where equation (1) is the objective function to minimize no. of vehicles K = $|Veh|$, whendiless than Q then capacity cannot be divide, the second function is to minimize the total travelling distance of all vehicles, and it is denoted by equation(2), equation (3) to (9) are conditions (constraints), equation (3) represents that K number of vehicles depart from the initial depot, equation (4) it allow exactly one upcoming node for each vehicle leaving from the initial depot, equation (5) represents is relationship between constraint, equation (6) represents the capacity of the customer in VL must be satisfy, equation (7)denotes the capacity of the customer in Vs is transferred by a vehicle, equation (8) denotes that the total quantity transfer by each vehicle is not greater than the whole capacity, and equation (9) represents that each customer is visit the vehicle and those customer will be selected.

IV. NSGA-II ALGORITHM

A general NSGA-II procedure to be implemented in routing problem is considered in the below steps, which is given in [13]:

Step 1: Generate a random parent population $Pt$of size N.

Step2: Sort the random parent population based on non-domination sort.

Step3: For each non-dominated solution, assign a rank equal to its non-domination level (1 is the best level, 2 is the next best level, and so on).

Step 4: Create offspring population,Qt of size N using selection, crossover and mutation operators.

Step 5: From the first generation, onwards, creation of each new generation considers the following steps:

a) Create the new population Rt of size 2N by combining the parent population $Pt$and the offspring population Qt.

b) Sort the new population Rt according to the fast non dominated sorting procedure to find all non-dominated fronts (F_1 , F_2 , F_3 , ... F_l)

c) Generate the new parent population Pt+1 of size N by adding non-dominated solutions starting from the first ranked non-dominated front F1. When the total non-dominated solutions greater than the population size N, avoid some of the lower ranked non- dominated solutions. This is achieved by sorting process which is based on the crowding distance

d) Perform selection, crossover and mutation operators on the newly generated parent population Pt+1 to create the new offspring population Qt+1 of size N

Step 6: Repeat Step 5 until the maximum number of iterations is reached.

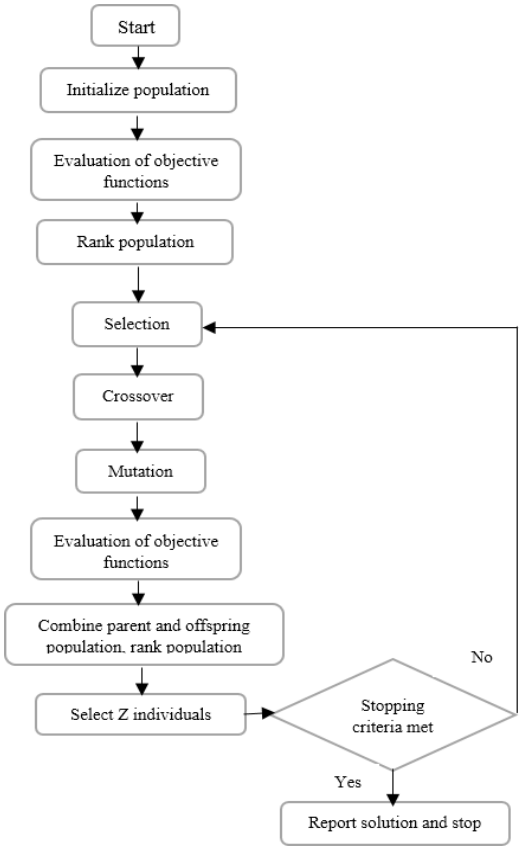

Fig 1: The Flowchart: NSGA-II Algorithm

V. RESULTS and DISCUSSION

The proposed work tested on VRPLIB E022.dat small scale instance set from Solomon's VRP data set. In E022 instance set, customer's id, x and y position, delivery demand is given. This dataset contains 22 customers and maximum capacity = 6000.

TABLE I

SATISFACTORY SOLUTION OF E022 FOR CVRP PROBLEM

Vehicles	*Customers*	*Distance (kms)*	*Capacity*	*Sequence*
1	8	159	5600	1→18 →16 →13 →8 →9→ 14→ 6 →10 →1
2	5	107	4500	1 →20→ 12 →4 →21 →11 →1
3	5	240	4400	1→22→ 7 →17→ 5 →3→ 1
4	3	101	1600	1 →2 →15→ 19→ 1

In table 1, we can see that 4 vehicles are used to travel and visit all customers. This result contains distance of each route and capacity of each vehicle and sequence of each route. This results have been obtained after 1000 iterations.

The Table II contains average results taken after 20 runs.

TABLE II

RESULTS FOR E022 INSTANCES FOR CVRP

No. of Iterations	*Total traveling Distance (kms)*	*Vehicles*
500	611	3
1000	671	4
1500	637	3
2000	631	4
2500	589	4
3000	568	4
3500	546	4
4000	520	3
4500	499	4
5000	470	3

The table II contains the no. of iterations with respect to distance and no. of vehicle that have been used. This results show that when number of iteration increases then results goes near to the optimal.

The graph is plotted based on table II. It shows convergence rate.

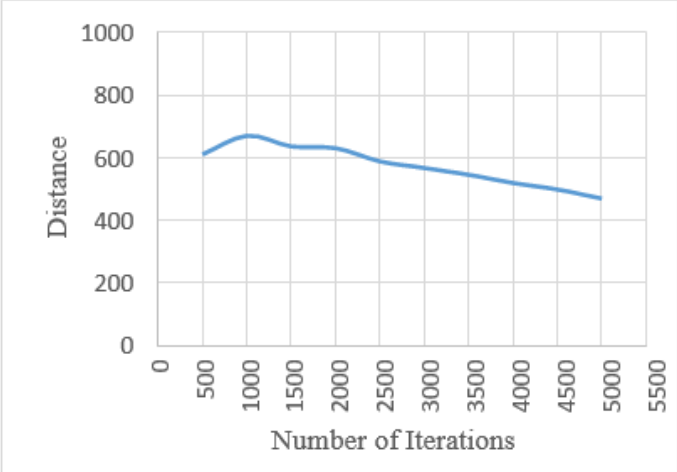

Fig 2: Convergence Graph

VI. CONCLUSION

In this paper a capacitated vehicle routing problem is solved using NSGA-II algorithm. The NSGA-II algorithm minimizes the total distance and number of distribution vehicles. The computational results show that when number of iterations increased then total distance is minimized. The obtained solution of selected CVRP problem is nearer to the optimal solution of E022 instance set of VRPLIB. In future modified NSGA-II algorithm can be proposed to solve the selected CVRP to obtain better solution. Also, the NSGA-II can be proposed to solve large size CVRP on multi-core or many-core systems.

Digitization and Storage of Personal and Public Records in Open Standard Storage Format

Prathamesh Awati, Aditya Khandelwal, Mrs. Swati Abhang, Ramkrishna Maurya
Information Technology Department, Thakur College of Engineering & Technology, Mumbai
awatiprathamesh8@gmail.com, Aditya.khandelwal2001@gmail.com, Swatiabhang@gmail.com, ramkrishnamaurya732@gmail.com

Abstract — **Digitization is the process of converting any hardcopy or nondigital record into digital format. This can include, among other things, digitizing text, photos, and converting analogue voice recordings to digital media. Records are information that an organization creates, receives, and maintains as evidence, whereas an archive is a document that contains the historical background of the nation and any organization.Our project is split into two phases digitization and storage. The system is designed to digitize any hardcopy or nondigital record into a softcopy or digital record during the Digitization phase. The system enables this by scanning the hard copy with a device with a camera, such as a smartphone. Afterwards, the digitized copy is converted into a specific format. And after the digitization phase, the file must be stored in a safe and secure manner so that it can be easily retrieved anywhere and at any time. To achieve this, we used the IPFS system to store the files. The Inter-Planetary File System (IPFS) is a distributed file storage protocol that enables computers all over the world to store and serve files as part of a massive peer-to-peer network. All files will be securely stored and encrypted using IPFS. Digitization is now a global necessity, and almost every country is attempting to make the transition. Many large- scale businesses and corporations have fully embraced digitization.**

Keyword: Digitization, record, secure, storage, organization, IPFS.

I. INTRODUCTION

Digitization is the process of converting different types of information into a digital format. Records are information that is created, received and maintained by an organization as evidence while an archive is a document that contains historical background for the nation and any organization. The term digitization is the key phrase that describes the process of making an electronic version of a 'real- world' object enabling the object to be stored, retrieved and manipulated on a computer and this is cemented over the internet.

The process of transforming any hardcopy or nondigital record into digital format is known as digitization. This can include digitizing text, photos, and converting analogue voice recordings to digital media, among other things. Many challenges inside an organization can be addressed through digitization. We have the option of implementing the digitization program in a different way depending on the desired goal. The decision to digitize should be founded on a balanced review of company needs, risks, and costs.

II. BACKGROUND

Digitization can address many issues within organization. We have a choice to roll out the digitization program differently looking at the specified outcome. as an example, if disaster preparedness could be a key concern, we may want to focus more of our efforts on digitizing indispensable records. On the either side, if the goal is to produce greater access to public records, it might be important that which records are accessed most frequently and start the digitization process there. Our Project is divided into two main phases, the digitization phase and the storage phase. In the Digitization phase, the system is designed to digitize any hardcopy or a nondigital record into a softcopy or a digital record. After this digitization phase, next is to store that file in a safe and secured way, so that it can be easily retrieved anywhere and anytime, to make this possible we have used the IPFS system for storing the files.

Since Digitization has become a very important and core part of the developing world, the project is very supreme and important for the growing technical world. Everywhere there are traditional paper methods being rejected and people switching to more developed and digitized. This project will play a crucial role in that particular space and fulfil all required needs.

III. OBJECTIVE

The main objective of the project is to create a well-developed system, where people can easily digitize their hardcopy documents and store them in a proper, safe and secured way, so that can be easily accessible from anywhere in the world. Secondly, having a speedy and easy to use interface, so that it can be easily understood the users and they can carry out their tasks in an efficient way. The project has a wide scope in present as well as the future, as these kinds of systems are in very high demand and almost every industry, company, business and even a common man requires these systems in their daily use of work. Also, government companies and government itself are trying to shift to this kind of

systems, as government works are majorly done in papers. So, in future we can make technological and design changes, which can even help government in future.

IV. PROBLEM DEFINITION

All the existing systems have all the available services for storage of files, documents, digitizing documents, or any other type of file but most of the systems do not have a secured way to store the file in the proper storage format. Most of the system use technology to store the data but it does not have a totally secured way of storing files. Taking this into consideration and finding this as a problem, the replacement for this can be a more secured way of storing the files which can be a IPFS system i.e., an Interplanetary File system which is a protocol and peer-to-peer network for storing and sharing data in a distributed file system. IPFS uses content- addressing to uniquely identify each file in a global namespace connecting all computing devices.

The problem is defined as follows:

1) The system into existence does have a totally secured way of storing files.

2) They do not have the facility to store a numerous format of files.

3) File sharing system is weak and are not advanced.

V. RELATED THEORY

IPFS: The Interplanetary File System (IPFS) is a protocol and peer-to-peer network for storing and sharing data in a distributed file system. IPFS uses content-addressing to uniquely identify each file in a global namespace connecting all computing devices. How Data is Stored: Data is stored in chunks of 256 KB, called IPFS objects. Files larger than that are split into as many IPFS objects as it takes to accommodate the file. One IPFS object per file contains links to all of the other IPFS objects that make up that file. When a file is added to the IPFS network it is given a unique, 24-character hash ID, called the content ID, or CID. That's how it is identified and referenced within the IPFS network. Recalculating the hash when the file is retrieved verifies the integrity of the file. If the check fails, the file has been modified. When files are legitimately updated, IPFS handles the versioning of files. That means the new version of the file is stored. How IFPS works: The IPFS decentralized web is made up of all the computers connected to it, known as nodes. Nodes can store data and make it accessible to anyone who requests it. If someone requests a file or a webpage, a copy of the file is cached on their node. As more and more people request that data, more and more cached copies will exist. Subsequent requests for that file can be fulfilled by any node— or combination of nodes— that has the file on it. The burden of delivering the data and fulfilling the request is gradually shared out amongst many nodes. This calls for a new type of web address. Instead of address-based routing where you have to know the location of the data and provide a specific URL to that data, the decentralized web uses content based routing.

VI. LITERATURE SURVEY

1. Stephanie Routhier Perry (2014). Digitization and Digital Preservation: A Review of Literature. This paper focuses more on the difference between digitization and digital preservation. This paper talks about the problem caused in the digitization of the documents into different formats and the problems that occur. Also, it mentioned that data storage is a critical necessity for services that help fulfill the expected requirements of the digital world. Finally, this article exhibited two scenarios of data storage immutability in IPFS and blockchain systems for the storage of large mutual agreements, as well as the blockchain encounter. Although blockchain is a secure system for storing transaction data, there is still a possibility of security breaches.

2. Mathis Steichen, Beltran Fiz, (2018). Blockchain-Based, Decentralized Access Control for IPFS- IEEE Confs on Internet of Things, Green Computing and Communications,

Blockchain, Computer and Information Technology.

This paper addressed the requirement of blockchain applications to share larger files containing sensitive information. It was mentioned, the files cannot be uploaded via unaltered ipfs nodes or efficiently stored on the blockchain. For this reason, it has been considered how to develop and deploy acl IPFS, an access control-focused extension of IPFS built on blockchain technology. A use-case for acl- IPFS has also been described, and experiments have been carried out to demonstrate the system's effects in comparison to the original IPFS. The contact with the blockchain is mostly to blame for the observed extra latency, which has been found to be apparent but unimportant to operations.

3. Mercy Gill, Usha Kakde (2021). Integrating Blockchain and the Interplanetary File System, a resilient platform for storing students' file.

This paper has brief overview of digitization and digital preservation techniques. As well as this paper contain a workflow process for digitization. The main problem stated here is about the steps that are required over the digitization process, which are to be followed. It talks the integration of Blockchain and Interplanetary File system which indeed includes the decentralized system and database to keep a permanent record of information and stores it in consecutive blocks and pattern.

IX. CONCLUSION

Seeing digitization as one of the most important factors in the advanced development of technology and future, it is very much essential to have a very relevant way to digitize. With not only just digitization, security and transparency are two other factor which plays a great role in the future development. Using blockchain and the IPFS system, the factors are included which leads to a perfect build-up of a system which requires a proper stay up of the storage of files which could encrypt and store it securely. Lastly, Digitization is the future and is the effective solution for maintaining transparency, accessibility and timeliness of records.

X. FUTURE SCOPE

Seeing digitization as one of the most important factors in the advanced development of technology and future, it is very much essential to have a very relevant way to digitize. With not only just digitization, security and transparency are two other factor which plays a great role in the future development. Using blockchain and the IPFS system, the factors are included which leads to a perfect build-up of a system which requires a proper stay up of the storage of files which could encrypt and store it securely. Lastly, Digitization is the future and is the effective solution for maintaining transparency, accessibility and timeliness of records.

Generative Adversarial Networks:Theory, Applications,Challenges and Setting Up PyTorch on GPU Using Docker

Amar R. Palwankar, Dr. Rajesh Bansode, Dr. Vinayak A. Bharadi
Thakur college of Engineering and Technology Mumbai India, Finolex Academy of Management and Technology,Ratnagiri, India
amar.palwankar@famt.ac.in, rajesh.bansode@thakureducation.org, vinayak.bharadi@famt.ac.in

Abstract—**GAN stands for Generative Adversarial Networks(GAN) and is one of the most interesting topics in Deep Learning.GAN consist of two parts: Generator and Discriminator. They are in conflict with each other, hence the name "Adversarial"[3].GAN can be used to generate new data from existing data as well as creating images from given words (text-to-image conversion).GAN are a type of deep learning model that can learn how to recreate data with high dimensionality, such as images, audio, video, and textual data[1]. Specialized GAN can also generate 3D objects.The challenge is that GAN can be difficult to train, and existing solutions for better network architectures, functions, and optimization algorithms are not enough to address challenges[1].Hence In this paper, GAN theory ,challenges, applications, future scope and PyTorch based configuration for running code on NVIDIA GPU device are discussed.**

Keywords—Adversarial, deep learning, training, realistic, gpu, pytorch

I. INTRODUCTION

AI systems have the capability to think independently and make decisions based on the current events. Machine Learning is related to AI and Deep Learning is a branch of ML. Deep Learning attempts to imitate how the human brain works. Neural networks within Deep Learning have neurons that take in information and interact with other neurons in order to process it. Training GANs is difficult, because both networks need to find a point where their loss functions are at a minimum. Research is being done to simplify this process.[5]

Generative Adversarial Networks (GANs) is a type of deep generative model that was first introduced in 2014 by Goodfellow[2]. This model is used in various applications to handle complex and high-dimensional data. It works by using two neural networks, a generator and a discriminator, to compete with one another to reach a Nash equilibrium. The generator creates fake data that it then sends to the discriminator, which attempts to determine whether the data is real or created. In the process, the generator tries to learn the probability distribution of the real data. Despite its effectiveness, GANs suffer from several issues such as mode collapse, instability, and non-convergence[1].Adversarial trainingcan be difficult and is often referred to as unstable because there may be times when the generator has difficulty understanding what the desired results should be. This instability can be addressed with different techniques like Laplacian Adversarial Networks, Deep Convolutional Generative Adversarial Networks and Adversarial Gradient Loss Predictors. These provide different ways to help the generator provide the desired results[8].

To try to combat these issues, researchers continue to innovate the design of the network architecture, the choice of loss functions, and the optimization algorithms.In this research paper, the authors look at two common problems in the field of training models: model collapse and non-convergence. They then provide the latest solutions to these issues. The rest of the paper is divided up into various sections, which goes into detail about things like the architectures, principles, and algorithms of Basic GANs, how GANs have been improved, two typical GAN variants, and applications where GANs have been used. The final section is a conclusion of the paper.

II. CHALLENGES IN TRAINING GAN

A. Mode collapse:

GANs are trained on data with multiple parts or models to it, but they often generate limited diversity, meaning they may only create one type of output. This condition is called the "mode collapse problem" and has been the subject of many different studies looking to find a way to fix it[12].

B. Vanishing gradients

When one part of the GAN (the generator or discriminator) has become too dominant, it can lead to a situation where there is not enough learning. This is known as "vanishing gradients," as it can make it hard for the GAN to learn, because it will not be receiving enough input from the discriminator about the legitimate data it should be creating. Lastly, it can be difficult to select the right hyperparameters (such as batch size, momentum and learning rate) which may be necessary for the GAN to effectively learn and generate output[12].

III. BACKGROUND:HOW DOES GAN WORK?

Generator:

The Generator takes random noise created from the training data as input. The training data can be an image and the Generator then tries to create an image which is as close to the real image in the training dataset as possible. The Generator's goal is to create a fake image that is convincing enough to 'fool' the Discriminator.

Discriminator:

The Discriminator is a component of a Generative Adversarial Network (GAN). Its job is to determine which input is real (taken from training data) and which one is fake (generated by the Generator component). In order to do this, it needs to be trained using the training data. The Discriminator is taking input from two sources: the real data from the training data set, and the fake data from the Generator component. It then tries to classify the inputs as either real or fake. If it gets the classification wrong,it results in a classification error[4].

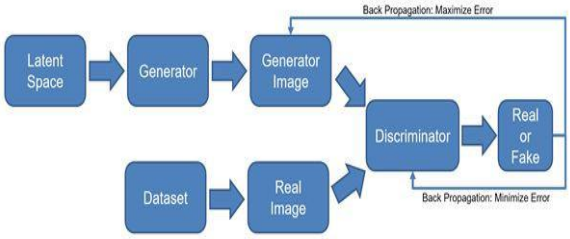

Figure 1: GAN Architecture

Step 1: Training of Discriminator starts with training data, x. Goal of Discriminator is to increase the probability of getting correct label. Output should be real for the training data and fake for data generated from the Generator.

Step 2: Take a random input from the training data and introduce noise to create random noise data z.

Step 3:Generator takes the random noise data z and tries to reconstruct the input x hat.

Step 4: Discriminator takes input from two sources. One input is the real input from the training data. Other input is the data generated by the Generator. Discriminator classifies input as real or fake. Based on classification, classification error is computed.

Step 5: It then back propagates the classification error to update the Discriminator. Goal of Discriminator is to minimize the classification error.

Step 6: Classification error is also back propagated to update the Generator. Goal of the Generator is to increase the Discriminator classification error.

Generator G produces a probability Pg as distribution of the samples G(z) obtained from z.

To learn the generator's distribution Pg over data x, we define a prior on input noise variables Pz(z),

D(x) represents the probability from the training data x rather than Pg.GANs need to optimize below min max objective function.

$$\min_G \max_D = V(G; D) = \min_G \max_D E_{exp_{real}}[\log D(x)] + E_{zp_z}[\log(1 - D(G(z)))] \quad (1)$$

IV. TYPES OF GAN'S

A. Fully connected GAN's

A fully-connected neural network is a type of computer algorithm that can learn from input data. The GANs introduced in this paper are not very advanced, and have numerous drawbacks. They are only suitable for working with very simple datasets such as MNIST or CIFAR-10[7].

