduate programme in architecture

TABLE I.CLASS DISCRETISATION

Class	Possible value (CGPA Range)
Pass	5.00 – 2.40
Fail	2.39 – 0.00

Fig. 1. Class discretisation

Table ii. The pre-processed input and output variables

Attribute	Description (Domain)
Grades obtained in 'O' level Examinations Pass	
Mathematics (MATH)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
English (ENG)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Physics (PHY)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Biology (BIO)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Chemistry (CHEM	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Technical Drawing/Fine Arts (TD)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Economics (ECON)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Further Mathematics (FM)	Grade of a student (numeric: from 9 - A1 to 0 - no grade)
Total UTME scorea (JAMB)	Total score (numeric: from 1 to 0)
Direct entry (DE)	Mode of entry (binary: yes-1 or no)
Academic Success	CGPA at graduation (Binary: 1Pass or 0-Fail)

Total UTME score = student's UTME score / 400

F. MACHINE LEARNING MODELS

In the current study, linear discriminant analysis and nearest neighbour modelling techniques were utilized to predict students' academic progress. The machine-learning methods (linear discriminant analysis and k-nearest neighbour, respectively) were implemented in the R programming language and Rminer R-package (R Core Team, 2015). (Cortez, 2010). To investigate the relationship between a group of independent factors and a dependent variable, traditional linear regression models are used. It is crucial to understand that the linear regression model cannot accurately predict a dependant variable that is categorical (i.e. a classification problem). So, in the current work, two machine-learning algorithms were used.

A machine-learning method called K-nearest Neighbor (kNN) has been used for classification and regression problems. K-NN is utilised for classification in this study. The core idea of the kNN algorithm, according to Parsian (2015), is that no prior assumptions are made about the function f:

$$y = f(x_1 + x_2 + ... + x_n)$$

The independent variables xi is here, and the dependent variable y is. Given that no parameter is estimated, the function f is nonparametric. The technique dynamically locates k observations in the training data that are comparable to p (the k nearest neighbour) given new data sets (i.e. test data). A similarity measure that is calculated between the data based on independent factors identifies the neighbours. The Euclidean distance between the independent variables in the training set (x1,x2,….,xn) and test set (p1, p2,….,pn)can be expressed as:

$$\sqrt{(x_1 - p_1)^2 + (x_2 - p_2)^2 + ... + (x_n - p_n)^2}$$

Results

The procedures used before fitting the model are discussed in the section before that. The training data sets were fitted using k-nearest neighbour modelling and linear discriminant analysis.

This section displays the models' overall prediction accuracy.

VII. ACKNOWLEDGMENT

This paper and the research behind it would not have been possible without the exceptional support of Our supervisor, Mrs.Pranjali Kasture. This research was supported by Thakur College of Engineering and Technology. We thank our faculties from our institution who provided insight and expertise that greatly assisted the research We would also like to show our gratitude to Mrs. Pranjali Kasture for sharing their pearls of wisdom with us during the course of this research.

VIII. CONCLUSION

The analysis of students' academic growth using machine learning techniques is the main topic of the paper. Binomial logical regression, a decision tree, entropy, and a KNN classifier are all used in the investigation. This procedure can make it easier for the instructor to assess student performance and plan more effective lessons and can predict the marks of students on the basics of available data

to raise their academic performance. In future additional features are added to our dataset to acquire better accuracy.

Flood Prediction Using Machine Learning

Avinash Umesh Chaudhary, Gaurav Rakesh Ojha, Karan Rajesh Makwana
Thakur College of Engineering and Technology Mumbai, India
chaudharyavinash324@gmail.com, gauravojha51.go@gmail.com, karanmakwana1410@gmail.com

Abstract— **Flood is one of the most unavoidable natural disasters. No place is fully protected from this disaster so every country always tries their level best to prepare themselves for this disaster. Many countries face this disaster every year and have to suffer through lots of loss in all terms financial, environmental, human lives, and many more which cannot be compensated no matter what is done. Flash floods are the most dangerous type of flood because they combine the destructive power of the flood with incredible speed. Flash floods occur when heavy rainfall exceeds the soil's ability to absorb it. They also occur when water fills normally dry creeks or streams, or enough water accumulates to cause streams to overflow their banks, causing rapid water rises in a short period of time. They can occur within minutes of causal collisions, limiting the time available to warn and protect the public. As one of the methods of artificial intelligence, machine learning significantly contributes to the advancement of predictive systems to provide better performance and cost-effective solutions. Accurate and timely prediction of floods is essential for reducing their impact. In recent years, machine learning algorithms have been increasingly used for flood prediction due to their ability to analyze large amounts of data and identify complex patterns. This paper provides a review of the technology of flood prediction using machine learning, including the different algorithms used, the advantages and disadvantages of the technology, and the challenges and future directions of the field.**

Keywords—Flood, Flood Prediction, Machine Learning

I. INTRODUCTION

Floods are among the most devastating natural disasters, causing devastating damage to human life, infrastructure, agriculture and socio-economic systems. Governments are therefore under pressure to create reliable and accurate maps of flood risk areas and to plan sustainable flood risk

management with a focus on prevention, protection and preparedness [1]. Flood prediction models are very important for risk assessment and management of extreme events. Robust and accurate forecasts will greatly contribute to water resource management strategies, policy proposals and analyses, and further evacuation models [2]. Therefore, the importance of advanced systems for short- and long-term forecasting of floods and other hydrological events for damage reduction is strongly emphasized [3]. However, predicting flood lead times and locations is inherently complex due to the dynamic nature of climate conditions. Therefore, today's large-scale flood forecasting models are largely data-specific and include various simplistic assumptions [4]. Flood forecasting machine learning (ML) models help with flood warnings and mitigation or prevention. For this purpose, machine learning (ML) techniques have gained popularity due to their low computational requirements and their reliance mainly on observational data. Accurate forecasts help mitigate flood impacts. In recent years, machine learning algorithms have become a promising tool for flood prediction due to their ability to analyze large amounts of data and identify complex patterns. The use of machine learning algorithms for flood prediction has been increasing, as the algorithms can provide more accurate and faster predictions than traditional methods. There are various advantages of machine learning that can help to predict flood, some of them are mentioned below as:

• Improved accuracy: Machine learning algorithms can analyze large amounts of data and identify complex patterns, leading to more accurate predictions.

• Faster predictions: Machine learning algorithms can process large amounts of data quickly, leading to faster predictions.

• Integration of multiple factors: Machine learning algorithms can consider multiple factors that contribute to floods, including rainfall measurements, river levels, and land use patterns.

Machine learning have great benefits as mentioned above but there are also some dependencies or requirements which needs to be fulfilled or can affect the accuracy of

the flood prediction model, few of the requirements are as follows:

• Need for high-quality data: Machine learning algorithms rely on high-quality and comprehensive data to make accurate predictions, which can be a challenge.

• Risk of overfitting: There is a risk of overfitting the algorithms to the data, leading to inaccurate predictions. Need for regular updates: Machine learning algorithms need to be updated regularly as new data becomes available, which can be time-consuming and costly.

A good and accurate model can be a great help to government to plan in planning the further plans for tackling the flood situations which will help large masses and countries which have to suffer through this disaster every year.

II. RELATED WORK

The following are some review of research work regarding flood prediction using machine learning:

• Amir Mosavi, Pinar Ozturk, Kwok Wing Chau (2018) work review

There work states the enormous progress made in field of ML in past two decades and various advantages of using Machine learning in predicting flood. Researchers aim to discover more accurate and efficient predictive models by introducing new ML techniques and hybridizing existing ones. The main contribution of this paper is to show state-of-the-art ML models in flood forecasting and provide insights on the best models. This article specifically examines the literature evaluating ML models through qualitative analyzes of robustness, accuracy, efficacy, and speed to provide a comprehensive overview of various ML algorithms used in the field. This paper presents the most promising forecasting methods for both long-term and

short-term floods. In addition, the most important trends for improving the quality of flood forecasting models are considered. Among them, hybridization, data decomposition, algorithm ensemble, and model optimization are described as the most effective strategies to improve ML methods.

• Nur-Adib Maspo1, Aizul Nahar Bin Harun2, Masafumi Goto1, Faizah Cheros1, Nuzul Azam Haron3 and Mohd Nasrun Mohd Nawi4 (2019) work review

The study aims to evaluate existing machine learning (ML) approaches for flood forecasting and to evaluate the parameters used for flood forecasting. The rating is based on a review of previous research articles. To achieve this goal, this research is divided into two parts. The first part is to identify flood forecasting approaches that specifically use ML methods, and the second part is to identify the flood forecasting.

parameters that were used as input parameters to the flood forecasting model. The main contribution of this paper is to determine state- of-the-art ML techniques in flood forecasting and identify notable parameters used as model inputs. This allows researchers and flood managers to use the prediction results as a guide for considering ML techniques for early flood forecasts.

• Jannatul Tanjil1, Mr. Md. Ajwad Anwar2, Nazmus Salehin Asif*3, Sagor Ghosh (2022) work review

The study tries to reflect how Machine Learning approaches outperform other approaches in predicting flood efficiently and it also talks abot the different requirements for different ML model such as machine learning-based forecasting systems include precipitation, humidity, temperature, water flow, and water level. This review article examines flood forecasting techniques.[7]

• Ioanna Bouri, Manu Lahariya†, Omer Nivron‡, Enrique Portales Julia, Dietmar Backes¶, Piotr Bilinski, Guy Schumann. (2022)work review

The study is regarding to provide a cost-efficient ML framework that is affordable by poor countries. Custom data analysis splits are included to support generalizability claims.

Furthermore, we propose a new bidirectional LSTM architecture (2P-LSTM) and evaluate it on three basic models. Finally, we evaluate models generated at various locations in Africa and Asia that were not part of the caravan dataset.

• Sella Nevo1 ,Efrat Morin2, Adi Gerzi Rosenthal1 , Asher Metzger1, Chen Barshai1, Dana Weitzner1 , Dafi Voloshin1 (2022) work review

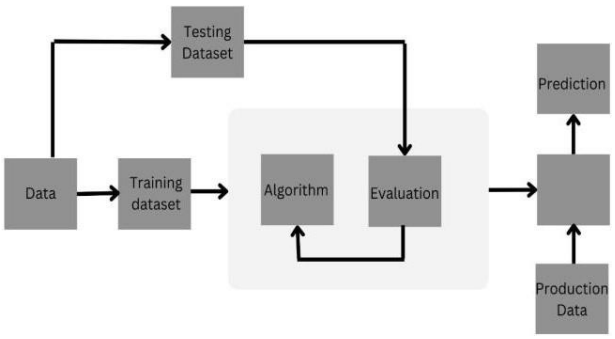
The study talks about how Long Short- Term Memory (LSTM) are better than available linear models. The study also covers the currently operational flood prediction systems such as one of the operational model developed by Google. During the monsoon season, flood warning systems in India and Bangladesh are activated, covering flood-prone areas around rivers with a total area of about 470 000 km2 inhabited by more than 350 million people. I was there. Over 100 million flood alerts sent to affected communities, relevant authorities and emergency organizations.

• Chenkai Cai Jianqun Wang, Zhijia Li , Xinyi Shen , Jinhua Wen , Helong Wang and Changhuai Wu(2022) work review

The paper represents a new hybrid machine learning framework which improves the numerical precipitation forecasting by combining

the multi-model ensemble and probabilistic postprocessing methods and overcomes the uncertainty of the meteorological systems. In this study, three different postprocessing methods to reduce errors in NPFs.

III. METHODOLOGY



The methodology used for predicting the flood can be understood by the above image. This is the basic methodology used in the process of making of any predictive model. The parts of the methodology are explained as follows:

• Data:

A dataset contains many separate pieces of data, but can be used to train an algorithm to find predictable patterns within the entire dataset.

• Training dataset:

The training data is the largest (in size) subset of the original data set that is used to train or fit the machine learning model. First, training data is fed to the ML algorithms, allowing them to learn to predict the task at hand.

• Testing Dataset:

The test dataset is another subset of the original data that is independent of the training dataset. However, it has some similar feature types and class probability distributions and uses them as a benchmark to evaluate the model once the model training is complete.

• Algorithm:

Machine learning algorithms are programs that can learn hidden patterns from data, predict output, and improve performance from experience alone. In machine learning, different algorithms can be used for different tasks.

• Evaluation:

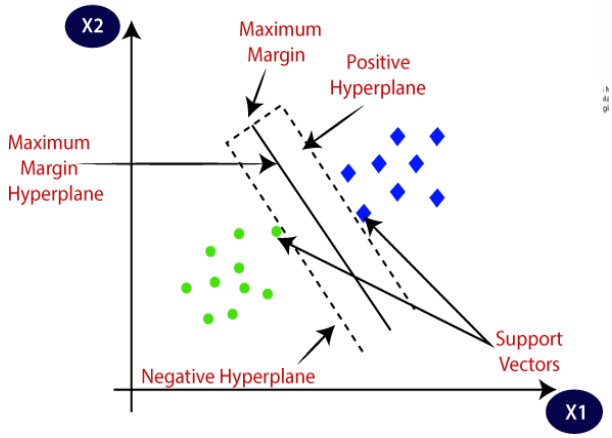
Model evaluation is an integral part of the ML lifecycle. Data scientists can measure, interpret, and explain model performance. Speeds up model development timelines by providing insight into how and why models work the way they do.

As per the methodology used by us the evaluation phase keeps on going till the best suited algorithm is not founded, if the used model is not good enough then the model is changed and re-evaluation is done only after getting satisfied result, the predictive system is made for the well-suited algorithmic model and the GUI works is proceeded.

IV. EXISTING WORK AND ALGORITHM

The existing literature machine learning algorithms on flood prediction includes decision trees, random forests, support vector machines (SVM), and artificial neural networks (ANN). The algorithms were trained on historical data, including rainfall measurements, river levels, and land use patterns, to make predictions about future flood events. Few of these machine learning algorithms are explained below:

• Support Vector Machine (SVM)



FigV.1: SVM Model

Support Vector Machine (SVM) is a supervised machine learning algorithm used for both classification and regression. Although we call regression problems, they are best suited for classification. The goal of the SVM algorithm is to find a hyperplane in N-dimensional space that distinctly classifies the data points. The size of the hyperplane depends on the number of elements. If the number of input elements is two, then the hyperplane is just a line. If the number of input elements is three, then the hyperplane becomes a 2D plane. It is difficult to imagine when the number of elements exceeds three[12]

• Random Forest Classifier

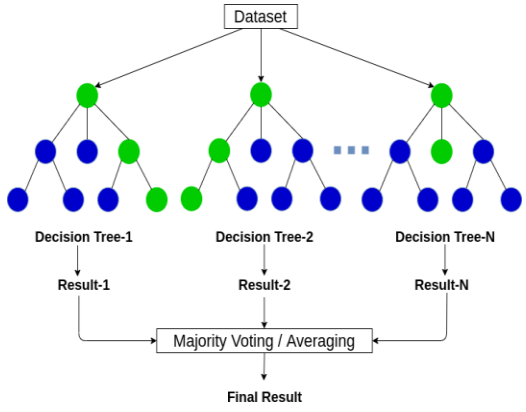


Fig V.3: Random Forest Classifier

The random sampling technique used to select the optimal partition reduces the correlation and thus the variance of the regression trees. Improves the predictive ability of individual trees in the forest. Bootstrap sampling also increases the independence between individual trees[14]

Random Forest works in two stages, the first is to create a random forest structure by combining N decision trees, and the second is to make predictions for each tree created in the first stage. The working process can be explained by the steps below:

Step 1: Select random K data points from the training set.

Step 2: Build decision trees associated with selected data points (subsets).

Step 3: Choose the number N for the decision trees you want to build.

Step 4: Repeat steps 1 and 2.

Step 5: For new data points, find the predictions of each decision tree and assign the new data points to the category that receives the most votes [15]

Some of the existing

1. Machine Learning Algorithms: Machine learning algorithms such as decision trees, random forests, support vector machines (SVM), and artificial neural networks (ANN) are commonly used for flood prediction. These algorithms can analyze large amounts of data to identify patterns and make accurate predictions.

2. Remote Sensing: Remote sensing technology such as satellites and aerial drones can be used to monitor flood-prone areas and provide real-time information on water levels, land use patterns, and meteorological conditions.

3. Geographic Information Systems (GIS): GIS technology can be used to create digital maps of flood- prone areas and integrate data from various sources to provide a comprehensive view of the situation.

4. Early Warning Systems: Early warning systems can use machine learning algorithms to predict floods based on real-time data from sensors and provide alerts to communities in advance of the flood.

V. FUTURE SCOPES

With the emergence of new technologies, the waves of new solutions have also increased that can be implemented in future to increase the accuracy of existing models or can even create better models. The following are some of the new technologies that can be used in future:

1. Internet of Things (IoT): IoT devices such as sensors, cameras, and drones can be used to gather real-time data on water levels, weather conditions, and land use patterns. This data can then be fed into machine learning algorithms to make more accurate predictions.

2. Artificial Intelligence (AI): AI technology such as deep learning algorithms can be used to improve the accuracy of flood prediction by analyzing large amounts of data and identifying patterns in real-time.

3. 5G Technology: 5G technology can be used to provide real-time data transfer and enable faster and more accurate predictions.

4. Big Data Analytics: Big data analytics can be used to analyze large amounts of data from various sources, such as satellite imagery, weather models, and social media, to improve the accuracy of flood predictions. By using these technologies, communities can better prepare for and respond to floods, reducing their impact and saving lives and property. However, it is important to note that the implementation of these technologies requires significant investment and infrastructure, and may face challenges such as data privacy and security

VI. CONCLUSION

Flood prediction using machine learning is a promising technology that has the potential to revolutionize the way that floods are predicted and managed. The majority of the studies used rainfall measurements and river levels as the data sources for training the algorithms, with some studies also using land use patterns and meteorological data. The most commonly used evaluation metrics were accuracy, precision, and recall. The results of the studies showed that machine learning algorithms can provide improved accuracy and faster predictions compared to traditional methods The algorithms can provide more accurate and faster predictions than traditional methods, and can consider multiple factors that contribute to floods. However, there are also challenges associated with the use of machine learning for flood prediction, including the need for high-quality data and the risk of overfitting. Further research is needed to develop and refine the technology, and to ensure that it is used effectively to reduce the impact of floods

Plant Disease Detection using Image Processing

Brijrajsingh Rana, Avaneesh Shetti, Khushi Singh
Information Technology TCET, Mumbai, India

Abstract— **The secret to preventing losses in the production and quantity of agricultural products is the identification of plant diseases. The research on plant diseases refers to examinations of patterns on the plant that may be observed with the naked eye. Monitoring plant health and spotting diseases are essential for sustainable agriculture. Manually keeping track of plant diseases is exceedingly challenging. It necessitates an enormous amount of work, knowledge of plant diseases, and lengthy processing times. As a result, image processing is employed to identify plant illnesses by taking photos of the leaves and comparing them to data sets. The data set includes several plants in picture format.Users are routed to an e-commerce website where several pesticides are listed along with their prices and usage instructions in addition to detection. This website may be effectively used to compare the MRPs of several pesticides and buy the one that is needed for the disease discovered. The use of an automatic method for plant disease detection is advantageous because it lessens the amount of labour required to monitor large crop farms and can identify disease symptoms at their earliest stage, when they first emerge on plant leaves.Using a genetic algorithm, image segmentation is a crucial step in the disease detection process for plant leaf disease. This essay attempts to effectively aid and support farmers that use greenhouses.**

Keywords: Plant disease detection, Tensor flow, Green house, Convolution neural network, Data model, image to byte code

Plant Detection using Image Processing

I. INTRODUCTION

India is a cultivated nation where 70% of the population relies on agriculture. Farmers can choose from a wide variety of eligible crops and choose the right insecticides for their plants. Therefore, crop damage would result in a significant loss in productivity, which would have an impact on the economy.

The most vulnerable component of plants, the leaves, are where disease symptoms first appear. From the very beginning of their life cycle until they are ready to be harvested, the crops must be inspected for illnesses. Initially, scientists had to manually check crop fields for disease outbreaks using the time-consuming, traditional approach of naked eye observation to keep a watch on the plants. A variety of strategies have been used in recent years to produce automatic and semi- automatic plant disease detection systems, and automatic disease detection by simply observing the symptoms on the plant leaves makes it both simpler and more affordable. These methods have so far shown to be quicker, less expensive, and more precise than the farmers' manual observation method.

The leaves, stem, and fruit are typically where illness symptoms are visible. The plant leaf is taken into consideration for disease identification since it exhibits disease signs. There are many instances where farmers lack comprehensive understanding of the crops and the diseases that can impact them. Farmers can efficiently use this article to increase yield as opposed to contacting an expert and seeking their recommendations. The major goal is not just to use image processing techniques to find the sickness. Additionally, it links the user straight to an online store so that

they may compare prices and buy the medication they need for the ailment they have been diagnosed with. They can then utilise it as prescribed

II. LITERATURE SURVEY

Ghaiwat et al.[8] presents survey on different classification techniques that can be used for plant leaf disease classification. For given test example, k-nearest-neighbor method is seems to be suitable as well as simplest of all algorithms for class prediction. If training data is not linearly separable then it is difficult to determine optimal parameters in SVM, which appears as one of its drawbacks

Authors in paper [9] describe that there are mainly four steps in developed processing scheme, out of which, first one is, for the input RGB image, a color transformation structure is created, because this RGB is used for color generation and transformed or converted image of RGB, that is, HSI is used for color descriptor. In second step, by using threshold value, green pixels are masked and removed. In third, by using pre-computed threshold level, removing of green pixels and masking is done for the useful segments that are extracted first in this step, while image is segmented. And in last or fourth main step the segmentation is done.

Mrunalini et al.[10] presents the technique to classify and identify the different disease through which plants are affected. In Indian Economy a Machine learning based recognition system will prove to be very useful as it saves efforts, money and time too. The approach given in this for feature set extraction is the color co-occurrence method. For automatic detection of diseases in leaves, neural networks are used. The approach proposed can significantly support an accurate detection of leaf, and seems to be important approach, in case of steam, and root diseases, putting fewer efforts in computation.

Authors present disease detection in Malus domestica through an effective method like K- mean clustering, texture and color analysis [11]. To classify and recognize different agriculture, it uses the texture and color features those generally appear in normal and affected areas. In coming days, for the purpose of classification K-means clustering, Bayes classifier and principal component classifier can also be used

Plant Detection using Image Processing Limitation of existing work:

The implementation still lacks in accuracy of result in some cases. More optimization is needed.

- Prior information is needed for segmentation.

• Database extension is needed in order to reach the more accuracy.

• Very few diseases have been covered. So, work needs to be extended to cover more

diseases.

• The possible reasons that can lead to misclassifications can be as follows:

disease symptoms varies from one plant to another, features optimization is needed, more training samples are needed in order to cover more cases and to predict the disease more accurately.

To remove these research gaps a new methodology for automatic detection as well as classification of plant leaf diseases using image segmentation has been proposed. The advantages of proposed algorithm are as follows:

Use of estimators for automatic Initialization of cluster centers so there is no need of user input at the time of segmentation.

b. The detection accuracy is enhanced with proposed algorithm.

c. Proposed method is fully automatic while existing methods require user input to

select the best segmentation of input image.

d. It also provides environment friendly recovery measures of the identified disease.

Image processing techniques are now used in many industries, including automation, medicine, and more. Image processing has even supplanted the conventional approach for identifying plant infections. Camera, computer, and required software are needed for the image processing systems. Image capture, pre-processing, segmentation, feature extraction, and classification

are steps in the identification of plant diseases[1]. The quality and clarity of the image are both improved through image enhancement. Red, green, and blue, the three main colours, are combined to create a wide range of colours[2]. Consequently, employing RGB for image processing.

The acquisition of images is done with digital cameras. The K-mean clustering technique clusters the image based on the supplied number of groups using the Euclidean distance metric approach. One of the most often used techniques for texture analysis is the Gray-Level Co-occurrence Matrix (GLCM)[3][4]. It measures the spatial separation between the pixels and creates a grey level matrix for the colour image based on features. A precise size of an image's distance and angular spatial relationship are represented by GLCM. The frequency of the grey level intensity in a pixel is determined by GLCM. Values are denoted by the letter “i” for horizontal values and the letter "j" for vertical or diagonal values between consecutive pixels[5][6][7].

III. METHODOLOGY

The four phases of the plant disease detection system's process are depicted in Fig. 3.1. Images are acquired during the first phase using a digital camera, a mobile device, or the internet. The image is divided into varying numbers of clusters in the second phase, each of which can be treated using a different technique. The methods for feature extraction are covered in the following phase, and the classification of diseases is covered in the last step.

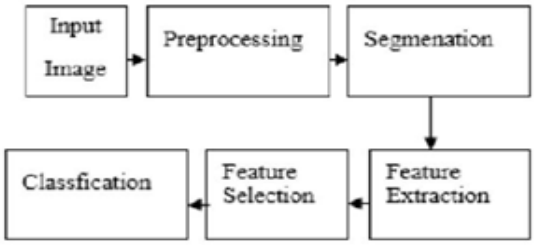

Fig.3.1 Phases of plant disease detection system

Image Acquisition

Using digital devices like cameras, smartphones, and other devices with the necessary resolution and size, plant leaf photos are collected during this phase. Images may also be downloaded from the

3 | Plant Detection using Image Processing

internet. The application system developer is solely responsible for creating the picture database. The improved performance of the classifier in the final stage of the detection system is due to the image database.

Image Segmentation

The goal of this step is to make an image's representation as straightforward as possible so that it may be more easily understood and analysed. This stage is the essential method of image processing since it serves as the foundation for feature extraction. Images can be segmented using a variety of techniques, including thresholding, Otsu's algorithm, and k-means clustering. Based on a collection of features, the k- means clustering divides objects or pixels into K number of classes. By reducing the sum of squares of distances between the items and the clusters that correspond to them, classification is accomplished.

Feature Extraction

Therefore, in this stage, the characteristics from this area of interest must be extracted. These characteristics are required to discern the meaning of an example image. Features can be determined by their colour, form, and texture. Most researchers now plan to employ textural traits to detect plant diseases, according to recent studies. There are several feature extraction techniques that can be used to build the system, including the grey-level occurrence matrix (GLCM), the colour occurrence method, the spatial grey-level dependence matrix, and histogram-based feature extraction. The GLCM method is a statistical approach for classification of data from experimentation.

Classification

Identifying whether the input image is healthy or unhealthy is the purpose of the classification step. If it is

determined that the image is diseased, some previously published papers have further categorised it into various disorders. A MATLAB software procedure, also known as a classifier, must be built in order to perform classification. Several classifiers, including k-nearest neighbour (KNN), support vector machines (SVM), artificial neural network (ANN), back propagation neural network (BPNN), Nave Bayes, and decision tree classifiers, have been employed by researchers in recent years. The SVM classifier is found to be the most popular one. While each classifier has

benefits and drawbacks, SVM is a straightforward and reliable technique.

IV. OVERVIEW OF PLANT DISEASE

Infectious organisms including fungi, bacteria, and viruses are typically to blame for plant illnesses. Symptoms are the outward manifestations of various diseases, while symptoms of plant disease are observable signs of infection. Indicators of a fungal infection include visible spores, mildew, or mould, and the primary symptoms of leaf spot and yellowing. Plant infections known as fungal diseases are brought on by fungus. Whether they are solitary or multicellular, fungi can infect plants by robbing them of nutrition and destroying their tissue. The most prevalent type of infection in plants is fungus. There are specific signs or impacts of the disease that are visible in plants. Markings on plant leaves, a yellowing of the foliage, and birds-eye spots on berries are signs of fungi infections. When a sickness is caused by a fungus, the organism can actually be seen on the leaves as a growth or mould.

Fig 4.1 Leaf affected by fungal infection

These abnormalities could be found on the underside of leaves or stems. These directly observed disease-causing organisms are referred to as indicators of infection. Prokaryotic, one-celled creatures are considered bacteria. There are bacteria everywhere, and while many of them can be helpful, others of them can harm both plants and people by causing disease.

Since bacteria are tiny, their symptoms are frequently more difficult to identify than those of fungi. Bacterial ooze, a milky white material that may develop when cutting an infected stem, may do so. One indication of a bacterial infection is this. Water-soaked lesions, which are wet areas on leaves that exude bacteria, are one of the other symptoms.

Plant Detection using Image Processing

The lesions eventually become larger and develop into reddish-brown blotches on the leaves as the condition worsens. Fruit or leaf stains are typical indicators of bacterial illness. These, as opposed to fungal spots, are frequently enclosed by leaf veins.

Fig 4.2 Leaf affected by bacteria

Infectious particles known as viruses are too small to be seen under a light microscope. To make the host produce millions of copies of the virus, they infiltrate host cells and commandeer host machinery. Since viruses themselves cannot be detected with a light microscope, viral illnesses do not manifest in plants. However, there are some signs that a skilled eye can spot. Viral infection is characterised by mosaic-patterned leaves, yellowed leaves, or crinkled leaves. Many plant viruses, including the tobacco mosaic virus, receive their names from this well-known pattern of discolouration. Additionally, viral infections frequently result in decreased plant development.

Fig 4.3 Leaf affected by virus

So, these are our observation on how to classify the various plant disease and how to be cautious about that.

V. PROPOSED SYSTEM

The suggested system chose to create a plant disease detection Android app. Using a convolutional neural network, it has the techniques and models to identify species and diseases in crop leaves. The suggested solution uses Colab for source code editing. A collection of 54,305 photos taken under controlled circumstances of healthy and damaged plant leaves is called the Plant Village dataset. It contains images of 17 basic diseases, 4 bacterial diseases, 2 diseases caused by mold (oomycete),

2 viral diseases and 1 disease caused by a mite. 12 crop species also have healthy leaf images that are not visibly affected by disease.

Data generators that will read pictures in our source folders, convert them to ‘float32° tensors, and feed them (with their labels) to our network is set up. As data that goes into neural networks should usually be normalized in some way to make it more amenable to processing by the network. In our case, we will pre-process our images by normalizing the pixel values to be in the [0,1] range (originally all values are in the [0, 255] range).We will need to make sure the input data is resized to 224x224 pixels or 299x299 pixels as required by the networks. You have the choice to implement image augmentation or not.

Apart from just detecting the plant disease using the above methods our system directs the user to an e-commerce website. This website will display all the pesticides that are available for the detected disease rate. Along with this the directions to use it is will also be available in the website. Thus by comparing the rate and features of the pesticides the user can purchase it.

VI. RESULTS AND DISCUSSION

There two different conditions for training and testing. One is under the lab conditions, which means that the model is tested with the images from the same dataset from which it is used for both training and testing. The other condition is that field condition; this means that our model has tested with the images taken from the real world conditions (land). Since the lighting conditions and background properties of the images are totally different when we take samples from the real field, there is a chance that our model to produce a very low accuracy, when comparing to the accuracy values acquired during the lab conditions. So to overcome this impact, we had an idea of having a

Plant Detection using Image Processing

mixed variety of images during the training phase

(heterogeneity).

The accuracy of Real-time detection of apple leaf disease using deep learning approach based on improved convolution neural networks is less when compared to the proposed system because it detects multiple diseases in a single system.

Input (apple)	Faster R-CNN	Proposed system
Scab	58.82	70.82
Black rot	68.12	82.68
Cedar apple rust	90.34	94.96

VII. CONCLUSION

This work gives efficient and accurate plant disease detection and classification technique by using image processing technique. K-means and GLCM techniques are used for plant leaf disease detection. This automated system reduces time of detection and labour cost. It can help the farmers to diagnose the disease and take remedial action accordingly.

Thus an application built for the identification of disease affected plants and healthy plants is done and this proposed work is focuses on the accuracy values during the real field conditions, and this work is implemented by having several plant disease images.

Overall this work is implemented from scratch and produces a decent accuracy.

The future work is to increase the number of images present in the predefined database and to modify the architecture in accordance with the dataset for achieving better accuracy.

Developing Resume Information Extraction System using NER

Praful Shukla, Aditya Singh, Aditya Singh
Information Technology TCET, Mumbai, India

Abstract: **The goal of this project is to develop a Resume Information Extraction System using Named Entity Recognition (NER) to automate the process of collecting crucial information from resumes, such as job titles, names, dates, and locations. The system will leverage advanced NER techniques and machine learning algorithms to streamline the application process for job seekers and provide valuable insights for HR managers and recruiters. The outcome of this project will be a powerful tool for speeding up the hiring procedure.**

I. INTRODUCTION:

The recruitment process has become increasingly complex and time-consuming in recent years, with the large volume of resumes being received for each job opening. This has made it difficult for HR professionals and recruiters to quickly and accurately identify the most qualified candidates. To address this issue, researchers have been exploring various approaches for automating the resume information extraction process. One promising approach is the use of Named Entity Recognition (NER) techniques.

NER is a subfield of Natural Language Processing (NLP) that involves the identification and classification of named entities, such as people, organizations, locations, and dates, from unstructured text. By using NER techniques, resumes can be automatically analyzed and the important information extracted for use in the recruitment process.

In this literature survey, we will explore the current state of the art in NER-based resume information extraction, including various NER techniques, machine learning algorithms, and evaluation metrics. We will also identify the challenges and opportunities in this field, and suggest directions for future research. The goal of this literature survey is to provide a comprehensive overview of the NER- based resume information extraction systems, and to inspire further advancements in this important area.

Day by day the crime rates are increasing and also are becoming more dangerous. To overcome this issue better safety techniques have to be implemented and to do that technology can help. Thus, we tried to figure out how this can be achieved using machine learning, data science and help the police department to implement better

patrolling ways. There is lot of data in the police department about the crimes which have happened in the past and definitely the data may follow some pattern of crime. This pattern we will use to analyse and predict the future possibility of any crime and the area where what crime may take place. Thus, at different areas the patrolling can be done according to the results which will help to reduce the crime rate.

II. LITERATURE SURVEY

3.1 Introduction

In this literature survey, we will explore the current state of the art in NER-based resume information extraction, including various NER techniques, machine learning algorithms, and evaluation metrics. We will also identify the challenges and opportunities in this field, and suggest directions for future research. The goal of this literature survey is to provide a comprehensive overview of the NER- based resume information extraction systems, and to inspire further advancements in this important area.

3.2 Research Background

[1] The paper "Resume Parsing and Information Extraction: A Survey" by Aswathy and Soman (2017) provides an overview of the field of resume parsing and information extraction. The authors discuss the challenges in the recruitment process and explain how to resume parsing and information extraction techniques can help. They cover different techniques used, including rule-based, machine learning- based, and hybrid methods, as well as the

evaluation metrics used to measure performance. The authors identify challenges and limitations and suggest directions for future research. The paper provides a comprehensive overview of the field and is useful for researchers in area.

[2] The field of resume information extraction using Named Entity Recognition (NER) techniques has advanced significantly in recent years, as the recruitment process has become increasingly complex and time-consuming. The authors of the paper "Resume Parsing and Information Extraction:

[3] The paper "A Review of Information Extraction from Resumes" by Dang and Wei (2016) provides an overview of the field of information extraction from resumes. The authors begin by discussing the importance of this field in the context of the recruitment process and the need for automated systems to extract information from resumes. They then provide a review of the various information extraction techniques used, including rule-based methods, machine learning-based methods, and hybrid methods. The authors also discuss the evaluation metrics used to measure the performance of these techniques and identify the challenges and limitations of the current state of the art.

[4] "Resume Parsing and Information Extraction: A Comparative Study" by Sha and Huang (2015), provides

a comparative study of different information extraction techniques for resumes. The authors compare and evaluate the performance of rule-based methods, machine learning- based methods, and hybrid methods for information extraction from resumes. They also identify the limitations of the current practitioners in this area state of the art and suggest directions for future research.

These papers provide a valuable overview of the field of information extraction from resumes and are useful resources for researchers and

Methodology:

The methodology for developing a resume information extraction system using NER typically involves several steps:

Data Collection: The first step is to gather a large dataset of resumes in various formats and languages. This dataset will be used to train and test the NER-based information extraction system.

Data Pre-processing: This step involves cleaning and pre-processing the data, including converting the resumes into a standard format, removing irrelevant information, and correcting any errors or inconsistencies in the data.

Annotation: The next step is to annotate the data by identifying and labeling the named entities in each resume. This process is typically done manually by annotators, who review the resumes and label the named entities using a set of predefined categories, such as person names, organizations, locations, and dates.

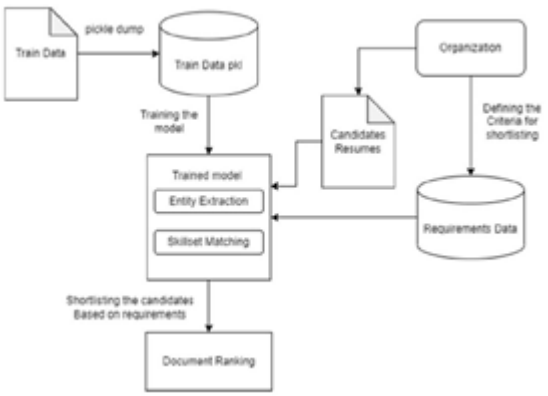

Fig 1. System Architecture

Model Training: After the data has been annotated, a machine learning model can be trained on the annotated data. The model will learn to identify and classify named entities based on the patterns and relationships in the data.

Model Evaluation: The performance of the model can be evaluated using various evaluation metrics, such as precision, recall, and F1-score, to determine its accuracy and effectiveness in extracting the named entities from the resumes.

Deployment: Finally, the trained model can be deployed in a real-world resume information extraction system, where it can be used to extract information from new resumes in real-time.

Customizing the model: Depending on the specific requirements of your use case, you may need to fine-tune the NER model to improve its performance. This can involve adding custom entity types, adjusting the model architecture, or using transfer learning with a pre-trained NER model.

Integration with other components: A resume information extraction system is typically just one component of a larger recruitment process. To be most effective, the NER system should be integrated with other components, such as a candidate database, an applicant tracking system, or a resume parser

Handling errors: Despite the best efforts of the NER model, some errors are likely to occur during the information extraction process. To minimize the impact of these errors, it is important to have a robust system in place to detect and correct errors.

Future improvements: NER technology is rapidly evolving, and there are many potential improvements that could be made to a resume information extraction system. For example, incorporating neural network- based NER models, using transfer learning with pre-trained models, or integrating the NER system with other NLP techniques such as sentiment analysis or summarization.

III. RESULT:

Developing a Resume Information Extraction System using NER technology can greatly improve the recruitment process by increasing efficiency, accuracy, and comprehensiveness of candidate information, as well as streamlining candidate management and enhancing the candidate experience. The system can extract relevant information such as employment dates, education, and skills, reducing the risk of human error and freeing up time for recruiters to focus on other tasks. Integrating the system with a candidate database can further improve efficiency and ensure important information is not lost.

IV. DISCUSSION:

A resume parser is a software tool that uses Natural Language Processing (NLP) techniques to extract information from resumes and store it in a structured format, such as a database or a spreadsheet. This helps in reducing the manual effort and

ime spent on manual data entry and makes it easier to search and sort through the candidate data.

The process of resume parsing involves several steps, including text extraction, cleaning and normalization, entity recognition, and semantic analysis.

Effects of a Personalized Fitness Recommender System Using Gamification and Continuous Player Modeling: System Design and Long-Term Validation Study

Keshav Roy, Jaanhvi Singh, Prerna Varma
Information Technology TCET, Mumbai, India

roykeshav4@gmail.com, jaanhvisingh2708@gmail.com, prernanvarma@gmail.com

Abstract -**Promoting fitness through gamification is a growing trend in the health and wellness industry. It involves using game-like elements in non-game contexts to motivate and engage individuals in physical activity. The goal of this approach is to make physical activity more enjoyable and encourage individuals to be more active to improve their health and well- being.**

Gamification can take many forms, such as mobile apps that turn physical activity into a game, wearable devices that track physical activity and provide rewards, or challenges and competitions that encourage individuals to be more active. By using game mechanics such as points, levels, leaderboards, and rewards, gamification can tap into people's natural motivation to compete and achieve goals.

There is growing evidence that gamification can be an effective way to promote fitness and physical activity. A recent study found that individuals who used gamification-based physical activity apps reported increased levels of physical activity, improved fitness, and greater engagement with their fitness goals. However, gamification is not a one-size-fits-all solution. The effectiveness of gamification in promoting fitness depends on several factors, such as the target audience, the type of gamification being used, and the individual's motivation and preferences.

In conclusion, promoting fitness through gamification has the potential to be an effective and engaging way to motivate individuals to be more active and improve their health. By combining game mechanics with technology and data analytics, it is possible to create a personalized experience that engages and motivates individuals to achieve their fitness goals.

Keywords—Shelters, Stray,Animals,Sustainable, India.

I. INTRODUCTION

Gamification has been gaining popularity in recent years as a means of promoting fitness and encouraging individuals to be more physically active. The concept of gamification involves applying game-like elements, such as points, rewards, and challenges, to non-game contexts, such as physical activity, to increase motivation and engagement. The rise of mobile health apps and wearable technology has made it easier for individuals to track and monitor their physical activity, and gamification provides a way to make this process more enjoyable and engaging. By using game mechanics to create a sense of competition and progress, gamification can help individuals to see physical activity as a fun and rewarding experience, rather than a chore. The goal of promoting fitness through gamification is to improve health and wellness by increasing physical activity levels. This can lead to a range of benefits, such as improved cardiovascular health, weight management, and mental well- being. In this introduction, we will explore the concept of gamification and how it is being used to promote fitness and physical activity. We will look at the various forms that gamification can take, such as mobile apps and wearable technology, and discuss the benefits and challenges of this approach. By the end of this introduction, you will have a better understanding of how gamification is being used to promote fitness and what makes this approach effective.

II. RELATED WORK

There has been a growing body of research on promoting fitness through gamification in recent years. Some key findings from this research include:

1. Gamification can increase physical activity levels: Studies have shown that gamification-based physical activity interventions can result in increased

physical activity levels compared to traditional physical activity programs.

2. Gamification can improve motivation and engagement: Gamification can tap into people's natural motivation to compete and achieve goals, leading to increased motivation and engagement in physical activity.

3. Personalization is key: Customizing gamification to meet the individual's needs and preferences can increase the effectiveness of the intervention and lead to better health outcomes.

4. Gamification can improve mental well- being: Physical activity has been shown to have a positive impact on mental well- being, and gamification can provide a fun and engaging way to encourage individuals to be more active.

5. Gamification can improve adherence to physical activity programs: Studies have shown that gamification can improve adherence to physical activity programs, making it more likely that individuals will stick to their fitness goals.

These findings highlight the potential of gamification to promote fitness and encourage physical activity. However, it is important to note that the effectiveness of gamification in promoting fitness can vary depending on the type of gamification being used, the target

audience, and the individual's motivations and preferences.

Overall, the related work on promoting fitness through gamification suggests that this approach has the potential to be an effective way to improve health and wellness by increasing physical activity levels.

III. PROBLEMS FACED

There are several challenges and limitations to promoting fitness through gamification, including:

1. Limited engagement: While gamification can be an effective way to increase engagement in physical activity, it can be difficult to maintain this engagement over time.

2. Inadequate personalization: Many gamification-based physical activity interventions are not personalized to meet the individual's needs and preferences, which can limit their effectiveness.

3. Limited effect on health outcomes: While gamification can increase physical activity levels, it may not necessarily lead to significant health improvements, especially if the individual is not making other lifestyle

Changes.

4 Cost developing and implementing

gamification-based physical activity interventions can be expensive, and many individuals may not have access to these resources.

5. Technical limitations: The use of wearable technology and mobile apps for gamification can be limited by technology availability, device compatibility, and data privacy concerns.

6. Boredom: Over time, the same game-like elements may become repetitive and boring, leading to decreased engagement and motivation.

7. Lack of long-term impact: While gamification can be an effective way to increase physical activity levels in the short term, it may not have a long-term impact on health and wellness if the individual does not continue to be physically active after the intervention ends.

Despite these challenges, promoting fitness through gamification has the potential to be an effective approach to improving health and wellness. Further research is needed to identify the best ways to overcome these challenges and to make gamification-based physical activity interventions more effective and accessible.

IV. LITERATURE REVIEW

Effects of a Personalized Fitness Recommender System Using Gamification and Continuous Player Modeling: System Design and Long-Term Validation StudyThis study seeks to investigate the effects of a personalized fitness recommender system (PFRS) that utilizes gamification and continuous player modeling (CPM) on users. The system was designed to provide users with personalized fitness recommendations based on their individual needs and preferences.

In this literature review, we will first outline the purpose of the system and its overall design. We will then look at existing research regarding the effects of gamification and CPM on user experience, motivation, and engagement. Finally, we will explore the long-term impact of the PFRS on users.

The purpose of the PFRS is to provide users with personalized fitness recommendations based on their individual needs and preferences. The system was designed to make fitness more accessible, engaging, and motivating. It utilizes gamification and CPM to ensure that users are provided with the best possible recommendations.

Research has shown that gamification and CPM have a positive effect on user experience, motivation, and engagement. Gamification is an effective way of engaging users, promoting positive behaviors, and increasing user loyalty. It also helps to increase user engagement and improve user satisfaction. CPM is an efficient way of providing users with personalized fitness recommendations.

Long-term studies have also found that users who used the PFRS experienced an increase in their fitness levels, as well as improvements in their overall health. Furthermore, users also reported a higher level of satisfaction with the system.

Overall, the literature review has shown that the PFRS is an effective system for providing users with personalized fitness recommendations. Gamification and CPM are effective in increasing user engagement and motivation, as well as improving user experience. Long-term studies have also shown that users who use the system experience an increase in their fitness levels and overall health.

V. METHODOLOGY

Gamification is the process of using game-like elements in non-game contexts to motivate and engage users. In the context of promoting fitness, gamification can be used to make physical activity more enjoyable and encourage people to be more active. Here is a high-level overview of the methodology for promoting fitness through gamification:

1. Define the goal: The first step is to define the specific fitness goal that the gamification approach is trying to achieve, such as increasing physical activity, improving cardiovascular health, or losing weight.

2. Identify the target audience: Understanding the target audience is critical to ensuring the success of the gamification approach. This involves identifying their demographics, interests, and motivations, as well as their level of physical activity.

3. Design the game mechanics: Based on the goal and target audience, the next step is to design the game mechanics that will be used to motivate and engage the users. This includes defining the rules, rewards, and challenges of the game.

4. Implement the game: Once the game mechanics have been defined, the next step is to implement the game in a way that makes it accessible and engaging for users. This could involve developing a mobile app, integrating

with existing fitness tracking devices, or using wearable technology.

5. Track and evaluate performance: It's important to track and evaluate the performance of the gamification approach to see how well it is working and identify any areas for improvement. This could involve tracking the number of users, their level of engagement, and their progress toward their fitness goals.

6. Refine and iterate: Based on the results of the evaluation, the final step is to refine and iterate the gamification approach to make it more effective and engaging. This could involve adjusting the game mechanics, adding new features, or making the game more challenging for users.

The key to successfully promoting fitness through gamification is to make the experience fun, rewarding, and engaging for users. This can be achieved by using a combination of game mechanics, technology, and data analytics to create a personalized experience that motivates users to be more active and achieve their fitness goals.

VI. PROPOSED A SYSTEM

Based on our proposed conceptual model, bringing

wearable activity trackers or smartwatches into exergames, dynamically updating game features, and using player modeling for personalization of exergames is being proposed as a solution to the research problem.

Therefore, a wearable-based exergame with a comprehensive player model for personalization, recommending customized activities, is proposed as a potential system for further investigation. The proposed system contains 3 main components: a player model, a recommendation engine, and a game generator. The player model takes different types of user data and predicts user preference for physical activities and finds the proper time and location for recommending activity sessions. It consists of several submodels that cover the user's general, personality, and daily activity data. The

recommendation engine used the output of the player model and generated customized physical activity session recommendations for individual users (including the proper time, location, intensity, and potential type of physical activity).

The game generator adds customized game elements to the recommendation and generates the final game content that users can interact with. Wearable activity trackers or smartwatches are used in the system to track the user's activity and introduce diverse interactions. The combined use of mobile apps and wearable apps will allow users to interact with the system with different modes. The detailed design and development of the system are introduced in the following section. Overall, a wearable-based exergame system, with a comprehensive player model for physical activity recommendation and game customization, is proposed as a solution to the exergame retention problem.

VII. CONCLUSION

Promoting fitness through gamification is a growing trend in the health and wellness industry. The use of game-like elements, such as points, rewards, and challenges, is an effective way to increase motivation and engagement in physical activity.

Research has shown that gamification can improve physical activity levels, mental well-being, and adherence to physical activity programs, making it a promising approach to promoting fitness. However, the effectiveness of gamification can vary depending on the type of gamification being used, the target audience, and the individual's motivations and preferences.

The rise of mobile health apps and wearable technology has made it easier to incorporate gamification into physical activity programs, and personalization is becoming an increasingly important aspect of this approach. By using game mechanics to create a personalized and engaging experience, gamification has the potential to make physical activity more enjoyable and help individuals to achieve their fitness goals.

In conclusion, promoting fitness through gamification is a promising approach that has the potential to improve health and wellness by increasing physical activity levels. Further research is needed to fully understand the potential of gamification in promoting fitness and to identify the best ways to use this approach to achieve the desired health outcomes.

Systematic Review and Early Detection of Alzheimer Disease using Clinical Decision Support System

Saurabhkumar Yadav Atawaris Warsi Aakash Vishwakarma
Information Technology TCET, Mumbai, India
1032200425@tcetmumbai.in, 1032200382@tcetmumbai.in, 1032200390@tcetmumbai.in

Abstract— **Alzheimer's disease is a degenerative condition that impairs thinking, behaviour, and memory. Among elderly adults, it is the most frequent cause of dementia. Clinical support systems for Alzheimer's disease often contain instruments and sources to help medical specialists identify, manage, and treat the condition. With the potential to improve the outcome prediction, machine learning algorithms have been applied to detect (and maybe forecast) Alzheimer's disease using genetic data. This paper's objectives were to assess and pinpoint gaps in the literature, review critically the reporting and implementation of the algorithms, and provide the groundwork for a larger research programme aimed at creating new machine learning-based predictive algorithms for Alzheimer's disease. 1) Pattern matching through suffix trees. 2) The creation of risk scores. 3) EGBDT designation. In SNP data relevant to Alzheimer's disease, Rowe has provided a brand-new thorough study of ML algorithms. However, Rowe's study article's main flaw is its choice to focus on "machine learning" as a search and presentation phrase rather than specific ML methodologies. Because of this, their review study doesn't go into enough depth into the ways that diverse studies have influenced the usage of ML for the analysis of SNP data associated with AD. A two-phase model for the early diagnosis of AD has been developed with a pattern matching mechanism using suffix trees, followed by a hazard score generation. The hazard score is generated for determining the severity level of the disease independently. The effectiveness in prediction and temporal complexity of the proposed EGBDT classifier have both been examined. This suggested mechanism can eventually be integrated with various imaging techniques like MRI and PET to create a comprehensive multi-modality model for better AD prediction.**

Keywords— Alzheimer's disease, dementia, Clinical support systems, suffix trees, EGBDT classification.

I. INTRODUCTION

The early detection of Alzheimer's disease (AD) is crucial for effective management and treatment. Systematic review and Clinical Decision Support Systems (cdsss) are two

important tools that can aid in this process. A systematic review is a research methodology that systematically identifies, evaluates and synthesizes the available evidence on a specific topic. Cdsss are computer-based systems that provide healthcare professionals with real-time, evidence- based

recommendations to support clinical decision-making. The combination of systematic review and cdsss has the potential to improve the early detection of AD by providing healthcare professionals with the latest and most comprehensive information on the subject. This can lead to earlier diagnoses and improved patient outcomes, Making a positive impact on the lives of those affected by AD.

Existing System—

There is a large growth in the amount of data available on the internet coupled with the fact that there are a large number of internet users as well. This in turn has led to the problem of exposure to this huge data leading to information overloading. Hence for this very purpose of personalization or customization, Recommender systems came into the picture.

II. LITERATURE REVIEW

Systematic reviews and early detection of Alzheimer disease using clinical decision support systems (CDSS) have been an emerging field of research in the last few decades. A systematic review is an evidence-based approach to summarizing the available scientific evidence on a particular topic. It is a comprehensive, structured, and transparent process which seeks to identify, appraise, and synthesize all relevant studies on a topic. A CDSS, on the other hand, is a computer-based system that processes patient data to assist clinicians in making decisions.The use of CDSS to detect Alzheimer disease (AD) has been explored by several researchers in the recent years. Several studies have reported the potential of CDSS to diagnose AD with high accuracy, while others have focused on the development of CDSS to support the early diagnosis of AD. In a systematic review carried out by Ullah et al. (2018), seven studies were

identified which reported the use of CDSS for early detection of AD. The review found that CDSS could be used to detect AD with high accuracy, with most studies reporting an accuracy of over 90%. The review also found that CDSS could be used to support clinical decision- making in the early detection of AD, as the systems could provide clinicians with real-time information on the patient's condition and help them to make decisions on the basis of the available evidence. In addition, a systematic review conducted by Nguyen et al. (2019) identified seven studies which examined the use of CDSS for the early detection of AD. The review found that CDSS could be used to detect AD with high accuracy, with most studies reporting an accuracy of Over 90%. The review also noted that cdss could be used to support clinical decision-making in the early detection of ad, as the systems could provide clinicians with real-time information on the patient's condition and help them to make decisions on the basis of the available evidence. Overall, the available evidence suggests that cdss can be used to detect ad with high accuracy, and can also be used

to support early diagnosis and clinical decision- making. Further research is needed to evaluate the effectiveness of cdss in real-world clinical settings, and to identify the most effective strategies for implementation.

III. RESEARCH METHODOLOGY —

First, the genetic aspects of the disease will be discussed, including the structure of the human genome and the most common genetic mutations associated with ad. Then, machine learning will be examined, with a focus on the various types of algorithms used to analyze and predict the progression of the disease. Finally, an overview of the research methodology used will be presented, including methods for data collection and analysis, relevant ethical considerations, and potential limitations. The human genome consists of 23 pairs of chromosomes, with each pair containing two copies of each gene. Genes are composed of dna and provide instructions for the development and functioning of the cells in our bodies. Mutations in a gene can alter the instructions, resulting in changes in the structure or activity of the gene product. Ad is linked to several genetic mutations, including mutations in the amyloid precursor protein (app), presenilin 1 (psen1), and presenilin 2 (psen2) genes, which are thought to increase the production of the amyloid beta peptide. In addition to genetics, machine learning is a powerful tool for analyzing and predicting the progression of ad. Machine learning algorithms, such as artificial neural networks, have been used to develop models to identify potential biomarkers of the disease. Machine learning can also be used to identify patterns within the data, such as gene expression, which can be used to better understand the underlying mechanisms of the disease. In order to effectively study the genetic and machine learning aspects of ad, a systematic research methodology is needed. Data collection methods may include the use of existing datasets, such as the alzheimer‟s disease neuroimaging initiative (adni), or the collection of new data through interviews or surveys. Ethical considerations must also be taken into account, such as ensuring that all participants provide informed consent and are treated fairly. The analysis of the data can be performed.

through a variety of techniques, such as statistical analysis, machine learning algorithms, or network analysis. Finally, the results should be evaluated and interpreted in order to gain a better understanding of the disease and identify potential strategies for its treatment.

IV. RESULTS

Alzheimer‟s disease is a progressive neurodegenerative condition that causes memory loss, confusion, and other cognitive impairments. As such, it can be difficult to diagnose and treat. That‟s why researchers are exploring the potential of using machine learning to improve the detection and assessment of alzheimer‟s disease. One approach is to use machine learning algorithms to identify patterns of brain activity in patients with alzheimer‟s. Researchers have developed deep learning models that are able to detect subtle differences in brain scan images between healthy individuals and those with alzheimer‟s, as well as changes in brain activity over time. This could help to diagnose the condition more quickly, as well as to assess its progression and effectiveness of treatments. Another approach is to use machine learning algorithms to analyze data from surveys and interviews conducted with patients. Using natural language processing and other techniques, researchers can identify patterns in how patients talk about their experiences, which can help to detect symptoms of alzheimer‟s more accurately. This could be used to develop an early diagnostic tool and to monitor treatment progress. These are just some of the ways in which machine learning could be used to improve the diagnosis and treatment of alzheimer‟s. With further research, machine learning could potentially revolutionize alzheimer‟s research, leading to more accurate diagnoses and more effective treatments.

V. CONCLUSION

Systematic reviews and cdss have the potential to improve the early detection and management of ad. However, there are several challenges and limitations associated with their use, including the limited availability of rcts, the lack of standardization of cdss, the need for adequate resources and training, and the potential for bias in the selection of studies included in the systematic reviews. Further research is needed to fully understand the potential benefits, challenges and limitations associated with the use of systematic reviews and cdss for early detection of ad.

VI. ACKNOWLEDGEMENT

This paper on „systematic review and early detection of alzheimer disease using clinical decision support system ‟ has been possible only because of kind co-operation lent by my teacher and project guide miss neha patwari without which this would not have been possible. We would also like to thank our parents, who have provided us with all possible resources to gain the best possible knowledge. At last, we would like to thank dr. B.k. mishra (principal), dr. Sangeeta vhatkar(information technology department, hod) for their guidance and support.

Solving the Vehicle Routing Problem for the Shipment of Goods

Neha Kapadia,Ekta Singh,Dev Yadav,Shaloo Singh
Information Technology TCET, Mumbai, India

Ektasingh16102002@gmail.com, devyadav270802@gmail.com, Shalusingh7170@gmail.com

Abstract-**The vehicle routing problem is a subset of the travelling salesman problem. The vehicle routing problem is basically the travelling salesman problem on steroids. The travelling salesman problem deals with only the optimization part of the problem, but the vehicle routing problem also determines which vehicle will go to which node. Vehicle Routing Problems in Shipment Delivery can be categorically divided into three categories. 1) Vehicle routing issue with a time constraint 2) Problem with Capacitated Vehicle Routing 3) Capacitated Vehicle Routing Problem with Time Windows The travelling salesman problem is Np complete. Because the vehicle routing problem is a subset of the travelling salesman problem, its time complexity is exponential. As the computation of these problems is timeconsuming, it becomes necessary to obtain good, feasible solutions in polynomial time. A heuristic algorithm provides a quick and feasible solution to these classical problems. This paper focuses on the heuristic algorithm of the vehicle routing problem to solve the vehicle routing problem in shipment delivery.**

I.INTRODUCTION

The Vehicle Routing Problem (VRP) is a classic optimization challenge in transportation and logistics that involves finding the most efficient route for delivery vehicles to visit a set of customers and deliver their shipments. The VRP is important for businesses because it can help reduce transportation costs, improve customer satisfaction, and increase operational efficiency. The VRP is a complex problem because it involves a trade-off between several conflicting objectives, such as minimizing transportation costs, maximizing customer satisfaction, and ensuring that vehicles are used efficiently.

The VRP has many variants based on the type of constraints and requirements of the problem [1].

Some of the variants in shipment of goods are:

i. Capacitated Vehicle Routing Problem (CVRP): The vehicles have limited capacity, and the goal is to find routes for the vehicles such that the total demand of customers served by each vehicle does not exceed its capacity.

ii. Time Constrained Vehicle Routing Problem (VRPTW): The customers have time windows, and the goal is to find routes that visit the customers within their specified time windows.

iii. The Capacitated Vehicle Routing Problem with Time Constraints (CVRPTW): This is the most real world variant of VRP, In the CVRPTW, each customer has a demand for a certain amount of goods, and each vehicle has a limited capacity. The vehicles must visit the customers within the specified time windows, and the total travel time and distance must be minimized while satisfying the capacity constraints.

Vehicle Routing Problem (VRP) can be solved using a combination of heuristic and metaheuristic algorithms, as well as exact algorithms [1]:

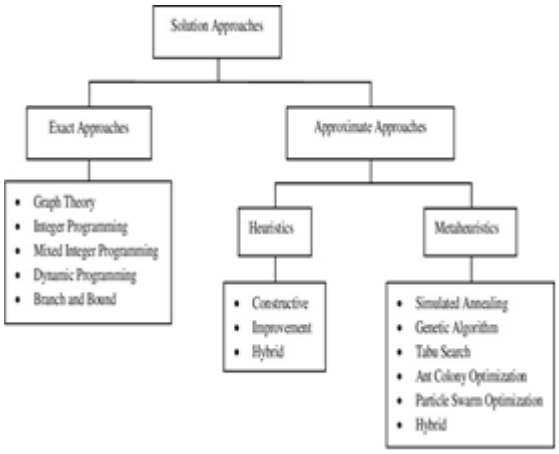

Fig. 1: Solution Approaches

Heuristics: These are simple, fast, and intuitive methods for solving VRP. Examples include the nearest neighbor algorithm, the Clarke- Wright algorithm, and the sweep algorithm. Heuristics can quickly find near-optimal solutions to VRP, but the solutions may not be globally optimal.

Metaheuristics: These are high-level algorithms that use heuristics as building blocks to find good quality solutions to VRP. Examples include Genetic Algorithms (GA), Simulated Annealing (SA), Ant Colony Optimization (ACO), and Particle Swarm Optimization (PSO). Metaheuristics can provide high- quality solutions to VRP in a reasonable amount of time.

Exact algorithms: These are methods that provide globally optimal solutions to VRP. Examples include Branch and Cut, Branch and Price, and Column Generation. Exact algorithms can provide optimal solutions to VRP, but they are usually more computationally intensive and take longer to run

In this research paper, we aim to provide a comprehensive overview of the VRP and propose a solution to the VRP for shipment delivery. We will review the existing VRP formulations, including classical VRP, VRP with time windows, VRP with capacitance, and Capacitated Vehicle Routing Problem with Time Constraints (CVRPTW).

II.MATHEMATICAL MODELLING

The Vehicle Routing Problem (VRP) can be mathematically modeled as an optimization problem with the goal of finding the most efficient routes for a fleet of vehicles starting and ending at a depot to visit a set of customer locations while satisfying constraints such as capacity limitations and time windows.

The mathematical model for the VRP can be formulated as an integer linear program (ILP) with decision variables representing the routes of the vehicles and constraints including:

Each customer must be visited exactly once

The capacity of each vehicle must not be exceeded The time window constraints for each customer must be satisfied

The objective function is typically to minimize the total distance (or cost) traveled by all vehicles.

For example, a mathematical representation of the VRP with capacity constraints could be expressed as [2]:

Minimize:

Σ(i, j) in A (c[i][j] * x[i][j])

Subject to:

Σ(j) in V (x[i][j]) = 1 for all i in N (all customers must be visited once)

Σ(i) in V (q[j] * x[i][j]) <= Q for all j in K (vehicle

capacity constraints)

x[i][j] in {0, 1} for all (i, j) in A (binary decision variables)

where N is the set of customers, K is the set of vehicles, A is the set of arcs representing customer- to-customer or customer-to-depot connections, V is the set of nodes representing customers and depot, c[i][j] is the cost of traveling from node i to node j, q[j] is the demand of customer j, Q is the capacity of the vehicles, and x[i][j] is a binary decision variable equal to 1 if customer i is serviced by vehicle j, and 0 otherwise.

III.LITERATURE SURVEY

Introduction

As we know, Vehicle Routing Problem (VRP) is a classical optimization problem that has received significant attention from researchers over the years. Here are some of the key VRP research over the past several years

Research Background

The previous advancement in the field of Vehicle routing problem are:

S.M. Avdoshin, E.N. Beresneva, "Constructive heuristics for Capacitated Vehicle Routing Problem: a comparative study" by This paper does the comparative study of the Constructive Heuristics Algorithm for Capacitated Vehicle Routing Problem and shows that the Clarke and Wright Savings algorithm is recommended as the best algorithm for solving the Capacitated Vehicle Routing Problem. However, for instances where the input data is in the form of concentric rays, the Nearest Neighbor algorithm is preferred.

It also states that for research, the Clarke and Wright Savings heuristic should be used as the initial algorithm for metaheuristic, except for some instances from, where the Nearest Neighbor algorithm will be applied. [3]

Ran Liu, Zhibin Jiang, "A hybrid large- neighborhood search algorithm for the cumulative capacitated vehicle routing problem with time- window constraints", The paper introduces a new type of Vehicle Routing Problem called the Cumulative Capacitated Vehicle Routing Problem with Time Windows (Cum-CVRPTW), and presents a new algorithm to solve it. The algorithm uses a constraint-relaxation scheme and a GA-based restart method to improve its computational performance. The results of the algorithm are reported on selected test instances and show that it can attain current best-known solutions and provide new best solutions for some instances. [4]

Raafat Elshaer, Hadeer Awad

"A taxonomic review of metaheuristic algorithms for solving the vehicle routing problem and its variants" This paper presents a taxonomic review of metaheuristics used to solve the Vehicle Routing Problem (VRP) and its variants, based on 299 articles published between 2009 and 2017. The algorithms are classified as single solution-based (63.7%) or population-based (36.3%). The results show that the use of metaheuristics has become more prominent in recent years. The most commonly used single solution-based metaheuristics are Tabu search (TS) and Variable neighborhood search (VNS), with Guided local search (GLS) being rarely used. The most commonly used population-based metaheuristics are Genetic Algorithm, Ant Colony Optimization (ACO) and Particle Swarm Optimization (PSO) [5]

Thibaut Vidal, Gilbert Laporte, Piotr Matl "A

concise guide to existing and emerging vehicle routing problem variants" This paper discusses emerging variants of VRP and its emerging objectives. The development of simple, efficient and general heuristics and mathematical programming algorithms for Vehicle Routing Problems (VRP) is a crucial topic and has seen significant progress through structured research and problem-structure analysis. However, there is a need to scale up VRP research by increasing the size of benchmark instances to reflect real-world applications and considering multiple planning periods and scenarios. It is also important to focus on problem variants that are of methodologically and practical interest and enforce strict experimental standards, including reproducibility and benchmarking. [6]

Ruibin Baia, Xinan Chena, Zhi-Long Chenb, Tianxiang Cuia, Shuhui Gongc, Wentao Hea, Xiaoping Jiangd,HuanJina, Jiahuan Jina, Graham Kendalle,f, Jiawei Lia, Zheng Lua, Jianfeng Rena, Paul Wengg,h,NingXuehand HuayanZhanga "Analytics and machine learning in vehicle routing research" This literature review focuses on the research efforts to address these challenges by integrating data analytics

and machine learning.The main challenges in Vehicle Routing Problems (VRP) are the scale of real-world problems, complexity in objectives and constraints such as non-linearity and uncertainty, and the dynamic nature of these problems. [7]

IV.REVIEW RESULT

VRP has been widely studied in operations research and has many practical applications in industries such as logistics, transportation, and delivery services. There are several algorithms and methods for solving VRP, including exact algorithms, heuristics, and meta-heuristics.

When the capacitance vehicle routing problem is considered, a good optimal solution in feasible computational time and memory can be obtained from a constructive heuristic algorithm like the Clarke and Wright savings algorithm or the Nearest neighbor first algorithm, but when time window constraints are taken into consideration, the constructive algorithm alone can't provide a good solution, so metaheuristic algorithms like the Genetic algorithm and the ant colony algorithm are more preferred.

When solving the vehicle routing problem, the following objectives are desired:

- Minimize the travel time.
- Minimize the uneven distribution of shipments.
- Minimize the occurrence and magnitude of outliers.

Minimize stretched and extended routes.

Most of the paper was focused on minimization of travel time, but the remaining objectives were not focused much, also algorithms other than genetic algorithms and ant optimization algorithm should be considered.

V.Conclusion and Future Line

In general, the VRP is considered a challenging problem due to its combinatorial nature and the need to balance trade-offs between multiple objectives. However, with advances in computational power and optimization algorithms, it is becoming increasingly possible to find near-optimal solutions for even large- scale VRP instances in a reasonable amount of time.

Overall, VRP remains an active area of research, with ongoing efforts to improve existing methods and develop new approaches for solving this important optimization problem.

Crime Modelling to Interpret and Generate Behavioural Analysis of Crimes

Tanisha Shaikh, Hrishikesh Yadav, Shravya Shetty
Information Technology TCET, Mumbai, India

Abstract: **The aim of the Crime Modelling is to create a portal which is useful for the police department to reduce the crime rates. As the number of crime activities and forms are increasing drastically it has become a topic of utmost importance to design an effective way to reduce the crime rates. It will help the police department to unlock more potentials by understanding the crime in a better way with the help of analysis done on the FIR data/ Investigation data. It would also help to fight against the crime in the most efficient manner by proper planning of patrolling. The FIR data is very useful to understand the patterns and trends of the crime. The technology domain we have used to build the Crime Modelling is Data Science & Machine Learning. The Deep learning model would be going to learn from the pattern and behaviour in the previous FIR/ Investigation data and result in the place which will be prone to any crime type according to the level of crime.**

The Behaviour Analysis here is built on the dynamic analytics where the generic model would be going to filter the data according to the request input of the user and also framing the question according to that. Taking out the intuition from the analysis is the difficult task after plotting the visualization. The paper also focuses on making intuition by using the Deep learning transformer which results the intuition in a human-readable statements. The purpose of this paper is to provide a predictive and new analysis approach for the better decision making in the police department which will ultimately help to reduce the crime rates.