B. DCGAN

A DCGAN (Deep Convolutional Generative Adversarial Network) is an improved version of a traditional GAN (Generative Adversarial Network). DCGANs use convolutional and convolutional-transpose layers in their discriminator and generator in order to make the process more efficient. These convolutional layers allow for the understanding of the statistical distribution of the original samples. DCGANs also use a special type of algorithm called a CNN (Convolutional Neural Network) which is mainly used to find important features in a given image, such as edge detection. Finally, DCGANs have been found to be more stable in generating images than in normal GANs. In order to prevent GAN instability, the authors recommend replacing any pooling layers with strided convolutions for the discriminator and fractional-strided convolutions for the generator. Furthermore, they suggest removing fully connected hidden layers, adding batch normalization for both the generator and discriminator, using the ReLU activation function in the generator and the Tanh activation function in the output layer, and using the Leaky ReLU activation function in the discriminator[6].

C. Conditional GAN-CGAN

The generative network's job is to create 'fake' samples in order to fool the discriminator network. Furthermore, both the generator and the discriminator are able to use some kind of arbitrary input data to produce more precise results.A Conditional GAN is a type of Artificial Intelligence system that uses two networks, an encoder and a decoder, to generate data. The encoder maps an input label into a low-dimensional space, and the decoder does the opposite and maps the low-dimensional space back into the label. This allows the system to generate new data based on the input labels[9].

D. Info GAN

A GAN utilizes an information-theoretic approach where it can learn disentangled representations without needing to be supervised. Instead of having the

latent variables be known in advance, they propose drawing them from different distributions such as Bernoulli, Normal, and multiclass. Then the discriminator is tasked with reconstructing these latent variables. In order to ensure that the GAN model is successful at creating a representation of the input data that includes interesting features, the authors propose forcing the GAN to have a high information content between the generated samples and a small subset of the latent variables C[11].

E. LAPGAN

LAPGAN stands for Laplacian Generative Adversarial Networks. It is a type of algorithm where GAN (Generative Adversarial Networks) is used together with a Laplacian pyramid with different levels. In the coarsest level of the pyramid, the GAN is trained to map a noise vector to an image with the lowest resolution. Then, the GAN at each other level takes the image generated in the coarser level and uses it as a condition to produce the image at that level. With this technique it's possible to create images with great resolution[6].

F. Vari GAN

Vari GAN is a type of artificial intelligence that is used to create multi-view human images from a single view. It follows a coarse-to-fine approach, meaning it generates images in multiple steps. In Vari GAN, there are three main networks: a Coarse Image Generator, Fine Image Generator and Conditional Discriminator. The Coarse Image Generator uses a Variational Auto Encoder (VAE) to generate a low resolution image from an input image and target view. The Fine Image Generator is built with a U-Net architecture which is named after its symmetric shape. U-Net takes the low resolution image and converts it into a higher resolution image that is conditioned on the original input image. Finally, the Discriminator examines the conditioned high resolution image to measure the difference between the generated image and the ground truth. It achieves this by using an adversarial loss and a content loss based on the L1 difference[10].

G. VGAN

Vondrick proposed a generative adversarial network for video (vGAN). This type of network uses two interactive networks (the generator and the discriminator) to create and improve videos. The generator has two-streams, the background stream which uses 2D convolutional layers and the foreground stream which uses spatial-temporal 3D convolutional layers. The discriminator takes the total generated video as input and tries to distinguish between real and generated videos. This network generates tiny videos of about one-second duration, but requires large memory space since it treats videos as 3D cubes[5].

H. TGAN

TGAN stands for a type of deep learning network, called a "Temporal Generative Adversarial Network", which was proposed by Saito.. TGAN goes beyond vanila GAN by having one extra element: a temporal generator. This is a type of generator which produces a series of latent frame vectors from a random variable. The image generator then takes those frame vectors and produces individual video frames, which then go to the discriminator for evaluation. Finally, for the training to be stable, TGAN adopts the same WGAN model but with a twist: it applies a technique called singular value clipping instead of weight clipping to the discriminator[7].

V. APPLICATIONS

COMPUTER VISION

GANs (Generative Adversarial Networks) are currently being used mainly in the field of computer vision - this refers to using powerful computer algorithms to process and interpret images. Specifically, GANs are used for image enhancement (making images look clearer and sharper), image transformation (changing an image from one form to another, like converting a picture to a line drawing), image compounding (putting multiple images together to form one), and video production (putting together video clips to create a new video).

IMAGE RESOLUTION ENHANCEMENT

Super-Resolution Generative Adversarial Network (SRGAN) as a way to improve the resolution of images. This network takes a low-resolution image as input and produces an image with 4 times the high-resolution detail. One year later, Wang proposed the Enhanced Super-Resolution Generative Adversarial Network (ESRGAN) which is designed to make the images produced by the SRGAN more realistic and to reduce unwanted noise in the images by changing the structure of the network and the format of the loss function[4].

IMAGE TRANSLATION

Pix2pix is an image-to-image conversion method developed by Isola that uses Conditional Generative Adversarial Networks (GANs). It enables the transformation of an image from one domain to another. Experiments have shown that pix2pix is effective for graphics and visual tasks. Improvements on the method have resulted in pix2pixHD, which produces higher-resolution images with better clarity and quality. Although pix2pix is very successful in image conversion problems, it only works with data that has a pairing between the input and output image domains. To address this, CycleGAN, DiscoGAN, and DualGAN were proposed. These three methods use a different approach to make it possible to train image conversions on unpaired data[8].

NATURAL LANGUAGE PROCESSING

SeqGAN and RankGAN are both types of GAN which Yu et al. and Lin et al. proposed as replacements for traditional methods in lecture, literature and music generation. Li et al. proposed GANs as a reinforcement learning problem, where the output of the discriminator is used as a reward for the generator. This means that the generator is rewarded for producing conversational exchanged that are so realistic it is like two real people having a conversation.

IMAGE INPAINTING

Image inpainting is a process of restoring parts of images that have been damaged or lost. Many deep learning techniques have been developed to attempt to solve this problem, and the challenge they face is filling in large gaps of an image. Convolutional networks are often employed because they are good at generating an image with the right features to fill in the gaps[12].

VIDEO GENERATION

Video prediction is a way of predicting what will happen in a video in the future. VGAN and TGAN are two ways of making a GAN that generates videos. VGAN assumes the video is made up of a single background and a mobile foreground. TGAN uses a generator to create latent frame vectors and an image generator to turn them into video frames. MoCoGAN uses content, which is the objects in a video, and motion, which is their movement, to generate a video. It does this through a unique adversarial learning scheme that involves image and video discriminators. Experiments with different datasets have proven that MoCoGAN successfully creates videos that have the same content but different motion, or different content but the same motion[11].

VI. ENVIRONMENTAL SETUP USING DOCKER

1-Model is developed using Pytorch framework that is to be executed on NVIDIA GPU hence Pytorch is configured by pulling respective docker image and started as container in docker environment.

Following commands were executed on fedora36

#docker pull pytorch/pytorch:1.4-cuda10.1-cudnn7-devel

#docker run --gpus all -it -p 5080:8888 --rm --ipc=host -v /home/amar/:/amar/ --name amarpytorchproject pytorch/pytorch:1.4-cuda10.1-cudnn7-devel

#jupyter notebook --ip 0.0.0.0 --port 8888 --no-browser --allow-root &

Above command will generate a url that will enable us to access jupyter-notebook for running PyTorch code.

Following are the digits generated by the GAN based model ,trained on publicly available MNIST dataset.

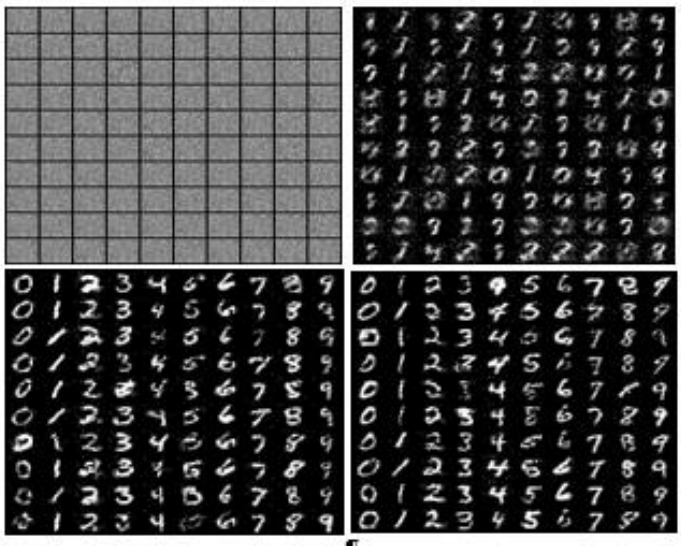

Figure 2: “GAN based” model output after few epochs

We noted following observations.

1-Running a GAN based models which processes images/videos to generate output, there is need of powerful GPU.

2-It takes huge time to generate the results on Intel i5 based CPU.

3-But it is found that running same model on NVIDIA GPU like TitanX,we observed huge deduction in execution time, almost greater than 4 times.

4-Thus it proves that ,GAN is able to generate realistic looking data which humans cannot identify its origin. The same data can be used further as training data to enhance the accuracy of models where highest accuracy is expected.

TABLE 1. Summary of Architecture-Variant GANS

Type	Description	Findings
Fully connected GAN	Fully connected neural networks are used for both the generator and the discriminator.	-Applied to some simple image datasets, such as MNIST and CIFAR-10. It does not perform well in terms of generalization for more complex image types.
Semi-supervised GAN	In comparison to fully connected GAN (FCGAN), the discriminator in SGAN is multi-headed.	It uses softmax and sigmoid to classify real data and differentiate between real and fake samples.
Bidirectional GAN	An encoder (E), a generator (G), and a discriminator comprise the architecture (D)	BiGAN) is developed for learning the inverse mapping, -The batch size is 128 and the weight decay as 2.5×10^{-5}.
Conditional GAN	The extra information y (which can be a class label or other modal data) is fed to both the discriminator and the generator by CGAN.	Dropout is applied to both the generator and the discriminator with a probability of 0.5. -Momentum is used with an initial value of 0.5 and was eventually increased to 0.7.

InfoGAN	Unsupervised learning of interpretable representations by maximising mutual information between conditional variables and generative data.	Batch normalisation is used in conjunction with the Adam optimizer. The discriminator uses Leaky ReLU with a leaky rate of 0.1, while the generator uses ReLU.
Laplacian Pyramid of Adversarial Networks	Used to generate higher-resolution images from lower-resolution GAN input.	The discriminator employed three hidden layers with sigmoid output, whereas the generator employed a five-layer CNN with ReLU and batch normalisation.
Deep Convolutional GAN	For Generator, a deconvolutional neural network architecture is used.	DCGAN uses the spatial up-sampling ability of the deconvolution operation for G, which makes the generation of higher resolution images using GAN

VII. GAN-BASED SEGMENTATION METHODS

A. GANs applications in brain tumor segmentation

Brain MRI images and CT scans are commonly used in medical imaging to diagnose and monitor specific patient illness progression, as well as plan possible treatment.Alzheimer's and brain tumours are two of the most fatal diseases. Manual segmentation and identification of pathologies in brain images, on the other hand, are time-consuming and tedious tasks.The imbalanced datasets of brain tumour images pose significant challenges in medical imaging, directly affecting the training process of the proposed models. GANs have recently gained traction in the research community for their ability to syn- thesize brain images.[13]

B. GANs applications in skin lesion segmentation

Malignant melanoma is a dangerous form of cancer which is highly increasing in numbers. In 2018, it had 1.04 cases reported, which is a frightening statistic. Unfortunately, if these cancers are not diagnosed quickly, the survival rate of people with melanoma can be less than 15% in five years. However, there is hope because a quicker response can bring the survival rate to greater than six times. Dermatologists use detemoscopy which involves monitoring and magnifying the skin's pigmentation. But this takes a lot of time and expertise. Thankfully, the advancement of deep learning models in computer vision can help dermatologists more accurately detect skin-related cancers.Stacked adversarial learning is a technique used to learn the features of skin lesions, such as the characteristics of an area of skin affected by cancer. Feature diversity means that it can take various types of information about a lesion and use it to detect it. FCN stands for fully convolutional network which is a type of network used to generate the lesion samples needed for skin lesion segmentation. GAN stands for generative adverserial networks, and this type of network is used to help with the task of segmenting images of skin lesions.[13]

C. GANs applications in cardiac segmentation

Cardiac segmentation is the process of segmenting three dimensional images of the heart so that specific parts, such as more vulnerable parts, can be identified and studied. Cardiac magnetic resonance imaging (CMRI) is used to detect cardiac diseases, so it contains important details for evaluation of treatments. However, echocardiography, which is another way to evaluate the heart, can be challenging due to low spatial resolution and deformable appearances, which make it difficult to correctly label the imaging. Thus, the authors of [102] proposed a model using generative adversarial networks (CGANs) to try to address some of these challenges and improve segmentation of cardiac short-axis in MRI.[13]

D. GANs applications in liver tumor segmentation

The World Health Organization (WHO) reported in 2017 that liver cancer had become the second most deadly type of malignant tumor (a type of cancer) worldwide. Thus, researchers all over the world are actively studying how to prevent and treat liver diseases. Early detection of liver lesions (abnormalities) is important because it will lead to better treatment plans and help patients to recover faster. To detect liver lesions in the early stages, researchers have come up with different methods and frameworks based on computed tomography (CT) images. For example, Frid Adar et al. proposed a method that uses Generative Adversarial Network (GAN) which is a type of machine learning, to augment (or “increase”) the medical images when the dataset is limited.[13]

E. GANs applications in retina diseases segmentation

Diabetic retinopathy and Glaucoma are two of the leading causes of vision loss and blindness. Early detection and screening are vital in preventing permanent vision loss as these diseases cause damage to the blood vessels of the eyes. Research focusing on the segmentation of retinal vessels has employed deep learning-based models. A GANs-oriented, semi-supervised network has been proposed for segmentation tasks, which is more effective than traditional CNN networks. Additionally, residual learning techniques were applied to improve the architecture of the Convolutional Neural Networks (FCNs).[13]

VII. CONCLUSION

In recent years, GANs have become very popular in the scientific world, and have been used for a wide range of applications, including speech generation and cybersecurity. However, training a GAN can be difficult, as it can encounter two major problems: mode collapse and non-convergence. One way to address these

challenges is to change the network architecture, objective function, or optimization algorithm to create a more powerful model. In response to these solutions, researchers have created many different GAN variants with different capabilities. This article provides an overview of the original GAN framework and explores the various GAN variants created through different optimization techniques. It also summarizes the existing research on GANs and discusses how different approaches address the common challenges.[12]

VIII. FUTURE DIRECTIONS

GAN can be used to create meta-universe scene which are in huge demand in movies and animations. Efficient GAN can be built for generating high-resolution images without blurriness, working with images of different resolutions. They have also been used in video and 3D model generation, but the results are imperfect hence better and fast GAN models are expected[11]. All of these challenges will need further research and exploration, if GANs are to reach their full potential[9].

IoT-based Automated System for Water-related Disease Prediction

Kiran Kishor Maharana, Surajit Mondal, Harshkumar Vishwakarma
Information Technology Thakur College of Engineering and Technology, Mumbai, India
Kiran11621@gmail.com, Monsurajit640@gmail.com, Harshkv9322@gmail.com

Abstract – **Water is an essential nutrient that has a key function in the human body. All bodily fluids, including blood, lymph, etc., are derived from pure drinking water. Therefore, proper water monitoring is crucial for producing safe, pure, and hygienic water. The majority of homes get their water from wells. To maintain a safe and dependable source of drinking water, it is essential to regularly test the quality of our well water. The test results enable us to accurately describe a water system's problems. This aids in ensuring that the water supply is adequately protected against potential pollution and that the right treatment has been selected and is functioning as intended. Everyone on the earth needs clean drinking water, and today this is frequently a known issue owing to various water-borne illnesses including cholera, diarrhoea, etc. The goal of the research is to address these issues. To determine the contents, the water samples are observed. Then, machine learning, deep learning and neural network algorithms are employed to estimate purity using those contents. The results are then examined, and every disease that could be brought on by drinking that water is screened for.**

Keywords – Water-borne Disease, Water Quality, LSTM, SMOTE, Data Augmentation, Prediction, Forecasting

I. Introduction

Safe and readily available water is important for public health, whether it is used for drinking, domestic use, food production, or recreational purposes. Improved water supply, sanitation, and water resource management can significantly contribute to lowering poverty while boosting a nation's economic growth. More than 2 billion people reside in nations with water shortages, which are predicted to get worse in some areas due to population expansion and climate change. At least 2 billion people throughout the world consume water that has been tainted with feces. The biggest threat to the safety of drinking water is microbial contamination brought on by feces contamination. Arsenic, fluoride, and nitrate pose the greatest chemical dangers in drinking water, but new contaminants such as pesticides, medicines, per- and polyfluoroalkyl substances (PFASs), and microplastics also cause public concern. Water that is safe and plentiful makes it easier to practice cleanliness, which is important for preventing many neglected tropical diseases as well as acute respiratory infections and diarrheal diseases. Drinking water that has been tainted by microorganisms can spread diseases like diarrhea, cholera, dysentery, typhoid, and polio, as well as cause 485,000 diarrhea-related deaths annually.

In 2020, 5.8 billion people, or 74% of the world's population, used a drinking water service that was safely managed, or one that was on-site, readily available, and uncontaminated. The rest 2 billion individuals without access to well-managed services included –

- 1.2 billion people have access to basic services, i.e., a better water source within a 30-minute roundtrip;
- 282 million people without access to basic services or who must travel more than 30 minutes to access a better water source;
- 368 million people use unprotected wells and springs to get their water;
- Collecting untreated surface water from lakes, ponds, rivers, and streams on behalf of 122 million people.

According to the World Health Organization (WHO), water-related illnesses are the greatest cause of sickness and death globally, taking the lives of more than 3.4 million people annually. Young children make up the majority of the victims, and the vast majority of them pass away from illnesses brought on by organisms that flourish in raw sewage- contaminated water sources. According to analysts, preventing disease and death caused by dirty water and poor sanitation would result in enormous financial benefits for both production and health. According to one estimate, depending on the nation, there would be an economic return of between $3 and $34 for every dollar spent. Also, Water-borne diseases can become major problems after natural disasters if large numbers are forced to live temporarily in crowded areas with poor sanitation and limited supply of safe water. Research suggests that, in some settings, climate change could affect water-borne diseases, because changes in temperature and rainfall can affect the survival of disease-causing organisms. Hence, there is a need for continuous monitoring of water quality and gaining insights from collected data to estimate unsolicited events like a disease outbreak. Currently, there are low-efficient system that can predict diseases based on water quality mostly which is analyzed manually on which human health readily depends. Therefore, there is a requirement for an automated water quality monitoring system that can also analyze the water quality data, estimate probable disease spread, and raise alerts on the occurrence of such events.

There are some milestones for the project implementation:

- Conceptualizing Framework by setting monitoring parameters
- Sample location and frequency
- Sampling techniques, building applications, and apparatus
- Sampling timetables
- Checking qualification and accreditation standards for testing data
- Developing techniques for validating sampling results and quality assurance
- Specifications for reviewing and analyzing findings
- Specifications for record-keeping and documentation, including how monitoring results will be documented and preserved
- Requirement for results reporting and communication with stakeholders

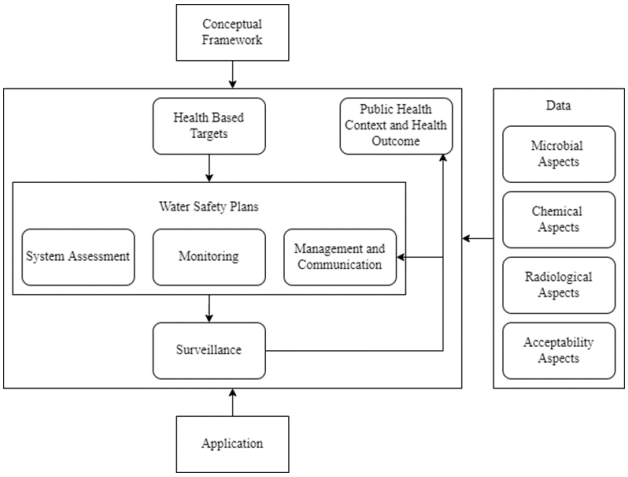

Figure 01: Interrelationship between Individual Module

II. Literature Survey

Detection of rotaviruses in river water and sewage water in Shanghai by RT-PCR, Ming Yang, Wenhui Qiu, et. al. For this project water samples were collected from around 21 sites. Those samples were tested in the lab using various chemical methods thus concluding the results, The results have revealed that rotavirus amplicons have a positive control and thus environmental water samples can be noticed as a specific band in agarose gel thus after electrophores is, which also suggested that virus particles are recovered from water samples using sodium chloride, aluminum chloride precipitation method, and also using the RT nest PCR method it was effective to detect the rota-virus present in water samples. Developing an underwater monitoring and alert system for water-borne disease management, N. M. K. Varma, et. al. This Project is known as an Underwater acoustic sensor network that can collect ocean, river, and lake data such as salt content, temperature, pH, turbidity, and also oxidation in the water supplies. In this, they are adding preprocessing and rule-based engine functionalities to the underwater surface gateway thus sending the warning message to the local healthcare center. Government healthcare centers receive the data from the underwater surface gateway via the internet and the equivalent data can be processed using big data analysis for water-borne disease protection and its management.