I. INTRODUCTION:

The crime affects the social and the economic status of the country/state. It is important to understand and reduce the crime rates. As we know, lots of data gets generated in the police department of FIR records or Investigation records. This data is useful to understand the trends & pattern of crime. CrimeDekho would also help to fight against the crime in the most efficient manner by proper planning of patrolling. The action can be taken according to the result made by the analysis and prediction done on the data.

Day by day the crime rates are increasing and also are becoming more dangerous. To overcome this issue better safety techniques have to be implemented and to do that technology can help. Thus, we tried to figure out how this can be achieved using machine learning, data science and help the police department to implement better

II. LITERATURE SURVEY

3.1 Introduction

As we know, the number of criminal activities and crime forms are increasing drastically it has become a topic of utmost importance to design an effective way to reduce the crime rates. It was a topic discussed from many years and the various methodologies were developed to fight against the crime rates. The solution discussed in this paper will help the police department to unlock more potentials by understanding the crime in a better way with the help of analysis done on the FIR data/ Investigation data.

3.2 Research Background

The previous advancement in the field of decision making for the patrolling procedure and the predictive policing are:

Telugu Maddileti,Vaddemani Sai Madhav, K V Sai Sashank,G. Shriphad Rao, “Crime Data Analysis Using Machine Learning Models”, This paper discusses the existing system which uses K-nearest neighbor to predict the next type of crime at a particular location, and also shows how the proposed

system is better than the present existing system. This paper compares many machine learning models among themselves to find the most efficient machine learning to tackle this problem. [1]

Mingchen Feng, Jiangbin Zheng, Jinchang Ren, Amir Hussain4, Xiuxiu Li , Yue Xi, and Qiaoyuan Liu,”Big Data Analytics and Mining for Effective Visualization and TrendsForecasting of Crime Data”, Holt- Winters with multiplicative seasonality is used for predicting the crime rates of further years by using the time series dataset. This paper focuses on Triple Exponential Smoothing (Holt-Winters) on the dataset provided by the Chicago, Philadelphia, San Francisco Police Department. Collapsing the features of types of crime results in greater accuracy when multi classification models like gradient boosting and Random Forest are used [2].

LSTM model works better for time series forecasting of the crime rates per year. The categorization while collapsing should be done on the basis of the level of seriousness of the crime so that accuracy will increase and also it will give a useful result.

[3] Lawrence McClendon, Natarajan Meghanathan, ”Using Machine Learning Algorithms to Analyze Crime Data”, The Linear Regression, Additive Regression, and Decision Stump algorithms using the same finite set of features, on the communities and crime unnormalized dataset to conduct a comparative study between the violent crime patterns from this particular dataset and actual crime statistical data for the state of Mississippi that has been provided by neighborhoodscout.com. Linear regression algorithm was found to be very effective and accurate in predicting the crime data based on the training set input for the three algorithms.The relatively poor performance of the Decision Stump algorithm could be attributed to a certain factor of randomness in the various crimes and the associated features; the branches of the decision trees are more rigid

and give accurate results only if the test set follows the pattern modeled.

III. METHODOLOGY:

The solution would be divided into the two phases: Prediction and Behavioural Analysis. We have the record of the individual FIR data/ Previous crime records which is also helpful to guide police department on taking the action prior to the incident. To reduce the crime rates there is a need to be ready for it beforehand. It is possible to use the human and other resources efficiently by predicting the place which will going to be more prone to the crime. The zone would also show the risk tonality. Categorizing the seriousness of the type of crime, it would be better to take an action on the basis of risk tonality. The category in the risk tonality that we are using at the time of pre-processing are low- risk, intermediate-risk, high-risk, serious- risk. The same risk tonality would be visible in a geospatial manner. For doing the prediction on when and where will need the data consisting of the Timestamp and the geolocation details (Longitude & Latitude).

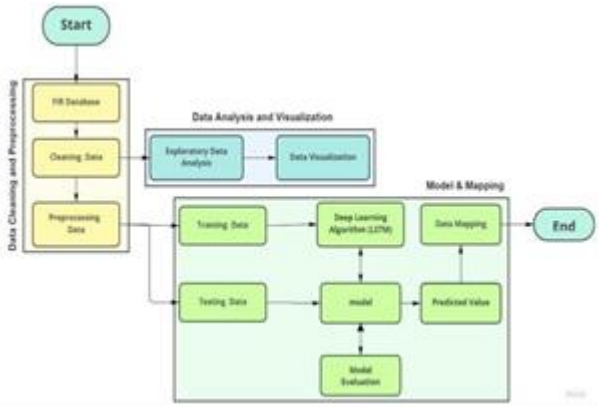

Fig. 1. Working of Predicitve Policing Model

From fig.1, we can observe the working of the predictive policing model. The model would help to generate the data points of the location with the risk tonality which would be helpful to use the human resources effectively for patrolling and also taking the action to prevent the crime rates.

First, the data is FIR or crim record data is taken from the database and then the cleaning og the data is performed. The cleaned data can be used for the analysis purpose and also to take out the insights for decision making. The cleaned data is then preporcessed to make it ready for the model. The preporcessed data is then separated into training data and testing data. The training data is sent to the Long Short Term Model (LSTM) which is a Deep Learning model. The testing data is used for the model evaluation. The predicted value which is the data point of the location of the most prone zone of the crime with the risk tonality got generated and that value would be useful to plot on the map. The reason to use the LSTM model is that the FIR Data stored is present is the TimeStamp data which is useful to forecast the possible crime of future dates.

On the top of Data Analysis, we have included the dynamic analytics features so that there should not be any boundation in the analysis area of the FIR data. In Dynamic Analytics, the concerned individual/admin can go to the admin panel and can write the title of the analysis question and as per the question framed the

value of the provided attributes should be filled. After putting the data, the data goes to the generic model prepared which makes an analysis as per the newly condition added by the admin side.

Extending the Dynamic Analytics feature of our solution, here we would be focusing on taking out the intuition out from the analysis. Taking out the intuition from the analysis is the difficult task after plotting the visualization. For the same, the solution is focused on using the GPT3 Transformer which is a Deep Learning Transformer.

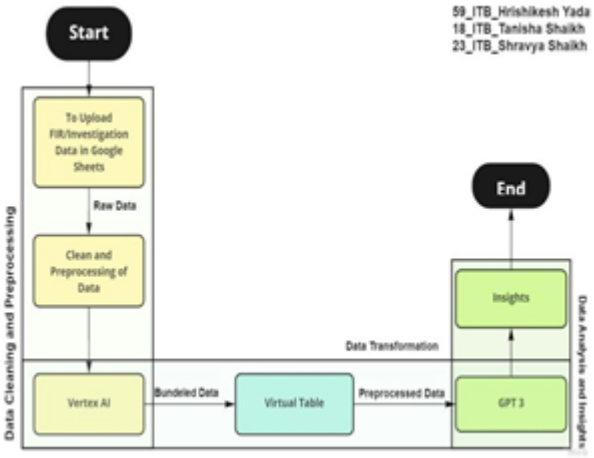

Fig. 2. Working of Analytical Model

From fig.2, we can observe the working of the analytical model. The model would help to generate the intuition out from the data after performing the data analysis and the intuition would be in a human contextual statement which would be an easier task to analyse the result and make out the co- relation and intuition from the same.

The raw data would be first stored in the google sheets and after that it is used for cleaning and pre-processing purpose. To convert the raw data and pre-process the data, the vertex.AI would be used which converts it into the bundled data which is

needed by the transformer. Virtual Data also helps to pre-process the data and then the data is sent to the transformer. The GPT3 Transformer used to first find apply the analysis on the pre-processed dataset and after it takes out the intuition out from it.

IV. RESULt:

The main use case of the application is in the police department to make the better decision making and also to use the human resources in more efficient manner like for patrolling and surveillance purpose. The predictive policing helps police to know which area are more prone to which crime also with the risk tonality so that the action can be taken according to that. It will be useful to guide police on where to patrol and where to efficiently

use the resources. The analysis done on the previous crime records and converting it into the intution would be helpful to understand the behaviour of the crime records and also for planning and decision making according to that.

V. DISCUSSION:

The whole solution is based on the FIR/Investigation Data which are the previous crime records. There are various police department in foreign countries like Chicago, New York, Philadelphia, etc. used to provide the FIR/Crime Records of each case for the research purpose. That dataset doesn't contain the details of the culprit but it contains the details about the crime incident registered and other details associated to it which is very helpful for the decision making purpose and prediction purpose. But, In India it is bit difficult to get the authentic FIR/Crime Records to make the model learn by using that behavioural pattern.Still, there is a need of implementation of using the previous record to the full potential and then using resources efficiently.

Ai Driven Sentiment Analysis

Adarsh Yadav, Anand Yadav
Information Technology TCET, Mumbai, India

Abstract- **Sentiment analysis is a highly studied area within natural language processing (NLP). NLP has a variety of applications, including voice recognition, machine translation, product review analysis, sentiment analysis, and text classification, such as email categorization and spam filtering. Historically, sentiment analysis has relied on lexicon-based techniques, but with advancements in artificial intelligence, machine learning algorithms are increasingly playing a major role in sentiment analysis. Currently, deep learning techniques are widely used for sentiment prediction. There has been a significant amount of research into NLP using deep learning methods, including Convolution Neural Network (CNN) and Recurrent Neural Network (RNN), particularly Long Short-Term Memory (LSTM). The choice of method depends on the application domain, and these techniques can be used either in combination or as standalone solutions. This survey focuses on the various types of deep learning methods used in different sentiment analysis applications, both at the sentence level and aspect/target level. Additionally, the survey compares the advantages and disadvantages of these methods and evaluates their performance.**

I. INTRODUCTION

Sentiment analysis (SA) is a method of uncovering the emotions conveyed within a context. This technique allows machines to predict the emotions, attitudes, or personalities expressed by individuals through different aspects. It identifies the underlying human emotions in a context, giving machines the ability to accurately understand these emotions.

In the past, people used to share their knowledge and opinions in person, with family members, friends, and neighbors. However, with the evolution of technology, these exchanges have shifted to an online environment, making SA an important tool. Technology has given individuals the ability to be exposed to thousands of opinions in just minutes. For instance, someone might post their views on a recent product purchase or a social issue on a social media platform. These reviews also extend to movies, hotels, and restaurants.

As people become more fond of online communication, both the number of individual opinions and the need for sentiment prediction in business areas have increased. This allows organizations to better understand the needs, likes, and dislikes of the general public. Sentiment analysis and opinion mining (OM) are fields that have greatly benefited from these innovative approaches, which involve automated methods of perceiving and recognizing human feelings.

This paper aims to provide a comprehensive review of AI-driven sentiment analysis and opinion mining of emotions. It covers multiple approaches and methodologies, including implicit and explicit data extraction. The paper also includes a taxonomy of sentiment analysis, a discussion of the pros and cons of SA based on previous research, and a highlight of the various levels of SA, open issues, research issues, and future directions in the field

II. LITERATURE SURVEY

3.1 Introduction

Sentiment Analysis (SA), also known as Opinion Mining, is a field of study in Natural Language Processing (NLP) that aims to determine the sentiment expressed within a given context. With the rise of the Internet and social media, there has been a proliferation of opinions and reviews being expressed in digital platforms. These opinions often reflect the attitudes and sentiments of individuals towards products, services, events, topics, and more. As a result, the need for Sentiment Analysis has become increasingly important for businesses, organizations, and individuals who want to gain insight into the prevalent moods and dispositions of individuals concerning certain subjects.

The goal of Sentiment Analysis is to classify the expressed opinions into different categories such as positive, neutral, and negative. This classification enables organizations and individuals to understand the overall sentiment expressed towards a particular subject and make informed decisions. AI-driven Sentiment Analysis has become a popular approach in recent years, with the advent of machine learning and deep learning techniques. These techniques have allowed for more accurate sentiment analysis, and have been applied in a wide range of domains, including social media analysis, product reviews, and customer feedback analysis, among others.

This literature survey aims to provide an overview of the current state-of-the-art in AI-driven Sentiment Analysis, including the research methodology and techniques used, the various applications and domains, and the advantages and limitations of these approaches. The survey will also discuss the future directions for the field and provide an outlook for the future of Sentiment Analysis

3.2 Research Background

Sentiment analysis (SA) has been an active area of research for several decades now. The first use of computational methods in sentiment analysis was recorded in the 1960s with the use of rule-based systems and keyword analysis. However, with the advancements in natural language processing and machine learning, there has been a significant improvement in the accuracy of sentiment analysis. With the rise of social media platforms, there has been a massive growth in the amount of opinionated text data that has led to an increased demand for sentiment analysis.

The traditional methods of sentiment analysis include lexicon-based processing, which uses a predefined list of words with associated sentiment scores. However, this approach is limited in its ability to understand the

context of the text. With the advancements in machine learning, various algorithms have been proposed to overcome this limitation, including decision trees, support vector machines, Naive Bayes, and artificial neural networks.

In recent years, deep learning techniques such as Convolution Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) have emerged as the most popular methods in sentiment analysis. These techniques use large amounts of data and multi-layer neural networks to learn and predict the sentiment in text. Long Short-Term Memory (LSTM) is one of the most widely used RNNs in sentiment analysis and has shown remarkable performance in several benchmarks.

In addition to traditional and deep learning methods, there have also been efforts to incorporate transfer learning in sentiment analysis. Transfer learning enables sentiment analysis models to be trained on large datasets and then fine-tuned for a specific domain or task.

The research background section of a literature survey for AI-driven sentiment analysis would provide an overview of the history of sentiment analysis, traditional methods, recent advancements, and the current state-of-the-art techniques. The section should also discuss the challenges faced in sentiment analysis and the need for continuous improvement in the field

III. METHODOLOGY

AI-driven sentiment analysis uses various computational and statistical methods to analyze and categorize opinions expressed in text. Some common methodologies used in AI-driven sentiment analysis are:

Rule-Based Method: This is a basic approach where pre-defined rules are applied to the text to categorize it as positive, negative or neutral. The rules can be based on the presence of certain words, patterns, or expressions in the text.

Lexicon-Based Method: This method uses dictionaries or lexicons of positive and negative words to categorize the text. The sentiment score is computed based on the count of positive and negative words in the text.

Machine Learning Method: Machine learning algorithms, such as Naive Bayes, Support Vector Machines (SVM), and Random Forest, are used to train the model on a large annotated dataset to identify the sentiment of the text.

Deep Learning Method: Deep learning techniques such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) are used for sentiment analysis. These models can learn complex patterns and relationships in the data, leading to improved performance in sentiment analysis.

The choice of methodology depends on the specific requirements of the sentiment analysis task and the availability of annotated data for training the models.

The methodology of AI-driven sentiment analysis can vary depending on the application and the research goals. However, the general steps in sentiment analysis typically involve

Data Collection: This involves gathering a large dataset of texts, such as social media posts, customer reviews, and online news articles, that express opinions and sentiments about a particular subject or entity.

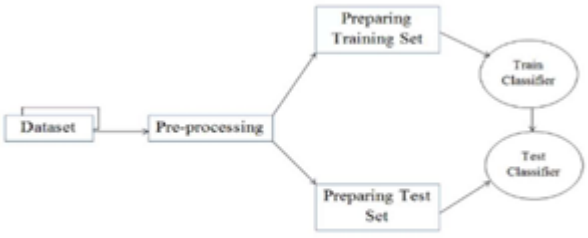
Data Pre-processing: This step involves cleaning and prepping the data for analysis. This includes removing duplicates, stop words, punctuation, and any irrelevant information from the data set.

Feature Extraction: This involves creating numerical representations of the texts for analysis. Commonly used techniques for feature extraction in sentiment analysis include Bag-of-Words (BoW) models, term frequency-inverse document frequency (TF-IDF) models, and word embeddings.

Sentiment Classification: This step involves training a machine learning algorithm on the feature-rich data to learn patterns and relationships between the features and the sentiment expressed in the texts. Common algorithms used in sentiment analysis include Naive Bayes, Support Vector Machines (SVM), and deep learning models such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN).

Model Evaluation: The final step involves evaluating the performance of the sentiment analysis model. This can be done using metrics such as accuracy, precision, recall, and F1-score. The evaluation helps to identify any biases in the model, and the results can be used to fine-tune the model or improve the feature extraction techniques.

It's important to note that the methodology of sentiment analysis can be adapted depending on the specific needs and goals of the research, and new techniques and models are constantly being developed to improve the accuracy of sentiment analysis.



IV. RESULT

The results of AI sentiment analysis can be evaluated in a variety of ways, depending on the specific application and the methods used. Some common evaluation metrics used in sentiment analysis include accuracy, precision, recall, and F1-score.

Accuracy measures the proportion of correctly classified instances compared to the total number of instances. Precision is the proportion of true positive predictions compared to all positive predictions, while recall is the proportion of true positive predictions compared to all

actual positive instances. The F1-score combines both precision and recall into a single measure of performance.

In addition to these metrics, other evaluation methods may also be used, depending on the task and the data. For example, in some sentiment analysis applications, it may be appropriate to evaluate the model based on the confusion matrix, which displays the number of true positive, true negative, false positive, and false negative predictions.

The results of AI sentiment analysis can also be visualized in a variety of ways, such as through bar charts, line graphs, or heat maps. These visualizations can help to highlight patterns and trends in the data, and can be used to inform further analysis or improvement of the model.

It's worth noting that the results of AI sentiment analysis are not always perfect and the model may make mistakes. However, with the advancements

in AI and deep learning techniques, the performance of sentiment analysis models is continually improving, and it is likely that their accuracy will continue to increase in the future.

Conclusion for AI Driven Sentiment Analyzer

The conclusion of the study of AI-driven sentiment analysis highlights the potential of this field in providing valuable insights into the attitudes and emotions of individuals. The study of AI-driven sentiment analysis has shown that this technique can be used to effectively analyze and understand the emotions expressed in text data. The results of the study demonstrate the potential of AI-driven sentiment analysis to provide a comprehensive view of the attitudes and emotions of individuals. The findings also suggest that AI-driven sentiment analysis can be an effective tool for decision-making in various domains, including marketing, customer service, and product development. The study concludes that further research is required to fully exploit the potential of AI-driven sentiment analysis and to develop new methods that can better handle the complexity of text data.

Natural Language Processing for Sarcasm Detection

Aryan Shetty, Aryan Shetye, Kuldeep Tak
Information Technology TCET, Mumbai, India

aryanshetty1604@gmail.com, aryanshetye03@gmail.com, kuldeeptak.1007@gmail.com

Abstract— **Our research focuses on identifying sarcasm in news headlines by fusing extracted elements from machine learning with hand-crafted contextual variables. Before being coupled with meticulously created feature sets, a feature set is retrieved from a Convolutional Neural Network (CNN), Bidirectional Gated Recurrent Unit (GRU), and Bidirectional Long Short Term Memory (LSTM) architecture. These individually designed feature sets are developed based on their corresponding contextual justifications. Each feature set has been created expressly with the goal of detecting sarcasm in mind. The goal is to identify the best attributes. Some sets function properly even when used independently. In the absence of a combination, other sets are not particularly important. Accuracy, Precision, Recall, and F1-measure outcomes of the experiments are all favorable.**

Keywords: Sarcasm, headlines, CNN, GRU, LSTM, Accuracy, Precision, Recall, F1-measure

I. INTRODUCTION

Sarcasm is the art of use of words that mean the opposite of what you really want to say especially in order to insult someone, to show irritation, or to be funny. Though evinced in many ways, identifying sarcasm is a difficult yet important task in opinion mining. This is because the computational systems which rely on or exploit polarity of the text can be misled by sarcastic sentences where the literal sentiment of the text is different from the one that is implied, often involving a strand of hostility.

Consider this sentence "I am glad I am going to college while all my friends have a holiday." This sentence contains words like 'glad' which denote a positive sentiment.

However, the sentence in its entirety clearly has a negative sentiment. The inability of the most advanced sentiment analyzers to accurately identify sarcasm has a direct influence on NLP systems, ranging from review summarization systems to chat bots.

The work of Riloff et al. (Riloff, Qadir, Surve, De Silva, Gilbert and Huang, 2013), which demonstrates that sarcasm can be detected by the contrast between a positive sentiment word and a negative state, is the one that is most closely related to the work presented in this paper among the various computational linguistics studies on sarcasm detection. The SASI method developed by Tsur et al. (Tsur, Davidov, and Rappoport, 2010) finds semi-supervised patterns that indicate instances of sarcasm.

II. OVERALL ARCHITECTURE

According to [1]-Sarcasm as a restriction of sentiments, sarcasm can be communicated in five different ways: This category includes a variety of elements like sentiment and mood. It makes use of contrast and historical comparison. Multiple viewpoints are taken into consideration for sarcasm identification because it is a complicated style of expression. In comparison to the other categories, this demands more work. Sarcasm as a manner of expressing emotion: One of the most prevalent ways to express emotion is through sarcasm. It is frequently employed in unfavorable circumstances or to express aggression. Sarcasm as a function of familiarity: When compared to friends and family, strangers have a harder time recognizing sarcasm. Language familiarity makes the process easier as well. Written sarcasm as an expression: In addition to vocal communication, sarcasm is frequently utilized in writing, particularly on social media. We are debating the first, second, and fifth strategies among these.

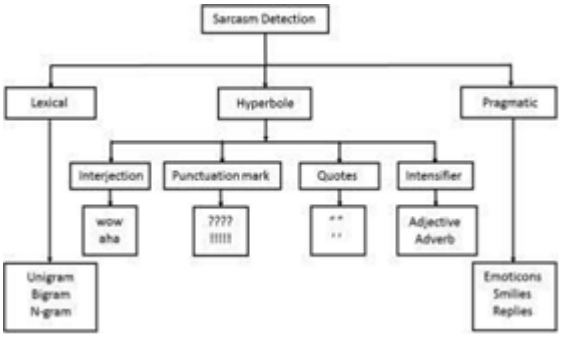

Fig. 1

III. RELATED WORK

Many researchers have conducted experiments and looked at the usage of various feature types in text datasets as well as various techniques for sarcasm detection. Generally speaking, there are two types of sarcasm detection techniques: supervised and semi-supervised. Additionally, new techniques for detecting sarcasm, such deep learning and bootstrapping, are being developed.

Satirical comments in product evaluations on Twitter and Amazon [11] were identified using the semi-supervised sarcasm identification algorithm (SASI) by Davidov et al. The first reliable algorithm for sarcasm detection is this one. In reviews and tweets, they employed punctuation- and pattern-based features. While Lukin and Walker used the Bootstrapping approach to use pattern-based characteristics [9] to detect rudeness and sarcasm in

online discourse. Sentiment-related, punctuation-related, pattern-related, syntactic, and semantic characteristics [2] are used in a pattern- based technique developed by Bouazizi and Ohtsuki to identify sarcasm. By utilising two classifiers—Support vector machine (SVM) and Logistic regression (LogR) [10]—Gonzalez-Ibáez et al. analysed lexical and pragmatic elements in tweets, retrieved using unigrams and dictionary- based for categorising sarcastic, positive, and negative tweets. In order to identify sarcasm and irony in Microblogs, Fersini et al. devised an ensemble method called Bayesian Model Averaging (BMA), which takes into consideration feature sets such pragmatic particles and PoS tags [7]. Cocea et al. used machine learning algorithms, n-grams, unigrams characteristics, coupled with extra features like emotion label, polarity label, amount of hashtags, etc. to identify sarcasm from student response on Twitter. [6].

By Kunneman , sarcasm recognition in Dutch tweets with the hashtags "#sarcasm," "#irony," "#cynicism," etc. was analysed and investigated. They confirmed the French tweets as well and discovered that the hashtag often denotes a polarity change.

Ghosh et al. reframed the sarcasm detection challenge as a literal/sarcastic sense disambiguation (LSSD) [5]. Unsupervised techniques and an SVM classifier with a modified kernel employing word embedding were used to analyse the twitter data. A big data strategy was developed using a framework based on Hadoop.

IV. METHODOLOGY

Rule-Based Methodologies:

Many academics employ rule-based methods to recognise sarcasm using particular data that may be described in terms of rules. These guidelines mainly rely on signs of sarcasm. Hashtags are frequently used to emphasise sarcasm and are a crucial signal of it. For instance, "Wow, you are very smart. Never use sarcasm. This method was utilised by Maynard et al. [8] to identify sarcasm in tweets. They tokenized hashtags in tweets using a lexicon- based method, and they developed a number of rules for hashtag pattern usage. Their tests show that the hashtag tokenization achieves 98% precision, sarcasm detection 91% precision, and polarity detection 80% precision. In their study on sarcasm, Bharti et al. [4] used two rule-based classifiers, i.e. Interjection word start algorithm (IWS), which makes advantage of the hyperbolic feature, and parsing-based lexicon generation algorithm (PBLGA), which builds parse trees of sentences incorporating sentiment and situation phrases. This method has the benefit of allowing for error analysis corresponding to many rules.

Statistical Approaches:

Based on this method, several learning

algorithms and characteristics may be used to identify sarcasm.

Most ways employ the feature known as "bag- of-words," which is a feature creation tool that represents a text as the bag (multiset) of its words while ignoring syntax and even word order. For sarcasm detection, however, statistical techniques encourage us to employ a variety of feature types and their combinations, including pragmatic, pattern-based, lexical, contextual, etc. For these methods, we may experiment with several classifier types, including SVM, Naive Bayes, Logistic Regression, etc.

The SVM classifier employed by Riloff et al. [18] used lexical characteristics such bigrams and unigrams to obtain 64% accuracy and 39% recall. While Dmitry et al. [11] combined k-nearest neighbours with pattern-based features and punctuation-based features (KNN).

Distributional Approaches:

This method takes into account the Distributional Hypothesis, which claims that words that often occur in related situations have comparable

meanings. The context vector that was created from the data therefore conveys the sense of the target word and serves as a stand-in for the meaning's purpose. Geometric methods like cosine similarity are applied to context vectors to determine how similar their meanings are.

This method was used by Ghosh et al. [5] and included the classification methodology and word embeddings. They have employed Cosine similarity as a geometric approach together with Distributional Semantic Models (DSMs), which follow the Distributional Hypothesis. They noticed that this method overcame the difficulties of an extra feature and the problem of classification strategy, achieving 7% to 10% F1-score

Deep Learning Approaches:

As a subset of a larger family of machine learning approaches based on learning representations of data and employing high level abstractions in data by using a deep graph, deep learning-based techniques are becoming increasingly popular for sarcasm detection. Think about a deep neural network.

A visual neural network was modified by Rosanno et al. [3] for picture datasets from Instagram and Tumblr. Deep network adaptation architecture was used to test the multimodal fusion of textual and visual data in order to identify sarcasm in the fusion. They found that by including image-related information, their method enhances sarcasm recognition.

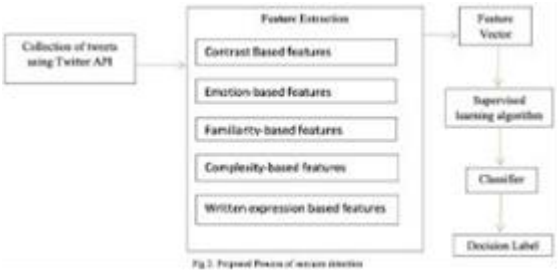
V. IMPLEMENTION

We assembled tweets using the Twitter API that had the hashtags for sarcasm (#sarcasm, #sarcastic), direct positive sentiment (#cheerful, #happy,

#delighted), and direct negative sentiment (#sorrow,

#angry, #grief), respectively. To remove quotes, retweets, spam, tweets in other languages, and tweets with URLs, we developed the appropriate filtering. The initial dataset was made up of Tweet IDs (individual identifiers that Twitter assigns to each tweet) and their corresponding classification tags, such as Sarcastic or Non-Sarcastic. Tweepy, a Python

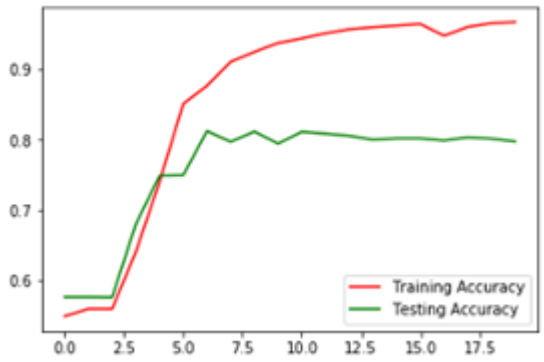
package created as a wrapper around the Twitter API to facilitate use of the same in Python, was used to further develop the dataset. Tweepy was used to harvest tweet information from the Twitter servers, including the text, date, and author name. Another dataset, available at http://thinknook.com/twitter-sentiment-analysis-training- corpus-dataset-2012-09-22/, was employed. It consists of 16 lac tweets with the tags "positive," "negative," or "neutral."

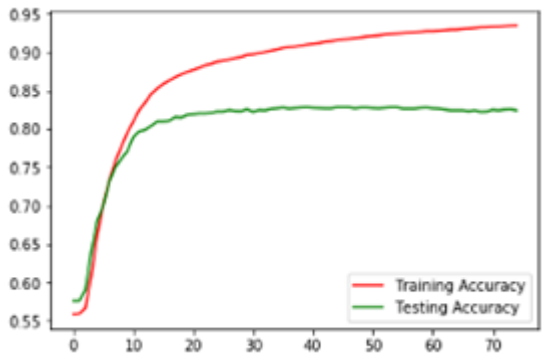


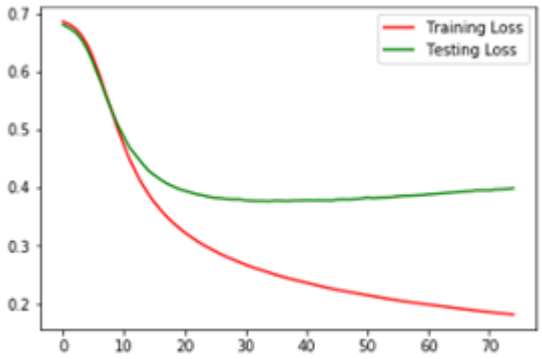
VI. RESULTS AND DISCUSSION

We used three models to get different results with varying accuracies.

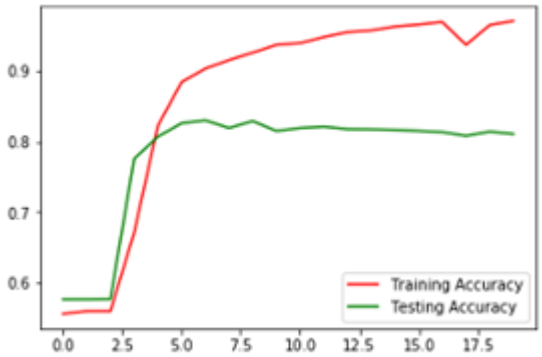
The results of all three are shown below

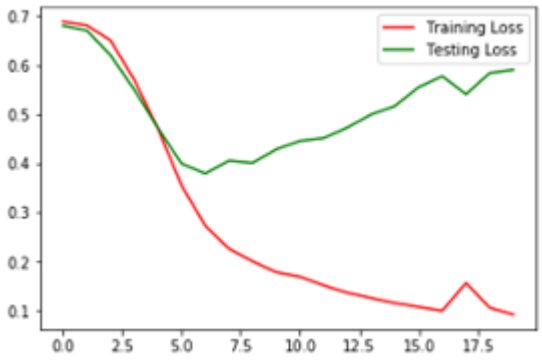






Convolutional Neural Network (CNN)





Bidirectional Long-short Term Memory (LSTM

VII. CONCLUSION

Over the past few years, sarcasm detection analysis has grown significantly, necessitating that we look back and assess the picture that these independent successes have presented. The study provided illustrations that included the techniques, datasets, and performance metrics. The results of even a limited implementation of the SCUBA framework are fairly reliable, as is clear from the results mentioned above. This demonstrates unequivocally that including variables that characterise the psychological and behavioural aspects of the user helps the process of automatically identifying sarcasm. Ensemble approaches consistently perform

better than singleton classifier algorithms, which is consistent with the theoretical prediction. For both the BigFeatureSet and each feature set separately, Gradient Boosting performs best. The results produced

by the multi- layered perceptron model are the most ludicrous, erroneous, and inconsistent. The train-test split of 10:90 typically produces the best accuracy results. Gradient Boosting with L1 and L2 regularised logistic regression produce results

that are nearly identical. The sparse nature of the data generated by feature set 3 is likely the reason why basic algorithms performed relatively better on it than on other feature sets

VIII. FUTURE WORK

Future effort could undoubtedly be directed toward increasing the feature set to include more features that are reflective of the user's behaviour in light of the good results obtained. Additionally, because tweets only contain short lines, it is difficult to identify sarcasm in them. The same method might be used to recognise sarcasm on additional social networking websites (To classify posts as sarcastic on face book for example). Due to individuals not recognising the posts as ironic, this could significantly reduce the propagation of bogus news. Finally, the current method only functions with static datasets. In the future, it might also be tried to include incremental categorization capabilities

Legal Contract/Document Summarization using NPL and Machine Learning

Ranjeet Saw, Manav Sanghvi, Rahul Saw
Information Technology TCET, Mumbai, India

Abstract-**The process of reading legal documents can be overwhelming and challenging, particularly when specialized knowledge is necessary to understand their content. With the increasing volume of legal documents available, it has become more important than ever to extract essential information from these documents without having to read them in their entirety. This study seeks to enable rapid comprehension of large legal documents by providing a summarization method that offers flexibility and convenience for the reader. By leveraging natural language processing concepts, including vector representation, text ranking algorithms, and similarity techniques, the study presents a way to generate a summary that encapsulates the most critical information from the document in a concise and accessible manner. The paper provides a detailed explanation of each algorithm used at every step of the process to achieve the desired outcome. Ultimately, this study proposes a comprehensive approach to legal document summarization that alleviates the burden of reading complex documents in their entirety**.

Keywords:Natural Language Processing, Word Embeddings, PageRankAlgorithm, Text Rank Algorithm.

a. I INTRODUCTION

Natural language processing has brought us document summarization, a technology that is bound to revolutionize the way we approach reading. With the overwhelming amount of information available these days, people no longer have the luxury of reading a document from start to finish just to get the gist of it.

While human summarization is a tried-and-tested method, it's a time-consuming process. Enter automatic text summarization, which is the process of using computational techniques to shorten a large document and create a summary that contains only the most critical information. Two primary approaches are used in automatic summarization: extractive summarization and abstractive summarization.

In extractive summarization, the sentences are extracted from the original document but the extracted sentences are not modified in any way. Abstractive summarization constructs an internal semantic representation for the original sentences and then use this particular representation to obtain a summary that is closer to how a human being might express. Abstractive summarization is computationally much more complex and challenging than extractive summarization, It requires both natural language processing and a deep understanding of the domain of the original document. Most of the existing methods uses statistical methods such as frequency of occurrence, inverse document frequency or linguistic information such as term distribution, sentence position to extract the most relevant sentences from the document. However these methods ignore the relationship between different granularity information such as the relationships between the sentences. Hence the proposed system takes into consideration the similarities between different sentences before calculating the ranks of individual sentences in the document. Many researches are ongoing in the field of document summarization because text summarization becomes different and unique problem for each domain of research.

II. MOTIVATION

Very large volume of information in the legal domain is generated by legal institutions across the world. For example, a country like India having 24 high courts [97] (provincial courts) and

600 district courts [96] puts the legal proceedings in the public domain. This is of paramount importance as a huge number of cases are pending in different courts of India (as of 2011, High Courts 4, 217, 903, Supreme Court of India 57,

179) [77]). Also, this massive quantity of data available in the legal domain has not been properly explored for providing legal information to general users. Since most court judgments are generally long documents, headnotes are generated which act as summary of the judgments.

However headnotes are generated by experienced legal professionals only. This extremely time-consuming task involves considerable human involvement and cognitive effort. Automatic processing of the legal documents can help legal professionals quickly identify important sentences from the documents and thus reduce human effort. Text summarization can be applied in extracting important sentences and thus in generating headnotes.

III. TEXT SUMMARIZATION

3.1 Introduction to Text Summarization Automatic summarization is the technique of reducing a text document with a system in order to create a summary that retains the most important information of the original document. With increasing amount of electronic documents, use of such systems become progressively pertinent and inevitable. Substantial amount of research has been directed to explore different types of summaries, methods to create them and also the methods to evaluate them. Das et al. [13] surveyed some of the approaches both in single and multiple document summarization, giving importance to empirical methods and extractive

techniques. The authors discussed issues of automatic summarization, some techniques, and their evaluation that were attempted during

1991-2007. Nenkova et al. [73] provided an

overview of the most prominent methods of automatic text summarization. The authors discussed how representation, sentence scoring or summary selection strategies alter the overall performance of the summarizer. They also pointed out challenges to machine learning approaches for the problem. The paper surveyed the body of works published during 1995-2010.

3.2 Single Document Summarization

When a document is too long to go through in detail, and/or the user in a hurry to have a quick overview of its content, a summary of the document concerned seems immensely helpful. Single document summarization is, therefore, an important research issue. In extractive summarization traditional approaches deal with sentence level identification of the important content. Several techniques have been applied to select important sentences from a document. In the following we attempt to categorize some of the recent approaches. This classification is not a comprehensive list, for which one can refer to [13] [73] [65]. Instead we include the papers which were published after those surveys and are not therefore part of the surveys.

IV. LEGAL TEXT SUMMARIZATION

Legal text summarization is a process of generating summaries from court judgments. The summarization here is different from that of other genres.. On the other hand, in general text summarization, important information is extracted without the constraints. Legal documents are much longer than office memos or newspaper articles or magazine articles. They exhibit wide range of internal structure (sections, articles and paragraphs in statutes, sections and sub-sections in regulations). The importance of individual documents is determined, to a great extent, by their origin.

The same text would be interpreted differently if it occurs in a higher court opinion than in the opinion issued by a lower court. Citations play a major and crucial role in legal documents which indicate important information about the case. Due to the reasons, legal text summarization demands special attention and straightway application of successful techniques of general text summarization may not be effective here. Below we discuss a few classes of summarization techniques that have been tried till date. Although they may have similar groupings as with general text categorization for a few cases, there are differences at finer level of application.

V. PROPOSED SYSTEM

As stated earlier, the proposed system would be focusing on generating extractive summary from the

given document using different natural language processing techniques such as word embedding, similarity measures, and ranking algorithm

The overall flow of the system can be explained with the help of following steps:

1) Initially we will concatenate all the text present in the document.

2) Then we would split the text into individual Sentences This can be done using the tokenizer of the natural language tool kit package of python.

3) Then we would remove all the punctuations, numbers and special characters from all the individual sentences.This can be achieved with the help of regular expression and python packages.

4) Then all the alphabets are converted into lower case alphabets This is done so there would not be any problem because of character case sensitivity in the sentences.

5) Then we would remove all the stop words from the sentences because stop words do not

contribute any meaningful context to the sentences and would only waste processing time in the next step of vector conversion.

After all the above steps we would get clean sentences which are free from stop words and all other unwanted punctuations, numbers and special characters.

VI. CONCLUSION

Text summarization has been an active area of research for the last two decades, with more focus on extraction-based summarization than on abstractive summarization. However, there has been a recent shift towards automatic summarization of legal documents and other specialized texts. This survey paper provides an overview of text summarization techniques, with a focus on legal text summarization. It covers state-of-the-art techniques, datasets, and metrics, and presents a comparative study. The paper also discusses issues specific to legal text summarization, such as document structure and terminologies, and highlights the need for further research to improve comparative analysis of results.

Smart Bin Waste Prediction using Machine Learning

Sushan Uchil, Aditeya Prajapati, Vishal Patwa

Abstract—Smart bin waste prediction is a method for forecasting the amount of waste that will be generated by a community or municipality. By using machine learning algorithms, the system can analyze patterns in waste generation and make accurate predictions of future waste levels. This information can then be used by waste management organizations to optimize their collection and disposal schedules, reducing costs, and improving efficiency. The use of machine learning in smart bin waste prediction has been shown to be a reliable and effective method for managing waste and has the potential to transform the waste management industry.

I. INTRODUCTION

Waste management is a critical issue for communities and municipalities worldwide, as the generation of waste continues to increase with the growing population and consumption patterns. In order to effectively manage waste and minimize its negative impacts, it is important to have accurate predictions of future waste levels. Smart bin waste prediction is a method for forecasting the amount of waste that will be generated by a community or municipality using machine learning algorithms.

The smart bin waste prediction system works by analyzing patterns in waste generation and making accurate predictions of future waste levels. This information can then be used by waste management organizations to optimize their collection and disposal schedules, reducing costs and improving efficiency. For example, by knowing how much waste will be generated, waste management organizations can adjust their collection routes to ensure that they are not collecting partially full bins, which can be a waste of resources and lead to higher costs.

Machine learning algorithms used in smart bin waste prediction can include decision trees, random forests, and neural networks, among others. These algorithms can analyze large amounts of data and identify complex relationships between different factors, such as weather conditions, population density, and waste generation patterns. This allows for more accurate predictions of future waste levels and helps to minimize the risk of waste being left uncollected.

In conclusion, smart bin waste prediction using machine learning has the potential to revolutionize the waste management industry. By providing accurate predictions of

future waste levels, waste management organizations can optimize their collection and disposal schedules, reducing costs and improving efficiency. Additionally, by minimizing the risk of waste being left uncollected, smart bin waste prediction can help to improve public health and reduce environmental impacts..

II. OVERVIEW OF SMART CITY IOT APPLICATIONS FOR WASTE MANAGEMENT:

Smart city IoT applications are playing an increasingly important role in improving waste management in cities. By integrating IoT technology with existing waste management systems, cities can collect and analyze data in real-time, making more informed decisions about waste collection and disposal.

One of the key applications of IoT in waste management is smart bins. Smart bins are equipped with sensors that can detect the fill level of the bin and transmit that information to a central management system. This allows waste management organizations to optimize their collection routes and minimize the number of partially full bins that are collected, reducing costs and improving efficiency. In addition, smart bins can also be equipped with other sensors, such as air quality sensors, that can provide additional information about the environment around the bin.

Another important application of IoT in waste management is route optimization. By collecting data on waste generation patterns and traffic conditions, waste management organizations can optimize their collection routes to minimize the distance traveled and reduce the carbon footprint of waste collection. This can also help to improve public health by reducing the amount of time that waste is left uncollected.

In addition to optimizing collection routes, IoT technology can also be used to improve the recycling process. For example, smart recycling bins can be equipped with sensors that can identify the type of material being deposited and sort it accordingly. This can help to increase the efficiency of the recycling process and reduce contamination of recyclable materials.

IoT technology can also be used to monitor the environmental impact of waste management. For example,

sensors can be used to monitor air and water quality near landfills and waste management facilities, allowing authorities to take action to mitigate any negative impacts. In addition, IoT technology can be used to monitor the emissions from waste management facilities, helping to reduce their carbon footprint and improve sustainability.

Finally, IoT technology can also be used to educate the public about waste management. For example, smart bin systems can provide feedback to users on the amount and type of waste they are generating, encouraging them to recycle and reduce waste. This can also help to raise awareness about the importance of waste management and encourage more sustainable behavior.

In conclusion, smart city IoT applications have the potential to transform the way waste is managed in cities. By collecting and analyzing data in real-time, waste management organizations can make more informed decisions about waste collection and disposal, improving efficiency and reducing the environmental impact of waste management.

III. MATERIALS AND MODELS

3.1 - A Intelligent Waste Management System. -is section introduces the intelligent waste management system that contains combinations of Internet of things and machine learning. Internet of things can be used for real time monitoring and collecting the waste. -e waste can be collected by placing sensor-based dustbins in different places. Arduino and microcontroller-based dustbins can collect the waste within small area, and it cannot be classified based on its characteristics. So, IoT based waste management system can be selected for continuously collecting and monitoring the waste.

But existing systems did not give concentration on hazardous waste that produces poor odor and poisonous gas. So, intelligent based waste management system can be proposed to monitor the hazardous waste and non hazardous waste. Sensor based dustbins can be placed in different places that contain sensors like ultrasonic sensor etc.

3.2 - Machine Learning Algorithms. IoT with machine literacy algorithm can be used in waste operation system to develop the smart megacity in effective manner. - e waste can be classified depending on its characteristics by using ML classifier algorithm. ML algorithm can be classified into three major types. - ese are supervised literacy, unsupervised literacy, and underpinning algorithm, which are shown in Figure 7. substantially, supervised learning algorithm is used for waste collection and operation to develop the effective smart megacity.

Because it provides better affair and to break bracket and retrogression challenge. So, this work substantially focuses on supervised literacy- grounded waste operation system. operations of Machine literacy algorithms shoot the

covered data through an android operation, and these kinds of android operation are well suited for deep literacy approach, and they collect the real time data with the help of Bluetooth technologies.

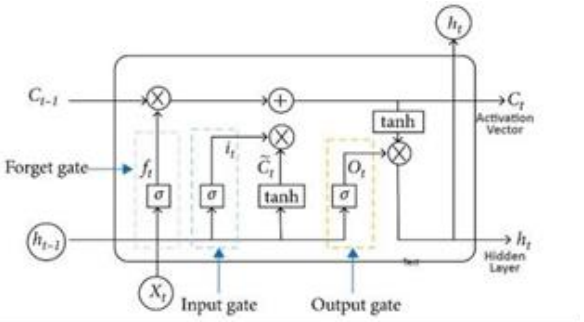
3.2.1 – LSTM – Long Short-Term Memory (LSTM) is a type of Recurrent Neural Network (RNN) that is widely used for time series analysis and sequence prediction problems, including smart bin waste prediction. LSTMs are designed to handle the problem of vanishing gradients in traditional RNNs, allowing them to remember information from long sequences and capture long-term dependencies.

In the context of smart bin waste prediction, LSTMs can be used to analyze time series data collected from smart bins and predict the fill level of the bins at future points in time. The LSTM network can be trained on historical data of bin fill levels and use that information to make predictions about future fill levels.

One of the key advantages of LSTMs for smart bin waste prediction is their ability to handle the unpredictability of waste generation patterns. By analyzing multiple historical sequences, the LSTM network can learn the underlying patterns of waste generation and make predictions accordingly. In addition, LSTMs can handle non-linear relationships between features, making them well-suited to the complex and non-linear relationships that often exist between bin fill levels and waste generation patterns.

However, it's important to note that LSTMs can be computationally expensive, particularly for large and complex data sets. In addition, the training process for LSTMs can be challenging, and requires careful selection of hyperparameters, such as the number of hidden layers and the number of neurons in each layer.

In conclusion, LSTMs are a powerful tool for smart bin waste prediction, allowing for the analysis of complex time series data and the capture of long-term dependencies in waste generation patterns. However, care must be taken in the selection and training of LSTMs to ensure accurate predictions and prevent overfitting. Due to the gradient difficulties in deep neural or recurrent networks, the LSTM architecture was introduced by Hochreiter and Schmidhuber to overcome the problems in training long-term dependencies. The LSTM design comprises a set of repetitively associated sub-networks denoted as memory blocks. The thought behind the memory block is to preserve its state over time and control the data stream through non- linear gating units. Figure 2 shows the structure of an LSTM block, which includes the doors, the input flag x(t), the yield h(t), the enactment capacities and peephole associations. The input block and all the gates are recurrently connected with the output block.



3.2.2 – Logistics Regression- Logistic regression is mainly focused on classification and prediction of data depending. on its characteristics. Here, the dependent variable is denoted as binary forms. It can be classified into binomial, multinomial, and ordinal. Figure 8 shows the types of

logistics regression. In binomial regression, the two types of dependent variables are possible, for example, pass and fail, win and loss, etc. In multinomial regression, the dependent variable must have the three or more possible values in unordered manner .

In ordinal regression, the dependent variable must have three or more possible values in ordered manner. -e following assumptions are considered in logistics regression.

These are binomial regressions representing the target values in terms of binary values. It does not have multiple collinearity, which means that the variables are independent of each other. -ese variables must have proper meaning. It can be used in huge model. Here, the input is linear function.

3.2.3 – Bidirectional LSTM Model - Due to its design, an LSTM network can execute only the forward passes on consecutive information, which eventually implies the unidirectional model of data processing.

An instinctive way to mitigate this confinement is to utilize a clone copy of the LSTM arrangement but in the opposite order proposed by Schuster and Paliwal . Hence,

combining the LSTM forward and backward networks, a

Bidirectional LSTM (BiLSTM)

is made, which can be utilized to show conditions bidirectionally. Figure 4 demonstrates

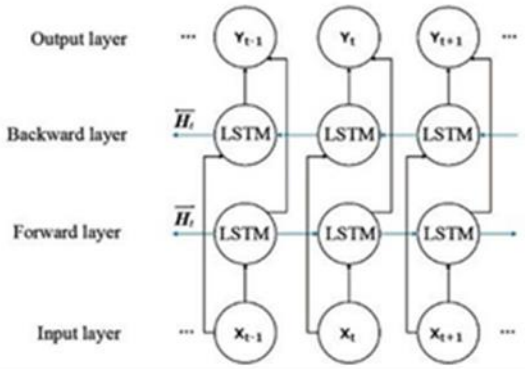
the structure of the BiLSTM network, which is an arrangement of handling sequence processing that comprises two LSTMs networks: one taking the input in a forward

layer and

the other in reverse order in a backward layer. The forward layer is accompanied by the

inputs coming from the input layer, and the backward layer generates the outcomes in the

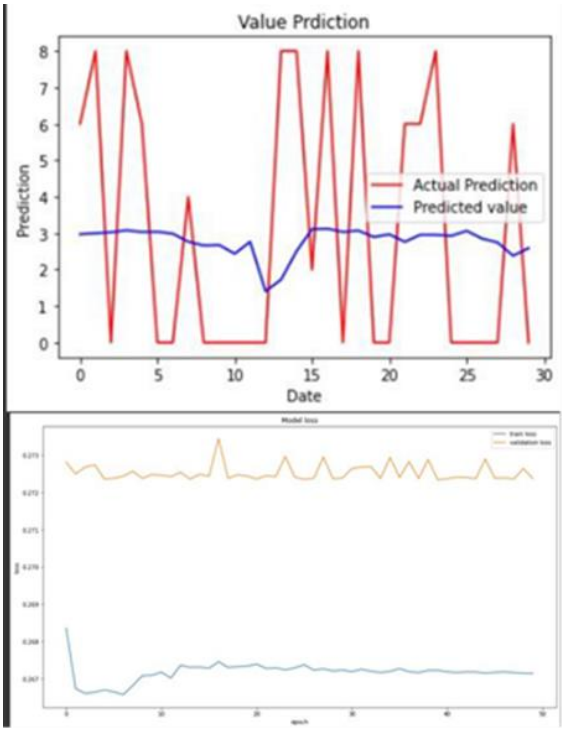
output layer.



IV. RESULTS AND DISCUSSION

This section presents the results and discussion for the all the machine learning algorithms and methodologies used in order to achieve accurate prediction of smart bin waste. As the the available data of smart bin prediction was a time series data (The data was obtained from Australian government website of the smart bin they have installed in their cities).

The data was a time series data consisting of the date and all the details regarding when the bin was full of waste with the help of the sensors attached to it. As it was time series data the ARIMA and SARIMA models were applied. but the predictions and accuracy were very poor and the irrespective of different it input it always gave a constant output so we understood that we would need a machine learning model that would consider/remember the past characteristic of the data and predict the values accordingly.So we implemented the LSTM models and as a result the results were satisfactory as we previously got the a constant output for any inputs here in lstm model the outputs were various according to the input but the accuracy was not satisfactory so for improvement of the accuracy Bi-lstm was used and it gave good results.



In future the for more accurate prediction we will be using

GRU, clustering and decision tree for better accuracy

Precision Agriculture using Deep Learning

Anshit Raina, Aditya Rajauria, Suraj Rajbhar
Thakur college of Engineering and Technology, Mumbai, India
1032200755@tcetmumba.in, 1032200957@tcetmumba.in, 1032200405@tcetmumba.in

Abstract—**Any country's ability to grow economically depends heavily on its agricultural sector. The task of meeting the current population's food needs has become difficult due to the growth in population, frequent fluctuations in the climate, and scarcity of resources. Smart farming, sometimes referred to as precision agriculture, has become a cutting-edge technique to address contemporary issues with agricultural sustainability. Machine learning is the engine that powers this cutting-edge technology (ML). The machine can now learn without being expressly programmed thanks to it. The next agricultural revolution will be largely driven by machine learning and IoT (Internet of Things) enabled farm equipment. Crop recommendations, fertiliser use, and plant disease detection in crops are the areas of focus. To measure crop quality and yield, ML with computer vision is examined for the categorization of various sets of crop photos. This strategy can be applied to improve livestock output by identifying reproductive trends, diagnosing eating disorders, and predicting the behaviour of cattle using data from collar sensors. Drip irrigation and other intelligent harvesting methods are also being evaluated, which greatly decreases the need for human labour in irrigation.**

Keywords—precision agriculture, deep learning, convolutional neural network , agricultural engineering, machine learning, recommendation.

I. INTRODUCTION

According to the data, almost 65% of all living things depend on agricultural products, either directly or indirectly. To meet the requirements of the expanding population, which has nearly doubled over the past 50 years, this sector has undergone different transformations. Population growth and climate change are viewed as being damaging to agriculture's ability to meet its needs. Additionally, agricultural goods are in danger due to a number of issues, such as a drop in pollinators, a variety of crop diseases, incorrect irrigation, technology, water scarcity, and many others. The adoption of cutting-edge technologies in the agricultural sector could make it possible to take preventative actions against this problem. It has been able to develop a sympathetic solution to this issue by combining computer vision with Deep Learning and Machine Learning, two branches of Artificial Intelligence. All of these technologies are combined in the field of precision agriculture, which views them as crucial elements in overcoming agricultural difficulties like those related to the environment, food productivity, sustainability, and quality. The most common form of sensing is satellite- based, while infrared and thermal imaging are utilised in a limited but expanding number of applications. The most widely used method of image analysis was machine learning with image processing. The most well-known machine learning techniques include K-means, SVM, artificial neural networks (ANN), and random forest.

II. OVERVIEW OF DEEP LEARNING

Deep learning (DL) is an extension of conventional machine learning because it incorporates complexity into the model and data that may be sent via a range of functions that allow hierarchical representation of the data through several levels of abstraction. Due primarily to its feature learning capabilities, deep learning is being employed more and more in a range of application fields. By combining lower-level characteristics into higher-level features, deep learning algorithms may automatically extract features from a given raw dataset. using deep learning to resolve difficult problems till the text has been styled and formatted, keep your text and graphic files apart. Avoid using hard tabs, and only use one hard return to mark the end of a paragraph. There should be no pagination added to the paper. No need to number text heads; the template will take care of that. Deep learning (DL) builds on standard machine learning by allowing for the hierarchical representation of the data through the use of a number of levels of abstraction, as well as the addition of complexity to the model and data that can be transferred via different functions. The primary driver of deep learning's rising adoption across a variety of application areas is its capacity to learn features. Deep learning algorithms have the ability to automatically extract features from a raw dataset and then compose higher-level features from the lower-level features. Deep learning systems are capable of resolving challenging issues.

III. PROPOSED SYSTEM

Remote sensing is used to manage a broader variety of resources through smart agricultural systems, which also reduce waste and increase productivity. a system that combines local sensors for temperature and insolation monitoring with smart irrigation and control that also monitors pH and other environmental factors. Because farmers have more time to focus on their farms' actual problems, such as using their expertise to solve pest problems, water in any location, and amend soil conditions through the use of sensing and automation, production yields can rise thanks to remote monitoring provided by smart farming systems The anticipated crop and the accuracy level would be displayed in the suggested system after gathering input data from users such as air temperature, soil humidity,soil pH, and rainfall. Support Vector Machine Learning Algorithm enables us to analyse data more effectively. When compared to other precision systems, ours also allows for users to buy and trade agricultural products directly.

IV. ADVANTAGES OF PROPOSED SYSTEM

1) Higher yields and more profitability

2) Less waste

3) Better quality produce

4) Better accuracy

5) More cost efficient farming

6) Improved farming procedure

7) Saves time

V. PRECISION AGRICULTURE

In agriculture, which dates back thousands of years, the environment is used to generate food. It is regarded as the primary source of employment in the majority of nations. Farmers made irrational farm alterations as a result of ignorance regarding soil types, yields, crops, and weather conditions, inappropriate use of intrants, issues with irrigation, and crop failures. The fact that the shipments were small and there were technical and financial shortages made this possible, though. Now, failing to keep track of this data could very well result in new issues and a rise in manufacturing costs. When the farms were expanded and divided into several hectare-sized sections, this situation needed to be changed. Modern digital technology's opportunities have significantly accelerated agriculture's move toward industrialization. Intensive agriculture is now a significant contributor to the efficiency of agricultural production processes, ushering in a new era of agriculture known as Agriculture 4.0 as a result of mechanization. The GPS, big data, internet of things, cloud computing, and picture feature extraction are examples of this. For instance, we can carry out modular interventions on farms depending on geographic locations. It is feasible to identify the crop disease from visual features. The precision agriculture notion, which refers to the right intervention at the right place and at the right time, was born out of this kind of thinking (Zimmerman, 2008; Zwaenepoel & Le Bars, 1997).

In reality, precision farming relies on the management of a parcel that incorporates information and communication technologies. It seeks to adjust farming methods in response to intra-parcel variability (soil texture, slope value, vegetation cover, etc.) in order to effectively manage the agricultural production cycle and maximize the farming interventions. The present issue is to increase agri-food production while maintaining environmental and human health standards as the world's population rises. Therefore, as a comprehensive agricultural system that focuses on information and production, precision agriculture meets the needs of farmers. Its objectives are to maximize production's long-term productivity, efficiency, and profitability while limiting unanticipated negative effects on the environment and animals (Tran & Nguyen, 2007). According to Gandonou (2005), precision agriculture is a group of technological advancements that have helped bring agriculture into the information age and are intended to provide farmers more control over their farming operations. Precision agriculture is essentially an improvement on the traditional decision support system for crop production.

Additionally, precision agriculture faces a number of agronomic, technological, and financial difficulties in addressing agricultural needs. Embedded instruments (such as biomass or chlorophyll sensors), aerial systems (such as satellites or drones), and mapping systems are used to address the technological problem. Enhancing input-yield ratios and choosing crop types that are suited to phytosanitary environments are the agronomic challenges. Limiting soil erosion and leaching losses of nitric nitrogen are related to the environmental problem. In order to promote optimal fertilisation while protecting the environment and human health, this is the goal. The economic side helps to ensure the farm's commercial profitability by lowering production costs, preventing the overuse of inputs, and preserving crop quality and yield.

Data gathered on plots of land, through connected objects, or by satellite technologies provide a wealth of information for precision agriculture. Therefore, there is a critical need to create tools and processes for storing, analyzing, interpreting, visualizing, and sharing the obtained data in order to extract new value from it. These agricultural applications serve as a means of generating knowledge relevant to decision support systems that can assist farmers and public or private decision makers (Wolfert, Ge, Verdouw, & Bogaardt, 2017). Artificial intelligence, machine learning, and deep learning have grown in popularity in scientific study since the industrial revolution and have a wide range of applications, including text mining, picture categorization, disease detection, and natural language processing. Many examples of deep learning's use in crop and soil management are available now (Liakos et al.,

2018). For these reasons, deep learning becomes a relevant answer that extends the traditional agronomic models to better help farmers in their position in the agricultural value chain.

2. Download : Download full-size image

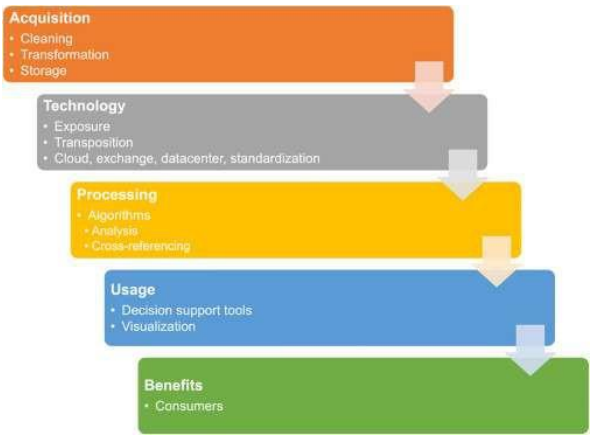

Fig. 1. Agricultural data processing.

Deep learning-enabled digital revolution in agriculture is a brand-new indicator of scientific and technological advancement. By offering a wide range of benefits to handle the frequent changes in external situations, it is beginning to alter farmers' perspectives. The new solutions have enhanced the agronomic and computer technologies already in use to boost output and modernize several aspects of precision agriculture. However, in order for farmers to practise sustainable agriculture, they must get technological support. As a result, deep learning has propelled the change and advancement of agriculture.

Digital agriculture has many advantages. Artificial intelligence and deep learning applications provide numerous chances to support the various stages of agriculture in order to overcome challenges and accomplish objectives (Gupta, 2019; N. Zhu et al., 2018):

1. Processing of agricultural information: It is essential for agricultural production to keep an eye on the health of plants and animals.

2. Models facilitate disease diagnosis, enhancing the potential for healthy crops to produce.

3. Optimal control of agricultural production systems: Agricultural production system control strategies frequently rely on the farmer's experience or professional expertise, which ignores the physiological state of the plants.

4. Crop management techniques have advanced to new heights, making it possible for farmers to manage crops with little effort.

5. Intelligent farm equipment: There are many different tasks involved in agricultural production.

6. Deep learning algorithms to assess agricultural data quickly and accurately.

7. Agricultural output alone is insufficient for agricultural economic system management. Numerous additional elements must be taken into account, such as agricultural product prices and quality. The forecasting of agricultural commodity prices is crucial.

8. AI has fundamentally changed how weather forecasting works, which is important for agriculture.

Deep learning methods have changed the landscape of the agricultural industry. Technology advancements have an impact on many agricultural operations. To manage the dangers brought on by the numerous technical integrations and information interpretation, humans must be the primary driving force behind this shift.

VI. EVALUATION METRICS

To train neural networks for deep learning, a sizable amount of training dataset is needed. They are taken advantage of by networks with intricate architectural designs and large training parameters. Additionally, training neural networks from scratch for hardware resources is an extremely expensive operation (computational speed and storage).

VII. DISTRIBUTION OF PAPER AND SOURCES

We began by studying the development of scientific productions. Fig. 3 displays the quantity of publications and their temporal distribution in relation to the use of deep learning in agriculture. We notice that starting in the year

2018, the number of publications began to rise dramatically

(with 74 publications). More specifically, publications continue to increase. It reached a peak of 495 in 2021 after increasing from 74 in 2018 to 337 in 2020.

1. Download : Download high-res image (230KB)

2. Download : Download full-size image

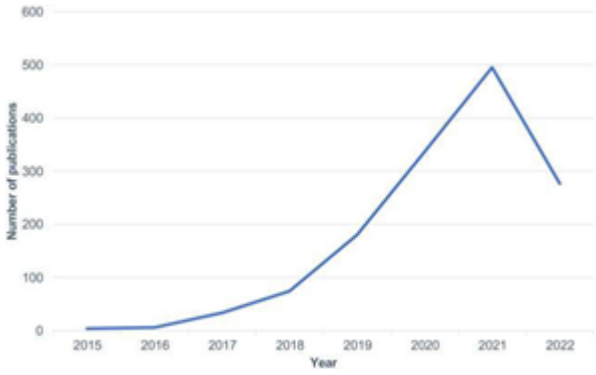

Fig. 3. Annual scientific publications.

First, we looked at the development of scientific productions. Fig. 3 displays the volume and temporal distribution of articles pertaining to the use of deep learning in agriculture. As of the year 2018, we can see that the number of publications has greatly increased (with 74 publications). Particularly, the quantity of publications continues. From 74 in 2018 to 337 in 2020 and 495 in 2021, it increased significantly.

VIII. RESEARCH DISTRIBUTION IN PRECISION AGRICULTURE

The potential of deep learning in agriculture to stop fungal infestations that lower agricultural output is summarized in this section. In other words, it draws attention to various literary works that discuss how to recognize pest insects, weeds, and illnesses in crops.

In agriculture, it takes time and is nearly impossible when farms are vast to recognize and identify issues and their hazards by the usual methods of expert visual inspection or biological analysis. In order to enable a machine to evaluate, process, and comprehend one or more images obtained from a data gathering system, neural networks use computer vision. Computer vision makes it easier to automaticallycount, locate, or recognize things, which greatly enhances the effectiveness of agricultural activities.

IX. FUTURE OF DEEP LEARNING IN AGRICULTURE

Due to modern technologies, agriculture has dramatically changed during the past few decades. Farmers benefit from improved operational efficiency

and profitability as a result of the new methods. Both the scientific and agribusiness sectors have become interested in the computational capacity of machines, the use of computer vision in IoT, and deep neural networks. We examined various works' experiments, network structures, or outputs to learn about their limits. While some research lack information regarding the experimental design, others are based on extremely few datasets (hardware, time, memory). The analysis's findings do, however, have certain drawbacks with regard to the usage of several classifiers and the display of the aspects that affect prediction.

First, statistical tests must be run to determine the significance of the obtained results if many classifiers are used in the experiments (Benavoli, Corani, Demar, & Zaffalon, 2017; Demar, 2006). Demar et al. investigated the safety, robustness, and applicability of various statistical non- parametric tests in machine learning to identify substantial variations in classification performance. The tests that have been suggested are the Friedman test with post hoc testing for the comparison of many classifiers on numerous datasets and the Wilcoxon signed ranks test for comparing two classifiers. For a clearer presentation of the test's results, Critical Difference (CD) graphs might be used.

X. CONCLUSION

The Precision agriculture is a recent science that is certainly still in its young phase. Deep learning can make a decisive contribution to the analysis of agricultural data, in this case by using computer vision to enable a machine to automatically analyze and understand the visual world. This offers the opportunity to develop intelligent systems, which appear to be one of the many possible ways to tackle the economic, environmental, and social challenges in agriculture.

Land Cover Detection Using Deep Learning

Suyash Verma, Ayush Yadav, Omesh Zutshi

1032200419@tcetmumbai.in, ayushyadav@gmail.com, 1032201233@tcetmumbai.in

Abstract—**Land cover and its change are crucial for many environmental applications. This study focuses on the land cover classification and change detection with multitemporal and multispectral Sentinel-2 satellite data. To address the challenging land cover change detection task, we rely on two different deep learning architectures and selected pre-processing steps. For example, we define an excluded class and deal with temporal water shoreline changes in the pre-processing. We employ a fully convolutional neural network (FCN), and we combine the FCN with long short-term memory (LSTM) networks. The FCN can only handle monotemporal input data, while the FCN combined with LSTM can use sequential information (multitemporal). Besides, we provided fixed and variable sequences as training sequences for the combined FCN and LSTM approach. The former refers to using six defined satellite images, while the latter consists of image sequences from anextended training pool of ten images. Further, we propose measures for the robustness concerning the selection of Sentinel-2 image data as evaluation metrics. We can distinguish between actual land cover changes and misclassifications of the deep learning approaches with these metrics. According to the provided metrics, both multitemporal LSTM approaches outperform the monotemporal FCN approach, about 3 to 5 percentage points (p.p.). The LSTM approach trained on the variable sequences detects 3 p.p. more land cover changes than the LSTM approach trained on the fixed sequences. Besides, applying our selected pre-processing improves the water classification and avoids reducing the dataset effectively by 17.6%. The presented LSTM approaches can be modified to provide applicability for a variable number of image sequences since we published the code of the deep learning models. The Sentinel-2 data and the ground truth are also freely available**.