Measuring the Water Quality in Bore well Using Sensors and Alerting System, S. Jayalakshmi, el. al. The main aim of this paper is to recognize the grade of water using the IoT. In this project executing a system for measuring the water value through devices like a TDS meter, DC motor, LM35 temperature sensor, and GSM. Micro- controller Avenue is the significance that is checked by using sensors. The recorded data is gathered in the centralized database server and if the water value is below the TDS meter values, a caution message is sent to owners using GSM. This atmosphere can have adjustable good water. In the proposed paper, the water quality is checked using the Turbidity sensor and also the motor's temperature using sensors.

An Affordable System for Remotely Monitoring Water Quality in Residential Water Tanks, Khaili, Asma & Almamari, et. al. In the following proposed project work, a system is projected to remotely sense, record, and determine the value of drinking water kept in domestic tanks. Various sensors are used to determine the pH, turbidity, oxidation, and temperature values present in the water. Three separate temperature sensors are used to check the temperature of the water, and also the temperature inside and outside of the tank is checked. The system sends caution messages to the landowner and the local establishments or societies (if they set) when one of the values is lower than the normal values. Implementation of Wireless Sensor Network for Real Time Overhead Tank Water Quality Monitoring Sowmya, C., C. D. Naidu, et. al. The main objective of this project is to examine the quality of the water in the overhead tanks in society simultaneously with help of using 3 calculating devices like pH, conductivity, and temperature sensors. The Application of Wireless Sensor Network technology is used for the examination of instant water quality. In this proposed project work the system design and implementation of WSN are presented in detail. In this WSN is used for checking water quality the gathered amount of sensor nodes with the ability of networking, which is deployed at various overhead tanks and water bodies in a particular surrounding.

III. PROBLEM STATEMENT

About 70% of the earth's surface is covered by water, which is one of the most critical resources for maintaining life. Rapid industrialization and urbanization have caused an alarming rate of water quality degradation, which has

resulted in terrible diseases. Traditional methods for estimating water quality involve costly and time-consuming statistical and laboratory tests, making the idea of real-time monitoring irrelevant today. Thus, with the goal of the need for a quicker, more practical solution because of the dire effect caused by it Proposing a model using time-series analysis powered with AI, ML, and DL to predict and forecast long and short-term trends related to water-borne diseases along with providing appropriate solutions. The suggested methodology will validate the potential for application in real-time for automated IoT-based water-borne diseases related detection systems by achieving reasonable accuracy with a limited number of parameters.

IV. OBJECTIVES

- To predict water-related various diseases using an IoT device that will analyze the quality of water with the help of AI, ML, and DL and eliminate the risk at an early stage.
- To ensure testing, monitoring, and frequent water quality surveillance of the drinking water supply and sources by the supplier to foster the provision of clean tap water to every rural home and public institution and to bring confidence in drinking water straight from the tap.
- To monitor reportable illnesses that are frequently brought on by waterborne pathogens, and detection of outbreaks.
- To study long-term trends, in demographic and geographic data, and provide appropriate solutions.
- To help government authorities to lower water-borne diseases through the proposed system by maintaining appropriate water quality levels through continuous monitoring.

V. SCOPE

- For making the general public conscious of the significance of drinking water quality and its connection to health, as well as the requirement for clean drinking water to be available in appropriate quantities for domestic use for drinking, cooking, and hygiene.
- Acknowledgment of surveillance is important and a community reaction is required.
- Converting suggestions of research's findings into a sizable IoT-based online monitoring system that uses sensors for the necessary metrics. Based on the real-time data supplied by the IoT system, the tested algorithms would make an immediate prediction of the water quality.
- The suggested IoT system would make use of pH, turbidity, temperature, and other parameter sensors. TDS for parameter readings and use of an Arduino microcontroller to convey those readings Transceiver.
- Before water is released for consumption, it would detect water of poor quality and alert the appropriate authorities. It should prevent as many individuals from consuming low- quality products. water and thereby reduce the severity of terrible illnesses like diarrhea and typhoid.
- Investigations into outbreaks with intervention studies to assess available choices for interventions.
- Case-control or cohort studies to assess the contribution of water to illness risk.
- In light of this, the system will facilitate would benefit from the application of a prescriptive analysis based on the anticipated values to help those who make decisions and policies.

VI. METHODOLOGY

This research will aid in the prediction of water diseases, prevent water contamination, and promote healthy use of the resource. Thus, the system will use a variety of sensors, such as pH, turbidity, oxidation, and conductivity sensors, to implement these various sensors to forecast and prevent the types of diseases that may arise.

Here, several sensors will function as needed; for example, the pH sensor will give our machine information on both acidic and non- acidic conditions. The total amount of light scattered by the floating items in the water is calculated by turbidity sensors. The number of suspended particles in a body of water increases with turbidity, which is a measurement of the water's capacity to either clean itself or decompose into waste. Here, the devices are getting the analog input from the sensors and giving it to the system to check the water quality, locate the diseases and the system will find with the aid of the various water quality datasets, and stop them in their tracks.

IoT will be utilized to forecast water quality in the system using cutting-edge technology like AI, ML, and DL. Predictive research is chiefly concerned with forecasting (predicting) outcomes, consequences, costs, or effects. This type of research tries to extrapolate from the analysis of existing phenomena, policies, or other entities to predict something that has not been tried, tested, or proposed before A Predictive research project often asks how- or how well something might work, or what the impact of something might be. The Predictive paradigm is a lot like a crystal ball trying to tell the future of something.

We have chosen predictive Research since we are going to forecast/predict the type of diseases that can occur if the current quality of water levels persists in the future.

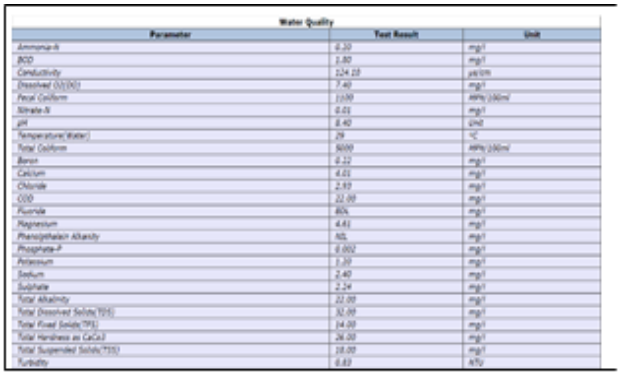
We would be following a deductive approach since we have formulated a set of hypotheses or your dissertation that need to be confirmed or rejected during the research process.

a. Data collection method and tools

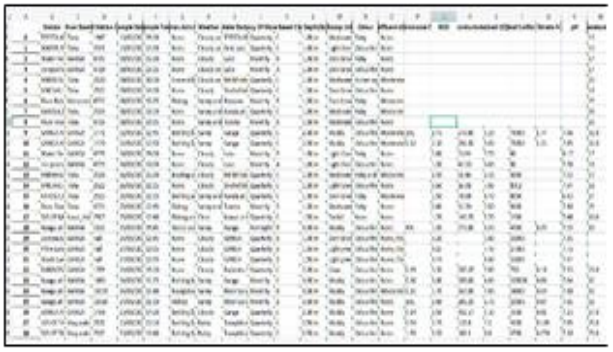
We required a water dataset with varied water quality attributes for these issue statements. The West Bengal Pollution Board updates the state of West Bengal's water properties in real-time regularly.

The river data sample page appears as follows:

The attributes provided by them are as follows:



Since the data was found on a website, web scraping was used to acquire the data, which was then put on an excel sheet with 10715 rows of data samples.



Tools used for data collection: Jupyter Notebook, Python, BeautifulSoup Library

Data Source:

http://emis.wbpcb.gov.in/waterquality/views ampledatacitizen.do

Code for Scraping:

https://colab.research.google.com/drive/17a k3TM0goYrqk3o01O1AnVlJYr740oLm?us p=sharing

b. Data analysis

- The process of data analysis is very important to avoid future costs and make the model more accurate.
- After collecting the data from scraping various preprocessing techniques were applied to the dataset starting from handling the noise and removing the outliers.
- Applying various feature engineering techniques to understand the structure of the dataset and get various insights from it.
- Applying data augmentation techniques to make the dataset as a time series data using various techniques.
- The Data analysis technique which can be applied to our project is Predictive Analysis since we will be finding patterns in older data as well as current events to analyze and predict future events.

VII. IMPLEMENTATION DETAILS

The first step is to collect water-related data with the help of sensors. Or by using pre- collected data also which contains attributes like temperature, TDS, Turbidity, pH, and conductivity. The data is easily available on many websites. After that collected data should be stored in the cloud. This is only for the monitoring and storing of the data. You can use a cloud service for the storage of the data. to improve the project, the system will display water quality data by using the P10 dot matrix display. Then for training and testing the data, there will be a need for an accurate dataset. Water quality-related datasets can easily be available on any health- related website like WHO or the West Bengal pollution control board or can simply find them on Kaggle. For training and testing of the data, the system will use a gradient boosting classifier machine learning algorithm. Use a spyder scientific environment that gives features like advanced editing and debugging. Scikit-learn a machine learning library developed in python language will be used for classification, support vector machine, regression, gradient boosting classifier, and many more algorithms. The algorithm will help in the prediction of the disease by providing appropriate solutions.

The next step is to integrate the model with the user-friendly dynamic website which gives an alert to nearby government offices or any water purifying plant. Push bullet application will be used which is the easiest way to transfer data from mobile to pc and vice versa.

If water quality is dangerous to health, then it will automatically give the notification to the devices. It will also forecast long and short- term trends.

Tools:

- IDE – Jupyter Notebook, PyCharm
- Database and Cloud Service – Firebase, AWS
- IoT Devices

Technologies:

- Frontend – HTML, CSS, JavaScript, jQuery, Bootstrap
- Backend – Django, Python

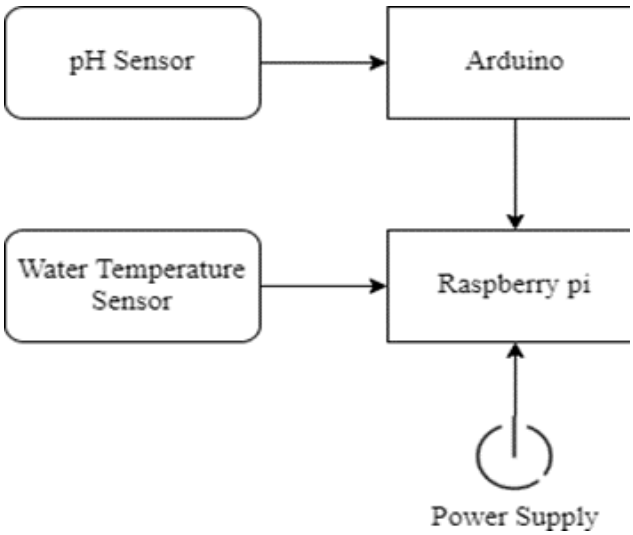


Figure 2: Block Diagram of Water Prediction Model

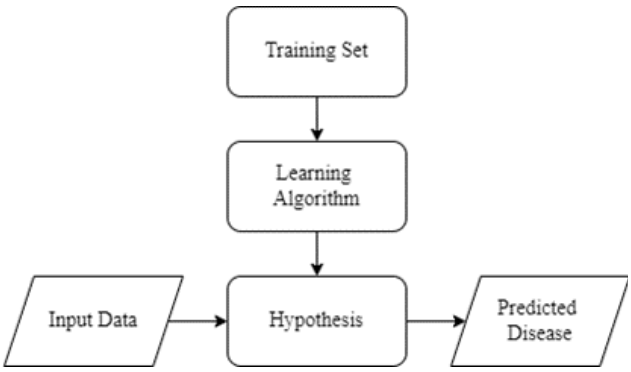

Figure 3: Software Working Module

VIII. Results and Discussion

The primary cause of illness and death worldwide is water-related disorders. Water infected with viruses, bacteria, metals, poisons, and other chemical contaminants is the main source of diseases linked to poor water quality. To estimate unexpected events like a disease epidemic, we, therefore, need to continuously check the quality of the water and gain knowledge from the data that has been collected. There is currently no technology that can forecast diseases based on water quality. Therefore, there is a need for a system to monitor water quality that can also evaluate the data, predict when diseases may spread, and issue alarms when such things happen. There are some completion dates for the project.

IX. CONCLUSION

Any region's health and economy are directly impacted by the quality of the water. To preserve excellent public health, it is crucial to provide a safe drinking water supply. As a result, it is difficult to determine the exact quality of the water. The prediction model must be accurate to prevent misleading results. As a result, water infections can likely be predicted by preventing the interaction with any dangerous chemicals.

The project will use Raspberry PI and Arduino with no analog sensor built into the raspberry pi. It can be further implemented on a single chip to reduce cost. This project can now only predict limited types of diseases. More diseases can be predicted after adding more datasets. This project can also be integrated with android phones by creating sensor modules that can be attached to android phones and the prediction part will be handled by the website app. Thus, using an IoT device and a system powered by AI, ML, and DL will examine the quality of the water and reduce the risk at an early stage, one can forecast numerous diseases that are related to the use of water. It will encourage the provision of safe tap water to every rural home and public institution and inspire confidence in drinking water straight from the tap, the supplier should ensure testing, monitoring, and regular water quality surveillance of the drinking water supply and sources. Keeping track of outbreaks and reportable illnesses that are frequently caused by waterborne pathogens.

Long-term patterns in demographic and geographic data will be easier to be studied, and relevant solutions will be offered before mishappening. At last, maintaining proper water quality levels through ongoing monitoring can assist government officials in reducing water-borne diseases.

Abstract: **Blockchain technology is a decentralized, distributed ledger that allows for secure and transparent recording of transactions. It operates on a network of nodes and is secured through cryptography, making it resistant to tampering and fraud. There are several types of blockchain networks, including public, private, and consortium blockchains.**

Blockchain technology offers several benefits, including increased security, transparency, and efficiency. It has the potential to transform various industries, such as finance, supply chain management, digital identity management, and smart contracts.

Despite its potential, blockchain technology also faces several challenges and limitations, such as scalability, interoperability, and adoption and regulation. Addressing these challenges will be critical for the future success and growth of blockchain technology.

Keywords: Blockchain technology, network, distributed ledger,smart contract

I. INTRODUCTION

Definition of blockchain technology:

Blockchain technology is a decentralized, distributed digital ledger that records transactions across a network of computers. It uses cryptography to secure and verify the integrity of these transactions. Each block in the chain contains a number of transactions and is linked to the previous block, forming a chain of blocks (hence the name "blockchain"). The ledger is maintained by a network of nodes, making it resistant to modification or tampering by any single node.

This technology enables the creation of a secure, transparent and tamper-proof record of transactions, without the need for intermediaries such as banks. Blockchain has the potential to revolutionize various industries, including finance, supply chain management, and voting systems, among others.

This paper provides an overview of blockchain technology, including its definition, structure, and basic principles. The different types of blockchain networks, including public, private, and consortium blockchains, are also discussed. The benefits and potential applications of blockchain technology are explored, including increased security, transparency, and efficiency, and its use in industries such as finance, supply chain management, digital identity management, and smart contracts.

Additionally, the challenges and limitations facing blockchain technology are evaluated, including scalability, interoperability, and adoption and regulation. Finally, the paper concludes by discussing the future scope and potential of blockchain technology and its role in shaping the digital landscape.

Overall, this paper provides a comprehensive introduction to blockchain technology, its benefits and applications, and the challenges it faces. It highlights the importance of understanding and exploring this emerging technology as it continues to evolve and play an increasingly important role in our digital world.

Brief history of blockchain:

Blockchain technology was first introduced in 2008 as the underlying technology for the digital currency, Bitcoin. The concept was presented in a whitepaper by an unknown person or group using the pseudonym Satoshi Nakamoto.

Since then, blockchain has evolved beyond its original use case in cryptocurrency. The technology has been applied in various industries and has received increased attention from businesses, governments, and individuals.

In 2015, the concept of smart contracts was introduced, allowing for the automation of contractual processes on the blockchain. This opened up new possibilities for decentralized applications, further expanding the potential uses of blockchain.

Over the years, various blockchain platforms and networks have been developed, each with its own unique features and uses. The rise of blockchain-based decentralized finance (DeFi) and non-fungible tokens (NFTs) has further popularized the technology and sparked new innovations.

Overall, the brief history of blockchain shows a rapid evolution from a niche technology to a potentially transformative tool with numerous real-world applications.

The purpose of the paper is to provide a comprehensive overview of blockchain technology and its key features to help the reader gain a better understanding of its potential uses and limitations. It should be written in a clear and accessible manner, suitable for a wide range of readers with varying levels of technical expertise.

II. HOW BLOCKCHAIN WORKS:

Blockchain networks work by maintaining a decentralized ledger of transactions that is distributed across a network of computers (nodes). Each node has a copy of the ledger, and transactions are verified and added to the ledger through a consensus mechanism.

Here is a step-by-step explanation of how a blockchain network works:

- Transaction: A user initiates a transaction, which is broadcasted to the network.
- Verification: The transaction is verified by network nodes, ensuring that the user has sufficient funds and that the transaction is valid.
- Package into a block: The verified transactions are packaged into a block, along with a unique code called a hash, and a reference to the previous block's hash.
- Distributed consensus: The block is then broadcasted to the network, where nodes compete to validate it and add it to their copy of the ledger through a consensus mechanism. This mechanism ensures that all nodes have the same version of the ledger.
- Addition to the chain: Once a block is validated, it is added to the chain and cannot be altered, ensuring the integrity and immutability of the ledger.

This process is repeated for each new transaction, forming a chain of blocks. The decentralized nature of the network and the consensus mechanism ensure that the ledger is secure and transparent, and that transactions are verified and recorded without the need for intermediaries.

A. Overview of a blockchain network

A blockchain network consists of several key components:

- Decentralized ledger: A blockchain network maintains a shared ledger of transactions that is decentralized and distributed across a network of nodes. Each node has a copy of the ledger, and transactions are verified and added to the ledger through a consensus mechanism.
- Nodes: The nodes in a blockchain network are computers that run the software that powers the blockchain. They are responsible for verifying transactions, adding them to the ledger, and maintaining the network.
- Consensus mechanism: The consensus mechanism is the process by which the network reaches agreement on the state of the ledger and the validity of transactions. Different blockchain networks use different consensus mechanisms, such as Proof of Work (PoW) or Proof of Stake (PoS).
- Cryptography: Cryptography is used to secure the transactions and the ledger. It ensures that the ledger is tamper-proof and that transactions are verified and validated by the network.
- Smart contracts: Smart contracts are self-executing contracts with the terms of the agreement between buyer and seller being directly written into lines of code. They can automate various processes and reduce the need for intermediaries.
- Tokens: Tokens are digital assets that can represent ownership of an asset, such as a stock or a physical commodity, or a unit of currency. They are often used in blockchain networks as a means of exchange.

Overall, a blockchain network is a decentralized, secure, and transparent system for recording transactions and tracking assets. It has the potential to revolutionize various industries by providing a trustless and secure platform for conducting transactions and exchanging assets.

III. TYPES OF BLOCKCHAIN NETWORKS

There are several types of blockchain networks, including:

- Public blockchains: Public blockchains are open networks that allow anyone to join and participate. They are typically transparent and secure, and offer a high degree of decentralization. Examples include the Bitcoin and Ethereum networks.
- Private blockchains: Private blockchains are restricted networks that are only accessible to a limited number of participants. They are often used for enterprise applications, where the goal is to maintain control over the network and protect sensitive data.
- Consortium blockchains: Consortium blockchains are hybrid networks that are partially centralized and partially decentralized. They are governed by a consortium of organizations, rather than a single entity, and offer a balance between transparency, security, and control.
- Hybrid blockchains: Hybrid blockchains are networks that combine features of public and private blockchains. They allow for both public and private transactions on the same network, and can provide a balance between security, privacy, and accessibility.

Each type of blockchain network has its own benefits and limitations, and the choice of network type depends on the specific use case and the requirements of the users.

Public blockchains offer the highest degree of decentralization and security, but may not be suitable for all applications due to scalability and privacy concerns. Private and consortium blockchains offer greater control and privacy, but may sacrifice some of the benefits of decentralization. Hybrid blockchains aim to provide a balance between the two.

IV. KEY FEATURES OF BLOCKCHAIN TECHNOLOGY

Here are some key features of blockchain technology:

- Decentralization: The blockchain network is decentralized and operates on a peer-to-peer basis, with no central authority controlling it.

- Immutable: Once data is recorded on a blockchain, it is extremely difficult to change or tamper with, making it highly secure.

- Transparent: All participants in a blockchain network can view and verify transactions, making it a transparent system.

- Secure: Blockchain uses cryptography to secure data and ensure that only authorized parties can access it.

- Tamper-Proof: The decentralized nature of the blockchain makes it resistant to tampering and fraud, as any changes to the data must be approved by a consensus of participants in the network.

- Traceability: Each transaction on a blockchain is recorded and linked to previous transactions, making it possible to trace the history of an asset from its creation to its current ownership.

- Efficiency: Blockchain technology eliminates the need for intermediaries, reducing the time and cost of transactions.

V. APPLICATIONS OF BLOCKCHAIN TECHNOLOGY

- Cryptocurrency: Cryptocurrency refers to digital or virtual currencies that use cryptography to secure transactions and to control the creation of new units. The most well-known example of a cryptocurrency is Bitcoin. Cryptocurrencies are typically decentralized and maintained on a public ledger that is secured by a blockchain.

- Supply chain management: Blockchain technology can be used in supply chain management to increase transparency and efficiency by allowing all parties involved in the supply chain to have access to the same information. This can help to prevent fraud, reduce errors, and improve the overall flow of goods and information.

- Digital identity management: Blockchain technology can be used to create secure, decentralized digital identities for individuals, organizations, and devices. This can help to prevent identity theft and fraud, as well as make it easier for individuals to manage and control their personal information.

- Smart contracts: Smart contracts are self-executing contracts with the terms of the agreement between buyer and seller being directly written into lines of code. They are stored on a blockchain and can be automatically executed when certain conditions are met. This can help to reduce the need for intermediaries, increase transparency, and increase the speed and efficiency of contractual agreements.

VI. LIMITATIONS AND CHALLENGES OF BLOCKCHAIN TECHNOLOGY

- Scalability: Scalability refers to the ability of a system to handle increasing amounts of transactions and data. Blockchain technology currently faces scalability challenges due to its limited processing power and storage capacity. This can result in slow transaction speeds, high fees, and long confirmation times.

- Interoperability: Interoperability refers to the ability of different blockchain systems to work together seamlessly. Currently, different blockchain systems use different protocols and technologies, which can make it difficult for them to interact with each other. This can limit the growth and adoption of blockchain technology.

- Adoption and Regulation: Adoption and regulation are two of the biggest challenges facing blockchain technology. Many

- individuals and organizations are still unfamiliar with the technology, and there is a lack of standardization and clear regulations. This can make it difficult for blockchain technology to be widely adopted and used in various industries and applications. Additionally, there is a lack of trust in the technology due to its association with illegal activities, such as money laundering and fraud. This can also limit its adoption and growth.

VII. CONCLUSION

Blockchain technology is a decentralized, distributed ledger that allows for secure and transparent recording of transactions. It operates on a network of nodes and is secured through cryptography, making it resistant to tampering and fraud. There are several types of blockchain networks, including public, private, and consortium blockchains.

Blockchain technology offers several benefits, including increased security, transparency, and efficiency. It has the potential to transform various industries, such as finance, supply chain management, digital identity management, and smart contracts.

Despite its potential, blockchain technology also faces several challenges and limitations, such as scalability,

interoperability, and adoption and regulation. Addressing these challenges will be critical for the future success and growth of blockchain technology.

In conclusion, blockchain technology is a rapidly growing and evolving field with tremendous potential for innovation and progress in the years to come. As we continue to explore its capabilities and overcome its limitations, we can expect to see it play an increasingly important role in our digital world.

Abstract— **NFT market development platforms are shaping the future of future startups to beat the competition. Build your own marketplace to create, sell, and trade NFTs using our NFT marketplace development platform. "NFT Marketplace" is a stage where consumers can hold, display, sell or produce Non-Fungible Tokens (NFTs). Non-Fungible Tokens (NFTs) are actually digital assets that are built on blockchain technology and reflect real-world objects. NFTs are certificates of ownership or authenticity of digital assets such as images, music, art, etc. NFTs are stored on the blockchain and contain information about the NFT's history and details. The NFT Marketplace allows creators to reach a wider audience with their NFT work. This system will be useful for buying and selling different types of NFTs on the NFT Marketplace platform.**

I. INTRODUCTION

Non-fungible tokens were first introduced in 2017. Unlike traditional cryptographic tokens, NFTs are unique digital assets that cannot be duplicated. All cryptocurrencies are basically Bitcoin, Ether or other tokens. These tokens are fungible because they are exchanged with each other and their value remains constant. So you can easily exchange one Bitcoin for another Bitcoin. However, this does not work for non-fungible tokens that represent rights to unique assets. Essentially, NFTs are a way to tokenize assets. For example, you can digitize your rights to a work of art and receive a token to prove it. There is only one token associated with your property and no similar token can be found. Exchanging Art Tokens for other Art Tokens is not the same or equivalent. Just like every real-world asset is unique, the NFTs it represents are also unique. Unlike Bitcoin or Ethereum, non-fungible tokens cannot be exchanged directly on various cryptocurrency exchanges. A special platform is required to buy and sell NFTs. The NFT Marketplace is a platform where users can create, store, buy and sell non-fungible tokens. In most cases, tokens can be auctioned off or purchased at a fixed price. To use the NFT marketplace, users must have a cryptocurrency wallet (e.g. MetaMask) to store their cryptocurrencies in order to transact. NFTs can be implemented on any blockchain that supports smart contract programming. Therefore, most NTS are built on Ethereum using the ERC-721 and ERC-1155 standards. Unlike normal tokens, which are fungible and have the same value, each NFT is unique and cannot be duplicated, exchanged or divided. Since NFTs are based on smart contracts (also known as self-executing contracts), each token contains a unique set of information (metadata) recorded in the smart contract, and the blockchain ensures immutability and security. Creating a NFT marketplace usually requires creating a token protocol on the Ethereum network. This is a special group of smart contracts (Figure 1) that provide implementation of certain functions in the market. Additionally, the protocol integrates with marketplace systems. In most cases, all NFT auction platforms share a common thread. First, users need to register on the platform and integrate digital wallets to store NFTs and cryptocurrencies. The platform's registration process is directly related to the cryptocurrency wallet and actually registers with the wallet. Users can then create collections by uploading items to display their work. Users will also be able to choose which payment tokens they will accept for their works and set a secondary selling fee if offered by the platform. The next step is to list the items you want to sell. Users can choose to bid on an auction or fixed price. When an item is sold, a transaction is created that initiates a private trading smart contract for the user's wallet. The platform may need to adjust the fee, and if approved, the NFT will be listed for sale and will be able to accept bids. Generally, NFT marketplaces charge a small fee on the purchase amount.

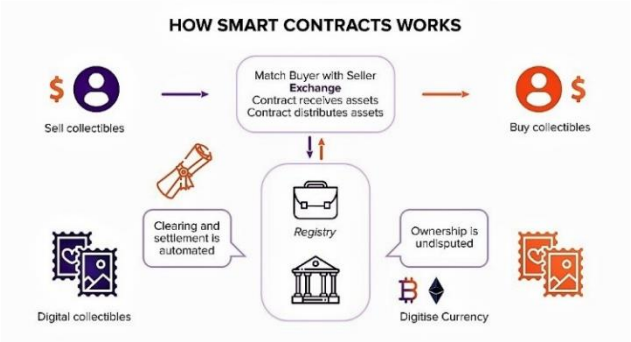

Fig. 1. Working of smart contracts.

II. RELATED WORK

Wajiha Rehman has published a research paper [1] that aims to provide a comprehensive overview of NFTs and their underlying technologies (e.g. blockchain and Ethereum). She also has many platforms for buying and selling NFTs, as well as NFT applications in various fields including education, fashion, sports and digital art. In addition, this white paper highlights key issues in the adoption of NFT technology in terms of security, privacy, environmental impact, ownership, governance, and ownership.The significant increase since the introduction of NFTs is discussed. The current technological and legal environment presents significant challenges related to the application of NFTs. Various NFT applications are being

sought in various fields. Qin Wang published a research paper [2]. The NFT ecosystem is being explored from various perspectives. We start with an overview of current NFT solutions, then provide technical components, protocols, standards, and desired features. We then discuss the evolution of security by discussing the design model's prospects, opportunities, and challenges. We will discuss some common issues in terms of usability, security, governance and scalability, covering both system-level issues arising from blockchain-based platforms and human factors such as regulation and society. Mieszko Mazur has published a research paper [3] examining the risk and return characteristics of NFT-based startups listed on cryptocurrency exchanges. His research has motivated the recent surge in NFT activity from creators, investors, and traders. This article begins by proposing a new classification of traditional NFTs, from blockchain NFTs to NFT DeFi via the NFT metaverse. Next, we set up our NFTs. You get 130% on the first day of listing. Long-term investment returns of multiples of 40 (approximately 4000%), four times higher than Bitcoin over the same period. It provides a positive, significant alpha and shows an above-average beta. It also shows that the NFT sector of the cryptocurrency market is leading the market recovery after the mid-2021 crash, generating returns close to 350%. The final analysis of the article shows that NFT infrastructure integrated into existing blockchains increases the market value of these networks. Z. Zheng published a research paper [4] describing the blockchain, the foundation of Bitcoin, which has recently attracted a lot of attention. The blockchain acts as an immutable ledger that allows transactions to occur in a decentralized manner. Blockchain-based applications are emerging in a variety of fields, including financial services, reputation systems, and the Internet of Things (IoT). However, there are still many challenges of blockchain technology, such as scalability and security. This article provides a comprehensive overview of blockchain technology. It provides an overview of blockchain architecture and compares some of the common consensus algorithms used in different blockchains. Technical issues and recent advances are also briefly listed. It also describes future trends in blockchain. Fakhar ul Hassan published an article [5] that provides an overview of blockchain-based network applications. They talked about how blockchain is challenging the status quo of the central trust infrastructure currently prevalent on the Internet, towards design principles that emphasize decentralization, transparency, and trustworthy auditability. Ideally, blockchain represents a decentralized, transparent, and more democratic version of the internet. Their goal in this article was to highlight the evolution of blockchain-based systems that seek to revive the existing mostly centralized networked application space.

III. PROPOSED METHODOLOGY

FIG. Figure 2 shows a conceptual diagram of the proposed NFT trading platform. You cannot buy or sell without an NFT environment. NFTs are traded on a decentralized website known as the NFT Marketplace, which lists all NFTs for sale by creators around the world. Make it easy for customers to find and purchase NFTs. A notable NFT trading platform is based on the Ethereum blockchain network. NFT marketplaces were originally introduced on the Ethereum blockchain network. These types of platforms require both buyers and sellers to use wallets to ensure smooth transactions.

Merchants can sell NFTs in several ways. Set a fixed price for a specific NFT and make it easy for customers to buy at the purchase price. Alternatively, sellers can add their NFTs to the auction listing and bid to determine the minimum bid price at which buyers can participate in the auction.

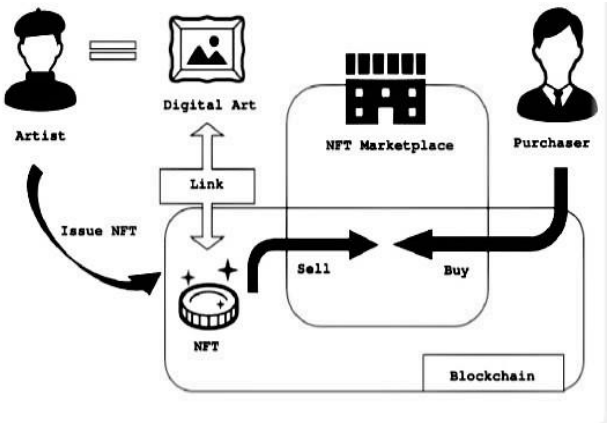

Fig.2. System Design of Proposed NFT Marketplace.

A. Working of Smart Contract

A smart contract is a computer program or trading protocol designed to automatically execute, control or document events and actions in accordance with the terms of a contract or agreement. The goal of smart contracts is to reduce the need for trusted intermediaries, arbitrage costs and fraudulent losses, and to reduce malicious and accidental exceptions. Operation of a smart contract that converts the contents of the contract into a block chain/code stored in the block chain. Thus, the terms of the contract appear in the form of proposals and autonomous orders based on blockchain technology. Such code is supported by programming that guarantees that an item can be executed when certain conditions in the contract are met. However, in the case of smart contracts or depending on the type, an external agent may need to intervene to ensure that the terms of the contract are being fulfilled. Based on external data and information, depending on whether the conditions of the smart contract are met, it is necessary to decide whether to execute the contract and fulfill the contract. A contract is executed immediately when its conditions meet.

Encrypted transaction logs are exchanged between participants without the involvement of third parties, so

there is no fear of information being tampered with for personal gain. Because blockchain transaction records are encrypted, it is very difficult to hack. Also, since each entry in the distributed ledger is linked to the entries before and after it, changing one entry would require a hacker to change the entire chain. Smart contracts eliminate the need for intermediaries to conduct transactions, as well as time delays and associated fees. Fig. 3 shows a smart contract in action.

Fig. 3. Working of a Smart Contract.

B. Features of NFT Marketplace

Currently, NFT Marketplace platforms dominate the cryptocurrency industry. Due to the skyrocketing income, several entrepreneurs and crypto enthusiasts are interested in creating their own NFT Marketplace platform. The following are the key characteristics that a trading platform must possess in order to achieve great success in the cryptocurrency industry. The NFT Store is an advanced control panel that includes NFT preview information, owner details, price history, and more. Advanced token retrieval options on the trading platform give users instant access to the right token. Provide users with a simple listing mechanism to list tradable non-fungible tokens without barriers. Instead of requiring buyers to register with random online wallets, give your marketplace users their own cryptocurrency wallets and help them store their NFTs fearlessly. Since the main purpose of NFT marketplaces is NFT trading, it is important to provide flexible pricing options, rates, etc. to enable users to transact smoothly. The ability to track the location of registered or traded NFTs on the platform helps users control trades and trades. As NFT users increase, it is recommended to have cross-chain functionality so that NFTs from various blockchain networks can be listed and traded here. These features will attract more NFT enthusiasts to the platform. Fig. 4 shows the features of a NFT Marketplace.

C. Working of NFT Marketplace

The NFT Marketplace is a place to list NFTs for sale. They are very similar to auction houses. NFTs are claimed to be true works of art and the highest bidder wins a prize. The more people bidding, the higher the price. This is why collections are so easy to sell. This creates a scarcity that increases the value and price of NFTs. NFT marketplace has numerous different features and types, which makes them quite distinct from eCommerce marketplaces. NFTs or digital assets can be stored, traded, and displayed to a large audience, and a unique business model is evolving.

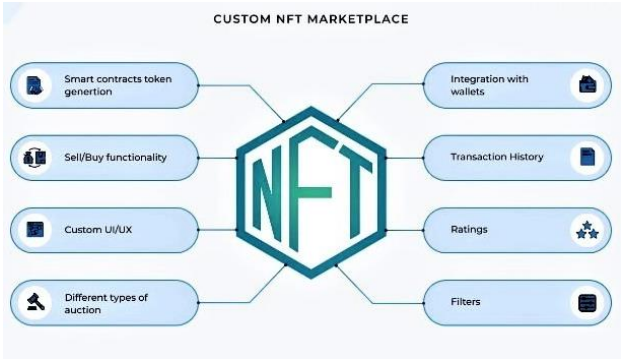

Fig. 4. Features of NFT Marketplace.

Unlike platforms like Spotify or Netflix, which offer unlimited digital content at a subscription fee, NFT marketplaces are built on the notion that, as with physical goods, digital content can be scarce, meaningful, and for sale. These platforms use blockchain technology to maintain digital provenance in much the same way that a traditional auction house can examine a piece of art to verify that it is an original rather than a copy. Some platforms even provide the option to burn items. This further reinforces the scarcity of digital products. Blockchain-based transaction ledgers can also make attribution easier by automatically distributing percentage revenue from resold goods among creators every time their NFTs trade hands. To use the NFT Marketplace, you need three things: Cryptocurrency Wallet: Choose one that is compatible with the blockchain network you want to use. For example, if you plan to buy or sell NFTs on the Ethereum blockchain platform, use a compatible Ethereum wallet such as MetaMask. Not an empty wallet: Before buying, listing or issuing NFTs, you need to pre-fill your wallet with some funds. User account: Create an account for the specific market you want to work with NFTs in. Fig. 5 shows the working of a NFT Marketplace.

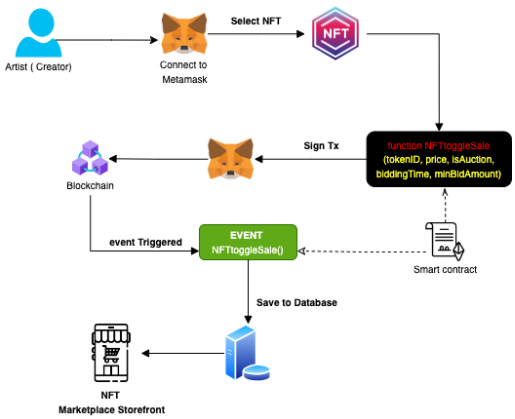

Fig. 5. Working of NFT Marketplace.

D. Blockchain Technology

Blockchain is a method of recording information that makes it impossible or difficult to change, hack or manipulate the system. A blockchain is a distributed ledger that replicates and distributes transactions across a network of computers participating in the blockchain. Blockchain technology is a structure that stores public records of transactions, also called blocks, in multiple databases called "chains" on a network connected through peer-to-peer nodes. This repository is commonly referred to as a "digital ledger". The properties of this book ensure the safety and security of its contents.

Each transaction in this book is authorized by the owner's digital signature, which authenticates the transaction and protects it from unauthorized access. Thus, information contained in digital registries is securely protected. Simply put, a digital ledger is like a Google spreadsheet shared by millions of computers on a network that stores transaction records based on actual purchases. What's interesting is that anyone can see your data, but they can't damage it.

IV. WORK FLOW

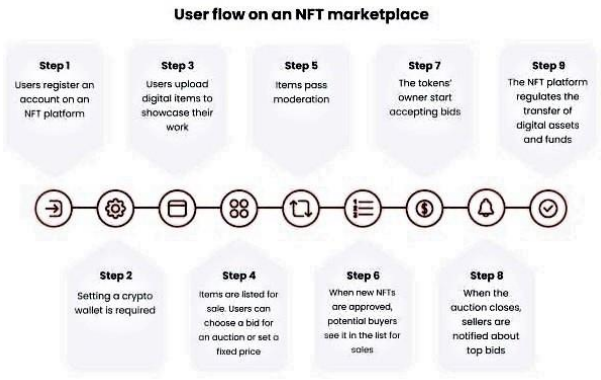

Fig. 6. Flowchart of the proposed system.

V. CONCLUSION

This article proposes a model for creating, listing and selling NFTs in the NFT Marketplace. The proposed method uses Solidity for writing smart contracts, JavaScript for React and testing, Ethers for interacting with the blockchain, and Hardhat as the development environment. It also uses Ipfs to store metadata and React routers for navigational components. The NFT Marketplace is a new-age marketplace for trading, selling, and buying digital works. As cryptocurrencies grow in popularity and value, it is safe to assume that NFT markets and entire blockchain networks will remain in demand in the long run. The effectiveness and applicability of the proposed method will be studied in the public NFT market and compared with other blockchain networks for secure transactions of NFT domains.

Performance Evaluation of Lightweight ASCON-Hash Algorithm for IoT Device

Rahul P. Neve, Rajesh B. Bansode
Thakur College of Engineering and Technology, Mumbai, Maharashtra, India

Abstract—**Lightweight cryptographic hashing algorithms are designed to be efficient and fast, making them suitable for use in resource-constrained milieus such as Internet of Things (IoT) devices, other embedded systems. These algorithms are optimized for limited computational power, memory, and bandwidth, while still providing a high level of security. Resources constrained devices typically have limited computational power, memory, and bandwidth, making it challenging to use traditional, computationally intensive cryptographic algorithms. Lightweight hashing algorithms are designed to address this challenge by providing a high level of security while being optimized for the limited resources of these devices. This allows them to be used in a wide range of applications, such as: Authentication: To verify the authenticity of messages and prevent tampering or replay attacks. Digital signatures: To provide non- repudiation and ensure that messages have not been altered in transit. Data integrity: To detect accidental or intentional modification of data. Key derivation: To generate cryptographic keys from a shared secret or password. This paper is focused on ASCON-Hash LWC , which his based on sponge structure. Detailed study on hash function of ASCON is done and algorithm is implemented on raspberry Pi to analyze actual result. After performing experiments on the ASCON-Hash ,it has been observed that there is possibility to optimize the algorithm by optimizing the permutation layer of hash function.**

Index Terms—Cryptographic algorithm, data integrity, decryption, encryption, hash functions, IoT, lightweight, resource constrain devices.

I. INTRODUCTION

THERE is extensive use of smart gadgets for variety of applications. Many smart gadgets come into resource constraint category, with limited processing capabilities in terms of memory, time and energy consumption. To maintain equilibrium of security triad (confidentiality, Integrity and availability) in resource constraint micro-controller like Raspberry Pi, Arduino Uno is matter of concern. For achieving confidentiality, encryption and decryption algorithms are used. To achieve Integrity hashing concept, need to be implemented.