Keywords—machine learning; multi-class classification; long short-term memory network (LSTM);fully convolutional neural network (FCN); multitemporal; time series; Sentinel-2

I. INTRODUCTION

Information about land cover and its changes are essential, for example, in natural resource management, urban planning, and natural hazard assessment and mitigation. Land cover classification and change detection are two crucial tasks in remote sensing, which have been addressed widely in the last few decades [1–3]. The two main reasons for this focus are the increasing availability of remote sensing data and the possibility of largescale automatic land cover detection due to growing computing power and innovative machine learning (ML) approaches [4,5]. Additionally, modern multispectral satellites, such as the Sentinel-2 mission, provide data with high spatial and temporal resolutions [4]. The task of detecting land cover changes based on ML approaches with multispectral remote sensing data includes several challenges [6]. In the following, we briefly describe six of the main challenges. (1) The quality of the necessary land cover ground truth (GT) varies widely depending on the study region, the data source, available information about its creation, the spatial resolution, and the consistency of the class definitions [7].(2) Besides the GT quality, the occurring classes vary from region to region. Therefore, individual case studies need to be conducted in the unknown region, enabling the MLapproach to adapt to the local land cover characteristics. (3) Certain land cover classes differ mostly semantically. These semantic differences, for example, occur for urban classes, which include combinations of buildings with different purposes. (4) Concerning the temporal and spatial resolution of the satellite data, this resolution can be too coarse for some land cover classes. For example, the extent of buildings can be smaller than the size of one satellite pixel, which complicates the classification task of this specific class.(5) Another challenging task arises, for example, in the context of inland waters. During a year, the water levels can change, which results in a non-constant shoreline. (6) Our last considered challenge is about the validation of the land cover change detection. The distinction between land cover changes and possible misclassification requires appropriate measures to be defined and adapted concerning the specific study region [3,8]. In this study, we address these six challenges in the development and application of ML approaches on multispectral Sentinel-2 data. Our overall objective is to provide a methodological workflow, including deep learning approaches, that yields a robust land cover change detection addressing the six main challenges. Sentinel-2, as part of the Copernicus program, provides freely available multispectral data with adequate spectral and temporal resolutions for land cover change detection. The primary contributions linked to the study's overall objective, as well as the novelties, can be summarized as follows:

Novel Dataset: The majority of studies in remote sensing focuses on only a few available land cover datasets [9]. We present the first land cover change detection study based on a land cover dataset from the federal state of Saxony, Germany [10]. The dataset is characterized by a fine spatial resolution of 3 m to 15 m, a relatively recent creation date, and a representative status in its study region. Therefore, this dataset is highly valuable. Innovative Deep Learning Models: While there are successful artificial neural network approaches commonly applied in ML research, these approaches are often not popular in the field of remote sensing [11,12]. We modify and apply fully convolutional neural network (FCN) and long short-term memory (LSTM) network architectures for the particular case of land cover change detection from multitemporal satellite image data. The architectures are successfully applied in other fields of research, and we adapt the findings from these fields for our purpose.Innovative Pre-Processing: In remote sensing, there is a need for task-specific preprocessing approaches [5,13–15]. We present pre-processing

methods to reduce the effect of imbalanced class distributions and varying water levels in inland waters to

apply convolutional layers. Further, we discuss the quality and applicability of the applied pre-processing methods for the presented and future studies. Comprehensive Change Detection Discussion: No standard evaluation of ML approaches with sequential satellite image input data and a monotemporal GT exists. We present a comprehensive discussion of various statistical methods to evaluate the classification quality and the detected land cover changes. Reproducibility: The presented ML models are freely available in Python on GitHub [16]. The Sentinel-2 data and the ground truth are also freely

available [4,10]. In the following, Section 2, we commence by briefly presenting the related work in the context of land cover classification and land cover change detection. Subsequently, we introduce the used land cover dataset and satellite data in Section 3.1. In Section 3.2, the ML methodology is described before we present the results of our study in Section 4. The achieved results are discussed in detail in Section 5. Finally, we provide concluding remarks and an outlook for possible future studies in Section 6. 2. Related Work The classification of land cover based on multispectral remote sensing data is, in current research, mostly based on supervised ML approaches. If remote sensing images are classified pixel-by-pixel, it can be referred to as image segmentation. The ML approaches can be categorized according to their input data: pixel-based approaches, spatial approaches, individually based on the corresponding spectral data. Typical examples for pixel-based ML models in the classification of land cover from multispectral data are Random Forest [17,18], support vector machines [19], and self-organizing maps [6,9]. The main disadvantage of pixel-based approaches is that they ignore spatial patterns, including information about the underlying classification task. This disadvantage is relevant in land cover classification since land cover classes, such as farmland or water bodies, often cover coherent areas that are larger than one pixel. These correlations between neighboring pixels can not be used directly with pixel-based ML approaches. Spatial classification approaches not only use one pixel for the classification but also use the two-dimensional (2D) spatial neighborhood. A popular spatial approach is based on 2D convolutional neural networks (CNNs) [20,21]. These CNNs consist of filter layers that can learn hierarchically: low-level features are learned in the first layers, more high-level features in the last layers. Most CNN approaches can only be applied monotemporally, meaning on one satellite image. Monotemporal land cover classification is difficult for classes, such as farmland and some forest classes, since their spectral properties change significantly over one year. Sequence classification approaches are alternative approaches that are able to learn from a sequence of images. Deep learning examples for sequence approaches are recurrent neural networks (RNN), LSTM networks, and 3D CNN. The RNN and LSTM approaches are often combined with other approaches, such as 2D CNNs. The combination of CNNs and RNNs in the classification of land cover outperformed the studied pixel-based approaches in severall studies [22–24]. Qiu et al. [25,26] combine a residual convolutional neural network (ResNet) and an RNN for urban land cover classification. LSTM approaches, an extension of RNNs, are also applied in land cover classification [12,27], crop type classification [11,28], and crop area estimation [29]. Rußwurm and Körner [11] rely on an LSTM network with Sentinel-2 data and a GT, including a large number of crop classes. The proposed LSTM classifies some crop types inconsistently over two growing seasons. Besides, the study's results imply that the LSTM approach can handle input data with cloud cover, and, therefore, no atmospheric corrections need to be applied. The LSTM application of van Duynhoven and Dragi´cevi´c [27] demonstrates good classification performance even with few available satellite images. The LSTM approach of Ren et al. [28] achieves about 90% overall accuracy in a seed maize identification with Sentinel-2 and GaoFen-1 data. The LSTM network outperforms approaches, such as Random Forest. Hua et al. [30] and You et al. [31] combine LSTM networks with 2D CNN and deep Gaussian processes. Besides, 2D CNNs can be extended from their 2D spatial convolution to 3D CNNs with an additional spectral axis for the convolution [32,33]. Another architecture for detecting changes in images are Siamese neural networks, which are applied on optical and radar data by Liu et al. [34], Daudt et al. [35]. Recent approaches, such as self-attention, are becoming more and more relevant in the field of multispectral remote sensing [30,36]. The detection of land cover changes can be divided into spectral-based approaches and post-classification approaches. Spectral-based approaches analyze the difference between the spectra from two or more multispectral satellite images to detect changes [1,2,37,38]. In contrast, post-classification approaches classify satellite images separately and compare the classification results afterward to detect changes [3,8]. The presented study relies on a post-classification approach to detect land cover changes. 3. Materials and Methods In this section, we introduce the applied dataset and methods. We describe the dataset in Section 3.1 and the ML approaches for the land cover classification and change detection in Section 3.2. In Section 3.3, the evaluation methodology

1. Dataset For the presented land cover study, we use a land cover dataset consisting of GT and Sentinel-2 input data. We introduce the GT in Section 3.1.1, describe the Sentinel-2 data in Section 3.1.2, and explain our pre-processing in Section 3.1.3. 3.1.1. Land Cover Ground Truth As GT, we rely on land cover vector data from the region around Klingenberg in the federal state of Saxony, Germany [10]. Klingenberg is located in the district Saxon Switzerland-Eastern Ore Mountains in about 500 m above sea level and is a rural area in a low mountain range. This GT data covers an area of 234 km2 with a spatial resolution of 3 m to 15 m. Figure 1 illustrates the GT aggregated in 2016 [10]. The GT consists of two separated parts. We have manually selected these parts to obtain one area of interest (AOI), including various features, for example, dams. The land cover data consists of 14 land cover classes. In the following, only the seven classes with the largest class areas are considered: Forest/Wood, Farmland, Grassland, Settlement Area, Water Body, Buildings, and Industry/Commerce. The

class Settlement Area contains the areas inside a settlement, which are neither buildings nor industrial or commercial areas. The smallest seven classes are summed up as Excluded, including railway systems and tracks, gardening, allotment gardens, sports and leisure facilities, roads and traffic areas, wasteland, and areas without available cover or use. We present an overview of all considered classes and their spatial coverages in Table

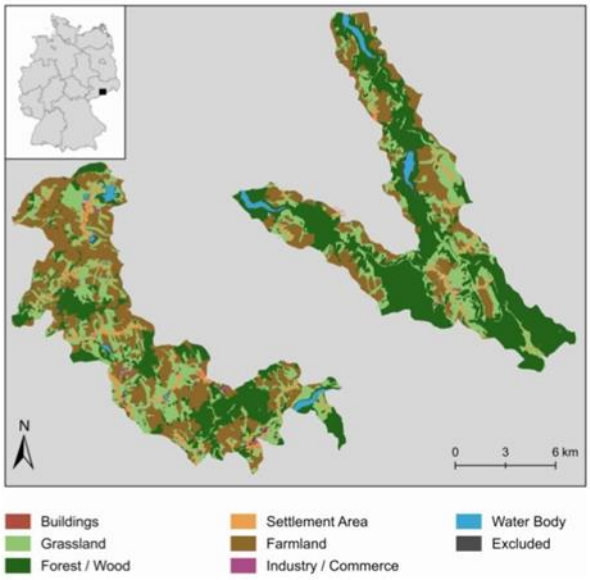

Figure 1. Visualization of the area of interest in Klingenberg, Saxony, Germany, and the land cover ground truth (GT)data

II. CONCLUSION

Land cover change detection is highly relevant for many applications and research areas, such as natural resource management. To address land cover change detection, we use multispectral Sentinel-2 data of 2016 and 2018 combined with a novel land cover GT. We rely on deep learning methods based on FCN and LSTM networks. These deep learning models are referred to as FCNB, LSTMF, and LSTMV. As pre-processing, we apply shoreline masking and the exclusion of small classes. The shoreline masking significantly improves the training and prediction of the ML approaches. Excluding the smallest classes prevents the dataset from a pixel reduction of 17.6% and makes the training much more meaningful. First, we train and classify satellite data of 2016. The overall best deep learning approach in the 2016 classification is the LSTMF, with an OA of 87.0%. Adding sequential information in the 2016 classification increases the performance by about 3 p.p. to 5 p.p. As expected, the classes Grassland, Forest/Wood, and Farmland benefit the most from adding sequential information, which show a significant variation over a year. Second, we classify satellite data from 2018 for the land cover change detection. Overall, our confidence measures consisting of a vote from classifications based on six different satellite image sequences are adequate. The most significant differences exist in Grassland and Settlement Area and the small classes Buildings and Industry/Commerce. We discover large coherent areas with land cover change near Farmland and Forest/Wood regions. As expected, confusion between urban classes occurs, which can mostly be explained by minor semantic differences. Grassland is confused with Farmland. In our presented LSTM approach, we build sequences from a fixed number of six satellite images. This choice increases the comparability of results. As the availability of Sentinel-2 satellite images per year has increased since 2018, future studies can modify our LSTM approaches to work with a variable number of images in a sequence. This modification would add more flexibility to the land cover change detection. Furthermore, future studies can focus on evaluating the GT quality, as described by Riese [6]. This evaluation can include comparisons with other imagery and OSM data. Besides, a possible exclusion of pixels along class borders can be evaluated (see Section 5.3). Finally, in a future study, the Excluded class can be further adapted and analyzed for the exploration of novel or unknown classes.

III. ACKNOWLEDGMENT

I would to like to thank Anil sir ,Vijay Sir, Aditya sir for guiding us throughout the research.they really support us in this research

Abstract- **Every aspect of our information is moved between smart devices in the digital world we live in thanks to cross-platform, external cloud services. To successfully execute our daily duties and official tasks that require access to all forms of essential data, smart technologies like smartphones are playing pivotal roles. Before the development of these smart technologies, protecting sensitive data posed several difficulties. Information security, however, has evolved into one of the most essential tasks for security experts since the introduction and widespread usage of such technology. Social media integration has increased the difficulty of completing this work successfully. There is various research that has been published to date suggests and creates a variety of authentication and security solutions for smartphone and cloud computing technologies. Multiple authentication threats and other associated problems in current smartphone and cloud computing technologies have been successfully handled by these studies. To the best of our knowledge, however, these studies are deficient in several areas, including logical authentication analysis, authentication implementation scenarios, and authentication assaults. These authentication ambiguities and inconsistencies prevent such studies from being fully taken into account for successful implementation. To explain current authentication dangers and issues in the literature, we undertook a thorough security analysis and assessment of several authentication frameworks and protocols for smartphones and cloud computing in this study. To show where the study is currently going, these authentication difficulties are further summarised and displayed in the form of several graphs. Finally, based on those findings, we highlight the most recent and current authentication uncertainties, dangers, and other relevant issues to address future directions and open research questions in the field of authentication for smartphones and cloud computing.**

Keyword: Handwriting popularity, Mobile Cloud Computing, Parallel classifier mixture.

I. INTRODUCTION

A digital environment where cross-platform, external cloud services are used to transport every informational detail from one smart device to another. Smart technologies, including smartphones, are playing vital roles in completing daily tasks and official assignments that call for access to many crucial data kinds. There are several research that suggests and develop various authentication and security techniques for Smartphone and cloud computing technologies. Multiple authentication threats and other applicable problems with contemporary smartphone and cloud computing technology have been efficiently solved by using those investigations [1]. The CCS dynamically arranges servers and VMs to function with several services, with each provider being broken down into several duties that might be done on VMs simultaneously. Although parallel execution and dynamic organization permit the CCS to deliver services efficiently, they also pose a severe threat to CCS security. As a result of the CCS being virtualized, VM security has emerged as a new security component that was absent from the conventional system. Similar elements of VM security include the isolation of distinct VMs and the simultaneous failure of co-located VMs because of an assault on the host server [2]. Cloud computing and Software-Defined Networks (SDN) have attracted a lot of interest from both academics and businesses. The network control plane and data plane are separated by SDN. A control program may quickly identify the real-time network status and configure high-level state approaches. The advancement of network functions is streamlined by the controller's centralization [3]. The core data plane in SDN can be effectively controlled through network programmability. The essential framework of SDN architecture is focused on applications and network services while network control is decoupled from forwarding capabilities and made programmable. SDN has made significant contributions to the networking paradigm for cloud computing [4]. Threats to data security are frequently used to describe data security. Because it is vulnerable to several dangers, the site of cloud computing is not exceptional. The main cause used for that cloud computation operates by fusing a variety of unique technologies. It is crucial to employ the threat control procedure to stabilize the advantages of safety risks and cloud computing. Reporting, designing, and implementing the management of patron security and internal security controls is the responsibility of the CSP [5]

II. BACKGROUND

To show where the study is currently going, these authentication difficulties are further summarised and displayed in the form of several graphs. Finally, using those findings as a basis, the author highlights the most recent and current authentication uncertainties, dangers, and other relevant concerns to address outstanding research questions and future directions in authentication for smartphones and cloud computing [1]. This study suggests a correlation metric for measuring the effectiveness of random services. This correlation statistic is more accurate and realistic since it fully

accounts for the impact of security considerations. The experimental findings illustrate the significant S-P correlation and the dynamic change in performance brought on by security considerations. Security must therefore be included while modelling and evaluating the QoS metric [2].

This paper proposes a novel methodology for trust assessment of cloud service security and reputation. The security of a cloud service is assessed using the security metrics that are specific to clouds using the security-based trust evaluation approach. Additionally, the reputation-based trust evaluation method uses feedback ratings on cloud service quality to analyse a cloud service's reputation. The proposed trust assessment methodology may more effectively and efficiently evaluate the trustworthiness of a cloud service than current trust assessment approaches, according to tests utilizing a real-world author service dataset and a synthesized dataset of security measures [3]. A thorough investigation of DDoS assaults in SDN and cloud computing settings was done by the author of this research. The author considers DDOS attacks in the context of SDN and cloud computing as far as their characteristics go, and they are examined in terms of new patterns and characteristics in distributed computing and SDN. The author then provides a thorough analysis of the defences against these attacks [4]. In this paper, the author provides a verification method that is mostly based on the concepts of BFT and blockchain technology to overcome those current issues. These CSPs are no longer required to work together or exchange information. These grab hash values can be examined by a customer to determine whether data manipulation has occurred [5].

III. PREVIOUS WORK DONE

To identify current authentication dangers and issues in the literature, the suggested technique undertook an extensive security analysis and assessment of major Smartphone and cloud computing authentication frameworks and protocols. To show where the study is currently going, these authentication difficulties are further summarised and displayed in the form of several graphs. Finally, using those findings as a basis, the author highlights the most recent and current authentication uncertainties, dangers, and other relevant concerns to address outstanding research questions and future directions in authentication for smartphones and cloud computing [1]. This study suggests a correlation metric for measuring the effectiveness of random services. This correlation statistic is more accurate and realistic since it fully accounts for the impact of security considerations. The experimental findings illustrate the significant S-P correlation and the dynamic change in performance brought on by security considerations. Security must therefore be included while modelling and evaluating the QoS metric [2]. In this paper, the author triumphs over those existing troubles by providing a verification scheme primarily based on the notions of BFT and blockchain technology. More than one CSP will be hired to save and perform computations on client information. Each CSP will need to periodically compute a grasp hash fee in their database to be stored on a public blockchain consisting of Bitcoin or Ethereum. These CSPs no longer need to collaborate or communicate with one another [5].

IV. EXISTING WORK DONE

Only a broad overview of the security model is given. The absence of any user-defined authentication roles in this framework posed the biggest authentication problem. Furthermore, the framework is dependent on external suppliers for brand-new services, and no external authentication scenarios are covered. Artificial neural networks are used to introduce a mobile biometric cloud framework. The presentation of a sophisticated mobile-based credential protocol [1]. STRAF is a brand-new methodology for evaluating trust in cloud services that is based on reputation and security. This framework, which is an expansion of the earlier work, may be broken down into three primary parts that collectively comprise [3].

Fundamentally, Mininet has been at the forefront of cutting-edge development and testing of novel controller applications. Mininet is used by some scientists as simulation equipment for lab tests. Each connected hub (switch, have, controller) in Mininet continues to function as a light-authority virtual computer. To only access the assets within its namespace, the virtual machine continues to run in its own Linux component namespace. Since it provides excellent authenticity and constant change from development to deployment, analysts have generally embraced it. These existing approaches are enhanced and developed by the simulation-based approach known as fs-Sdn [4].

The multi-CSPs, BC application, and client—whose functions are described below—will make up the three key components of the verification process, which correspond to the three main phases of the proposed verification method [5].

V. ANALYSIS AND DISCUSSION

The introduction of smartphones has eliminated the need for smartcards in several fields. In contemporary Smartphones like the iPhone and Samsung mobiles, Authentication is weak and is easily compromised via several breaches [1]. Results were obtained by way of analysing the primary and second experiments. The following optimization guidelines approximately balancing the safety and the carrier performance now are proposed.1) When the variety of to-be-had res theses (such as the CPU and the range of VMs) is restricted in CCS, and writer-depth safety mechanism may also convey a higher carrier overall performance.2) Deploying more VMs improves the service performance faster than enhancing the CPU processing creator of every VM. Three) To concurrently improve the safety and the service performance, making use of a writer CPU

with an excessive processing creator is better than deploying more VMs [2]. The method outperforms the opposite strategies, whilst the percentage of malicious remarks rating increases. As predicted, the above experimental consequences suggest that the STRAF combining the security-primarily based accept as true with evaluation technique and the reputation-primarily based believe evaluation technique is indeed beneficial in improving the considered assessment of cloud services [3]. Traditional networking devices determine the way to deal with an incoming packet primarily based on its IP destination deal, however, SDN pursues a float-based forwarding approach in which many header fields decide a way to take care of the approaching package. The idea of a centralized network manipulation plane is followed via SDN, and programmability is introduced. This can simplify community control and give the chance to organize protection methods at runtime. In this technique, SDN may respond quickly to malicious traffic and community irregularities [4]. The master hash for each CSP's database must be produced, and it is then kept on the BC. Clients will receive the block header for use in verification. The malicious CSP will be identified when the client checks the master hash values of each CSP since its hash value will be different from the others. As a result, customer data is not altered or destroyed without authorization or detection [5].

VI. PROPOSED METHOD

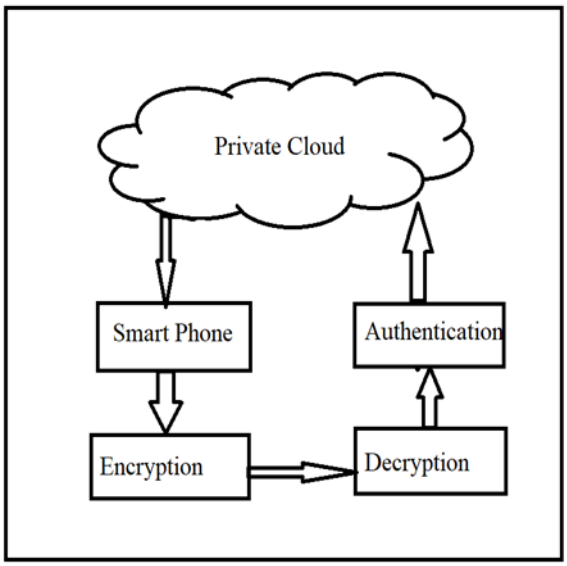

Figure 1: Proposed Method

A handwriting authentication system confirms the user's identification based on his biometric features to ensure secure access to cloud services. An application that serves as a conduit between the cloud and the mobile user is created on the client side. It is used to gather and encrypt biometric information (such as a handwritten password) in preparation for sending it to the cloud. The touch screen of the smartphone is used by the mobile user to enter his password. As a result, in addition to using the right password, the person can also be recognized by his distinctive handwriting. It is vital to encrypt the biometric data before it is delivered to the cloud to guarantee data security and privacy when using cloud services.

A. Pre-processing

The new image should be pre-processed before feature extraction because the input image comprises characters of various sizes and spacing.

B. Features Extraction

This module analyses and extracts the characteristics of handwritten characters for use in training and verification. It is a crucial phase since its efficient operation raises the verification rate and lowers misclassification. Handwritten digits can be used to extract two different sorts of information. Binary digit images are used to derive pixel density information. Each digit image is split into nine identically sized windows. Individual zones are the focus of feature extraction rather than the entire image. As a result, it provides greater details regarding the skeleton of the digits. To create the feature vector, the density of black pixels for each zone is calculated. For the remaining digit images, the same procedure is followed.

C. Classifier Process

The feature extractor's feature vectors are used by the classifier process to confirm the user's identification. Two inputs are needed for this verification: a real text test and an optional claimed human identity. After pre-processing and feature extraction on the written data, the system will compare the real feature values to those in the reference database before returning a result set.

VII. RESULT

The overall classification rate and error rate are the most typical metrics for classifier performance. A case's overall classification rate, also known as the recognition rate, is calculated as the proportion of cases that are correctly classified into all cases. A weighted voting rule and decision-making system achieve a higher recognition rate than a majority voting rule. The primary cause is that the majority vote rule provides all classifiers 329 identical weights without taking performance accuracy differences into account. The results of the overall performance evaluation, implementation evaluation, and validation evaluation from the related works, however. Whereas Figure 2 demonstrates the implementation problems that 94% of the authentication techniques have and shows how practically all authentication strategies fall short of adequately validating and verifying their security claims.

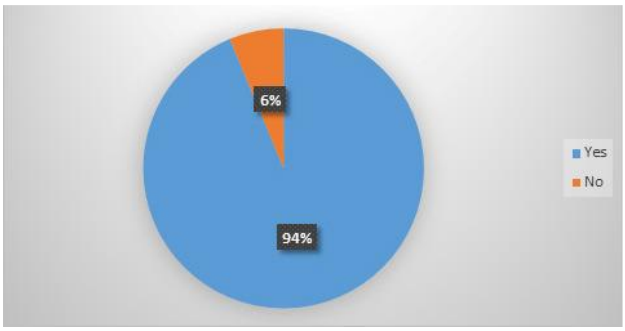

Figure 3: Implementation Analysis

VIII. CONCLUSION

In this contribution, a handwriting authentication device has been introduced. The manner permits comfortable get entry to confined facts in the cloud with the use of a cell telephone. It is composed of pre-processing, characteristic extraction, type, and authentication procedure. The classification procedure is primarily based on 3 one-of-a-kind classification strategies: ANN, KNN, and Euclidean Distance classifier. The classifier set of rules employs a parallel combination of classifiers to obtain first-rate accuracy on both recognition and error charges.

IX. FUTURE SCOPE

The underlined protection uncertainties, assaults, and future directions in existing smartphones and CC authentication frameworks have added a broader view and cognizance of the modern trend within the domain in addition to their practicality for implementation. Finally, this safety evaluation is anticipated to open similar study possibilities as part of future work to deal with the concerns raised in the area of Smartphone and CC authentication frameworks and protocols.

An Approach Towards Securing Information Using Blockchain & Cloud Services

Prachi Kale, Dr. A.B.Gadicha
P.R.Pote Patil College of Engineering and Management , Amravati, India
prachivs03@gmail.com

Abstract— **Within this last few years Cloud computing emerged an evergreen revolution and biggest transformation in the way of accessing & storing the information in IT sectors , Banking , Businesses & Healthcare. It's consumption and management also promisingly improved cost efficiencies, accelerated innovation, faster time-to-market, and the ability to scale applications on demand. When it comes to storing & accessing the data, primary priority is security & above it how to provide it to such a biggest platform becomes the matter of concern. With this rapidly developing platform both and, conceptually the legal/contractual, economic, service quality, interoperability, privacy issues still pose significant challenges with security. In this paper the main focus is on one of the critical platforms where there is a need of Cloud computing along with blockchain is Healthcare There were many revolutions done based on the data available in healthcare & discussing one of the such model which is going to propose to increase the security with the use Blockchain.**

Keywords—Cloud Services, security ,Data Privacy

I. INTRODUCTION

A . BLOCKCHAIN & HEALTHCARE

Due to pandemic the Healthcare system is overburdened & become one of the complex field to understand the root cause of the disease. Although this health sector is made up of lot of physicians from over more than hundreds of medical specialities and sub-specialities including other practitioners, researchers and patients who face several challenges related to increased fragmentation of patient data. Also there were revolutionary changes in every field & people are focusing more on remote & digitised way of working & accessing the information. Healthcare is also not an exception to this, where the cloud-based electronic health records (EHRs) have gained significant attention to enable remote patient monitoring. Going towards the recent development of Healthcare 4.0 using the components of Internet of Things (IoT) along with cloud computing to access medical operations remotely has gained the researcher's attention from a smart city perspective. This will mainly focus on the Data collection , Data Storing , aggregation, Data transmission, Data processing , Data sharing. Running behind this rapid growth of the data biggest & the most critical challenge is to provide security & privacy to the sensitive information like personal & the medical history of the individual (patient) from the Hackers [1] .To accomplish the bridge for providing security for storage, sharing, and accessing in cloud service provider, several cryptographic algorithms were designed till date. But implementing these algorithms without the help of some parameter is barely impossible. So with the algorithm along with some trusted third party which will give computational efficiency, service side verification, user side verifications with strong security is Blockchain. For data storage, Blockchain is a decentralized node network. It is an excellent technology for protecting confidential data within the system. For exchanging the critical data, this technology is very useful and it also keeps the data secure and confidential.[11] Blockchain technology helps to perform all the sensitive task that need to be performed for the Healthcare such as to preserve and exchange patient data through hospitals, diagnostic laboratories, pharmacy firms, and physicians. Blockchain applications can accurately identify severe mistakes and even dangerous ones in the medical field. For marketers, Blockchain helps to maintain the overview of the products which were used in the medicine because of which the health & pharmaceuticals do not need to perform any counterfeit medications it trace all of these medicines. This helps discover the cause of falsification. Blockchain can guarantee the confidentiality of patient records; when medical history is developed, Blockchain can also store it, and this record cannot be modified.[2]. For Blockchain there wont be any central authority who can control the content added to the blockchain, which is one of the key attribute i.e decentralization. The various protocols with peer to peer network passed the entries on to the blockchain. The another key attribute is persistence. It is practically impossible to delete the entries after being accepted on the blockchain because of its distributed ledger. Blockchains make audit and traceability possible by linking a new block to the previous by including the hash of the latter, and in this way forming a chain of blocks. The transactions in the blocks are formed in a Merkle tree where each leaf value (transaction) can be verified to the known root. This enables the tree structure to verify the integrity of the data by only storing the root of the tree on the[10]. All the attributes of Blockchain helped in Healthcare for maintaining all the critical information. There is a classification of Blockchain networks based on its type, how network members reach consensus and validate transactions or what platforms they run on [23]. For type a blockchain network can be public, private or consortium. A public blockchain is an open blockchain

like Bitcoin [10] or Ethereum [19] that allows anyone to join, and the rules for participating including accompanying source code are public. A consortium blockchain on the other hand runs like a public blockchain but is only accessible to a closed group of approved network members [11]. On the contrary, a private blockchain has centralised ownership and management. Similarly, for other classification which is based on how network members reach consensus on which transaction to validate and add to the blockchain. There were many different consensus algorithms, but they all fall under two broad categories: proof-based or vote-based . Proof-of- Work, Proof-of-Stake, Proof-of-Authority, Proof of- Activity and variants of these are all proof-based

II. RELATED WORK

A. Basic

For Healthcare, the data should be kept in such a way that it will be stored in a mass manner & should be secured from the Hackers .At the same time that data should be accessed at any time & also it can be shared in a remote basis. Blockchain is a perfect combination which will provide all the above with its attributes. As a distributed-ledger-technology (DLT) which is a shared-ledger with a growing ordered list of records stored and persisted in a `giant computer database. This database is formed from several inter-connected devices (phones, computers or embedded systems) not restricted by geography [12]. It does not require network participants to trust one another because it has cryptographically enabled inbuilt trust mechanism [13]. Each entry in this ledger is called a block (composed of messages and transactions) linked and time- stamped through cryptographic hashes [14] and validated by network peers.

B. Detailed Literature on Healthcare & frameworks

Hemant Mahajan [1] , in “Integration of Healthcare 4.0 and blockchain into secure cloud-based electronic health records systems” presented the systematic study of modern blockchain- based solutions for securing medical data with or without cloud computing. They implemented & evaluated the different methods using blockchain . They mention the further research scope, the research gaps, challenges, and future roadmap will be the outcomes of emerging Healthcare 4.0 technology.

F. Tang et.al in "An efficient authentication scheme for blockchain-based electronic health records,” Worked on creating a new EHRs paradigm which can help in dealing with the centralized problem of cloud based EHRs and proposed an identity-based signature scheme with multiple authorities which can resist collusion attack out of N from N −1 authorities. Furthermore, our scheme is provably secure in the random oracle model and has more efficient signing and verification algorithms than all the other existing authentication schemes of blockchain-based EHRs [5]

V. Jaiman deployed the model on Ethereum blockchain and evaluate different data sharing scenarios which consists of the creation of an individual consent model for health data sharing platforms. This model guarantees that individual consent is respected and that all the participants in the data sharing platform are accountable.[6]

Waad Y in A Framework for Securing EHR Management in the Era of Internet of Things proposed the platform which secures and enhances the process of accessing and managing EHR in hospitals databases. Specified the future scope for a safer access control, especially if the patient is not healthy enough to provide the OTP, the framework can be enhanced to grant patients’ access to their specific domains in which both sides will have customized access to the domains. [9]

EMEKA CHUKWU in A Systematic Review of Blockchain in Healthcare: Frameworks, Prototypes, and Implementations proposed a review based on the study of various articles , technical & architectual analysis for Blockchain and explained that how it is useful to solve the trust, security and privacy constraints of traditional EHRs often at significant performance, storage and cost trade-offs.[11]

Yang Yang et.al in Conjunctive Keyword Search With Designated Tester and Timing Enabled Proxy Re-Encryption Function for E-Health Clouds introduced a novel cryptographic primitive named as conjunctive keyword search with designated tester and timing enabled proxy reencryption function (Re-dtPECK), which is a kind of a time-dependent SE scheme. It could enable patients to delegate partial access rights to others to operate search functions over their records in a limited time period. The length of the time period for the delegatee to search and decrypt the delegator's encrypted documents can be controlled.

Jian Shen et. al. in Block Design-Based Key Agreement for Group Data Sharing in Cloud Computing presented a novel block design-based key agreement protocol by taking advantage of the symmetric balanced incomplete block design (SBIBD), that supports multiple participants, which can flexibly extend the number of participants in a cloud environment according to the structure of the block design. Based on the proposed group data sharing model, presented general formulas for generating the common conference key IC for multiple participants. [17]

Rui Guo et.al in An attribute-based encryption scheme with multiple authorities on hierarchical personal health record in cloud presented a personal health record hierarch ciphertext- policy attribute-based encryption scheme with multiple authorities which is used to provide security to hierarchy structure of outsourced data.[20]

Ayush in his "A Comparative study on Securing Electronic Health Records (EHR) in Cloud Computing" [23] explained that for Healthcare , there were certain frameworks which were used to maintain the data such as the Personal Health Record (PHR) framework & EHR (Electronic Health Record). PHR will converts a general clinical history of paper into a web- based electronic record. In this framework, a patient could share, oversee and control his PHR with approved clients, for example, family members, companions and wellbeing care [20]. EHR is a source that focuses on capturing clinical history and treatment of patient health information. These important patient-centered records can be successfully accessed by all authorized medical service providers (research institutes, authorities etc.) [21]. The method empowers an individual to collect, store, oversee, and share his state of being information inescapably. But with the advantages of these PHR systems there are so many flaws related to security. To keep this data secure After applying different techniques, the data on the cloud is now much more secure different cryptographic techniques are used to encrypt the data.

ZHEN PANG et.al in Electronic Health Records Sharing Model Based on Blockchain With Checkable State PBFT Consensus Algorithm proposed a patient-controlled EHRs sharing scheme which is based on cloud computing collaborating blockchain technology. In this the medical abstract and the access strategy are stored in the blockchain to avoid being tampered with. To achieve the fine-grained access control, we propose the attribute-based encryption scheme and multi-keyword encryption scheme to encrypt EHRs. Their experimental results show that their proposed sc-PBFT algorithm has better handling capability and lower consensus latency. Compared with the PBFT algorithm in the case of Byzantine nodes, sc-PBFT not only improves the robustness of the consortium blockchain network but also improves the handling capability. This proposed scheme stores data on-chain and offchain, which can ensure the authenticity and integrity of the shared data.[24]

C. Outcomes

There were several algorithms for Blockchain using which the things can be proposed to get the more security , privacy & accessibility than the existing algorithms. there is still additional work to improve the proposed consensus algorithms. Although the existing algorithm is able to capture and isolate the Byzantine nodes, it needs to restart the consortium blockchain network when deleting the consensus nodes in the information center.[24]. There is still scope to optimize the consortium blockchain network by which system can improve the ability to dynamically add or delete the consensus node. For imposing this need to attempt to use the zero-knowledge proof and homomorphic encryption, etc., to encrypt the identity and EHR of the patient. The main challenge is to keep the identification accurate in the digital health space for the health institutions , providers & the uses.Trust is the main concern as a part of security but Blockchain proved that there won't be any trust problem. Based on the way the data to be maintained there were several consensus mechanism which Blockchain follows , it is based on the way the data entries are accepted onto the distributed ledger by a distributed consensus protocol validating the data entries. These are as follows : Proof-of-Work (PoW) is the consensus protocol most strongly associated with blockchain due to its integration in Bitcoin. With Proof of Stake (PoS), the selection of an approving node is determined by the stake each node has in the blockchain. with blockchain due to its integration in Bitcoin. Practical Byzantine Fault Tolerance (PBFT) is based on a Byzantine agreement protocol. In PBFT, all nodes need to be known to the network, which limits the usage of this consensus protocol in a public blockchain.

III. GENERAL SOURCES FOR DATA COLLECTION IN CLOUD APART FROM HEALTHCARE

According to Secure Overlay Cloud Storage[5] with Access Control and Assured Deletion implement FADE , a secure overlay cloud storage system that achieves fine-grained, policy-based access control and file assured deletion. It associates outsourced files with file access policies, and assuredly deletes files to make them unrecoverable to anyone upon revocations of file access policies. To achieve such security goals, FADE is built upon a set of cryptographic key operations that are self-maintained by a quorum of key managers that are independent of third-party clouds. Current research on cloud security is still in the early stages, and no universal model or set of techniques has yet emerged. Methods include segregating user resources during data processing to prevent widespread virus in fiction, the use of a third-party auditor to verify the integrity of data stored in the cloud[8][9] and access control based on data attributes and semantics[6][7] Some trust management experts recommend applying multiple security policies to authenticate users, manage identities, and protect data from unauthorized users. Amazon administrators, for example, log and routinely audit any access to customers' data or operating systems.[7]Each of these research efforts aims to develop a security solution for a specific threat, yet such methods are incompatible with cloud services, which sometimes have vastly different security requirements. Some services involve public information that needs only basic security. Many researchers have investigated cloud computing security. In the ticketing system and tracking of the status of the reserved ticketing, but it creates a number of Problems related to this newly implemented system, this paper is regarding the solutions of the Problems related in consumption of time during the Ticketing Process in Indian Railways and the mode of payment other than the specified by the Indian Railways while taking ticket from their Ticketing.The data from Gmail blog , this is a official site that provide the

information about the Gmail services . As we all know that the facilities provide by the Gmail these are Gmail account , Gmail apps is a Google Apps is a suite of communication and collaboration tools, including Gmail, Google Calendar, and Google Docs. For the security the Gmail is provide the custom signature services in this services Email signatures are automatically inserted at the bottom of every message you send, and can be a great place to add your title, contact information, and even the latest news from your company. Just go to Settings at the top of your inbox and enter your signature text in the box at the bottom. Another facilities is provide by the Gmail is manage the multiple account If you're like a lot of business owners, you probably regularly receive email in several different accounts. By centralizing your correspondence in Gmail, you'll be able to keep track of it all more easily. Embrace labels. Folders are familiar, especially when it comes to work email. If you want to organize your emails in a similar way, make sure you're using Gmail labels. Combined with filters, they can be a powerful tool to manage your mail. Create labels for projects, vendors, customers, weekly reports, launches, to-do's -- the list goes on. You can also add custom colors to your labels, order them based on priority, and search the contents of specific labels. And don't forget that you can drag messages into labels, just like you can with folders. Use offline Gmail anytime you're not online. Despite having Internet access almost everywhere, work may take you to places where you just can't get online. Turn on offline Gmail from the Offline tab under Settings, and Gmail will download a local cache of your mail which synchronizes with Gmail's servers while you're connected. When you lose connectivity, Gmail automatically switches to offline mode, so you can continue to work, and your replies are automatically sent the next time Gmail detects a connection. Create canned responses and quickly reply to common questions. When it comes to emailing at work, you're probably used to sending out weekly reports, or answering the same questions from customers or colleagues multiple times. That's where canned responses can save precious time: turn on this feature in Gmail Labs, compose your response once, save it, then use it over and over again.

IV. CONCLUSION

Getting the data anytime anywhere is only became possible due to various cloud services available. To access this data remotely without getting hacked is a biggest challenge. These are various domains like IT , Banking ,Businesses & Healthcare which have the huge amount of data generated everyday. But this paper focuses on the Healthcare along with the few general sources to get the data.Healthcare is a very sensitive domain to work with the information Keeping that information safe is the biggest challenge & Blockchain along with various cloud services will be able to main it to some extent .As the data is growing with the fastest rate there should be a provision to dynamically add or delete consensus nodes in the information centre. So to achieve this the different algorithms can be used to get the data encrypted for the identity & Electronic health record of the patient.

Smart Waste Detection Using Different Sensors

Jeetendra Choudhary, Amit Jha
Thakur college of Engineering & Technology, Mumbai, Maharashtra, India
Choudharyjitendra236@gmail.com, amitj6723@gmail.com

Abstract: **This waste management is one of the serious challenges facing cities, and the systems currently in use in cities continue to use old and outdated paradigms that no longer serve local governments. Overflowing trash cans are still found, and emit a pungent odor, causing serious health problems and air pollution. Sensor Based Smart waste management system is used to identify the status of waste and bins and detect the percentage of waste using ultrasonic sensors and it will also be able to segregate the waste into categories of Hazardous and Non-Hazardous waste using Gas sensors and Proximity sensors. The Smart Waste Management System uses a web application and a mobile phone to simplify the solid waste and water waste inspection process, as well as the management system throughout the collection process of this presentation. The proposed system is based on GPS. The proposed device and implementation track Garbage Depot and monitors vehicle garbage trucks.**

Keywords: Smart waste management, sensors, GPS-based, E-waste

I. INTRODUCTION

Garbage endangers the environment and human health. Trash that accumulates in sewers can cause flooding, while its toxic emissions can pollute groundwater and air. Garbage produces gases such as hydrogen sulfide (H2S), methane (CH4), and ammonia (NH3), causing breathing problems such as shortness of breath, chest tightness, morning sputum, morning cough, and chronic cough. May cause organ disease. Toxic gases can also cause other health problems as they are taken from the lungs to other parts of the body.

Today's waste management system involves a large number of employees dedicated to a specific number of bins. This is done regularly every day. Such management can make the whole system inefficient, creating a situation where some bins are overflowing with bins and many other bins are left unfilled. This is caused by fluctuations in city population density and other random factors that make it impossible to identify trash bins that need immediate attention.

The introduction of sensor-based bins is a highly effective system for controlling waste management in cities. An ultrasonic sensor is embedded in the top of the trash can, and the ultrasonic sensor is used to measure the distance. This allows you to measure the amount of trash in your trash can.

Alert is sent to the appropriate personnel when a certain number of bins fills past the threshold. Proposed an efficient garbage collection system in smart city, using smart bins and Android apps for garbage monitoring to manage the whole system, optimal optimization based on multiple parameters for truck drivers Smart Garbage Collection, and Creation GUI that other users can use. The smart trash can uses the node MCU and ultrasonic sensor to monitor the trash level in the trash can and upload the data to the server in real time. Using the shortest path algorithm, the Driver finds the optimized path/route used to empty the bin given the level of waste in the bin.

II. BACKGROUND

Waste disposal systems are facing many problems as population growth has significantly degraded sanitary and sanitary conditions in the region. All trash and spilled trash not only affect this particular area but also spread to surrounding areas. malaria, dengue fever, cholera, diarrhea, etc. in all his neighborhoods can lead to a number of serious diseases. The existing garbage collection system is inefficient due to factors such as delayed garbage collection, excess garbage spilled from the trash, inefficient garbage collection and disposal, lack of budget, and lack of resources. Removing or reducing litter and maintaining cleanliness requires a smart litter collection system. The system proposes intelligent garbage collection with a smart trash can and shortest path algorithm. This system uses sensors to check the level of trash in bins. The garbage truck driver is then notified that the garbage can is full and the route that the garbage truck needs to travel.

III. WORKING OF THE SYSTEM

This proposed system monitors trash bins in real time. The ultrasonic sensor detects the amount of trash in the system, the gas sensor detects if there is combustible material in the trash, the proximity sensor detects all metals and non-metals in the trash, this data is will be Uploaded to the Firebase cloud using a Node MCU with an integrated Wi-Fi module. Trash becomes the active node when the threshold is reached. A network is formed when a certain number of bins become active nodes. The system then applies route optimization to provide drivers with optimized routes and garbage collection. This reduces overall time, fuel and costs

IV. IMPLEMENTATION

1. Smart Bins - Bins are connected to multiple sensors and can report bin status to the garbage collector. On the admin side, bin data is collected from the cloud database and the cloud. - Database is available.

2. GPRS Vehicle Tracking - Garbage trucks can be tracked using GPS modules and RFID tags. When the vehicle reaches the location with the designated trash can, it reads the transmitted vehicle and trash RFID tags.and will give the current status to cloud Also, from the cloud, data is pushed to the user's app and the admin's dashboard.

3. Android App - The Android App acts as a bridge between the user and the municipality's cooperation partners. It may offer features such as:

B. The daily activity of a clean society, chasing garbage trucks. Users can also interact with members of the community and express their opinions on topics.

It consists of a sensor device that periodically sends readings from a sensor to a web server through a mobile router. Data received by the web server is stored in the database. Users can then view the data using a laptop or mobile device . Our sensor consists of three gas sensors. H. MQ-136 detects the presence of hydrogen sulfide (H2S), MQ-137 detects the presence of ammonia (NH3) and TGS-2611 detects methane (CH4). These sensors are wired to the Arduino Uno. Sensor readings are sent wirelessly to a web server using the WiFi module of the NodeMCU ESP8266 connected to the Arduino Uno via serial connection. Both the Arduino Uno and NodeMCU are battery powered.

V. CONCLUSION

The proposedsystem has an intelligent trashcan that constantly monitors the level of trash and sends it along with the type of trash to a cloud server, where each trash can is uniquely identified. The main component used in these smart bins is the Node MCU. This is not only readily available and cheap, it facilitates us with a built-in Wi-Fi module. It uses ultrasonic sensors to calculate thelevel of wastein the bin, and gas and proximity sensors to detect hazardous waste types and transmit them through the node MCU. Uses cloud technology to store real-timemonitored trash data. Android Application provides an optimized garbage collection route to the driver. Additionally, the fill level of the trash can is monitored n real- time. On submission, this trash only eds to be emptied whenthe trash level in the trashreaches the threshold and becomes the active node A network is formed when a certain number of nodes are active. The Web Application is responsible for overall control of the system and presents the Graphical User Interface (GUI) to the drivers.. Thus, easy data transfer is provided. The location coordinates of the trash cans are displayed on the map andafter the trash can is activated the route is determined and he is shown to the truck driver. This route is optimized by taking into account parameters such as roads, traffic, fuel consumptioand n, the capacity of trash cans and trucks.

VI. FUTURE SCOPE

The main goal of this project is to reduce manpower and labor costs, along with advancing the smart city vision. We often see rubbish spilling out of bins onto Street, and this was a problem that needed immediate attention.

Intelligent trash can help reduce pollution. Garbage bins are often overcrowded and many animals, such as dogs and rats, invade or near them.

This creates a bad scene. In addition, birds are trying to remove litter from garbage bins. This project can avoid such situations. Also, messages can be sent directly to the sweeper instead of the contractor's office.

Abstract— **Remote sensing satellite images provide vital information for a plethora of applications including environmental monitoring, agriculture, urban planning, and resource management. However, the satellite images often suffer from missing information due to unfavorable weather conditions like heavy cloud cover and cloud shadows, rendering the data unusable. Hence, it becomes necessary to fill in the missing information by removing the dense clouds and cloud shadows in the image. The paper suggests utilizing Diffusion Models for satellite image reconstruction as a generative technique. The clouds from satellite images are removed by a mask and the removed regions are generated using unconditional Denoising Diffusion Probabilistic Model (DDPM) based inpainting approach. We compared the performance of the proposed method with other deep learning-based methods and achieved almost same results.**

Keywords— cloud removal, diffusion model, DDPM, cloud, image reconstruction, satellite imagery, image processing

I. INTRODUCTION

The acquisition of data for monitoring in a range of disciplines, which includes the identification of structures, the mapping of crops, and the detection of changes in land cover, depends heavily on remote sensing. Satellite images are also essential for keeping an eye on the earth's surface. Since these images are crucial for tracking mineral resources, forests, floods, droughts, urban planning, land surface, sea temperature, and other phenomena, they also have been widely employed in a wide range of fields, including environmental research, national defence, security, and weather monitoring. Approximately 67% of the Earth's surface is covered by clouds, as reported by Moderate Resolution Imaging (MODIS). Therefore, cloud elimination methods are being contemplated to address any unwanted issues that may arise in optical remote sensing. Unfortunately, this remote sensing data acquired from the satellite sensors suffers from missing information due to faulty satellite sensors or bad environmental conditions. Problems occur like images with cloud cover, shadows, etc. And solving these problems often requires multitemporal data or other pairs of data. Removing clouds from satellite images is a pervasive problem because clouds frequently obscure the surface and make it difficult to analyse satellite data. By identifying the cloud pixels in the image and substituting them out for clear pixels from other images that were either shot at a different time or from different sources, the cloud can be removed from the image. Both human and automatic techniques can be used to accomplish this problem. The majority of the time, the manual approaches entail manually modifying the cloud pixels as well as visual image inspection. On the other hand, automated techniques employ algorithms to recognise and eliminate the cloud pixels. The strategies used in automated cloud removal may be based on statistical or machine learning methods and may include thresholding, morphological procedures, or deep learning techniques. Depending on the quality and resolution of the satellite data, the complexity of the cloud structures, and the method used, the accuracy and efficacy of cloud removal can differ.

The aim of this work is to reconstruct the missing data in the satellite images due to cloud covering. We are not detecting the clouded regions but only reconstructing the missing areas when the clouded pixels are removed using masks. When viewing this issue more broadly, it may also be seen as a form of image inpainting where the clouded parts represent the areas that need to be eliminated. Many people have put out their own solutions for this issue in recent years, including deep learning and conventional image processing techniques. Based on extensive research and previous works, we used diffusion models approach as this is relatively new and has become very popular in recent times as compared to other deep generative models.

II. RELATED WORK

There are two types of techniques for reconstructing data currently available: conventional image processing approaches and deep learning techniques. Traditional image processing methods mainly utilize the basic characteristics of the image, but the models designed for this method often have restricted capability. With the advancement in computing power, deep neural networks have made significant strides in computer vision activities, such as image restoration, image denoising and image super-resolution reconstruction. A few scholars have attempted to apply deep learning methods to resolve the issue. Researchers in [1] built their model using two GANs. The first individual to recognise the intricate structures in SAR photos was trained using large datasets. The second method is employed to eliminate clouds while preserving the standard of areas that are cloud-free. They recommended dilated residual inception blocks (DRIBs) for generators based on dilated convolutions to

improve receptive view and prevent the missing information in satellite images.

Paper [2] proposed a texture complexity-guided sample generation technique that can produce training examples on its own with a balanced distribution of difficulty. The researchers investigated an SPL approach that could train a comprehensive network for cloud elimination across a variety of complexities by intelligently sorting training examples from the simplest to the most challenging. The experimental results indicate that when the size of the cloud is excessively large, the suggested method generates exceedingly impractical content. This is problematic as the cloud-affected region is too extensive to provide enough data for cloud removal.

A novel additive imaging model-based framework for thin cloud removal is proposed for multispectral remote sensing pictures [3]. U-Net has been used to obtain precise data on thin clouds. Slope-Net, a brand-new CNN architecture, is also planned. They proposed a novel thin cloud simulation method for training U-Net and Slope-Net. Compared to other thin cloud removal approaches, the suggested technique will result in cumulative estimation inaccuracy. Because the two kinds of cloudy photos are not totally consistent with one another, the results of eliminating thin clouds from real cloudy photographs are worse than those produced by removing thin clouds from simulated cloudy images.

Paper [4] cloud removal process has two stages. Cloud segmentation, which entails directly extracting the thick clouds using U-Net and segmenting the clouds, is the preliminary stage. The second part of the process is image restoration, which involves eliminating the dense cloud and reconstructing the irregularly missing regions that correlate to it using a generative adversarial network (GAN). When a sizable portion of an image is missing, the suggested method cannot reconstruct it with high accuracy. Another limitation of the two-stage approach is that the generator could provide erroneous images to fill in the gaps when the ratio of thick clouds is large.

Deep learning-based cloud removal technique for a multitemporal ZY-3 satellite image is described in paper [5]. The CNN architectures are made to both identify and get rid of clouds at the same time. The proposed approach cannot be used in scenarios where the land cover may vary dramatically.

In summary, even though there have been few other deep learning solutions for this problem, they have yet to apply a diffusion model approach for this problem, and depending on how it is implemented it can even perform better than previous models.

A. Diffusion Models

Diffusion models are based on non-equilibrium thermodynamics and employ a series of random diffusion steps in a Markov chain to introduce noise to data. The objective is to train the model to comprehend how to invert the diffusion procedure and construct preferred data samples from the noise. The DDPM is a generative model that learns the distribution of images in a training set, similar to other generative models. The procedure for generating new images involves selecting a random noise vector and gradually reducing the noise to arrive at a high-quality output image. In summary, diffusion models are neural networks that are trained to predict slightly less noisy images from a noisy input. At inference, they can be used to iteratively transform a random noise to generate an image.Generative models, such as GANs, VAEs, and flow-based models, have demonstrated significant success in producing high-quality samples, but each model has its own limitations. GANs are infamous for their potential for unstable training and limited diversity during generation due to their adversarial approach. VAEs use a surrogate loss function. Flow models require specialized architectures for reversible transformations. Diffusion models employ set methods during training and have a high-dimensional latent variable that matches the original data. There has been a surge in research into diffusion models in recent years, leading to them producing state-of-the-art image quality. Additionally, diffusion models don't require adversarial training like GANs. Although they may be more computationally demanding compared to other deep learning architectures, they outperform them in specific applications [8].

III. METHODOLOGY

This paper explores a new generative approach for removing clouds from satellite images and filling in the missing information through inpainting. A growing alternative to generative modelling, Denoising Diffusion Probabilistic Models (DDPM), are used in the process [6]. Recent research has demonstrated that diffusion models can even surpass the most advanced GAN-based image generation technique [8]. By reversing the diffusion process we train the diffusion model, beginning with a random noise sample and undergoing a specified number of iterations to produce the final image. DDPMs have shown they can produce a variety of excellent photographs despite being based on principled probabilistic modelling [6, 7, 8].

Our method employs an unconditional image generation DDPM in the same way as paper [9]. Rather than acquiring a mask-based generative model, we adapt the sampling procedure throughout the reverse diffusion iterations to condition the generation process. As a result, our model is not directly trained for the purpose of eliminating clouds. Nevertheless, with the alterations we make to the denoising procedure, we can employ it to address that problem. But for this we still need an unconditional image generation diffusion model which can generate satellite images from random noise. For this we use a pre-trained model which generates random bedroom images and fine-tune it on our dataset to

generate satellite images. This has an important advantage that we can use existing powerful DDPM which has been trained prior and reduce our training time as well as data required for training. We have implemented an enhanced denoising method that re-samples iterations to improve the conditioning of the image [9]. This technique enables the network to effectively integrate the generated image data of the cloud-covered regions throughout the entire inference process, resulting in better conditioning based on the available satellite image data. Since the original DDPM network remains unaltered, the model produces high-quality output for the generated area.

IV. IMPLEMENTATION

A. Dataset Details

We have used the cloud removal dataset from the paper [10]. It consists of two datasets: one that pairs a single cloudy image with a single clear image (singleImage, 97640 images), and the other that pairs three cloudy photos with a single clear image (multipleImage, 3130 images). We are not using the IR image and are instead using the singleImage dataset. The pictures have RGB channels with a size of 256x256px.

B. Model

We use the pretrained diffusion model which uses a UNet architecture from [7] which was trained on 256x256px LSUN Bedrooms class to generate unconditional images of bedroom. As we are only updating the weights during training the architecture of the model remains the same.

C. Training

For the fine-tuning of the model, we only need the clear satellite images without clouds as we need the model to generate clear satellite pixels without cloud for the inpainting part. The model takes a timestep t (random number during training) which determines the amount of noise in an image and a noisy image xt (generated by adding some noise in the clear image x0 based on t) then predicts the noise to be removed from the initial noisy image to give clear satellite image. The sampling part which does the image generation from predicted noise does not need to be trained and this part also does the inpainting of the clouded pixels.

D. Sampling

In the sampling part a mask of cloudy regions is used as a condition in the method to forecast missing pixels in the clouded portions of satellite images. As cloud segmentation is not the main aim of this paper we create the mask by simply doing the grayscale of the cloudy image and converting it to mask and inverting the mask to remove regions containing cloud pixels. This method does not give proper mask, but it is good enough to use in the sampling process to give a good result. To produce the removed regions, we are utilizing our trained unconditional denoising diffusion probabilistic model that makes use of the context of the known region during the sampling phase.

As the DDPM is trained to generate images resembling satellite images, it inherently strives to create structures that are coherent and consistent. We use this DDPM property to harmonize the input of the model to generate the regions which better harmonize with the satellite image. The sampling process is illustrated in Figure 1. The cloudy regions are removed using the generated mask which is later merged with cloud-free regions generated from model. Then we diffuse the output x_{t-1} (merged cloud-free image) back to x_t (image with t noise) by sampling from the model. Although this operation scales back the output and adds noise, some information incorporated in the generated region x_{t-1} is still preserved in x_t. It leads to a new x_t which is both more harmonized with x (input image) and contains conditional information from it. This resampling also increases the runtime of the reverse diffusion but as a result the generated region matches the neighbouring region and semantically correct.

E. Metrics

We quantitatively evaluated the performance of method using structural similarity (SSIM) and peak signal-to-noise ratio (PSNR) for pixel-level similarity between original clear image and cloud removed image. The PSNR computes the peak signal-to-noise ratio, between two images. The PSNR ratio is utilized to evaluate the quality of an image by comparing the original and reconstructed version. A higher PSNR value indicates a better quality of the reconstructed image. On the other hand, the SSIM is a perceptual metric that measures the degradation in image quality by evaluating the perceptual difference between two similar images. Unlike PSNR, SSIM is based on visible structures in the image. The SSIM metric has a range from 0 to 1, where a value of 1 signifies that the reconstructed image matches the original image perfectly. These scores are then compared to some of the previous works using different approaches.

V. RESULT AND DISCUSSION

Example results of our method is shown in the Figure 2. The images obtained can be seen to be almost same as the original cloud-free image. Although some of the generated regions seem to be different from the original clear image this is because no supplementary images were used to produce those regions unlike some of the previous works, so the region is randomly generated. This is not a problem if the cloudy regions are small but if there is cloud covering almost half of the region then the cloud-free image generated will be completely different from the ground truth image. The mask generation can also be improved to better detect the cloud pixels for proper removal of those regions.

We compared our PSNR and SSIM score with other deep learning-based models [2, 3, 4] in Table I. The PSNR of our method is 30.2501 and SSIM is 0.9153. When compared to other methods, our score is not the best, but it is still very good and can be further improved. This may be due to not using a supplementary image to get information for generating the missing regions as we are generating those randomly. The other reason may also be because the cloudy and clear images have problems such as time difference, light changes, and atmospheric disturbances. This results in lower score for pixelwise metrics as the image generated from cloud removal also have the same problem as original cloudy image. Our method can also automatically deal with dead pixels and deadlines in satellite images because of how the diffusion model works. It is currently challenging to utilize the DDPM optimization process for real-time applications because it is much slower than other methods. However, diffusion models have become popular, and new techniques have been developed to improve its efficiency.

Table I. Quantitative Evaluation Comparison

Methods	PSNR	SSIM
Method [3] (Thin Cloud)	34.2562	0.9832
Method [4]	20.1	0.807
Method [2]	30.4864	0.9351
Proposed	**30.2501**	**0.9153**

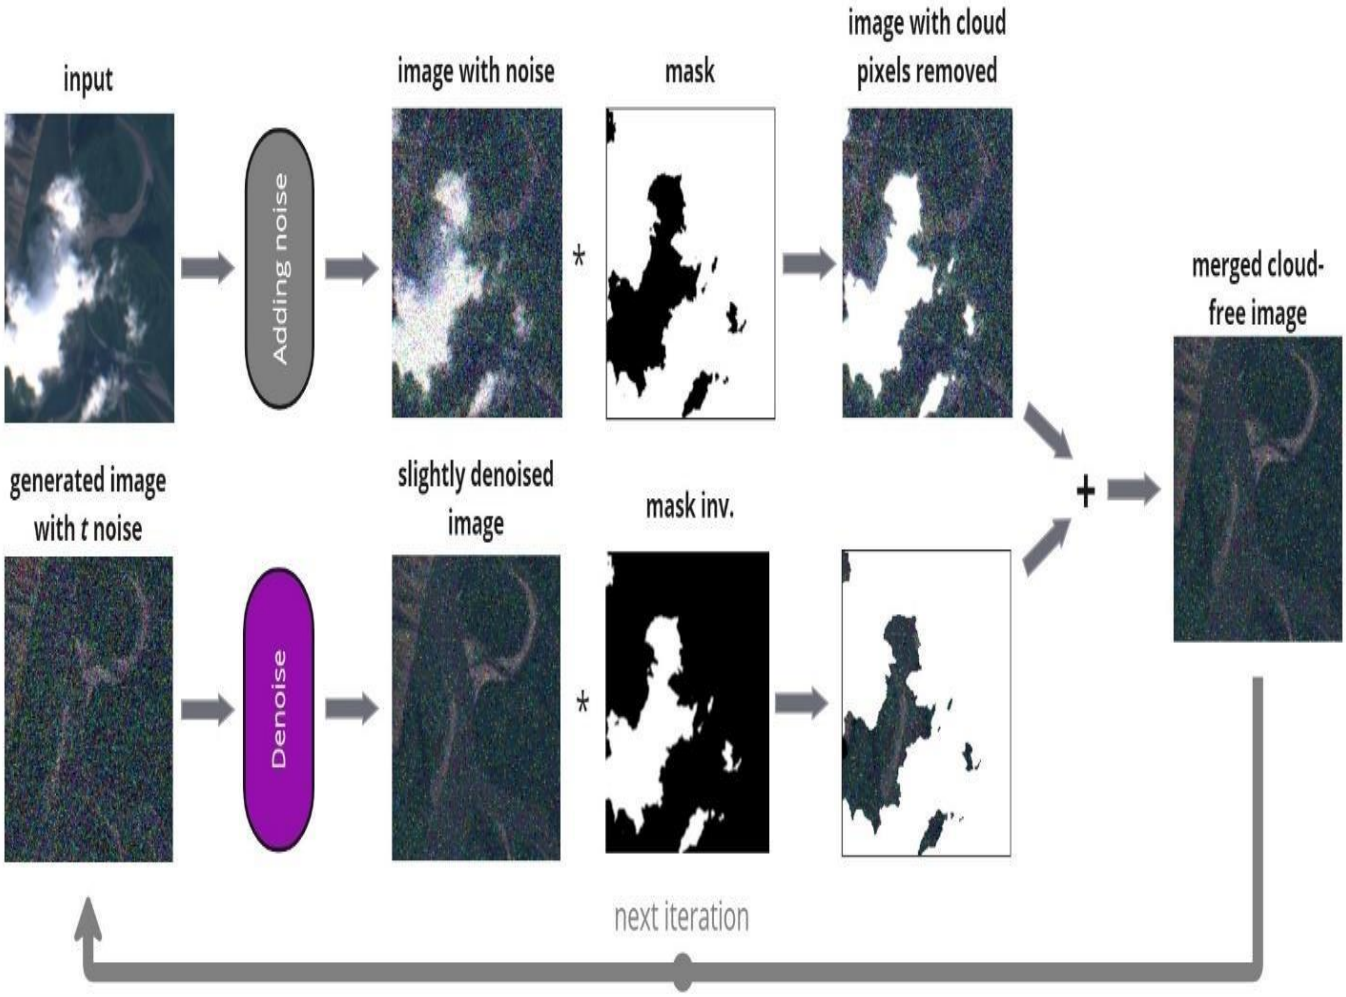

Fig. 1. Overview of Sampling process. Every few step, we merge the cloud-free region of the input and the inpainted part from the DDPM output (bottom) to create a cloud-free image.

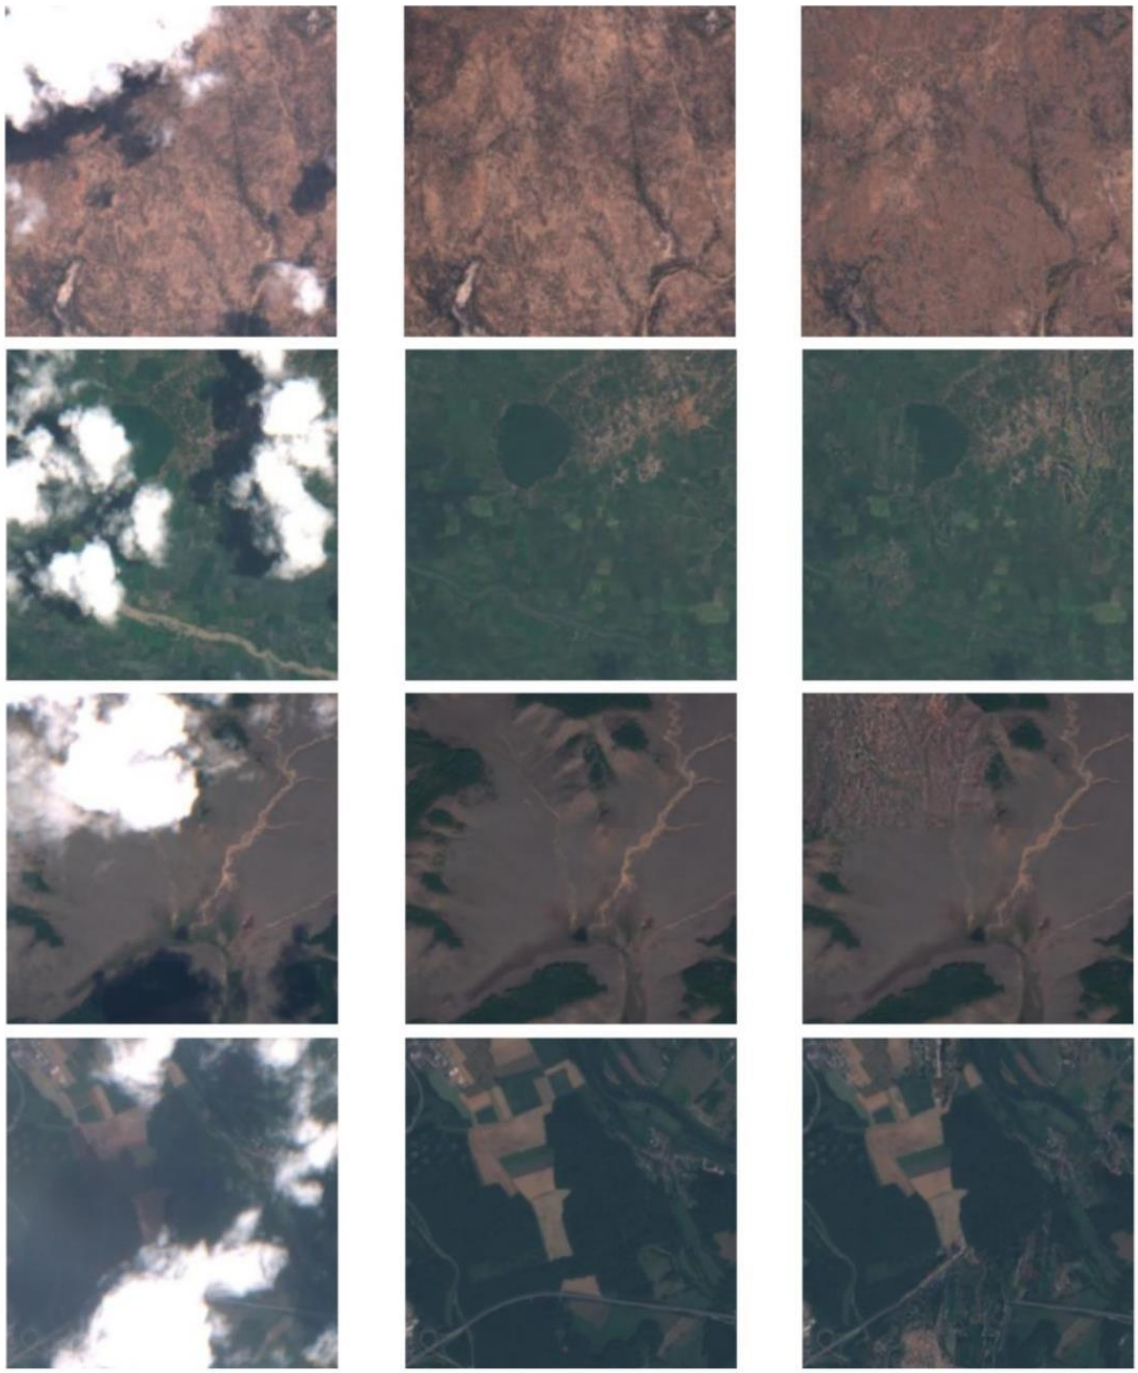

Fig. 2. Results of our cloud removal method. Columns from (left) to (right) show the original cloudy image, original cloud-free image and the cloud removed image from our method.

VI. CONCLUSION

In this paper, we have presented a novel approach of using diffusion models for reconstruction of missing data in satellite imagery due to cloud covering i.e., to remove clouded regions from satellite images. It is the most recent and popular approach towards image synthesis and never been used before for this problem. We can achieve same or better sample outputs compared to other methods. The proposed method only needs the cloudy image and mask of cloud regions to give cloud-free images. The results show that although the method performs well even for thick cloud removal, the output image is still a bit different from the ground truth image. The proposed method generates completely different region when the cloud-corrupted area is too large. Thus, for large cloud coverage there is a need to use another paired data which can provide sufficient information for the generation of the region.

VII. FUTURE SCOPE

The entire process can be better optimized with all the new techniques coming out recently for diffusion models and to note that we have used simple DDPM instead of the newer models which produce even better results with less time and processing. The reconstruction model can be utilized for data pre-processing and augmentation for various satellite image applications. The diffusion models

can be used in the missing data reconstruction of infrared and other types of satellite images, which is similar to proposed methodology. Data compression and image synthesis and reconstruction may potentially benefit from the diffusion model.

Abstract— The Time series is a collection of data points that are collected at constant time intervals. It is a dynamic or time dependent problem with or without increasing or decreasing trend, seasonality. Time series modeling is a powerful method to describe and extract information from time-based data and help to make informed decisions about future outcomes. This project explores how to retrieve csv times series dataset, visualizing time series dataset, how to transform dataset into times series, testing if the time series is stationary or not using graphical and Dickey- Fuller test statistic methods, how to transform time series to stationary, how to find optimal parameters to build seasonal Autoregressive Integrated Moving Average (SARIMA) model using grid search method, diagnosing time series prediction, validating the predictive power, forecasting 10 year future CO2 emission from power generation using natural gas.