Cryptographic hashing algorithms are mathematical functions that convert input data of arbitrary size into a fixed-size output, called a hash, such that for same input value the hash value will be same. These algorithms are designed to be irreversible function, meaning that it is practically impossible to reconstruct the original input from the hash.[1] Traditional cryptographic hashing algorithms, such as the widely-used SHA-1 and SHA-2, have some potential drawbacks that canlimit their effectiveness in certainscenarios:

- Vulnerability to collision attacks: Some traditional cryptographic hashing algorithms are vulnerable to collision attacks, which occur when two different messages produce the same hash value. This can lead to security vulnerabilities in systems that rely on the uniqueness of hash values, such as digital signatures and message authentication codes.
- Limited message size: Traditional cryptographic hashing algorithms often have a limited message size that can be hashed in a single operation. This can be a limitation in certain scenarios, such as when hashing large files or streams of data.
- No privacy protection: Traditional cryptographic hashing algorithms do not provide privacy protection for metadata associated with the hashed data, such as the length of the message or the identity of the sender and receiver.
- No key management: Unlike some cryptographic algorithms, traditional cryptographic hashing algorithms do not require key management, but they rely on the properties of the hash function to provide security. However, if the hash function is compromised, this can lead to security vulnerabilities.

Lightweight cryptographic hashing, also known as lightweight hash functions, refers to a class of hash functions that are designed to be implemented efficiently on resource- constrained devices, such as low-power microcontrollers or RFID tags. These hash functions are typically designed to have a small code and data size, low power consumption, and high processing speed, while still providing a level of security that is appropriate for the specific application.[2]

Some examples of lightweight cryptographic hash functions include PHOTON, SPONGENT, and LESAMNTA, which are designedto provide cryptographic security while also being efficient in terms of memory and processing power.

Lightweight cryptographic hash functions are important for securing the growing number of IoT kind devices, which often have limited resources and are vulnerable to attacks due to their connectivity to the internet. These hash functions can be used for tasks suchas message authentication and integrity checking, which are

important for ensuring the security of data transmitted between IoT devices. It's important to note that while lightweight cryptographic hash functions can provide a level of security that is appropriate for many IoT applications, they may have limitations in terms of the level of security they can provide compared to more complex hash functions. Therefore, it's important to carefully evaluate the specific security requirements of the application and choose a hash function that is appropriate for those requirements.

II DIFFERENCE BETWEEN TRADITIONAL HASHING AND LIGHTWEIGHT HASHING

Traditional cryptographic hash functions and lightweight cryptographic hash functions are both designed to perform the same basic task, which is to take an input message of arbitrary length and produce a fixed-size output that is representative of the message. However, there are several key differences between the two types of hash functions. Design: Traditional cryptographic hash functions, such as SHA-2 and SHA-3, are designed to be highly secure and resistant to a wide range of attacks, including collision attacks, preimage attacks, and second preimage attacks. These hash functions are designed to provide a high level of security, but can be computationally expensive and may not be optimized for low-power devices. On the other hand, lightweight cryptographic hash functions are designed to be efficient and fast on low-power devices such as microcontrollers and embedded systems. These hash functions typically use simpler designs and algorithms that are optimized for performance, but may not provide the same level of security as traditional hash functions.[3][4]

Security: Traditional cryptographic hash functions are designed to provide a high level of security, and are typically used for applications where data integrity and authenticity are critical, such as digital signatures and password storage. These hash functions are designed to be resistant to a wide range of attacks, and are often subject to extensive security analysis and testing.

Lightweight cryptographic hash functions, on the other hand, may not provide the same level of security as traditional hash functions, and may be vulnerable to certain types of attacks, such as collision attacks or hash-flooding attacks. However, these hash functions are still designed to provide a basic level of security and integrity, and are often used in applications where speed and efficiency are more important than absolute security.

Applications: Traditional cryptographic hash functions are widely used in a variety of applications, including encryption, authentication, and digital signatures. These hash functions are used in high-security applications where data integrity and authenticity are critical. Lightweight cryptographic hash functions are often used in low-power devices and embedded systems, where efficiency and speed are more important than absolute security. These hash functions are commonly used in applications such as sensor networks, RFID tags, and other devices where memory and processing power are limited.

III TYPES OF LIGHTWEIGHT CRYPTOGRAPHIC HASH FUNCTIONS

There are three major category of lightweight cryptographic hash function. Markel Damgard , block cipher and Sponge construction. These constructions also include substitution permutation network, Fiestel structure with arithmetic modular addition, circular fashion bit shift, exclusive Or operations. Below these constructions are described in brief.

A. Markel Damgard Hash Function:

Merkle-Damgård is a widely used construction for constructing cryptographic hash functions. It is named after Ralph Merkle and Ivan Damgård, who independently developed the idea in the late 1970s. The Merkle-Damgård construction is the basis for many popular hash functions, including MD5, SHA-1, SHA-2, and SHA-3.The Merkle- Damgård construction is based on a compression function that takes a fixed-size input and produces a fixed-size output. The compression function is used to process blocks of the input message and generate an intermediate hash value. The intermediate hash value is then used as the input to the compression function for the next block, until all blocks have been processed.

The Merkle-Damgård construction consists of three phases: padding, compression, and output.

Padding: The input message is padded so that its length is a multiple of the block size of the compression function. The padding is done in such a way that it is distinguishable from the original message, to ensure that the padding cannot be used to create collisions.

Compression: The compression function is applied to each block of the padded message, using the intermediate hash value from the previous block as an input. The output of the compression function is the intermediate hash value for the current block.

Output: Once all blocks have been processed, the final intermediate hash value is the output of the hash function. The security of the Merkle-Damgård construction depends on the security of the compression function and the strength of the padding. The compression function should be designed so that it is resistant to collision attacks, and the padding should be designed so that it is distinguishable from the message and resistant to length extension attacks.

One disadvantage of the Merkle-Damgård construction is that it is vulnerable to length extension attacks, which allow an attacker to append data to a hash output without knowing the input. This vulnerability has led to the development of other constructions, such as the sponge

construction used in SHA-3, that are resistant to length extension attacks.[5]

B. Block Cipher Hashing Construction:

The Lightweight (LW) block cipher is a family of small, efficient block ciphers designed for resource-constrained environments such as low-power devices. One common use of the LW block cipher is as a component of hash functions.

LW block cipher-based hash functions use the following construction:

1. The input message is padded to a multiple of the block size of the LW block cipher.

2. The padded message is divided into blocks of the block size.

3. An initial value (IV) is chosen and passed through the LW block cipher to produce the initial state.

4. For each block of input data, the current state is passed through the LW block cipher, along with the block of input data, to produce a new state.

5. After all the blocks have been processed, the final state is the hash value.

The LW block cipher consists of a number of rounds, each of which applies a non-linear function to the state, followed by a linear mixing operation. The non-linear function is typically based on an S-box, which maps an input to an output based on a fixed lookup table. The linear mixing operation typically involves the XOR or addition of various parts of the state.

The LW block cipher is designed to have a low gate count, low power consumption, and a small code size. It is also designed to be resistant to various attacks, such as differential and linear cryptanalysis.

C. Sponge Construction

Sponge functions are a class of cryptographic primitives that can be used for various purposes such as message authentication, encryption, and hashing. In particular, the sponge construction can be used to build a hash function.

A hash function based on the sponge construction operates as follows:

1. The input message is split into blocks of a fixed size, which is usually a multiple of the internal state size of the sponge function.

2. The sponge function is initialized with an initial state and a fixed output size.

3. The input blocks are fed into the sponge function, which updates its internal state by absorbing the input.

4. Once all input blocks have been processed, the sponge function enters the squeezing phase, during which it generates the hash output by repeatedly applying the sponge function and outputting a portion of the internal state.

5. The output is truncated to the desired length to obtain the final hash value.

One popular lightweight sponge-based hash function is

called the "ASCON-hash" function, which was selected as the second-round winner of the NIST hash function competition in 2017. ASCON-hash is a family of sponge functions that can generate hash values with a wide range of output sizes. It has a number of desirable properties, including resistance to various types of attacks and efficient implementation on a wide range of platforms.

Overall, the sponge construction provides a flexible and efficient framework for constructing cryptographic hash functions that can be tailored to specific requirements. Lightweight cryptography in particular emphasizes the needfor efficient and resource-constrained implementations, making sponge-based hash functions a promising choice for such applications. Some of the example of Lightweight Cryptographic hash: BLAKE2: It is a hash function that uses the Merkle- Damgård construction with a different compression function than SHA-2. BLAKE2 is faster and more secure than SHA-2, and supports multiple output sizes. The BLAKE2 hash function is initialized with a key and a salt, which are used to add additional entropy to the hash output. The key and salt are mixed into the initial state vector using a modified version of the ChaCha20 block cipher, and the hash function is then used to process the input message in a series of blocks. Whirlpool: Whirlpool is a hash function that uses the Miyaguchi-Preneel construction, which is similar to the Merkle-Damgård construction but with a different padding scheme. Whirlpool is designed to be resistant to collision attacks and is used in some digital signature algorithms.

SHA-3 is the latest hash function standard from NIST, and is based on the sponge construction. SHA-3 is designed to be resistant to length extension attacks, and supports multiple output sizes.

SipHash is a family of hash functions that are designed to be fast and secure on 64-bit platforms. SipHash uses a combination of XOR and modular arithmetic to mix the input message, and is resistant to hash-flooding and timing attacks.

XXHash is a fast non-cryptographic hash function that is designed to be efficient on 32-bit and 64-bit platforms. XXHash uses a combination of XOR, modular arithmetic, and bit shifts to mix the input message, and is resistant to hash-flooding attacks.

FNV-1a: FNV-1a is a simple and fast non-cryptographic hash function that is designed to be efficient on 32 -bit platforms. FNV-1a uses a combination of XOR and multiplication to mix the input message, andis resistant to hash- flooding attacks.[6][9]

IV. LIGHTWEIGHT ASCON-HASH ALGORITHM

This paper is based on the detail study and implementation of ASCON-HASH algorithm on raspberry pi (IoT controller) ASCON is a family of lightweight authenticated encryption algorithms that provide both confidentiality and authenticity of messages. In addition to the encryption and decryption functions, ASCON also includes a hash function that can be used to securely derive message keys and other cryptographic parameters.

The ASCON hash function takes an input message of any length and produces a fixed-size hash value as output. The algorithm uses a permutation-based design, where the input message is first padded to a multiple of the block size and then processed in blocks using a round function that mixes the input with a secret key and a nonce. The final output is computed by applying a finalization step to the last block and returning a portion of the internal state.

ASCON provides a high level of security with respect to both preimage and collision attacks, and is designed to be efficient in both hardware and software implementations. The algorithm has been thoroughly analyzed and is considered secure against a wide range of attacks. [4][8]

A. The ASCON-HASH algorithm operates as follows:

i. The input message is split into blocks of a fixed size (either 128 or 320 bits, dependingon the securitylevel desired).

ii. The sponge function is initialized with an initial state and a fixed output size of 256 bits.

iii. The input blocks are fed into the sponge function, which updates its internal state by absorbing the input.

iv. Once all input blocks have been processed, the sponge function enters the squeezing phase, during which it generates the hash output by repeatedly applying the ASCON permutation and outputting a portion of the internal state.

v. The output is truncated to the desired length to obtain the final hash value

ASCON – HASH Algorithm:
Plain Text P.T as input ,output Hash Message size l < h or l arbitrary if h=0 and produce output: Hash with fixed length Initialization:
S← $pa\ (IVh,r,a||\ 0c)$
Absorption:
$P.T1 \ldots . P.Ts \leftarrow P.T\ ||1||0*$
For each character of P.T
$S \leftarrow pa((Sr \oplus P.Ti)\ ||Sc)$
Squeezing
for i=1,….., t=(l/r) do
$Hi \leftarrow Sr$
$\boldsymbol{S} \leftarrow pa\ (S)$
return $|H1|| \ldots . ||Ht||l$

Where

IV: Initial Vector

a : number of rounds p : Permutation

M : Plain text or Message

c : constant

H : Hash output at each phase r : rate

l : length (256)

S : State

Initial State: Thenext step is toset theinitial state ofthe ASCON permutation. This state consists of a 128-bit state vector and a 64- bit associated data (AD) length. The state vector is initialized to a fixed value, and the AD length is set to zero.

Absorb Phase: The absorb phase is used to process the input message. The message is divided into blocks and each block is XORed with the state vector. Then, the ASCON permutation is applied to the state vector to mix in the message block.

Padding: If the input message is not a multiple of the block size, padding is added to the last block to make it a full block. The padding consists of a 1-bit followed by zeros, and is XORed with the state vector.[11]

The squeezing stage in ASCON-HASH consists of the following steps:

Squeeze Phase: The squeeze phase is used to extract the hash output from the state vector. This is done by repeatedly applying the ASCON permutation to the state vector and outputting a block of the specified hash size at each iteration. The size of each block is equal to the output size of the hash function, which is typically 256 bits.

Finalization: Once the specified number of blocks has been output, the final state vector is XORed with the key schedule to prevent multi-target attacks, and the final output is produced. The final output is equal to the concatenation of all the output blocks produced during the squeeze phase. The number of blocks output during the squeeze phase is determined by the size of the hash output and the block size of the ASCON permutation. For example, if the hash output is 256 bits and theblocksizeis 128 bits, thentwo blockswillbe outputduring the squeeze phase. The squeezing stage ensures that the final hash output is a fixed- size value that is unique to the input message. By repeatedly applying the ASCON permutation and outputting blocks of the specified size, the squeezing stage produces a hash output that is resistant to collision attacks and other types of attacks.

Substitution Layer: The substitution layer of ASCON-HASH is designed to provide diffusion and confusion properties to the hash function, which are necessary for

the security of the function. The nonlinear substitution operation and the linear diffusion operation work together to ensure that any small change in the input to the function results in a large change in the output, making the function resistant to attacks. Figure 1 shows substitution layer pS. [10]

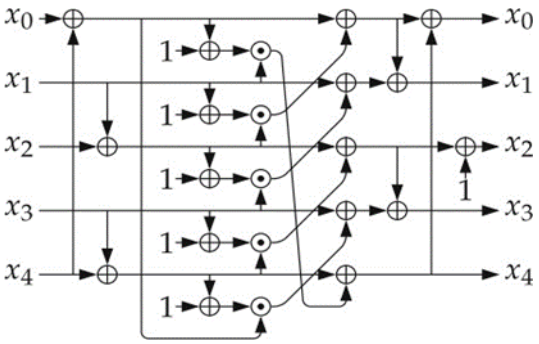

Fig 1: ASCON 5-bit Box

Linear diffusion: The state is transformed using a linear matrix multiplication operation. The matrix used in ASCON- HASH is designed to provide maximum diffusion in a small number of rounds. The linear diffusion layer of ASCON-HASH is a linear transformation that is applied to the state of the permutation to providediffusion, which is a key property ofany secure hash function. The linear diffusion layer operates on the state in a way that ensures that small changes in the input propagate uniformly to all bits of the state.

Figure 2 shows linear diffusion layer of ASCON- HASH consists of a matrix multiplication operation between the state and a fixed 5x5 binary matrix, denoted by M. The matrix M is carefully chosen to provide a good diffusion property while maintaining a small implementation footprint.

$$x_0 \leftarrow \Sigma_0(x_0) = x_0 \oplus (x_0 \ggg 19) \oplus (x_0 \ggg 28)$$
$$x_1 \leftarrow \Sigma_1(x_1) = x_1 \oplus (x_1 \ggg 61) \oplus (x_1 \ggg 39)$$
$$x_2 \leftarrow \Sigma_2(x_2) = x_2 \oplus (x_2 \ggg 1) \oplus (x_2 \ggg 6)$$
$$x_3 \leftarrow \Sigma_3(x_3) = x_3 \oplus (x_3 \ggg 10) \oplus (x_3 \ggg 17)$$
$$x_4 \leftarrow \Sigma_4(x_4) = x_4 \oplus (x_4 \ggg 7) \oplus (x_4 \ggg 41)$$

Fig 2: ASCON Linear diffusion Layer

The linear diffusion layer is applied to the state of the permutation in each round of the hash function, except for the first and last rounds, which do not have a diffusion layer. The number of rounds used in the hash function depends on the desired security level and the input size of the hash function. Overall, the linear diffusion layer of ASCON-HASH plays an important role in ensuring the security of the hash function, by providing a good diffusion property that ensures that any small change in the input results in a large change in the output.

V EXPERIMENTAL RESULTS AND OBSERVATIONS

Implementation of ASCON-HASH algorithm was carried out using python language on Raspberry Pi 3 model b controller. It consists of 1 GB of Random-access memory, Quad Core 1.2GHz Broadcom BCM2837 64bit CPU , BCM43438 wireless LAN and Bluetooth Low Energy (BLE) on board , 100 Base Ethernet , Micro SD port for loading operating system and storing data , Upgraded switched Micro USB power source up to 2mA with Vcc 5V.

Input as text file with varying size (i.e 100kb , 200 kb ,300kb, 400kb, 500kb) was provided to the algorithm and results are observed. Measurement parameters such as

TABLE I TIME TAKEN FOR ASCON HASHING ALGORITHM IN SEC , MEMORY AND ENERGY CONSUMPTION

File Size (Text File) In Kb	Hashing Time In Seconds	Memory Consumption In Kb	Energy in Mili Joules	Data Process In Kb/Sec
100	21.88	220	218	46.80073
200	45.06	380	450	45.45051
300	66	428	661	46.54545
400	87.4	528	874	46.31579
500	109.6	628	109.6	46.71533

Inference:

a. As the file size increase gradually rate of time & Memory consumption increase in linear way.

b. Average throughput for ASCON algorithm is 46 Kb/Secs

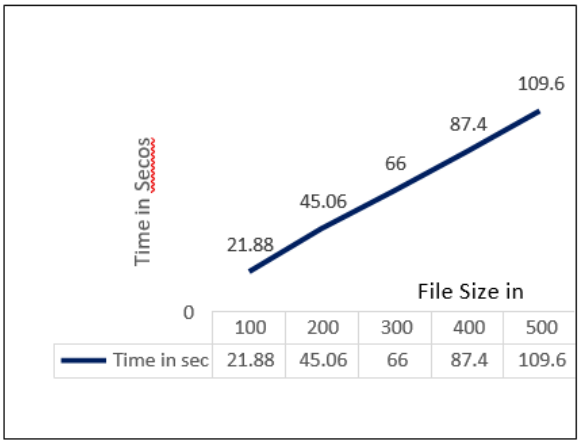

Fig 3 : Hash Algorithm Time Consumption in Sec Figure 3. shows the linear shift in the graph of time in secs verses input file size (i.e if input file size increases, in that case execution time of the algorithm increases in linear fashion. In same way figure 4. Shows that memory consumption increasingly steadily with increase in input

file size. As energy consumption parameter directly proportional to time , hence as execution time increases , energy consumption is also increases and same is depict in figure 5

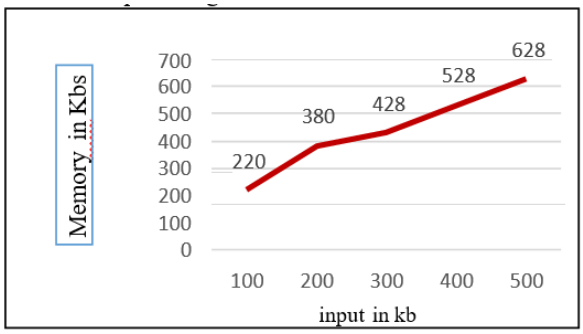

Fig 4 : Hash Algo Memory Consumption in Kb

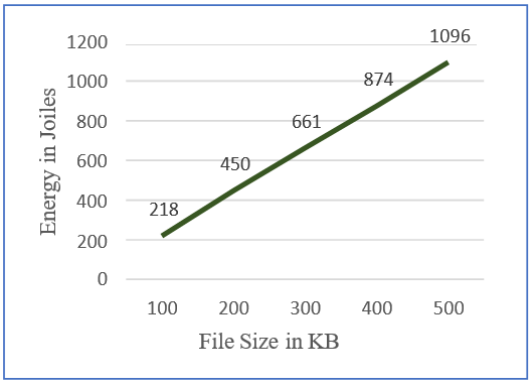

Fig 5: Energy consumption by raspberry pi 3

VI. DISCUSSION ON THE ACHIEVED OUTPUT

TABLE II TECHNICAL PARAMETER MEASURED, OUTCOME ACHIEVED, INFERENCE AND IMPACT

Technical Parameter Measured (for 100kB oftext file)	**Output achieved** ASCON-HASH	**Outcome as inference of output**	**Impact**
Hashing Time **Time in sec**	21.88 sec	Time required to create hash value of plain text calculated using time.start and time.Stop function and the difference is noted.	As ASCON-Hash Function consumes21.88 sec , it will effect energyconsumption parament
Memory Consumptionin Kb	220 kb	For memory consumption, psutil library with memory.rss fuction is used to calculate memory consumption during Hashingprocess	Gradually increase in input file size will linearly increases in memory consumption with the average rate of 102 bytes
Energy in Joules	218 millijoules	Energy is calculated as E= Vcc*I*t whereas Vcc is5V, I is current i.e 2mA and t is time taken for execution of decryption function for 100 kb text file.	Energy parameter is directly proportional to the time required for data processing and execution of hash function. Hence energy consumption increases as time for execution increases
Bit rate / Byte rate	46 kb /sec	Total size of data processed per unit of time . Bit rate of 46kb /sec is observed after execution of ASCON Algorithm for text file data.	It is observed that average byte rate is 46 kb / sec after providing the various input data, which shows that constant byte rate is maintained for the system.

VI. CONCLUSION

One of the main advantages of ASCON-HASH is its simplicity, which makes it easy to implement and verify. It has a small code size and memory footprint, making it an attractive option for use in low-power devices. It also offers a high degree of security, with a collision resistance of 2^128 and a preimage resistance of 2^256.

ASCON-HASH is based on thesponge construction, which means that it can be used for both hashing and message authentication code (MAC) generation. The algorithm has a flexible parameter set that allows users to adjust the security level and performance to meet their specific needs.Overall, ASCON-HASH is a strong and efficient hash function that can be used in a wide range of

applications, particularly those that require lightweight cryptography. However, as with any cryptographic algorithm, it is important to use it correctly and to ensure that it is implemented securely to avoid any potential vulnerabilities.

ASCON-hash can be optimized for better efficiency by optimizing substitution , diffusion , permutation layer of algorithm , but care should be taken to maintain security level of algorithm.

dba.irfan06@gmail.com, kmsubbu.phd@gmail.com, syednajamulhassan@live.com

Abstract— **For storing data across several clouds, many new strategies have recently been developed. Users automatically have some degree of information leakage control thanks to data distribution over various cloud storage providers (CSPs), as no one point of attack can leak all the data. Even when using numerous clouds, however, the unintended spread of data chunks can result in significant information leakage. In this article, we examine a significant issue with information leakage brought on by the haphazard distribution of data in multi-cloud storage systems. Then, we introduce the technique, a multi-cloud storage system that is cognizant of information leaks. By storing syntactically similar data on the same cloud, a methodology seeks to reduce information leakage from users across different clouds. We create a function to compute the information leakage based on these signatures and an approximate algorithm to efficiently create similarity-preserving signatures for data chunks. We then offer a powerful storage plan generation approach based on clustering for spreading data chunks over many clouds with little information loss. Finally, we assess our plan, which can stop information leaks more effectively than an impromptu placement. Additionally, our study of system attackability shows that our technique makes information attacks more difficult.**

Keywords—Multicloud storage, information leakage, system attackability, remote synchronization, distribution and optimization

I. INTRODUCTION

Users need widespread and expansive network storage to manage their ever-expanding digital lives with the increased acceptance of devices like laptops, telephones, and tablets. Due to their user-friendly interfaces and affordable storage prices, various cloud-based file-sharing and storage services, including Dropbox, Google Drive, and Amazon S3, have become popular in response to these needs. These centralised cloud storage systems are attacked, nevertheless, for seizing control of customers' data and allowing storage providers to utilize it to run marketing and advertising analytics [1]. Additionally, the data of users may be exposed through malevolent insiders, backdoors, bribery, and coercion, among other methods. Utilizing multi-cloud storage systems [2, [3, [4,] [5,] in which no single point of attack may leak all the information, is one potential way to lower the risk of information leaking. A malevolent actor would need to force all the numerous CSPs on which a user might place her data in order to obtain a complete picture of her data, similar to the one exposed in previous privacy attacks [6]. Don't put all your eggs in one basket, to put it simply, as the adage goes. But things are not quite that straightforward. rsync-related protocols are used by CSPs like Dropbox, among many others, to synchronize local files with remote files in their centralized clouds [8].

However, these fingerprints are only useful for exact equality checking because they can only determine whether the data nodes are duplicates. Finding identical chunks is rather simple, but effectively detecting similarity between chunks is a difficult issue because similarity-preserving fingerprints don't exist (or signatures). Simultaneously, if one wants to minimize information dissemination, the similarity is crucial. Simply put, two paragraphs of text with a single-word difference result in two distinct chunks. The two chunks would be viewed as distinct and placed separately if identification were the only factor taken into account, but since they both almost totally share the same information, they should preferably be combined.

We point out that the aforementioned issue persists even with encryption because, if the encryption key is compromised (for example, as a result of the CSP being forced to divulge it by a third party, such as the National Security Agency, or as a result of the CSP's own malice), the user's entire data can be easily leaked. Even if the encryption key is made public, information leakage can be minimized if encryption is carried out after nearly identical grouping chunks. Therefore, in order to limit information leakage in the multi-cloud storage system, we need more advanced approaches to identify data chunks that are nearly the same (or similar).

II. RESEARCH BACKGROUND

A. Problem Statement

Users automatically have some degree of information leakage control thanks to data distribution over various cloud storage providers (CSPs), as no one point of attack can leak all the data. However, even when using numerous clouds, uncontrolled data chunk distribution can result in excessive information leakage.

- Even when using numerous clouds, unplanned data chunk distribution can result in excessive information leakage.
- Redundancy of comparable data when several clouds' data are often modified.
- Data from numerous clouds is not sufficiently secure. There is a danger that everything will be lost.

B. Objective

Most of the time, individuals are using centralised multiple cloud storage services like Microsoft Azure, Dropbox, and iCloud to store their data, which gives them control over their data and creates a single point

of failure across numerous clouds. [7] Unplanned data releases on multi-cloud storage providers, however, would result in significant information leaks and single points of failure across numerous clouds. Therefore, the goal of this study is to identify the best methods for limiting information leakage in multicloud. Then, we introduce StoreSim, a storage system that is concerned about information leakage and stores comparable data in the same cloud. We created the MinHash technique to quickly produce similarity-preserving signatures for data chunks. We also created a function to calculate information leakage based on these signatures, which were hashed using fingerprinting algorithms like SHA-1 and MD 5. So that users' data could be stored effectively and securely using a multi-cloud storage system, we supplied optimal information leakage protection.

III. SYSTEM ANALYSIS

Proposed System:

We introduced the StoreSim system, which is aware of an information leakage storage system in the multi-cloud, to reduce information leakage during unplanned data releases. To prevent information from being lost over several clouds is used to syntactically store comparable data across the same cloud. By effectively creating similarity-preventing signatures for data chunks using the unique MinHash method, and designing a function to calculate information leakage based on these signatures provided by fingerprint techniques like SHA-1 and MD5, this system has fulfilled its purpose. A user can now store data across many clouds, edit each cloud's data as needed, and safely download data across multiple clouds. To reduce information leakage, we designed a cutting-edge system that is utilized to store data in a secure, effective, and efficient manner across a centralized multi-cloud storage system..

Advantages Of Proposed System

- Each data piece that is kept across several clouds is encrypted, making it impossible for anyone to access it without decryption.
- There is no issue with vendor lock-in, and users can easily keep their multiple cloud data throughout time.
- The suggested system includes cost efficiency, data integrity, and availability;
- Reduce the likelihood that all the information will be lost at once.

IV. PROJECT IMPLIMENTATION

A. *Proposed Modular Implementation*

I used three modules in this project job, and each module has its functions, such as:

1. Data Owner (Client) module
2. Metadata Servers module
3. Cloud Service Providers module

1. Data Owner module

This module is used to pre-process user data for optimization purposes, including binding, deduplication, chunking, and delta encoding. The owner must sign up for the system and use their username and password to log in. Following that, they will perform the following tasks, including:

- the user uploads their own files from a local PC to the system, divides them into chunks with a maximum size of the data unit, and then encrypts them before sending them to various clouds.
- The data owner has the ability to edit their own data once it has been posted to several clouds. By comparing the similarity across data chunks and using the jac card similarity to determine where to upload the updated data, users can modify both cloud data in this manner..
- By requesting cloud keys from the storage providers, the owner can get data that is stored across several clouds.

2. Metadata server's module

This module is used to keep data on the users who represented the files saved in the various cloud storage providers, as well as information about the files, cloud storage providers, and users. However, in order to visit this page, the user must first log in using a username and password that were explicitly chosen by the system's developer.

3. Cloud Service Providers module

I discussed cloud functionality in this module. To access files, see requests, and approve requests sent by other users or the data owner, the cloud user must first log in to the page where they will view files, view requests, and approve requests. After chunking different data, I used a cloud service that was coupled with my local system to store it.

V. Implementation And Result Analysis

A. Project execution process:

1. DBA home page:

The login credentials were successfully evaluated at the DBA login page, and their respective services are listed in this welcome file.

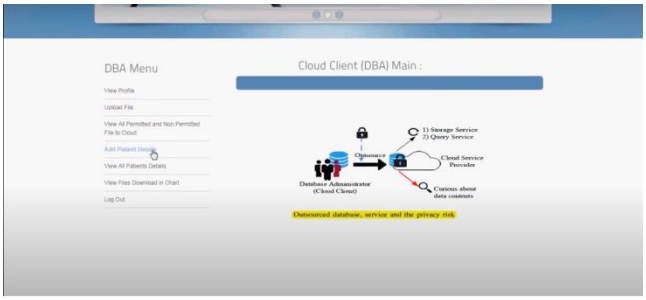

Figure 4: DBA home page

2. File upload page:

By choosing one of the servers on this file upload page, a new file can be uploaded together with the names of its attribute names, and content will load for submission.

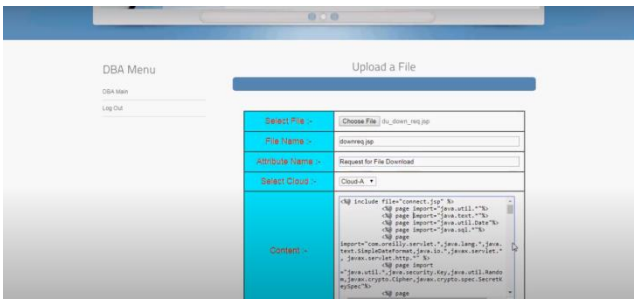

Figure 5: File upload page

3. File encryption page:

The content of a file that is being uploaded to a particular server must be encrypted with the proper Mac key and forwarded to the cloud server using this file encryption page.

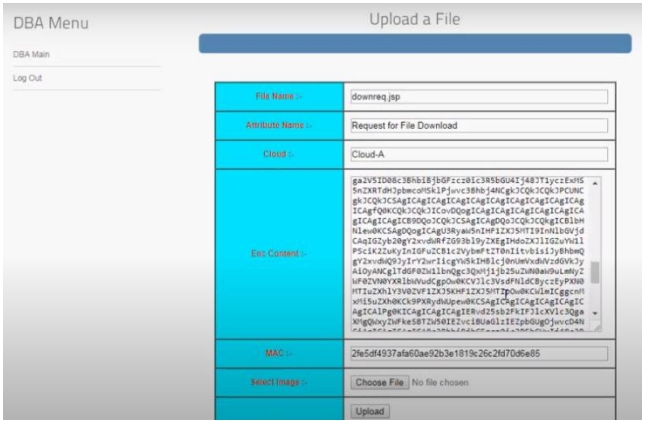

Figure 6: File encryption page

4. File upload acknowledgment page:

After the file's content has been successfully loaded and encrypted on the designated server, an acknowledgment will be displayed here in this file upload acknowledgment page.

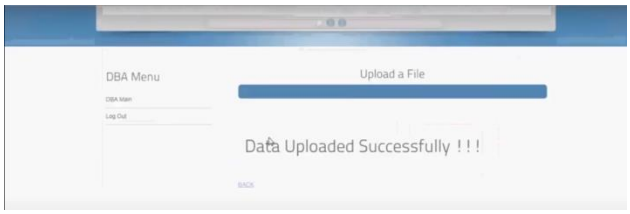

Figure 7: File upload acknowledgment page

5. Forward status page:

After a file has been successfully uploaded to a particular server, it will be reported here on this forward status page as the status of the forward content.

Figure 8: File status page

6. File permission page:

This file permission page will acknowledge all users whose corresponding requested file to a certain server has been approved or denied.

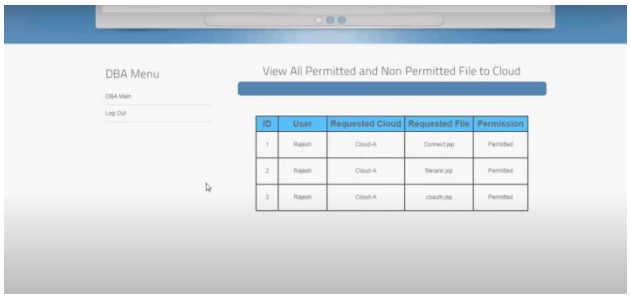

Figure 9: File permission page

7. File search page:

In order to filter or get the desired data, this File Search page's attributes, such as query type, table name, and query, are used as inputs.

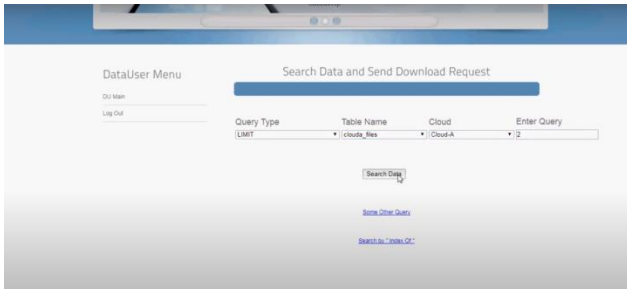

Figure 10: File search page

8. Search result page:

The download request is also made easier on this search result page, where results from a multi-keyword process are displayed in the form of a table.

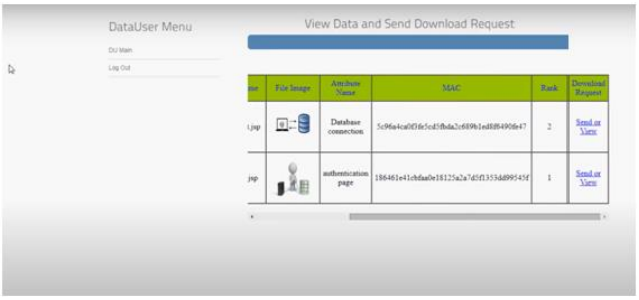

Figure 11: File status page

VI. Conclusion And Future Scope

Conclusion : To secure the database on the cloud in this project, we suggested a two-cloud strategy coupled with a set of connection protocols. Because most users store their data across numerous clouds for security reasons, Unplanned data dissemination across several clouds, however, may raise the degree of information leakage by increasing the likelihood that all data would be lost. I created a storage system that is aware of information loss in many clouds and stores similar data in the same cloud in order to minimise information leakage. I created a technique to quickly create similarity-preserving signatures for data chunks, and based on those signatures, I created a function to calculate the information leakage. Finally, I listed the best providers of multi-cloud storage that effectively reduce information leakage. Thus, we can successfully achieve data secrecy when accessing the database in the cloud, demonstrating the effectiveness and viability of the suggested access mechanism for use in bigger systems.

Future Scope : Software that satisfies every user requirement cannot be created. However, this system has some room for improvement in the future:

- A user will automatically receive an email notification whenever their cloud data is changed.
- System security will also upgrade as security technology does.
- Increasing the number of clouds beyond two to effectively manage information leakage.

Enhanced Shield Protection over Confidential Private Data in Public Cloud Store

Syed Ajwad Hussain, Subramanian K.M, Sridhar Gummalla
Shadan college of Engineering and Technology Hyderabad, Telangana, India
syedfarhanajwad@gmail.com, kmsubbu.phd@gmail.com, sridhar_gummalla@yahoo.com

Abstract— **A new paradigm called "cloud computing" makes it possible for users (data owners) to store their data on servers in the cloud and for users (data consumers) to access that data. This paradigm lowers the data owner's storage and maintenance costs. Also, the owner of the data no longer has physical access to it, which increases the security threats. Hence, a data integrity auditing solution is crucial for the cloud. The necessity to verify data ownership while preserving privacy has made this problem challenging. This paper suggests a secure and effective method of proving data ownership in order to overcome these challenges. We also add support for multiple owners, data dynamics, and batch verification to SEPDP. The auditor may easily and quickly verify that data is there using this approach, which is its most appealing aspect. No matter what kind of data is saved in the cloud by consumers, security and privacy are their top priorities. Data sharing should be permitted with conditional dissemination to regulate data access by establishing evaluation procedures and policies that will enhance network security and shorten network (data transmission time) between two virtual machines running on distinct physical machines. When we concentrate on the cloud computing domain in relation to data as a service, we need to place emphasis on the following characters, such as DO who owns the data we store there, in turn, DU who benefits from the data owned by DO, and of course, who consumes data-as-a-service through cloud servers by privileged access of service data, which is advised to be a reliable and adaptable mechanism. This procedure needs to be optimised with regard to the data stored on servers and the privacy of user interactions with cloud servers when it comes to data. Even though the Cloud Service Provider Authority claims to guarantee the accessibility of DO's confidential data, in some crucial circumstances corporeal identification may be lost for DO. Of course, sensitive information will be encrypted for services using advanced methods such AES by quad block modularization Block key. In addition, data interaction In order to improve the aforementioned process from a Data-as-a-Service standpoint, time delays must be taken into account. The process will be organised by a third-party authority that reduces necessary computational ad hocs in data possession in order to make it dependable and secure. Applying the aforementioned procedure enables us to get beyond problems with data security and transit across hybrid clouds, such as secure key management, the requirement for isolation management, data ownership difficulties, and the quality of data transit services.**

Keywords—Integrity verification, Storage-as-a-Service, Privacy preserving, Dynamic auditing, Batch auditing.

I.INTRODUCTION

In order to help nodal data stores reduce infrastructure costs, ease administrative strain during the data maintenance process, and provide worldwide access to data from remote node locations, the financial side of data storage-as-a-service may need to concentrate on a key approach[1]. As we try to boost process benefits including commercial aspects, data access sharing, utilisation, and synchronisation, it may be necessary to regulate the many privacy-related concerns connected with regulating data access through cloud service providers[3]. To maintain storage space that can be utilised to earn income, CSP must give up rarely used data. Rarely, this could result in data loss and corruption, endangering the privacy or reputation of anyone affected[2]. In a heterogeneous cloud infrastructure, data ownership for DO. The auditing authority (TPA), which unifies the CSP & DU procedures under one roof, enables job-oriented auditing features, and serves as a public evaluator, maintains these Block keys created via data modularization methods. The rate of change of computational transactions is substantially influenced by modular cryptographic algorithms[4]. In order to maintain the data integrity of a modular section of data stored at CSP through the assessment process led by TPA and improve data protection, we present a novel approach that primarily focuses on cryptographic operations, such as modular Block key generation, public key signature generation, and sophisticated evaluation phases for multiple data owners[5]. The organisation of the data integrity evaluation procedure is the responsibility of TPA as part of their agreement to deal with cloud servers of the untrusted variety[6]. Of course, there is always a chance that this procedure will be successful and unsuccessful. Protecting data privacy while building a secure auditing process is our top goal[8]. Simple actions, such as the addition, updating, and deletion of a specific modular chunk of data, are allowed in this process implicit facility of data metrics, which is made available to Data Owners, without modifying the meta form of another modular chunk of other data (DO) [7]. The numerous requests that are afterwards received from various D

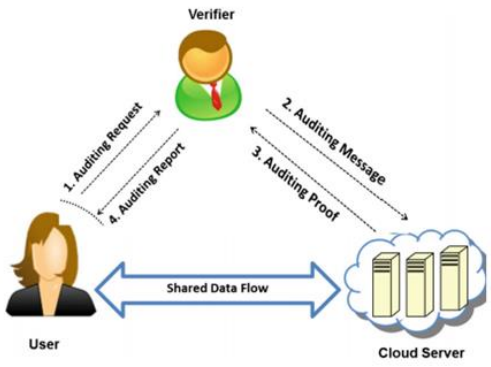

Fig: System Characters Model diagram.

Us should be handled by a thorough assessment mechanism for modular data that is powered by TPA.

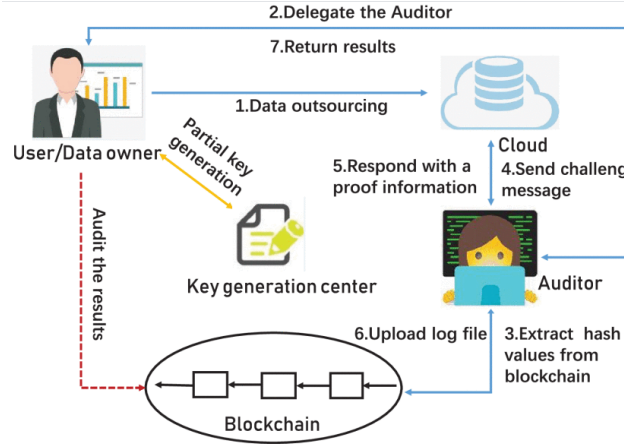

Fig: System Access Model diagram.