Keywords: SARIMA, ARIMA, time series, emission, seasonality

I. INTRODUCTION

As a greater amount of Environmental change has been one of the top issues on worldwide politicalplans lately for an Earth-wide temperature boost. An unnatural weather change is perhaps of the most holding and convoluted issue confronting the world. It is by and large brought about by ozone harming substance - chiefly CO2 outflow in the climate. Carbon dioxide (CO2) is one of the Green House Gases (GHGs), for the most part begins from human exercises and is accessible in enormous amount in the environment that causes worldwide natural issue and climate change (IPCC, 2014). India is an emerging country on the planet and its quick monetary development has prompted high expansion in GHGs discharge. The central point liable for CO2 outflow in India are nuclear energy plant, deforestation, business and private structures, transportation, concrete and steel industry and so on. (IEA, 2010). Gauge of CO2 outflows has turned into an overall worry as the GHG demonstrated to contribute most effects on ecological issues. Determining CO2 outflows is likewise one significant key to make mindfulness among public on the most proficient method to take care of natural issues. Understanding India's previous CO2 discharge way and make a solid forecast of its future emission is fundamental. This exploration tries to display and gauge CO2 emanations in India utilizing ARIMA models.

II. LITERATURE SURVEY

According to the literature, three techniques were used often to forecast time series data.According to Elshaboury, N., Mohammed Abdelkader, E., Al-Sakkaf, A., and Alfalah[1], the PSO-trained ANN model beats the conventional ANN model.The ANN-PSO model may thus be acknowledged as a trustworthy model for predicting MSW amounts in Poland based on social and economic factors.J.K. Solano-Meza and others .[2] To anticipate the production of solid waste, three alternative prediction algorithms were used.The first step in the process was to investigate how to utilise decision trees of various depths to demonstrate the usefulness of this tool for conducting a comparative study. Given the likelihood of generating adequate results with this tool owing to the restricted quantity of data, vector support machines were also created to generate regression models based on local radial functions, employing points (support vectors) in a particular neighbourhood as a supplementary alternative. Finally, neural network-based techniques were used to project the points' trajectories. A conclusion that SVM is the approach with the best behaviour in terms of the local trend of the points and assuming a high reliability in the recorded values can be drawn on the basis of this quantitative data. Noha EL KHATTABI, Zouhair EL HADRI, and Ismail BOULAHNA [3] Given that the SARIMA parameters (p, q, P, and Q) are chosen based on autocorrelation of Xt to its previous values, the resultant model allows us to claim that the monthly trash production in the city relies on that of the previous month as well as in the same month of the previous season.

III. OBJECTIVE

The principal objective of this framework is to foresee whether an individual or an administration body will actually want to foresee the carbon dioxide emanation on certain boundaries that sounds taken as information, truly. Further, if potential, we might attempt to test a couple of other AI models as well, so then we would have the option to concentrate on how different models fill in when contrasted with the ones we are utilizing.

IV. RELATED WORK

As per addressed measurements, the emanation of this gas is in an unacceptable level that jeopardizes ecological circumstances as one of the significant components to accomplish supportable turn of events. In this way, staying with responsibilities related on peaceful accords and local participation for public arrangements on manageability issues and accomplishing objectives like expanding worth of life quality, have changed over climate as one of the significant parts on connection to full scale approaches presently which different exercises areaffected. Thus, concentrating on the expectation

ofCO2 discharges is fundamental for legitimate preparation to accomplish monetary targets andstrategies for progressing development andpractical turn of events.

V. TEST STATIONARY

Initially, we need to produce a plot of the time series dataset. From the plot, we will get an idea about the overall trend and seasonality of the series. Later, we will use a statistical method to assess the trend and seasonality of the dataset. After trend and seasonality are assessed, if they are present in the dataset, we need to remove them from the series and convert non-stationary dataset to stationary dataset. A stationarity time series is one who's properties do not depend o the time at which the series is observed, thus, time series with trends or with seasonalities are not stationary as it affects the value of the time series at different time. A stationarity time series has constant variants and it always returns to long run mean. When forecasting or predicting the future, most time series models assume that each point is independent of one another because stationarityhas a tremendous influence on how data is perceived and predicted. A trend stationary process is not strictly stationary, but can easily be transformed into a stationary process by removing the underlying trend, which is solely a function of time. Similarly, processes with one or more unit roots can be made stationary through differencing. An important type of non-stationary process that does not include a trend-like behaviour is a cyclo-stationary process, which is a stochastic process that varies cyclically with time.

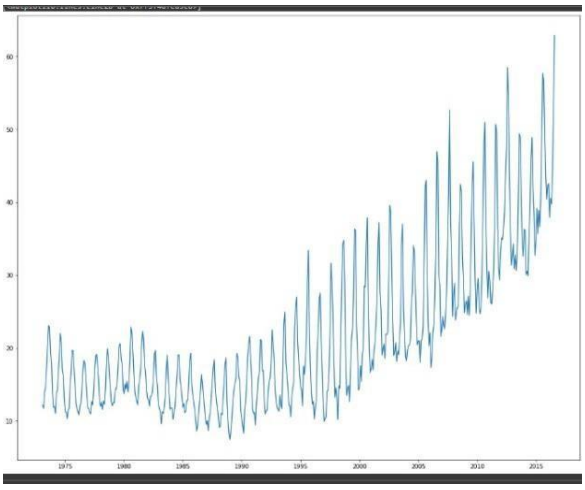

Fig. 5.1 Trend showing that data is not stationary

TEST STATIONERY USING DICKY-FULLER

A formal way of testing stationarity of a dataset is using plotting the moving average or moving variance and see if the series mean and variance varies with time. This approach will be handled by the TestStationaryPlot() method. The second way to test stationarity is to use the statistical test (the Dickey-Fuller Test). The null hypothesis for the test is that the time series is non-stationary. The test results compare a Test Statistic and Critical Values (cutoff value) at different confidence levels. If the 'Test Statistic' is less than the 'Critical Value', we can reject the null hypothesis and say that the series is stationary.

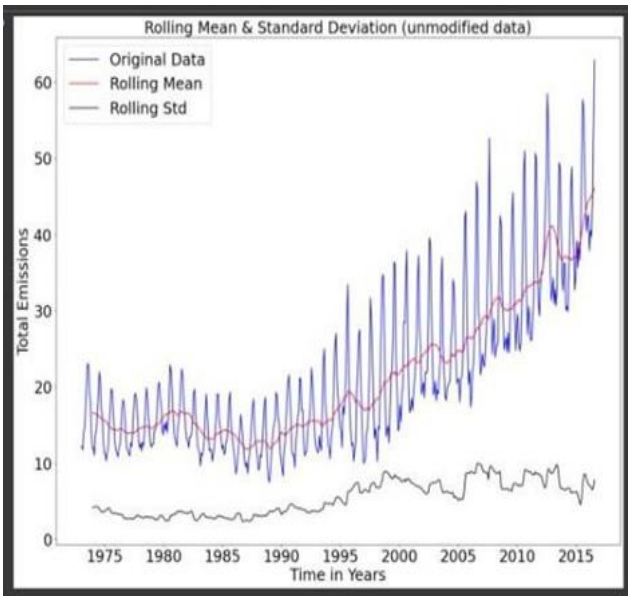

Fig. 5.2 Time Series has a unit root, indicating it is non- stationary

TRANSFORM DATA INTO STATIONARY

Most common technique trend ad remove them from the time series are:

- Aggregation: Taking average for a timeperiod like monthly average
- Smoothing: Taking rolling averages
- Polynomial fitting: Fitter regression model

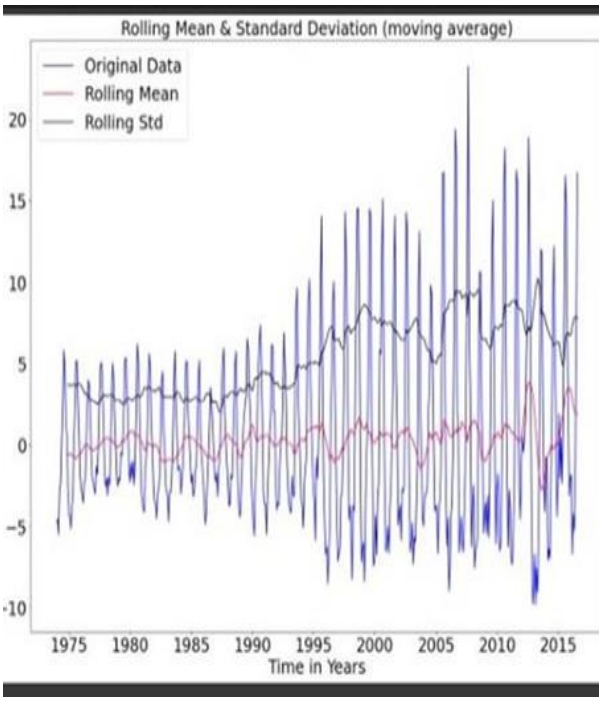

Fig. 5.3 Moving Average

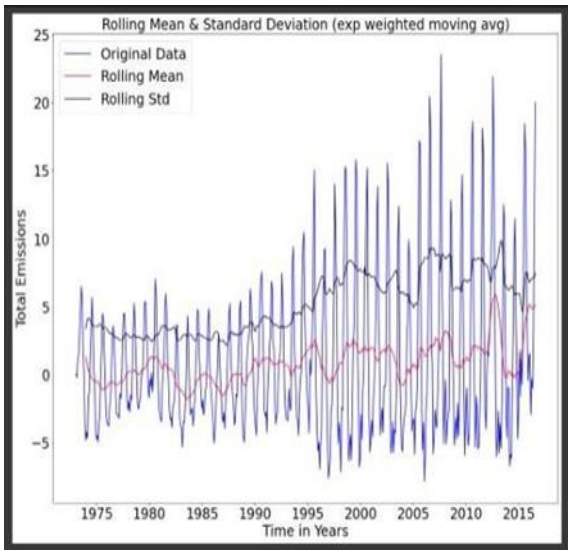

Fig. 5.4 Exponential Weighted Moving Average

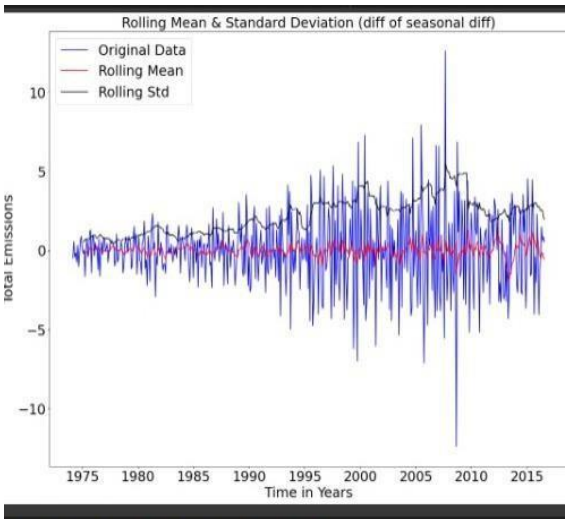

Fig. 5.5 Differencing

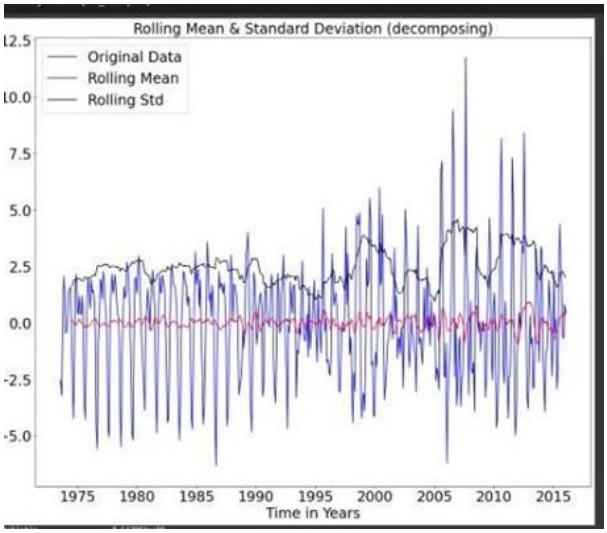

Fig. 5.6 Decomposing

MACHINE LEARNING ALGORITHM

When looking to fit time series dataset with seasonal ARIMA model, our first goal is to find the values of SARIMA(p,d,q)(P,D,Q)s that optimize our metric of interest. Before moving directly how to find the optimal values of the parameters let us see the two situations in stationarities: A strictly stationary series with no dependence among the values. This is the easy case wherein we can model the residuals as white noise. The second case being a series with significant dependence among values and needs statistical models like ARIMA to forecast future outcomes.Auto-Regressive Integrated Moving Average (ARIMA): The ARIMA forecasting for a stationary time series is a linear function similar to linear regression. The predictors mainly depend on the parameters (p,d,q) of the ARIMA model.

Autocorrelation Function (ACF): It is a measure of the correlation between the time series (ts) with a lagged version of itself. For instance at lag 4, ACF would compare series at time instant 't1'…'t2' with series at instant 't1-4'…'t2-4' (t1-4 and t2 being end points of the range).

Partial Autocorrelation Function (PACF): This measures the correlation between the ts with a lagged version of itself but after eliminating the variations already explained by the intervening comparisons.To find the optimal parameters for ARIMA models using the graphical method is not trivial and it is time consuming. We will select the optimal parameter values systematically using the grid search (hyperparameter optimization) method. The grid search iteratively explore different combinations of the parameters. For each combination of parameters, we will fit a new seasonal ARIMA model with the SARIMAX() function from the statsmodels module and assess its overall quality. Once we have explored the entire landscape of parameters, our optimal set of parameters will be the one that yields the bestperformance for our criteria of interest.

When evaluating and comparing statistical models fitted with different parameters, each can be ranked against one another based on how well it fits the data or its ability to accurately predict future data points. We will use the AIC (Akaike Information Criterion) value, which is conveniently returned with ARIMA models fitted using stats models. The AIC measures how well a model fits the data while taking into account the overall complexity of the model. A model that fits the data very well while using lots of features will be assigned a larger AIC score than a model that uses fewer features to achieve the same goodness-of-fit. Therefore, we are interested in finding the model that yields the lowest AIC value. We have obtained a model for our time series that can now be used to produce forecasts. We start by comparing predicted values to real values of the time series, which will help us understand the accuracy of our forecast. The get_prediction() and conf_int() attributes allow us to obtain the values and associated confidence intervals for forecastsof the time series.

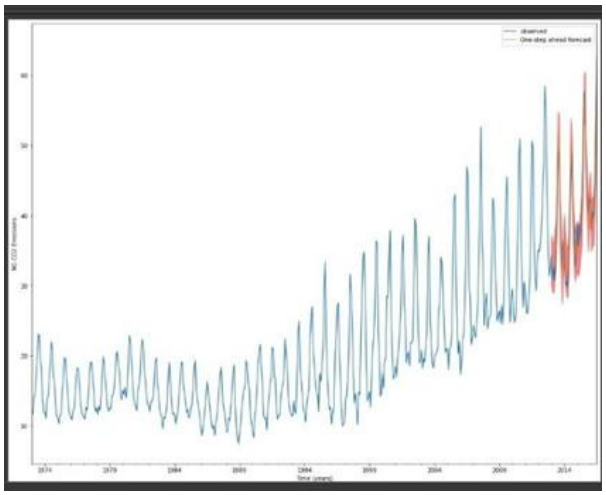

Fig. 5.7 Forecast aligns with the rue values showing an overall similar behaviour.

VI. RESULT AND ANALYSIS

Machine To find the ideal boundaries for ARIMA models utilizing the graphical strategy isn't inconsequential and it is tedious. We will choose the ideal boundary esteems deliberately utilizing the matrix search (hyperparameter streamlining) technique. The matrix search iteratively investigates various mixes of the boundaries. For every mix of boundaries, we will fit another occasional ARIMA model with the SARIMAX () capability from the details model's module and survey its general quality. Whenever we have investigated the whole scene of boundaries, our ideal arrangement of boundaries will be the one that yields the best presentation for our models ofrevenue.

Note: bigger scopes of p, d, q boundaries bring about dramatically longer inquiry time. Assuming you attempt bigger than 2, be ready to pause. I've found better AIC results with bigger worth reach; however, end model is basically something very similar.

While assessing and contrasting measurable models fitted and various boundaries, each can be positioned against each other in light of how well it fits the information or its capacity to precisely foresee future data of interest. We will utilize the AIC (Akaike Data Rule) esteem, which is advantageously gotten back with ARIMA models fitted utilizing details models. The AIC estimates how well a model squeezes the information while considering the general intricacy of the model. A model that fits the information very well while utilizing heaps of highlights will be doled out a bigger AIC score than a model that utilizes less elements to accomplish a similar integrity of-fit. Consequently, we are keen on finding the model that yields the most minimal AIC esteem.

The request contention indicates the (p, d, q) boundaries, while the occasional request contention determines the (P, D, Q, S) occasional part of the Occasional ARIMA model. In the wake of fitting each SARIMAX () model, the code prints out its particular AIC score.

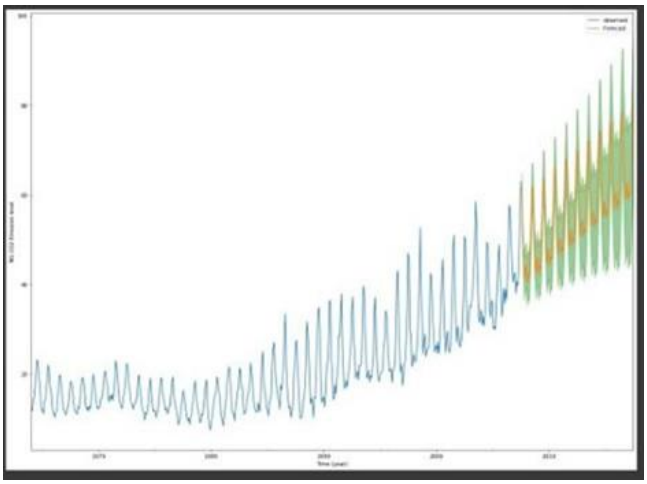

Fig. 4.8. CO2 emissions from natural gas expectedto rise

VII. CONCULSION AND FUTURE SCOPE

In this paper, we have investigated how to recover CSV dataset, how to change the dataset into times series, testing in the event that the time series is fixed or not utilizing graphical and Dickey-Fuller test measurement strategies, how to change time series to fixed, how to track down ideal boundaries to construct SARIMA model utilizing lattice search strategy, diagnosing time series expectation, approving the prescient power, determining 10-year future CO2 emanation from power age utilizing gaseous petrol.

The review shows that the ARIMA (2, 2, 0) model isn't just steady yet additionally the most appropriate model to estimate yearly complete CO2 in India for the following 13 years. The model predicts that by 2025, India's yearly absolute CO2 outflow will be around, 3.89 million kt. This is an admonition sign to Natural Financial experts in India, especially with respect to environmental change and an Earth-wide temperature boost. The consequences of this study are vital for the Indian government, particularly with regards to medium-term and long haul arranging.

For a huge progress in decrease of carbon dioxide outflows, it stays the obligation of each and every resident and each industry while the public authority stays the main regulator and initiator of cooperating to deal with the climate into what's to come. Since an unnatural weather change really do influence the world at large, the review results might be applied to each country, particularly the plan and execution of the energy review idea, energy the board and the energy preservation rehearses.

Future work: fostering a period series model of natural gas determining.

Abstract: **Point-of-interest (POI) suggestion has grown to be one of the primary services in location-based social networks (LBSNs) due to the widespread use of LBSNs. Users' primary behaviour in LBSNs is checking in to POIs, and this checking-in behaviour is influenced by the user's behaviour patterns and his or her social circle. Social influence is frequently employed on social networks to assist businesses draw in more customers. Each target user in social networks has a unique impact on several POI. The list of POIs with the greatest impact on recommending users is chosen in this study. Our objectives are to meet the service needs of the target audience while simultaneously promoting the locations of businesses (POIs). The problem of POI recommendation for location promotion is defined in this study. In addition, we tackle the optimization problem using submodular characteristics.**

Keywords: - location-based social networks (LBSNs), Point of interest (POI).

I. INTRODUCTION

Location-based social networks (LBSNs), including Foursquare, Gowalla, and Jiepang, have emerged as a new category of social networks due to the rapid expansion of mobile internet. Numerous academics have recently started working on location-aware systems. Users of LBSNs can upload images, remark on places or things to do, and invite others to check-in at places that interest them. Points of interest are these locales (POIs). POI recommendations are currently one of the primary location-aware services in LBSNs. Based on the personalities, preferences, and behavioral patterns of the user, POI recommendation systems often entail presenting users with some locations in which users may be interesting. In light of POIs, POIs (such as restaurants, hotels, and markets) must investigate checking-in data in order to draw more consumers; more people (For example, friends of users who visited these POIs) will be persuaded to visit these places. In this essay, we approach the impact on the firm as a location marketing The goal is to promote as many of these K recommended POIs to the target user as possible in order to impact as many users as possible. It does not apply to our POI recommendation problem because the authors of the prior study [1] developed a location-aware influence maximization problem to identify a group of seed users in social networks for maximizing influence spreads. Our issue has a set of POIs as its output result.

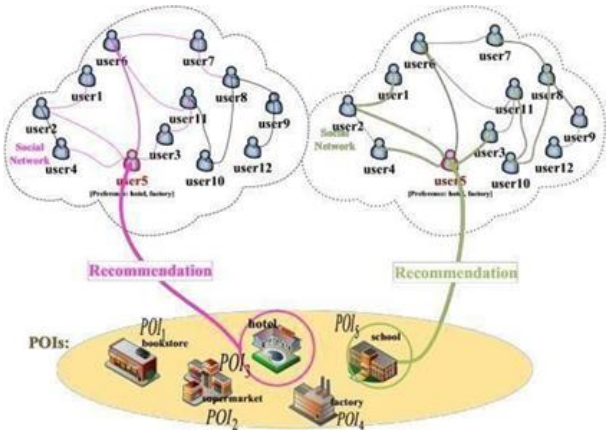

Fig. 1: An POI recommendation example

The following categories apply to existing POI suggestions based on the data source used [2]: User profiles, location histories, and trajectory data are the first three categories. By the methodology used, POI suggestions are divided into three categories: 1) content-based, 2) link analysis-based, and 3) collaborative filtering (CF)-based [2]. Several academics [3] [4] have determined how similar users are to one another based on where they resided, and researchers have used that information as the input for classic CF. The correctness of the advice is the primary factor considered by the majority of current studies. However, both users and retailers value recommendation systems equally. It not only assists a business in gaining more clients, but also connects people with locations that pique their interest. According to a social survey conducted by Marketing Letter, people are more likely to get knowledge from their friends when seeking it out in the real world. Businesses leverage social connections to increase revenues and their impact scope (IS). Online marketing and information sharing make full advantage of the influence of user or friend contact consider viral marketing. Social relationships are used in existing research to help resolve the sparsity and cold-start issues in recommendation systems [4][5][6]. According to the thorough analysis above, typical POI recommendations hardly ever consider how social interactions affect the promotion of a business' location through the POI suggestion process. in comparison to current functions, we take a look at an illustration in Fig.1 where a heterogeneous network with users and POIs is present (e.g., a bookstore POI1, supermarket POI2, hotel POI3, factory POI4, and school

POI5). The social impact over various POI types varies as a result of differences in people's authority and influence under various information categories. When user5 is the intended user, conventional recommendation techniques use users' checking-in behaviour to deduce the preferences and personalities of the individuals. The system's recommendation output is then a list of POIs that the user might be interested in, with recommendations that are guaranteed to be accurate. Friends are inextricably linked, hence this article makes the assumption that the target user's friends are successfully impacted by them under specific POI categories or POI. User 1, User 2, User 3, User 4, User 6, User 7, User 8, User 11, and there are eight users who have been persuaded. User 5's IS regarding POI 3 is not, however, the maximum. The users' IS concerning a unique POI (POI category) is referred to as the individual POI's IS in this study. As a result, POI3's IS is the aforementioned userset, and its influence scope gain (ISG), without taking into account user5's friends, is made up of users 7, 8, and 11. The right side of Fig. 1 shows that POI5 has an IS larger than POI3 and an ISG of users 7, 8, 9, 11, and 12. The system ought to suggest the target user with the POI5 while promoting the goods and services of enterprises. In order to promote POIs, this study suggests a POI recommendation system. Our suggested approach goes beyond being a tool used by companies to advertise their goods and draw in more clients. although it also suggests users visit select POIs that suit their preferences. To conclude, the following are our main contributions:

1. To explain the geographical impact between users, we model user mobility and define the user's IS under specific POI categories over the whole social network.

2. We offer a POI recommendation method due to IS overlaps under various POI categories. The algorithm successfully gets rid of the overlaps.

3. Lastly, we undertake extensive experiments on two sizable real datasets, and the results indicate that our algorithm's accuracy is on par with cutting-edge methods. Our approach has important benefits for location promotion.

II. POI RECOMMENDATION

In this section, we define POI recommendation problem for location promotion (POILP) in LBSNs.

A. Definition

Definition 1. (LBSN) A LBSN < G,C > consists of a social network G = < U,E >, where U is users set,

E = {(ui,uj)| one social connection from ui to uj, ui,uj ∈

, and check-in records C = {(u,l,t)}, (u,l,t) represents one check-in record where user u checks in a location l at time t. l = (lon,lat,a), lon is longitude, lat islatitude, a is one POI category, POI set in a given region $POI_{region} = \{\ell_1, \ell_2, \cdots, \ell_M\}$, POI category set in a given region POICregion = {a1,a2,⋯ ,am}.

Definition 2. (POILP) Given a LBSN < G,C >, a target user uT, a target location region Rtarget, the geography center of R_{taraet}: ℓ_{center}: $< lon, lat, POI_{reaion} >$, and a constant value K, the POI recommendation problem is to select a listof POIs POIre,POIre ⊆ POIregion, |POIre| = K, and thesystem recommends the target user uT with POIre, in orderto maximize the number of expected influenced users whowill check in Rtarget. Since existing researches [9] indicate different topics have different diffusion results. Similarly, every users' IS in LBSNs is different under different POI categories, since users have different topic preferences. This paper firstly discovers users' top-N influential POI categories in LBSNs.

B. Top-N Influential POI category Extraction

Definition 3. (Top-N IPOIC) Give a LBSN < G,C >, the targetuser uT ∈ U and his/her POI category preferences set POIuT = {a(1),a(2),⋯}, a constant N, this problem is to select a list of POIs pre,pre ⊆ POIuT . The number of the expected influenced users ϕ(uT,ai) by uT (as information source) is the maximum under POI category ∀ai ∈ pre. Then, we select top−N POI categories pre = {a(1),a(2),⋯ ,a(N)} according to the arrangement of the size of ϕ(uT,ai).

Learning influence between users This paper researches two aspects of influences between users in LBSNs : (1) geography influence; (2) topic-aware influence. The user u influences user) to check in the POI , which may denote, and the parameter β(∈ [0,1]) is a tradeoff between geographical influence and semantic influence , when v prefers to go the nearby place, β is bigger; when v prefers to go to places of interest, β is smaller.

The geographical influence [8] between users denotes $P^G_{u,v}(\ell) = \sum_l p_l^{(v)} f^{(v)}(d(l,\ell))$, wherein $f^{(v)}(d(l,\ell)) =$

. The topic-aware influence between users denotes For each POI category ai, the influence on ai denotes Pu,vai = ωu,v · Puai · Pvai. Puai is the probability of POI category $a_i.\ \gamma_\ell^{a_i} = P(T = a_i|\ell)$ Moreover, for each in LBSNs, we have a probability distribution covering the POI categories.

Computing User's Influence Scope This paper focuses on user's IS under special POI category. Thus, the definition of computing user's IS problem is that given a LBSN < G,C >, user , if ∃ a path from u to v, so that called as theuser u can arrive at the user v, and Path(u,S) denotes theset of users who u can arrive at. Our goal is to compute u'sinfluence scope under special POI category.

Actually, comparing with strangers, people are more easily influenced by friends. Path(uT,S) also represents the user uT influence scope of social network without

considering POI category preferences. Path(uT,S) is the results of the ideal state. Considering the influence between users in Path(uT,S),

we firstly identify users that are successfully influenced. paper supposes each user has an activated threshold value λujuniformly at random from [0,1]. When λuj, the user uj is very likely to visit the POI belong to the category ai. We regard this situation as ujis affected completely. In this paper, we set λuj as the probability expectation based on uj's history check-in POI categories recorders in advance. This paper selects the influenced users satisfying into the user set . Next, we select POI category a with the maximization IS about POIuT . Then, we select top based on the order of IS. Solving User Overlaps Problem Since each user has different influence scopes in social network under different POI categories, these different influence scopes have overlaps. The overlaps result in these top-N POI categories' ISG is not the maximum. The key is that how to design an appropriate objective function to eliminate these overlaps. represents ISG of the recommended POI category a. , wherein σ(·) denotes the number of the user set, and represents the friends of the target user uT.

C. POI Recommendation Algorithm

Firstly, POILP problem could be formulated as an optimization problem:

$$POI_{re} = \arg \max_{\ell_j \in POI_{region}} \gamma_{\ell_j}^{a_i}, \quad \forall a_i \in RC_{u_T}$$
$$s.t. \quad |POI_{re}| = K.$$

For the problem, we find out the recommended POI categories RCuT as the following: RCuT = argmax s.t.|RCuT | = K. Wherein POIuT = {a(1),a(2),⋯ ,a(K)}, K is a constant in advance. Since the function F(·) is monotone and submodular [9]. We give a greedy algorithm with a (1−1e) approximation [10]. It is stated by the Algorithm 1 in detail. Algorithm 1 POILP algorithm

Input: An LBSN $< G,C >$, the target user u_T, T_{uT} , K, $POIu_T$ = $\{a_1,a_2,\cdots\}$

Output: A list of POIs, $POIre$, and the corresponding recommended POI categories $RCre$, $|POIre| = |RCre| = K$

1: Initialize $RCre \Leftarrow \varphi$
2: Compute $\gamma_{\ell_j}^{a_i}(U_{u_T}^{a_i})$ for each $a_i \in POIuT$;
3: for $j = 1$ to K do
4: $a_j \leftarrow \arg \max$;
5: $\ell_j \leftarrow \arg \max_{\ell_j \in POI_{region}} \{P_{\ell_j}\}$
6: $RC_{re} \leftarrow RC_{re} \cup a_j$
7: $POI_{re} \leftarrow POI_{re} \cup \ell_j$
8: return $POIre, RCre$.

III. PERFORMANCE EVALUATION

The two authentic LBSN Foursquare and Gowalla datasets are used in this study. The checking-in behaviours of 36,907 users and 4,163 users are recorded in these datasets, respectively, along with location data, check-in time, check-in times, and friend relationships.

A. Comparative Methodologies

In this study, POILP is compared to other, more effective POI recommendation techniques. Ye.etc [4] offered a system for recommending locations based on users' interests, social connections, and geographic location. This method is known as location suggestion based on USG and uses the power-law probabilistic model and collaborative filtering (CF) as its technical components. Bao, etc. According to their weights in the category hierarchy, users' similarity in the category-based k-Nearest Neighbors algorithm (CKNN) suggested by [2] was calculated using user-based CF. On location features and user choices, Yin.etc [11] emphasized UP-based technique for POI recommendation with LDA is used. The aforementioned techniques, however, hardly ever take into account users' impact inside a certain POI category for an entire social network. The promotion of the location benefits from this influence.

B. Evaluation Method

Influence Scope Gain Comparison: Under the unique POI categories of POIre, POIre based on the function F() can maximise uT's ISG. Efficiency of Procedures: Comparing the proposed method to the methods outlined above allows us to confirm its efficacy. We make use of the recall ratio: and the precision ratio:to assess each method's ability to provide recommendations. The three metrics are calculated by taking the average of each of their values for 2000 users (the target users, abbreviated uT).

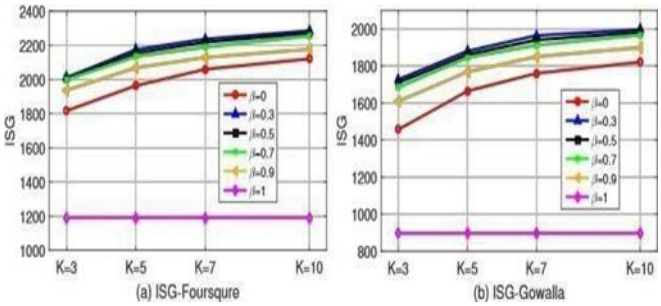

Fig. 2: Influence Scope Gain with Different β Values

C. Experimental Results

Fig.2 shows how well our technique performed on two datasets. K is assigned to a value between [3,5,7,10]. We establish the given target region range of the target geographic centre or location in order to ascertain whether a user actually wishes to check in the specified region or not. The visiting regional probability is computed using the region range. The target centre or location's radius is predetermined for our research. FIG. 2 shows

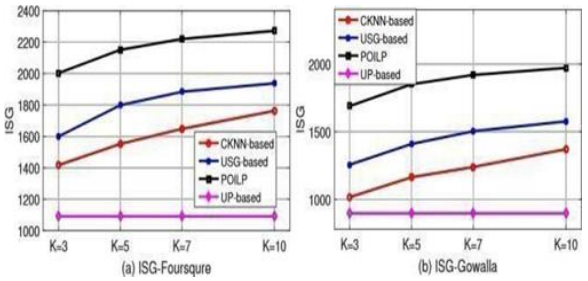

Fig. 3: Influence Scope Gain for Different Methods

Algorithms with β = {0, 0.3, 0.5, 0.7, 0.9, 1} on two datasets. β = 0represents users are only influenced by POI preferences; β 1 represents users are only influenced by spatial distance. In Fig. 2, we know ISG with β = 0.3 is the maximum. The performance of β = 0.5 is closed to β = 0.3. As our method is based on both geographical and topic influence, we give the two aspects of influences the same weight. Thus, this paper sets β = 0.5 throughout the following experiments. Our approach has significant advantages in the aspect of ISGunder the lists of recommended POIs in Fig.3. In Fig.4, UP- based

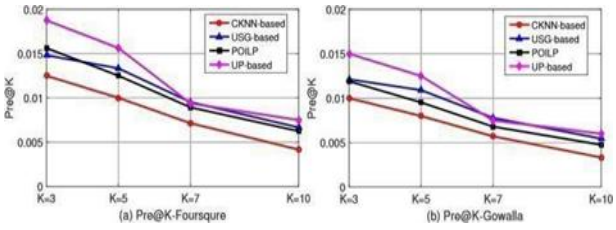

Fig. 4: Pre@K for Different Methods

Compared to the other methods, method produces more accurate recommendations. The UP-based method's suggestion performance is better because it is primarily focused on the target user's preferences. Our method outperforms the CKNN-based method in terms of recommendation precision, while POILP and USG-based methods have similar levels of recommendation precision. Recall ratio comparison results are shown in Fig. 5.