AES emphasises the length of the public key (Kp), the segment key (Ck) and segment divisions (Cs), the segment key length (Ck) and segment divisions (Cs), the total key length (Kn), and the bit length (n), i.e. Kn = (cnt(Ck)-cnt(Kp))*n*Cs. For instance, the segment key in this sample key has been extended to 512 bits by increasing the repetition count to 4 [10]. The total key length is Kn=(40-8)*4*4 or 512 bits because the segment divisions and hex key both have lengths of 4. The figure from the introduction chapter does a good job at illustrating the AES structure[9].

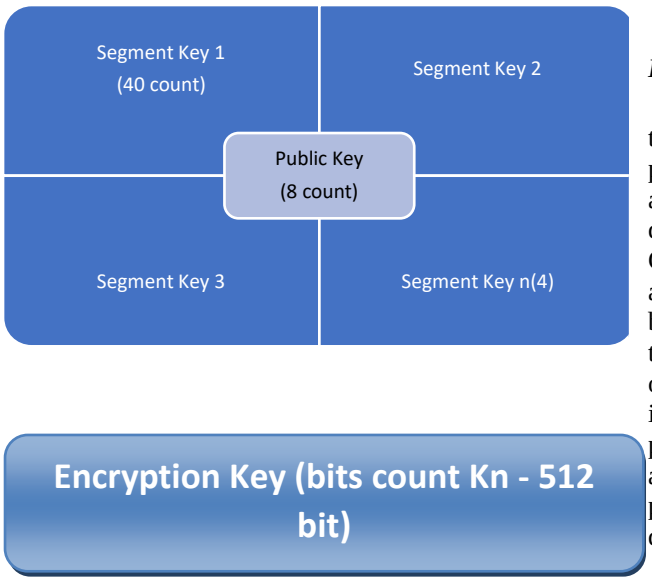

Fig: AES key Segment bitwise Integration Model diagram.

II. RESEARCH BACKGROUND

A. AIM OF THE PROJECT

The main objective of the project is to advance data security analytics by using panelized Block key generation, public key signature generation, and a sophisticated evaluation phase for the various data owners to maintain the data integrity of a modular section of information stored at CSP through the assessment process overseen by TPA.

B. SCOPEOFTHEPROJECT

We recommend a communitarian get-to-control strategy that designates interpretation centres in the entrance structure. According to a security study, our suggested approach can ensure information classification and has many other essential security properties. A detailed study of the execution demonstrates that our proposed conspiracy is adept at handling overhead and stockpiling.

C. TECHNICALAPPROACH

The technology method to securing data security is described as follows:

1. Data outsourcing;

2. Designating the auditor

3. Get the blockchain's hash values

4. Send a challenge via the cloud.

5. Support your argument with public key creation in your reply.

Upload the log file to get the results.

III. SYSTEM ANALYSIS

Proposed System:

We propose a novel scheme that focuses on three main divisions: modular Block key distribution, public key signature generation, and sophisticated analysis stage for the multiple data owners to maintain data integrity of a panelized section of data stored at CSP in order to increase the utility of data security analytics. Modular cryptography techniques also have a big impact on how quickly computing transactions transfer. This strategy even supports the numerous data owners, modular data assessment procedures, and important data dynamic activities indicated in the project report's introduction. Probabilistic data integrity analysis is facilitated by the modular data evaluation process at CSP, which includes a discrete phase for doing a probabilistic data integrity analysis.

Advantages Of Proposed System

- A comprehensive privacy preservation mechanism is built to enable safe data sharing on the cloud server.
- 2 In order to deal with the 512-bit Consolidated Block key, 2 AES through quad block modularization is being developed to strengthen the cryptography method maintained at CSP's endpoint.

➢ 3 CSP controls data access and usage to safeguard legitimate data requests while preventing or neutralizing hostile attacks.

IV. PROJECT IMPLIMENTATION

A. Proposed Modular Implementation

I used three modules in this project job, and each module has its functions, such as:

- Data Owner (Client) module
- Metadata Servers module
- Cloud Service Providers module

• Data Owners

The data owner can use this module to upload blocks, check them (data auditing), edit them, delete files, and see the blocks that have already been submitted.

• Data User

He enters his or her user name and password to log into this module. The receiver will do things like After logging in, access All Data Owner Files. request for file, File Download, View Response to File

• Third-Party Auditor

In this module, the sector is capable of doing the following tasks. Table in blocks View File Deleted or Modified Results View, and View Assailants

• Cloud Service Provider

The service provider manages a server that holds data and has the ability to access data owners, end users, and other users, among other things. View the Block Table, File Request, Attackers, and Transactions. View the findings, including the results and the file throughput and file time delay.

B. SYSTEM DESIGN

Data Flow Diagram:

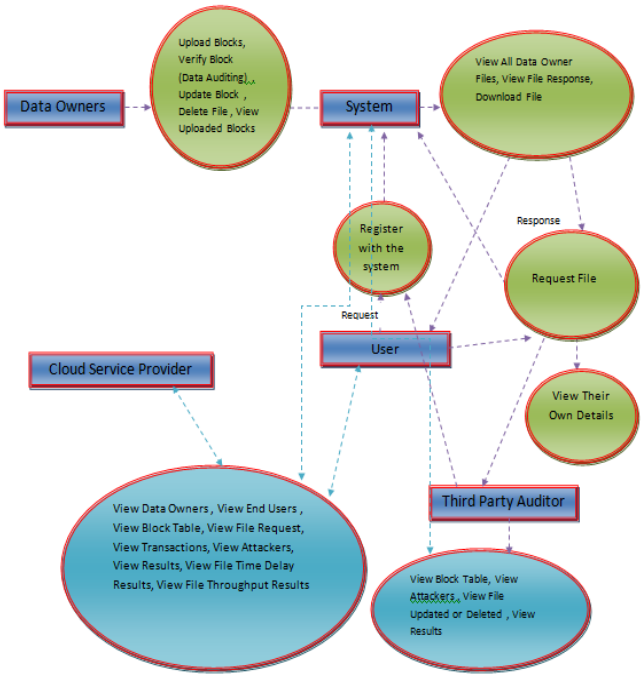

Figure 1: A Data Flow Diagram

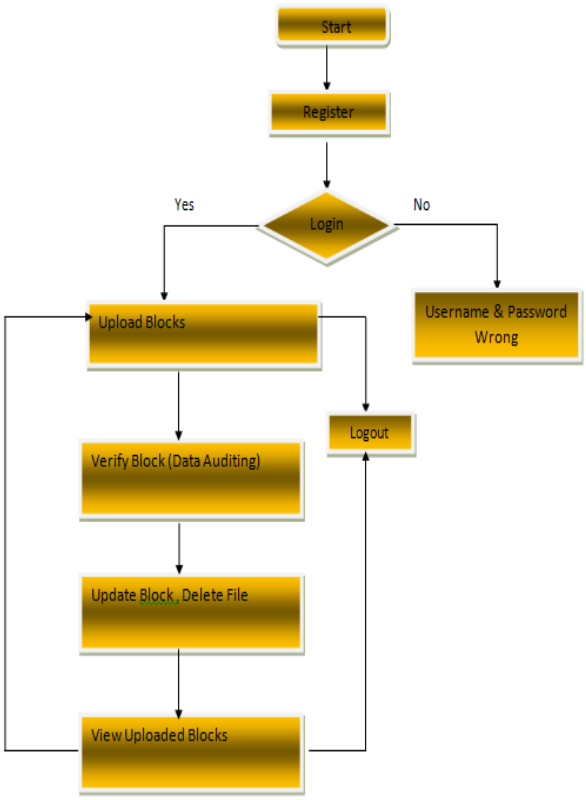
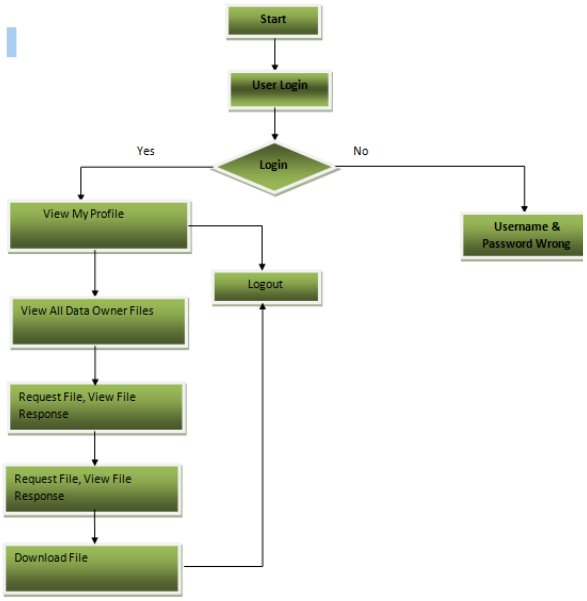
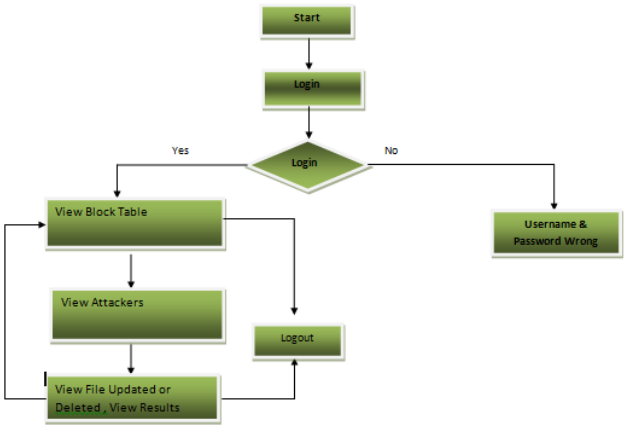
➢ **Flow Chart : Data Owners**



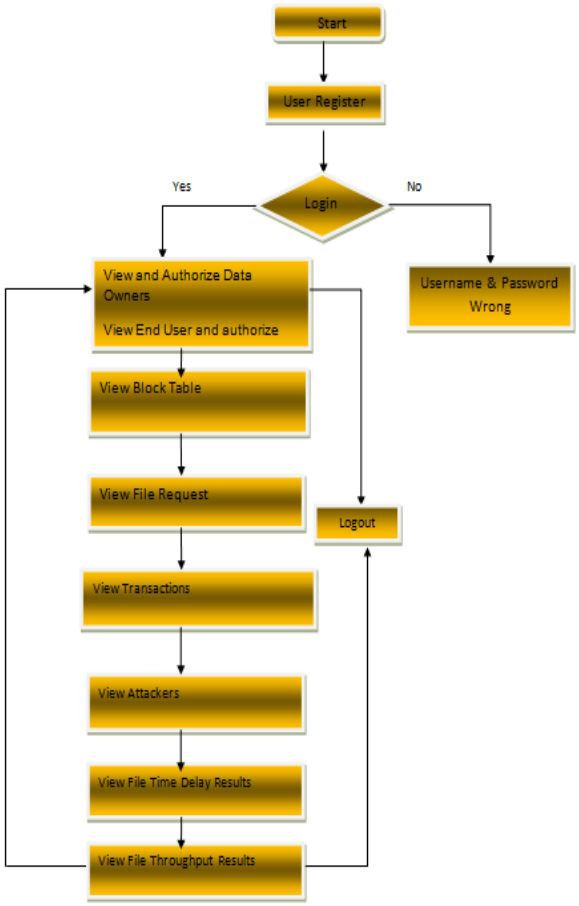
Flow Chart : User



Flow Chart: Third Party Auditor



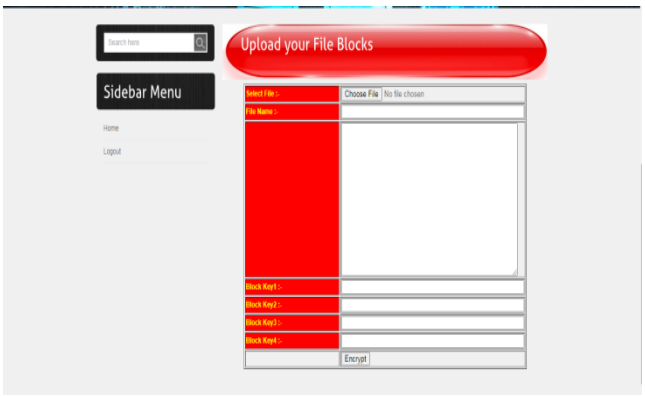
➢ Flow Chart : Cloud Service Provider

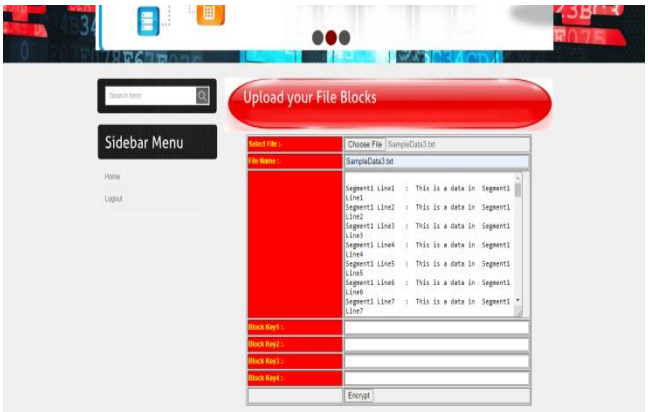


V. IMPLEMENTATION AND RESULT ANALYSIS

File upload page:

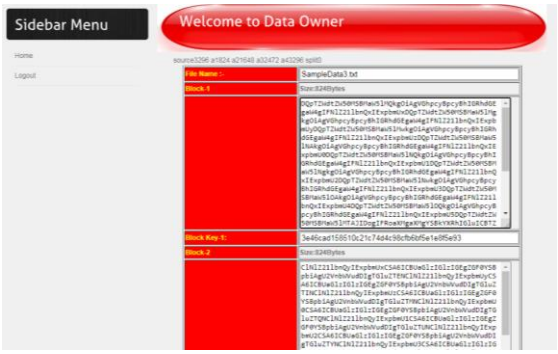
Users may upload files with recognized names that are Bean block partitioned and encrypted with special block keys using the data provider for this file upload page. The content of the entire file is divided into four smaller parts, each of which is encrypted with a separate block key.





File block key encryption page:

This page shows the file's encrypted content, which has been split into four parts and encrypted using a separate block key.

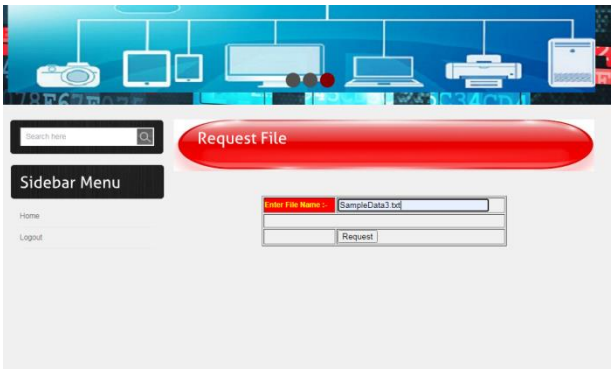


View all owner files page:

On the all owner files page for this view, each file that has been uploaded is displayed along with the name of the data owner who requested the upload.

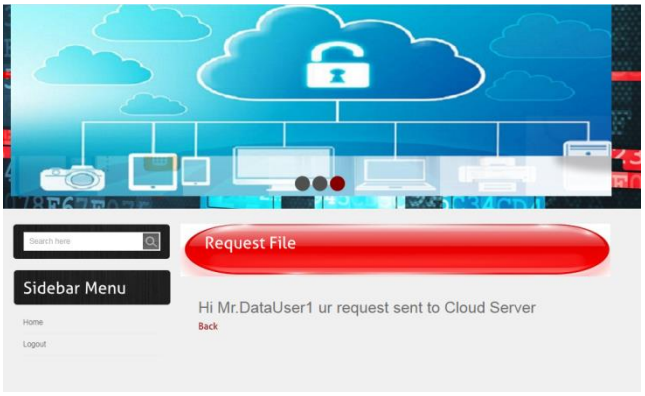
File request page:

Users of the website can submit a request for a certain share data file and initiate the file request process by clicking the request button in this file request form.



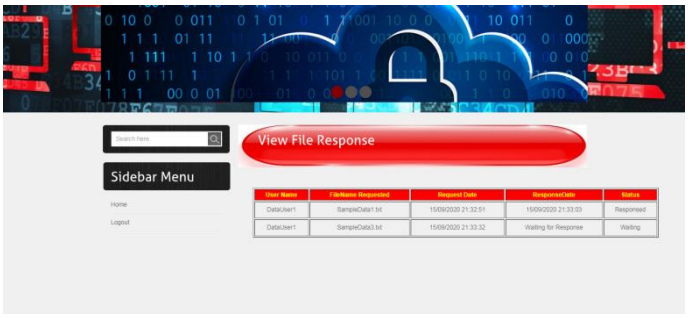
File request acknowledgment page:

The request acknowledgment as a result of the user requesting a certain shareable file is shown on this file request acknowledgement page.



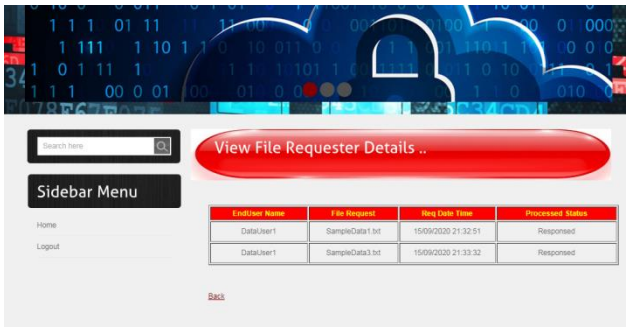
View file response page:

This view file displays the responsive page response status of each request that a data user made and then deleted for a specific file that is being served, along with the request date and response date.



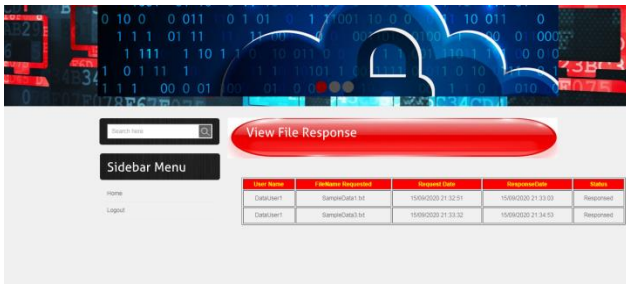
Cloud Server

View file requester details page:
In this view, the file request details page's cloud administrator may, at a specific time, approve the request for the file made by a data user.



Data User Status Page:

For each request that was deleted from a data user for a specific file that is being serviced, this Data User Status page provides the date and the outcome.

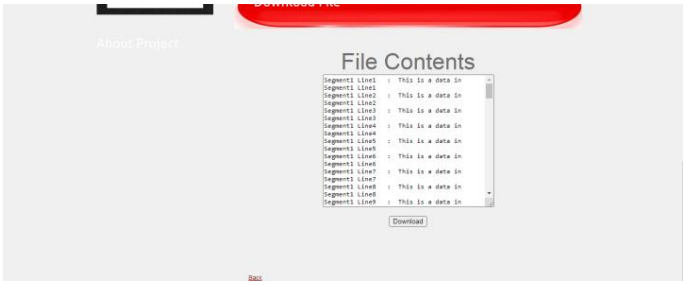


File download page:

You must first enter the file name, owner name, four distinct blocker keys, and a secret key on this page before the download for a specific file can begin.

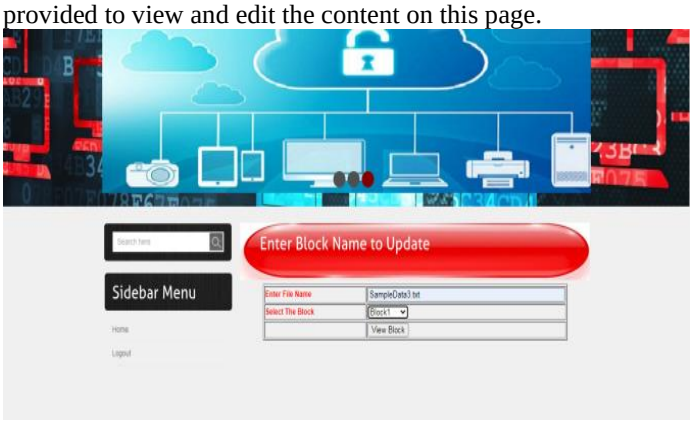
Request file key retrieval page:

The only parameters that must be entered by the data user on this page are the file name and owner name; all other parameters are automatically filled in the columns that were set by the cloud data store administration model, and we may click on download to finish the file download activity.



Update block page:

Enter a filename and a specific block name in the boxes provided to view and edit the content on this page.