The USG-based, UP-based, and POILP methods are all superior

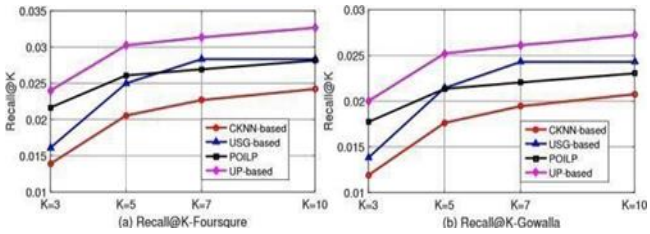

Fig. 5: Recall@K for Different Methods

than the CKNN-based approach. These findings show that the recall ratio of our suggested method and the USG-based method are comparable. The efficiency of our method is marginally lower than the UP-based method since it is based on both geographical and topic-aware impact. But most all, our POILP's ISG out performs cutting-edge techniques.

IV. CONCLUSIONS

We discussed the issue of location advertising in LBSNs in this study. The issue is framed as one optimization problem, specifically an ISG maximisation problem under a specific POI category. The Experimental analysis demonstrates that, in terms of location promotion, our strategy greatly outperforms other cutting-edge methods in terms of POI suggestion.

V. ACKNOWLEDGMENTS

We sincerely thank our guide Mr. Rahul Khokhale for his guidance and constant support and also for the stick to our backs. We also thank the project coordinators for arranging the necessary facilities to carry out the project work. We thank the HOD, Dr. Sangeeta Vhatkar, the Principal, Dr. B. K. Mishra, and the college management for their support.

Abstract—**Accurate and automatic computer system for classification of brain MRI images is very much needed in todays era in the medical field for analysis and prediction of the diseases. Since the invention of MRI scanning system many researchers have developed and presented numerous methods for systematic disease detection. This examination work exhibited another system of order for MRI Brian image in two kinds, for example, ordinary (normal) and irregular (abnormal). In this framework right off the bat discrete wavelet transform is applied on pictures for significant trademark extraction, at that point, the standard segment investigation method is utilized to expel the repetitive information, at last, it gives the measurement diminished element vectors. These highlights at that point given as a contribution to a portion support vector machine for the order of images. In this work, seven normal cerebrum infections pictures are considered as irregular. Altogether 160 MRI pictures have alluded for preparing and testing the framework. This proposed system is tried with four sorts of SVM pieces, and it is discovered that the SVM-GRB portion outflanks the arrangement and its precision is 99.38%.**

I. INTRODUCTION

Magnetic resonance imaging (MRI) technique is very important tool in medical field for detailed analysis of human body, it produces high resolution images of the anatomical structures, specifically in the brain, and generates rich information for disease diagnosis as well as for further research work [1–3]. The computer oriented automatic and perfect classification of the brain MRI images plays a major role in diagnosis of brain related diseases, specifically brain tumors [5–8].

Because of its multi-goals expository property, wavelet change can be utilized for include extraction from MR cerebrum pictures, as it gives the office to examination of pictures of different goals. Along these lines, it is computationally costly and requires enormous sum stockpiling [9]. The chief part examination (PCA) was utilized to lessen the element vector measurements and to improve the discriminative power [10]. PCA hence diminishes the computational expense of dissecting new information as it viably lessens the dimensionality of the information [11]. At that point, the information arrangement issue emerges .Many scientists have proposed different ways to deal with accomplish this objective, which can be separated into two classifications. The first is administered characterization, with help vector machine (SVM) [12] and k-Nearest Neighbors (k-NN) [13] and the other is unaided arrangement [14], with self-association highlight map (SOFM) [12] and fuzzy c-means [15]. The unaided classifier has lower execution than regulated one as far as grouping precision . Be that as it may, the grouping exactnesses of most existing techniques were lower than 95%, so the point of this paper is to locate an increasingly precise strategy. The regulated strategies for grouping, the SVMs depend on AI hypothesis [16–18]. Contrasted and different techniques, for example, counterfeit neural system, choice tree, and Bayesian system, SVMs have noteworthy favorable circumstances as it needn't bother with countless preparing tests to stay away from over-fitting [19].

In this paper, the portion SVMs, which stretches out unique straight SVMs to nonlinear SVM classifiers is created. This rendition of SVM classifier is acquired by applying the bit capacity which replaces the dab item structure in the first SVMs [20]. The change might be nonlinear and the changed space high dimensional; however the classifier is a hyperplane in the high-dimensional element space, it might be nonlinear in the first info space. The KSVMs enable us to fit the most extreme edge hyperplane in a changed component space [21].

II. PREPROCESSING

This proposed method consists of following steps:

1. Pre-processing of image
   a. feature extraction
   b. feature reduction;
2. Training the kernel Support vector machine classifier
3. Testing the new MRI image on the trained kernel SVM, for classification.

The detail schematic of the work is shown in Fig.1 as a standard classification method [22].

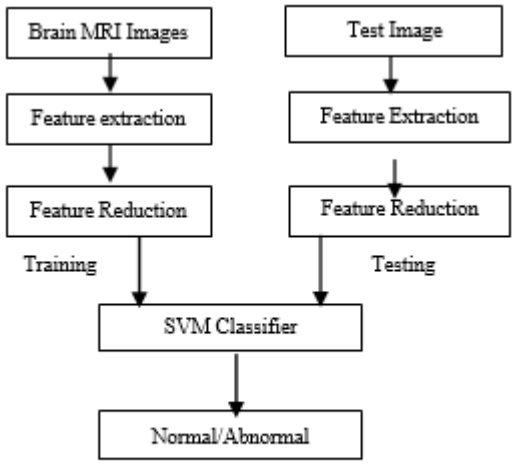

Fig. 1. Methodology of our proposed algorithm.

A. Feature Extraction

The Fourier transform is utilized for signal investigation, which separates a period space signal into constituent sinusoids of various frequencies. This changes the sign from time area to recurrence space. As FT has a disadvantage of disposing of the time data of the sign. Therefore, the nature of the grouping diminishes as time data is lost. Breaking down just a little segment of the sign at a time is called windowing or brief time Fourier change (STFT), utilized by Gabour [23]. It includes a window of a specific shape to the sign. STFT gives some data about both time and recurrence area however the accuracy of the data is constrained by the size of the window. The following stage is Wavelet change (WT): a windowing system with variable size. It jams both time and recurrence data of the sign. Another advantage of WT is that it produce rather than a time-frequency view of the signal. A time-scale view is a more natural and powerful way, because compared to "frequency", "scale" is commonly used term.

B. Discrete Wavelet Transform

The discrete wavelet transform (DWT) developed with the help of dyadic scales and positions which makes it powerful for implementation of the WT [24].

The important aspects of DWT are given as follows. Suppose x(t) is a square-integrable function, then the continuous WT of x(t) relative to a given wavelet ψ(t) is defined as.

$$W\psi(a,\ b) = \int_{-\infty}^{\infty} x(t)\psi a,b(t)dt \quad (1)$$

where

$$\psi_{a,b}(t) = \frac{1}{\sqrt{a}}\psi\left(\frac{t-a}{b}\right) \quad (2)$$

Here, the wavelet ψa,b(t) is calculated from the parent wavelet ψ(t) by translation and dilation: a is the dilation factor and b the translation parameter (both real positive numbers).

The most basic and important wavelet is the Harr wavelet, which is the simplest one and often the preferred wavelet in a lot of applications [25–27].

Equation (1) can be discretized by restraining a and b to a discrete lattice (a = 2b & a > 0) to give the DWT, which can be expressed as follows.

$$ca_{j,k}(n) = DS\left[\sum_n x(n)g_j^*(n-2^jk)\right]$$
$$cd_{j,k}(n) = DS\left[\sum_n x(n)h_j^*(n-2^jk)\right] \quad (3)$$

where caj,k and cdj,k refer to the coefficients of the approximation components and the detail components, respectively. g(n) and h(n) denote for the low-pass filter and high-pass filter, respectively. j and k represent the wavelet scale and translation factors, respectively. DS stands for down-sampling. Equation (3) is the fundamental of wavelet decomposes. It decomposes signal x(n) into two signals, the detail components cd (n) and the approximation coefficients ca(n). This is called one-level decompose.

The process of wavelet decomposition is depicted with the help of decomposition tree, as shown in Fig.2. The above down sampling process can be iterated with successive approximations being decomposed in all turn, so that one signal is down sampled into many levels of resolution.

C. 2D DWT

In case of 2D images, the DWT is applied to each dimension separately. Fig.3 shows the schematic diagram of 2D DWT which results in 4 sub-band (LL, LH, HH, and HL) images at each scale. The sub-band LL is used for next 2D DWT.

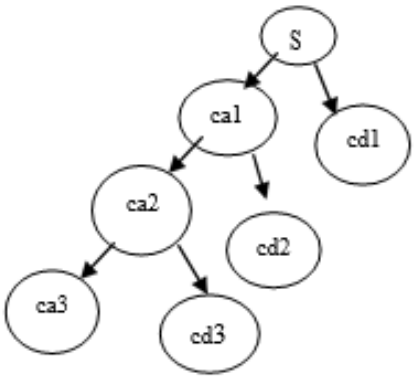

Fig. 2. A 3-level wavelet decomposition tree.

An image is segmented in various sub bands, the LL subband can be approximation component of the image, while the LH, HL, and HH are high frequency components of the image. As the level of decomposition increased, but coarser approximation component was

obtained. Wavelet transform gives a simple hierarchical framework for interpreting the image information. In this algorithm, level-3 decomposition is done via Haar wavelet which was utilized to extract features.

In this system symmetric padding method [28] was utilized to calculate the boundary value. When we filter the image, the mask will extend beyond the image at the edges,

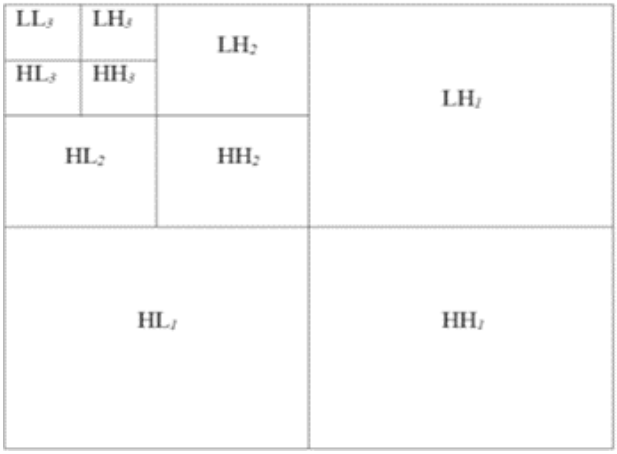

Fig. 3. 2D DWT decomposion

so the solution is to pad the pixels outside the images. As the border distortion is a technique issue related to digital filter which is commonly used in the DWT.

D. Feature Reduction.

Exorbitant highlights make characterization progressively muddled just as increment calculation times and capacity memory. It is required to diminish the quantity of highlights. PCA is best to diminish the element of an informational collection. It is accomplished by changing the informational collection to another arrangement of requested factors as indicated by their differences or importance. PCA comprising of countless interrelated factors while holding the vast majority of the varieties. This works by three way first, it orthogonalizes the segments of the info vectors so uncorrelated with one another, second requesting of the subsequent symmetrical parts so that those with the biggest variety start things out, lastly takes out those segments with least variety in the informational index.

III. KERNEL-SVM

The appearance of the support vector machine (SVM) is a milestone inside the subject of the framework contemplating. The gifts of SVMs incorporate inordinate exactness, rich numerical tractability, and direct geometric elucidation [29]. As of late, two or three ventured forward SVMs have developed quickly, among which the part SVMs are the most well known and successful. Piece SVMs have the accompanying advantages [30]: (1) well working by and by and have been surprisingly fruitful in such various fields as common language arrangement, bioinformatics and pc inventive and judicious; (2) have barely any tunable parameters; and (3) preparing routinely involves raised quadratic advancement [31]. Subsequently, arrangements are worldwide and for the most part explicit, as needs be keeping off the assembly to close by minima displayed by methods for various factual acing structures, comprehensive of neural systems. Information is seen as a p-dimensional vector, and our undertaking is to make a (p 1)- dimensional hyperplane. One sensible decision as the best hyperplane is the one that speaks to the biggest contrast between the two classes, for better conduct because of concealed information during preparing, i.e., better characterization.

Hence, in this work the hyperplane method is used so that the distance from the computed classification line to the closest sample data point on each side is maximized [32]. Fig. 4 shows the schematic of linear SVMs, where H, H1, H2 are three hyper planes lines, it can classify the two classes successfully, however, but H1 and H2 does not have the largest margin, so they will not give good results to new test data. The H hyperplane has the maximum difference value to the support vectors, so it is selected as the best vector for classification [33].

A. Principles of Linear SVMs

Given a p-dimensional N -size training dataset of the form

$$\{(xn, yn)|xn \in Rp, yn \in \{-1, +1\}\}, \quad n = 1, \ldots, N \quad (4)$$

where yn is either - 1 or 1 corresponds to the class 1 or

2. Each xn is a p-dimensional vector. The maximum-margin hyperplane which divides class 1 from class 2 is the support vector machine we want cconsidering that any hyperplane can be written in the form of

$$w \cdot x - b = 0 \quad (5)$$

where it denotes the dot product and w the normal vector to the hyperplane. It is needed to choose the w and b to maximize the margin between the two parallel (as shown in Fig. 5) hyperplanes as large as possible while still separating the data. So we define the two parallel hyperplanes by the equations as

$$w \cdot x - b = \pm 1 \quad (6)$$

In this manner, the errand can be changed to an improvement issue, i.e., we need to amplify the separation between the two parallel hyperplanes, subject to avoid information falling into the edge.

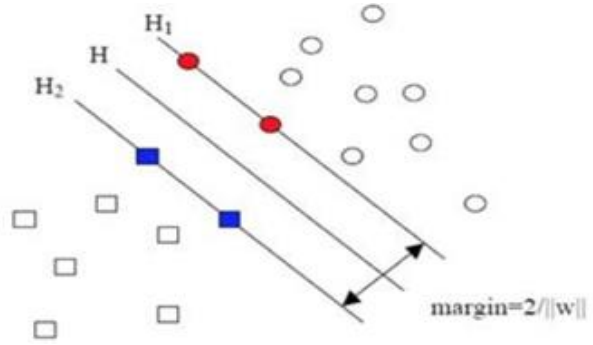

Fig. 4. Schematic of linear SVMs (H denotes for the hyperplane, S denotes for the support vector) [43].

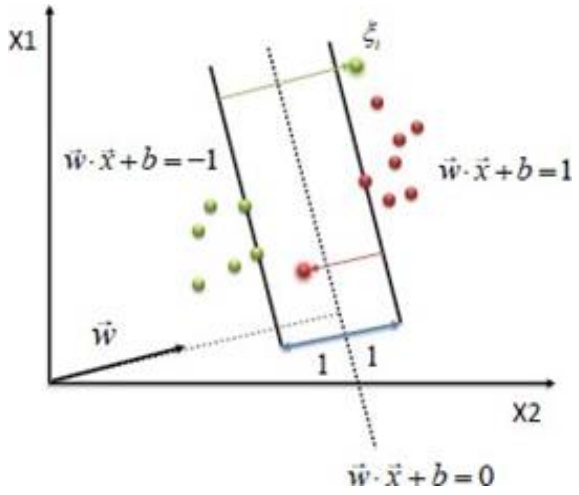

Fig. 5. : The concept of parallel hyperplanes (w denotes the weight, and b denotes the bias).

Using simple mathematical knowledge, the problem can be formulated as:

min ||w||

w,b

s.t. yn (w · xn − b) ≥ 1, n = 1, . . . , N (7)

In practical situations the ‖w‖ is usually be replace by

min 1 ‖w‖2

w,b 2

s.t. yn (w · xn − b) ≥ 1, n = 1, . . . , N (8)

The reason is that the ||w|| is involved in a square root calculation. After it is lowered with formula (8), the solution will will remain as it is, but the problem is altered into a quadratic programming optimization that is easy to solve by using Lagrange multipliers [34] and standard quadratic programming techniques and programs [35, 36].

Regular SMVs gives a hyperplane to classify data, so it cannot deal with classification problem of which the different types of data located at different sides of a hypersurface, the kernel strategy is applied to SVMs [37]. This algorithm is similar, except that every dot product is replaced by a nonlinear kernel function. The kernel is related to the transform ϕ(xi) by the equation k(xi, xj) = ϕ(xi)ϕ(xj).

The value w is also in the transformed space, with

w =∑ i αiγiϕ(xi).

Dot product with w for classification can be computed by

w · ϕ(x)=∑ i αiγik(xi, x).

By the other side KSVMs allow to fit the maximum-margin hyperplane in a transformed feature space. The transformed space is higher dimensional and the transformation may be nonlinear and; thus though the classifier is a hyperplane in the higher-dimensional feature space, it may be nonlinear in the original input space. For each kernel, there should be at least one adjusting parameter so as to make the kernel flexible and tailor itself to practical data. Three common kernels [38] are listed in Table 1.

TABLE I.THREE COMMON KERNELS (HPOL, IPOL, AND GRB) WITH THEIR FORMULA AND PARAMETERS.

Name	Formula
Homogeneous Polynomial	$k(xi, xj) = (xi \cdot xj)^d$
Inhomogeneous Polynomial	$k(x_i, x_j) = (x_i \cdot x_j + 1)^d$
Gaussian Radial Basis	$k(x_i,x_j)=\exp-\gamma\|\|x_i.x_j\|\|$

IV. CROSS VALIDAION

As for training of classifier some data set is used, so there is possibility to achieve high accuracy for classification only for this training dataset not yet other independent datasets. For this overfitting avoidance, we need to incorporate cross validation into our method. Cross validation will not improve the final classification accuracy, but it will make the classifier reliable and can be generalized to other independent datasets. Cross approval incorporates three sorts of strategies: Random subsampling, K-fold cross approval and forget about one approval. The K-overlay cross approval is executed because of its straightforwardness, effortlessness, and utilizing all information for preparing and approval. The philosophy is to make a K-fold segment of the entire dataset, K times rehashed to utilize K- 1 folds for preparing and a left overlay for approval, and finally, the normal mistake is determined for K tests.

The K folds might be absolutely haphazardly partitioned, as, a few folds may have been dispersed differently when contrasted with different folds. Subsequently, stratified K - crease cross approval was actualized, in which each overlay has appropriated about in comparative classes [39]. The following test is to locate the number of folds. In the event that K is set excessively enormous, the calculation will be tedious on the grounds that the inclination of the genuine mistake rate estimator will be little, and the change of the estimator will be huge. On the other hand, if K is set excessively little, the fluctuation of the estimator naturally turns out to be little, yet the inclination of the estimator will be enormous, henceforth the calculation time will diminish, [40]. In this study, initially K is determined as 5 for working on trial-and-error basis, which means that with increasing step as 1and if parameter K varying from 3 to 10, we can train the SVM by each value. At the end we will select the optimal value of K belonging to the highest classification accuracy.

V. EXPERIMENTAL RESULTS

A. Databaset

The datasets used for experimentation consists of brain MRI images having resolution 256 by 256. The abnormal brain MRI images of the dataset consist of the seven types of diseases viz: glioma, meningioma, Alzheimer‟s disease, Alzheimer‟s disease plus visual agnosia, Pick‟s disease, sarcoma, and Huntington‟s disease. The samples images of each disease are given in Fig. 6. The confusion matrix for training and validation purpose of images is given in Table 2.

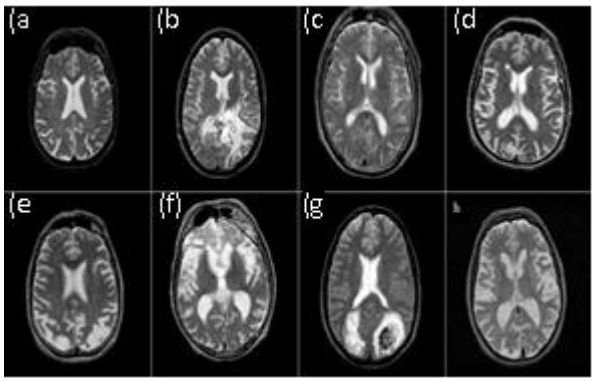

Fig 6 :Sample of MRI images: (a) normal brain; (b) glioma;(c) meningioma; (d) Alzheimer‟s disease; (e) Alzheimer‟s disease with visual agnosia; (f) Pick‟s disease; (g) sarcoma; (h) Huntington‟s disease[43].

B. Feature Extraction

To extract features from MRI images. wavelet transform is applied to the third level, it gives different characteristics, first level transform is shown in Fig. 7. The approximate coefficient matrix is used for input to get the prominent features only.

C. Feature Reduction

After getting the approximate wavelet coefficient image, PCA is applied to reduce the dimensions of features.

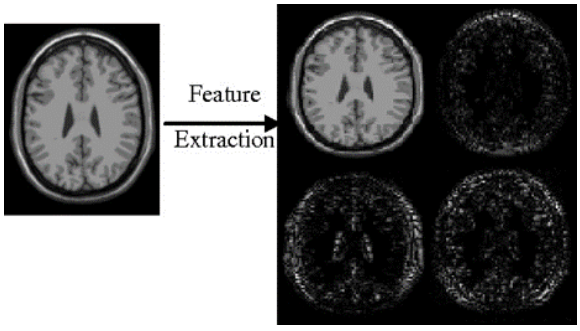

Fig 7: The procedures of 1-level 2D DWT: Brain MRI; level-1 wavelet transformed coefficients.

TABLE II. CONFUSION MATRIX OF OUR DWT+PCA+KSVM METHOD (KERNEL CHOSE LIN, HPOL, IPOL, AND GRB [13].

LIN	Normal(O)	Abnormal(O)
Normal (T)	17	3
Abnormal (T)	5	135
HPOL	Normal(O)	Abnormal(O)
Normal (T)	19	1
Abnormal (T)	4	136
IPOL	Normal(O)	Abnormal(O)
Normal (T)	18	2
Abnormal (T)	1	139
GRB	Normal(O)	Abnormal(O)
Normal (T)	20	0
Abnormal (T)	1	139

D. Classification Accuracy

SVM is tested with four different kernels (LIN, HPOL, IPOL, and GRB). Result indicates that the case of using linear kernel, the KSVM degrades to original linear SVM Hundreds of simulations are computed in order to estimate the optimal parameters of the kernel functions, such as the order d in HPOL and IPOL kernel, and the scaling factor γ in GRB kernel. The confusion matrices of our methods are listed in Table 2. The element of ith row and jth column represents the classification accuracy belonging to class i are assigned to class j after the supervised classification. The empirical study shows that the proposed combined DWT+PCA+KSVM method obtains good results on training and validation ofimage data. For LIN kernel, the classification accuracy is 94.58%; for HPOL kernel, it is 96.88%;for IPOL kernel, it is 98.12%; and for the GRB kernel, it is 99.38%. It indicates that, the GRB kernel based SVM is giving better results than other three kernels These methods are compared with other techniques given in literature like DWT+SOM [12], DWT+SVM with linear kernel [12], DWT+PCA+ANN [41], DWT+PCA+k NN [41]. The comparative results are shown in Fig. 8. It indicates that the method DWT+PCA+KSVM with GRB kernel performed best than other ten methods.

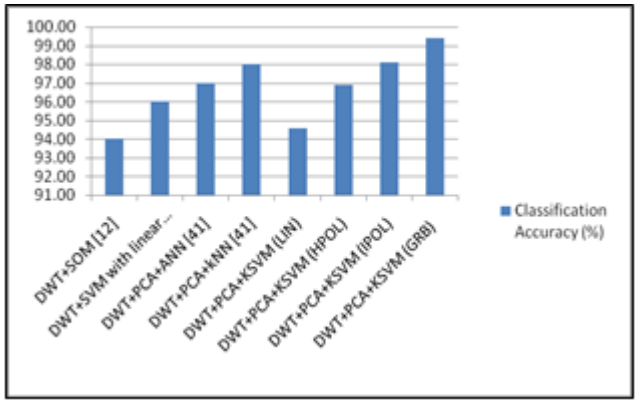

Fig 8: The comparative results of the existing systems(first four) with implemented methods (las four).

VI. CONCLUSION AND DISCUSSION

There are many techniques developed based on wavelet transforms, PCA, and kernel SVMs. The wavelet transform extracts the features from brain MRI images. The major contribution of this research paper is to present a novel method which uses DWT+PCA+KSVM for classification of normal MRI or abnormal MRI images. Four different SVM kernels as LIN, HPOL, IPOL and GRB are implemented. The experimental results indicates that the SVM-GRB kernel gives 99.38% classification accuracy on the dataset. It is better than the other existing techniques.

Abstract: **The Vehicle Routing Problem (VRP) is multi-objective optimization problem. The main objective of vehicle routing problem is to determine the set of optimal routes for the number of vehicles to service the group of customers. In this paper, we have selected the Capacitated Vehicle Routing Problem (CVRP) with objectives to minimize the total travelled distance and number of vehicles which are used in the tour. We applied Non-dominated Sorting Genetic Algorithm - II (NSGA-II) for the selected capacitated vehicle routing problem. The proposed work has been tested on standard VRPLIB instances. The computational results obtained are nearer to the standard optimal solutions.**

Keywords: Capacitated Vehicle Routing Problem, NSGA-II, Multi-objective Optimization, VRPLIB

I. INTRODUCTION

In supply chain management, logistics and transportation are major problem in product delivery. The vehicle routing problems are one of the NP- hard problems in the transport and distribution [1]. The vehicle routing problem (VRP) is similar to Traveling Salesperson problem (TSP). The primary objective of vehicle routing problems is to find the smallest set of routes, means to minimize total travel costs or total distance. All vehicles must have fixed load and some limited time window in which vehicle needs to fulfill the customer's request [2].

The objective of Capacitated Vehicle Routing Problem (CVRP) is to minimize the total travelling distance, and does not consider loading procedure in optimization. The classic model of CVRP is customer's demands are transfer in vehicle, when transferring a customer's demand d is greater than total capacity Q, then new vehicle is selected for further operation, and the whole d, is transfer into the new vehicle. This procedure continues, until all customer's demands are loaded in vehicle. In the CVRP, we can consider the transfer procedure in different way to reduce the number of vehicles [3].

There are various metaheuristics approaches to solve capacitated vehicle routing problem such as Genetic Algorithms, Ant Algorithms, Deterministic Annealing, Constraint Programming, Tabu Search, 2-Phase Algorithm, Simulated Annealing and Constructive Methods, etc. [4]. In [5] Enrique Alba et al. introduced cellular genetic algorithm (cGA), where the search model work with static and dynamic decentralization in which individuals are allocated in a particular topology and interact only with their neighbors. This approach improves the efficiency and accuracy of the existing results found in the literature. In [6] Ilgaz Sungur et al. proposed a robust optimization approach to solve the selected multi-objective problem such as VRP. This technique gives the routes that reduces the total vehicle costs and satisfy all customer requests in given constraints. The authors show that robust optimization is an effective developing routing problems including uncertainty as it does not contain distribution hypothesis on the basis of uncertainty or a cumbersome represents based on this technique. In [7] Maryam Razavi et al. have proposed ant colony approach to solve capacitated vehicle routing problem. In this paper two objectives are considered like minimize total distance and number of used vehicles. Ant colony approach evaluated using Solomon's standard benchmark problems.

Other heuristic approaches, were presented by Christodes [8], Toth and Vigo [9], Bodin et al. [10], Golden et al. [11], Fisher [12] to solve CVRP.

There are different datasets available to solve capacitated vehicle routing problem. There are three types of Solomon instances such as random, clustered and mix of both random and clustered. The geographical data are randomly generated, the instances R1 and R2 are random data, C1 and C2 instances are clustered data, and RC1 and RC2 instances are mix of both random and clustered structures. The instances R1, C1 and RC1 have a small scheduling problem and they allow only a few customers per route (around 5 to 10). In opposite, the instances R2, C2 and RC2 have a large scheduling problem and allow many customers (greater than 30) to be services

by the same vehicle. Researchers have considered below 100 customers as a small scale datasets and more than 100 customers considered as a large-scale dataset. The standard VRPLIB data set contains different instances. In this paper, we have used instance from VRPLIB dataset with 22 customers and maximum capacity 6000.

This paper presents application of Non-dominated Sorting Genetic Algorithm – II to solve multi-objective capacitated vehicle routing problem. This algorithm was proposed by researchers to eliminate the drawbacks of NSGA, particularly its non-elitist behavior and properties of the sharing parameter. The NSGA-II sorts the non-dominated individuals in the population same as in NSGA, and individuals ranked based on this process. The new selection process introduced in NSGA-II algorithm,

called tournament selection, where selection process is done based on crowding distance. To implement elitism, the offspring and parent population are combined and the non- dominated individuals from the combined population are considered to the next generation [13].

II. RELATED WORK

In [14] Ricardo Fukasawa et al. proposed Robust Branch-and-Cut-and-Price algorithm to solve the Capacitated Vehicle Routing Problem. They obtain lower bounds by using Lagrangean relaxation. This algorithm give the better performance as compared to existing results found in literature. In this paper CVRP contains equality and non-equality constraints to satisfy the objective function. The computational results show that the new lower bound is better than existing bound when the number of vehicle are more.

In [15] Habiheb Nzif et al. implemented genetic algorithm to solve CVRP. This algorithm uses new crossover operator designed by undirected graph to find the minimum routes to satisfy the requirement and to minimize overall transportation cost. The proposed work tested on benchmark instances and compared with other heuristics technique and they found that this technique is better than previous technique in the literature.

In [16] Alkin yurtkuran et al. proposes hybrid electromagnetic-like algorithm (HEMA) and it is based on population-based techniques. This algorithm improves the local search method and tested on benchmark instances. This algorithm proposed to minimize the travelling cost and minimize the distance. This algorithm is tested on Solomon datasets to obtain the best results. HEMA algorithm is very useful and compatible as compared to classical metaheuristics techniques. This algorithm requires more time to reduce the computational efforts.

In [17] Chou-Yuan Lee et al. implemented the framework known as enhanced ant colony optimization. This technique has advantages of simulated annealing and ant colony optimization. The simulated annealing technique provide good solution for ant colony optimization. This paper gives the better solution as compared with ant colony optimization algorithm. The objective of CVRP is to minimize the cost of vehicles with restrict capacity. The simulated annealing separately implemented on 14 small scale instances and 20 large-scale instances. The small-scale instances give the better performance than large scale datasets.

In [18] Glaydston Mattos Ribeiro et al. proposed large neighborhood search heuristic technique to implement CCVRP problem. The objectives of CCVRP are to minimize all customer's arrival time including the total travelling costs. This heuristic technique applied to standard benchmark instances and compared with two memetic algorithms. This technique gives optimal solution as compared to existing results found in the literature.

In [19] RanLiu et al. focuses on mathematical modeling and graph model for selected problem. The objective of selected problem is to optimize the empty vehicle. The authors take this problem as a large-scale problem. The proposed algorithm gives the two-phase method first phase method give the directed cycles and second phase created chains that makes the cycles. The performance of vehicle distance span and the location of the vehicle is explored.

In [20] Gilbert Laporte et al. implements the CVRP with stochastic demand in that minimize the cost of required routes. They give penalty for failure related to the return depot constraints. This paper implements the new lower bound with including failure for constraints. This problem implemented on 100 customer's instances and some vehicles. The proposed approach is heavily dependent on large bound and generate more effective lower bounds. This problem is taken into the large-scale problem and difficult to solve it.

In [21] Silvia Mazzeo et al. considered Ant Colony Algorithm with VRP. The objective of the selected problem is to minimize the weight of each vehicle that are loaded. This algorithm is based on mataheuristics techniques and gives the competitive results as compared with other heuristics solved by CVRP. The ACO technique gives the better performance up to 50 nodes.

In [22] Angel A. Juan et al. authors proposed SR- GCWS to solve selected VRP problem. The objective of selected problem is to minimize the vehicle and minimize the distance with satisfy the customer request. This algorithm is implemented on small and large scale datasets. 100 customers are included in small instances and more than 100 customers is gives large-scale dataset. This algorithm gives best solution compared with other benchmark problems.

From the above literature, we found that heuristics techniques are mostly used to solve selected problem. The primary objective of CVRP is to minimize the distance and other objective is depend on different capacitated problem.

III. PROBLEM DEFINITION

The objectives of CVRP are first to minimize the total travelling distance and second objective is to minimize distribution vehicles.

The vehicle can be divide in three sets V: $V0 = \{V0|\ d0 = 0\}$, $Vs = \{Vi|\ 0 < di \leq Q\}$, $VL = \{Vi|\ di > Q\}$, where $V0$is initialize depot,$VL$is the group of customers with large capacity and $Vs$is the group of customers with small capacity. The demand of each customer in VLmust be divide for transportation. These customers were served more times by different other vehicles. Each customer in Vs they not allow to divide their capacity, it allow the customer is services only one time by a vehicle. The total customers' capacity of each route should not be greater

than total capacity Q. The vehicles start and end with same depot [3].

pik denotes the ratio that belongs to customer i transported by vehicle k to dv , $0 \leq pik \leq 1$.

cij denotes the travelling distance between customer i and customer j.

xij =1 represents the vehicle k leaches from coordinate i to coordinate j, otherwise $xij = 0$

The mathematical model of CVRP is the follow [3]:

$$\min \ |Veh| \quad (1)$$

$$\min \sum_{k \in Veh} \sum_{j \in V} \sum_{i \in V} c_{ij} x^k_{ij} \quad (2)$$

Subject to

$$\sum_{k \in Veh} \sum_{j \in V/\{V_0\}} x^k_{0j} = K \quad (3)$$

$$\sum_{i \in V/\{V_0\}} x^k_{0j} = 1 \quad k \in Veh \quad (4)$$

$$\sum_{i \in V} x^k_{ih} - \sum_{j \in V} x^k_{hj} = 0 \quad h \in V/\{V_0\}, k \in Veh \quad (5)$$

$$\sum_{k \in Veh} p_{ik} = 1 \; i \in V_L \quad (6)$$

$$p_{ik} = \begin{cases} 1, & transported\ by\ vehicle\ k \\ 0, & otherwise \end{cases}$$

$$i \in V_s, k \in Veh \quad (7)$$

$$\sum_{i \in V/\{V_0\}} d_i p_{ik} \leq Q \qquad k \in Veh \quad (8)$$

$$\sum_{j \in V} x^k_{ji} \geq p_{ik} \qquad k \in Veh, i \in V/\{V_0\} \quad (9)$$