VI. Conclusion And Future Scope

Conclusion : In this project, we'll talk about things like data ownership, secure key management, the requirement for isolation management, and the quality of services for data transportation. We provide a novel scheme that concentrates on three main divisions: modular Block key generation, public key signature production, and sophisticated assessment phase for the different data proprietors in order to increase the utility of data security analytics. In addition to ensuring the data integrity of shared data in public cloud storage, this strategy strives to protect owner privacy. Additionally, modular cryptographic techniques have a substantial impact on how quickly computing transactions move. This approach supports even the numerous data owners, flexible data evaluation procedures, and large data dynamic activities that were indicated in the project report's introduction. The modular data assessment technique at CSP includes a special Block key mapping table, which makes probabilistic data integrity analysis easier. The TPA-driven computational transaction transition time is more efficient than the current methods. The overhead on cloud servers is quite low. A

sophisticated privacy security solution is used to safely disseminate data on the cloud server. In order to manage the 512-bit Consolidated Block key, the implementation of AES employing quad block modularization makes the cryptography mechanism stronger and is maintained at the endpoint of CSP. At CSP, data accessibility and consumption are controlled to accommodate valid data requests while preventing or neutralising hostile intrusions

Influential Propagation Model for Malware Detection in Public Cloud Security

Mohammed Abraruddin, Mohammed Abbas Qureshi, Subramanian K.M
Dept of CSE, SCET, Hyderabad, TS, India
abrar9160@gmail.com, mohammedabbas09@yahoo.com, kmsubbu.phd@gmail.com

Abstract: **Cloud-haze edge registering particularly distributed computing is giving different administrations in numerous regions all over the planet and assumes an essential part in digital physical-social frameworks (CPSS). Especially, virtualization is one of primary empowering advancements of distributed computing and understands the powerful arrangement of processing assignments through the relocation of virtual machines (VMs), so how to get the virtual climate in the cloud is extremely urgent. The reason for this paper is to resolve the issue of malware proliferation among VMs under the foundation as a help (IaaS) design. A dynamical proliferation, first and foremost, model is proposed to investigate the significant variables influencing the spread of malware, particularly the effect of introducing antivirus programming in VMs. On this premise, a hypothetical examination for this model is researched through differential elements, from which it can comprehend the scattering conduct of malware under an tainted cloud climate. At last, a few mathematical reenactments are led to check the relevance what's more, adequacy of the proposed model**

I. INTRODUCTION

CYBER-physical-social frameworks (CPSS) can make our regular routines smarter and more advantageous through giving forward-looking and customized administrations [1]. With the approach of the enormous information period and the prevalence of the Web of Things later on, CPSS administrations will definitely require different information support including the worldwide verifiable information and the nearby continuous information, which will include many issues such organization correspondence (e.g., [2], [3]), information capacity, handling and applications (e.g., [4], [5]). In this specific circumstance, analysts are enthusiastically creating cloud fog-edge processing as of late. In particular, haze edge registering has been broadly applied to handle the nearby real time information, which is a significant and compelling enhancement of distributed computing. As a strong worldview for carrying out the information concentrated applications, distributed computing has an indispensable job in putting away and handling information. It can offer administrations like foundation as a help (IaaS), stage as a help (PaaS), and programming as a help (SaaS) for clients on request. As one of the main strategies of distributed computing, virtualization breaks the limits of existence. Especially, it can partition an actual processing gadget into more virtual machines (VMs) with a similar usefulness and understand the unique organization of processing undertakings through the relocation of VMs. There is no question that virtualization will significantly further develop asset usage and save framework the executives costs [6]. Tragically, virtualization likewise presents new weaknesses that are turning into the assault focus of malware.The first malware created to stay away from virtual frameworks, be that as it may, because of different factors like benefit and advantage, malware producers started to focus on all processing gadgets, including physical and virtual machines [7]. Since the Web has solid engendering skill and is additionally the most significant transporter of PC infection transmission, so once malware shows up in a physical or virtual machine, it will spread quickly in the organization, which might make extraordinary harm human creatures, going from financial misfortunes to serious dangers to human existence. Therefore, examining how is fundamental to safeguard the virtual climate from malware assault in the cloud.

For the most part, the accompanying three viewpoints will speed up the spread of malware in the cloud. Right off the bat, the relocation of VMs will work with the dissemination of malware [8], [9]. By utilizing the weaknesses of VMs to embed malware, crooks can use the relocation of VMs to accomplish the motivation behind malignant assault. Significantly, the movement of VMs assumes a key part in distributed computing, by which the dynamic organization of figuring undertakings can be carried out. Besides, the homogeneity of VMs will likewise help the engendering of malware [10]. Here, the homogeneity primarily implies that VMs have the homogeneous design and settings, and the introduced programming projects are comparable. Practically speaking, there are a huge number of VMs in the cloud, assuming they are designed individually, it won't just require a ton of investment, yet additionally be inclined to mistakes. For comfort, only one of them is generally designed, and afterward the others are produced by replicating it. These tasks should now be possible consequently. Clearly, such homogeneity will give numerous potential open doors and decrease specialized trouble for assailants. Thirdly, the correspondence among VMs is the another spread method of malware. Distributed computing is a circulated equal registering, the finish of many figuring errands requires VMs to convey and help out one another through virtual organizations. The creators [8] guaranteed that the inside correspondence in the cloud is quite possibly of the most serious danger to distributed computing security. For different viewpoints, the work [11] gave a few motivations behind why the hoodlums are not difficult to control different VMs and get ready for different assaults. These focuses are likewise presented exhaustively in [12]. Through the previously mentioned weaknesses of VMs in the cloud, lawbreakers can to be sure effectively send off different assaults, for example, botnet assault, dispersed refusal of administration (DDoS) assault, ransomware assault and spyware assault. The work [13]

portrayed that malware can enter the virtual climate in its own specific manner, and might in fact make or control VMs to make them claimed without anyone else. When the quantity of controlled VMs arrives at a specific level, botnets will arise, and crooks can send off DDoS assaults whenever. Specifically, the botnets in the cloud can send off the DDoS assaults on targets outside the cloud [14]. What's more, when a cloud supplier offers types of assistance to the client, it permits the client to introduce programming and transfer information (e.g., picture, video, and different records) to the cloud. This additionally gives an open door to hoodlums to embed malware (e.g., ransomware and spyware) in the cloud. In addition, crooks are progressively disposed to take client security information for benefit, and ransomware assault has been quite possibly of the most famous assaults as of late. In [15], the creators expressed that malware can spread by sharing pictures from the picture vaults at VMs. In view of an examination of 5303 Amazon pictures of VMs, Balduzzi et al. [16] viewed that as 98% of Windows and 58% of Linux pictures contain applications with serious weaknesses. Plus, a pernicious client can transfer the contaminated picture to proliferate malware in the cloud [12].

To manage these dangers in the cloud, many measures have been taken to recognize and forestall the spread of malware. Among them, the actual host machines were utilized to screen the way of behaving of the VMs. The virtual organization is mindful to the correspondence among VMs and is a coherent organization in light of an actual organization, and the stockpiling what's more, computation elements of VMs additionally rely upon the physical have machines. In any case, the work [17] brought up that malware in the virtual climate is probably going to escape the reconnaissance of safety apparatuses. Moreover, a superior way for containing malware is to introduce antivirus programming for all VMs in the cloud similarly as actual machines forestall PC infections. It is unquestionable that this will for sure control the spread of malware to a huge degree. By and by, this will likewise build the expense of antivirus speculation and energy utilization. Eventually, it will definitely increment the above of cloud suppliers and clients, what's more, even antagonistically influence the worldwide environment. Li et al. [18] found by concentrating on Cyber Guarder (a security device planned for the green distributed computing) that the presentation cost of Cyber Guarder is more than 10% and the energy utilization is expanded by 5%. This additionally shows that it isn't prudent to introduce antivirus programming on all VMs in the cloud. To adjust the advantages and expenses of conveying numerous interruption discovery frameworks, the work [19] proposed an assault model and thought about various interruption discovery frameworks as per the expenses. Afterward, motivated by the use of the traditional scourge model in the study of disease transmission, the creators [12] investigated a helpless safeguarded tainted (SPI) cloud malware assault model. As the creators guarantee, this is the first numerical model to investigate the impact of hostile to malware programming on the spread of malware in the cloud. In addition, this work doesn't totally duplicate the traditional scourge model, and gives the comparing reasons. The elements of the model is additionally dissected. Be that as it may, it is worth focusing on that this model is laid out in an at first uninfected cloud climate. In other words, all VMs enter the virtual organization without contamination.

1.2 SCOPE OF THE PROJECT

Indeed, the authors pointed out that antivirus software updates always lag behind the emergence of new viruses, and it is not possible to remove all viruses from the network. In addition, our work is also different from the traditional computer virus propagation model. On the one hand, these traditional models do not consider the cloud environment. On the other hand, the model compartments and their transition are different.

1.3 OBJECTIVE

In this paper, a new dynamical propagation model of malware is developed. Specifically, it is found from the model analysis that the proposed model has a unique (viral) equilibrium. Furthermore, the stability of the equilibrium is analyzed. The unique (viral) equilibrium is globally asymptotically stable regardless of any threshold. This implies that once malware appears in a virtual network, it will always exist, and no matter what method is adopted, it cannot be completely eliminated. However, by adjusting system parameters, the proportion of infected VMs can be reduced to a relatively low level. This can provide directional guidance to curb the spread of malware. Finally, some numerical simulations are performed to illustrate the obtained theoretical results and verify the proposed model.

1.4 PROBLEM STATEMENT

To balance the benefits and costs of deploying multiple intrusion detection systems, the work proposed a attack model and compared different intrusion detection systems according to the costs. Later, inspired by the application of the classical epidemic model in epidemiology, the authors explored a susceptible-protected-infected (SPI) cloud malware attack model. As the authors claim, this is the first mathematical model to explore the effect of anti-malware software on the spread of malware in the cloud. Besides, this work does not completely copy the classical epidemic model, and gives the corresponding reasons. The dynamics of the model is also analyzed. But it is worth mentioning that this model is established in an initially uninfected cloud environment. That is to say, all VMs enter the virtual network without infection.

Inspired by the above discussion especially the work, this paper aims to address the issue of malware propagation among VMs under an infected cloud environment. Different from the work, our work allows the infected VMs access to the virtual network. Indeed, the authors pointed out that antivirus software updates always lag behind the emergence of new viruses, and it is not possible to remove all viruses from the network. In addition, our work is also different from the traditional computer virus propagation model. On the

one hand, these traditional models do not consider the cloud environment. On the other hand, the model compartments and their transition are different.

1.5 EXISTING SYSTEM

- Existing work allows the infected VMs access to the virtual network. Indeed, the authors pointed out that antivirus software updates always lag behind the emergence of new viruses, and it is not possible to remove all viruses from the network.
- In addition, these works are also different from the traditional computer virus propagation model.
- On the one hand, these traditional models do not consider the cloud environment.

1.5.1 EXISTING SYSTEM DISADVANTAGES

- Low Security
- Low effectiveness.
- Very difficult to handle malware.

1.6 PROPOSED SYSTEM

- The purpose of this paper is to address the issue of malware propagation among VMs under the infrastructure as a service (IaaS) architecture.
- Firstly, a dynamical propagation model is proposed to explore the important factors affecting the spread of malware, especially the impact of installing antivirus software in VMs.
- On this basis, a theoretical analysis for this model is investigated by means of differential dynamics, from which it is able to understand the dissemination behaviour of malware under an infected cloud environment.

1.6.1 PROPOSED SYSTEM ADVANTAGES

- To better understand how malware propagates in an infected cloud environment.
- Our system balances the benefits and costs of deploying multiple intrusion detection systems.

II. MODEL DESCRIPTION

Our objectives and inspirations have been depicted in the past segment, this part will present the proposed dynamical engendering model of malware exhaustively.

To describe the spread of malware in the cloud, as work [12], in this paper, each VM under IaaS engineering

is in one of three states: powerless, contaminated, and safeguarded. Obviously, these states can be changed into one another over the long haul under specific circumstances. On this premise, all VMs are separated into three gatherings: powerless compartment, contaminated compartment, and safeguarded compartment. Their implicationsare characterized as follows.In light of the above definitions, it is easy to see as the change between three states. There are a sum of six structuresof progress between them, i.e.,

• Susceptiblecontaminated (see Fig. 1);

• Susceptiblesecured (see Fig. 2);

• Infected ⇆ protected (see Fig. 3).

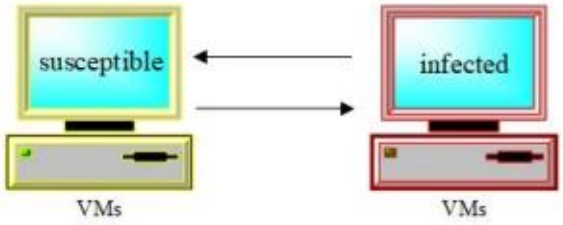

FIGURE 1: Susceptible⇆ infected.

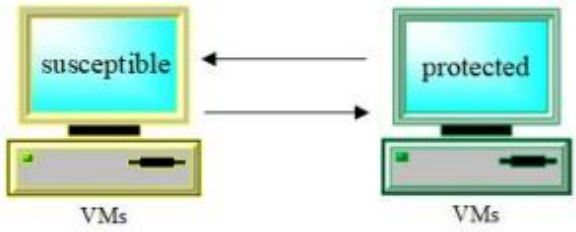

FIGURE 2: Susceptible⇆ protected.

Taking into account the expense of antivirus speculation and energy utilization, not all VMs will introduce antivirus programming. Since simply by reinstalling the framework can be 100 percent sure that the contaminated VMs are liberated from malware, here just consider introducing antivirus programming to safeguard defenseless VMs. Thusly, regardless of whether the malware in a contaminated VM is taken out, the comparing VM won't be resistant to malware assaults, furthermore, will be in a vulnerable state. In other words, contaminated → safeguarded is unthinkable. Essentially, secured → contaminated is likewise illogical. From one viewpoint, as indicated by the definition of safeguarded express, a safeguarded VM is difficult to be contaminated by malware during the whole time of antivirus programming. Then again, in a safeguarded VM, when the antivirus programming is uninstalled or obsolete, the relating VM will become vulnerable. In outline, susceptible tainted also, susceptiblesafeguarded are conceivable.

2.1 MODULES NAME:

This project having the following 4 modules:

- User Interface Design

- Admin
- Server
- Client User

2.2 TECHNIQUE USED OR ALGORITHM USED

Algorithm:Dynamical Propagation Model

To characterize the spread of malware in the cloud, like work [12], in this paper, each VM under IaaS architecture is in one of three states: susceptible, infected, and protected. Of course, these states can be transformed into each other over time under certain conditions. On this basis, all VMs are divided into three groups: susceptible compartment, infected compartment, and protected compartment. Their meanings are defined as follows.

- Susceptible: the state of an uninfected VM in the cloud that is vulnerable to malware attacks. That is to say, an uninfected VM in the cloud does not install antivirus software or the installed antivirus software has expired.
- Infected: the state of a VM in the cloud that has been infected by malware. That is to say, the malware has not been removed.
- Protected: the state of an uninfected VM in the cloud that is immune to malware attacks. That is to say, an uninfected VM in the cloud install the unexpired antivirus software.
- Susceptible compartment: the set of all susceptible VMs in the cloud.
- Infected compartment: the set of all infected VMs in the cloud.
- Protected compartment: the set of all protected VMs in the cloud.
- Susceptible $\leftrightarrows$ protected (see Fig. 2)
- Infected $\leftrightarrows$ protected (see Fig. 3).

III. REQUIREMENTS

3.1HARDWARE . REQUIREMENTS

- PROCESSOR: PENTIUM IV 2.6 GHz,Intel Core 2 Duo.
- RAM:512 MB DD RAM
- MONITOR:15” COLOR
- HARD DISK :40 GB

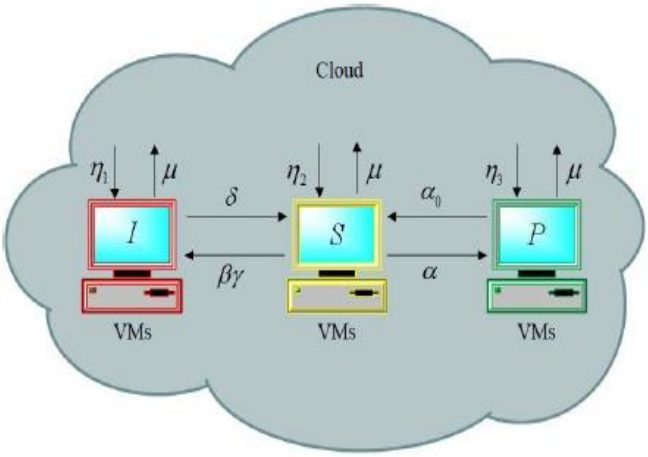
3.2 SOFTWARE REQUIREMENTS

- Front End: J2EE (JSP, SERVLET)
- Back End:MY SQL 5.5
- Operating System: Windows 7
- IDE:Eclipse

IV. SYSTEM ARCHITECTURE

Before proceeding with model analysis, let us introduce the meaning of some basic terms, which will be useful in the sequel.

- Dynamical System: dynamics is primarily the study of the time-evolutionary process and the corresponding system of equations is known as dynamical system [27]. In this paper, system (1) is a differential dynamical system.
- Equilibrium: equilibrium is a fixed point of a dynamical system, which is important in analyzing the local and global behaviours of the dynamical system. In this paper, an equilibrium represents a possible final propagation level of malware, which can be obtained by solving the first order differential dynamical system (1).
- Viral Equilibrium: in this paper, if the component of infected VMs in an equilibrium is not zero, this equilibrium is called viral equilibrium.
- Stability: long-term behaviour of an equilibrium of a dynamical system. In this paper, by analyzing the stability of equilibrium of dynamical system (1), the final propagation level and behavior of malware in the cloud can be predicted.



The transfer diagram of the proposed dynamical propagation model of malware

VI. FUTURE IMPROVEMENT

Right off the bat, our work has demonstrated that the last level of disease relies upon framework boundaries. Be that as it may, it is need of further research on control techniques, which restricts its practicality to a specific degree. Subsequently, it is crucial for study the specific control methodologies. Furthermore, it is worth attempting to apply profound learning methods to investigate the proliferation conduct of malware in the cloud.

VII.CONCLUSION

In this paper, a dynamical engendering model of malware for distributed computing security has been proposed. To better understand how malware proliferates in a tainted cloud environment, an extensive examination including the equilibrium and its security for the proposed model has been conducted. It is found from the model examination that once malware shows up in a virtual organization, it will constantly exist, and no matter what strategy is taken on, it can't be completely eliminated. Be that as it may, by changing framework boundaries, the proportion of tainted VMs can be diminished to a moderately low-level. At long last, a few mathematical recreations have been given to illustrate the got fundamental outcomes.

In spite of the fact that our work has accomplished a few outcomes about the propagation conduct of malware under a tainted cloud environment, in our view, there is still a lot of work to do in the future.

Block-Based Reversible Data Hiding with Secret Sharing

MD Muneer, Jothikumar.R, Muntaj Begum Shaik
Department of Computer Science and Engineering, Shadan College of Engineering and Technology, Hyderabad, Telangana, India
mohd.muneer89@gmail.com, drjothikumarr@gmail.com, muntajbegum.mtech@gmail.com

Abstract- **The three entities required by this research's technique for reversible data concealment in multiple encrypted image blocks are the data owner, the data hider, and the recipient. The source image is divided up by the resource owner into several blocks of pixels, which are then stream-encrypted and sent to the server. The server data hider tags the multi-part encrypted blocks by incorporating hidden bits into them. As a result, the original picture may be correctly reconstructed by the receiver by extracting additional data from the annotated encrypted blocks. Because of the procedure's security and dependability, sensitive data may be transferred securely without endangering the integrity of the original data. Because hostile attackers will be unable to modify the original data, it is also more resistant to tampering and manipulation. It is more effective as well since it reduces the need for extra data storage and transmission overhead. Numerous applications, including digital forensics and medical imaging, will benefit from this procedure**

I. INTRODUCTION

Data hiding is defined as the process of concealing data (representing some information) within cover media. In other words, the data concealing process connects two categories of data: embedded data and cover media data. The link between these two sources of data defines many applications. This approach assures that the cover may be retrieved without loss after the embedded data has been extracted. The RDH method is also utilized for distortion-incompatible coverings, such as military, legal forensic, and medical photographs, because to its high reversibility. Almost all modern RDH algorithms start with a high-peak prediction-error histogram and then reversibly embed data into it via histogram shifting.Because of the necessity to protect picture privacy, content owners are hesitant to display photos to data-hider, particularly photographs containing sensitive information. Encryption is a popular and effective method of safeguarding picture privacy because it transforms a meaningful image into a meaningless image that is impossible for any unauthorized user to identify. As a result, reversible data hiding in encrypted pictures must be designed (RDH-EI). In cloud storage, for example, the content-owner wishes to save the image in the cloud while maintaining privacy by encrypting the image before uploading it to the cloud. The cloud service provider will embed some additional data inside the encrypted picture for management purposes without accessing the content.The approved receiver, on the other hand, can fully reconstruct the original picture after decryption and data extraction as needed. The pixel correlation of a picture is lost after encryption; however, if the image is encrypted using an encryption technique that does not modify pixel position or pixel block location, such as the advanced encryption standard (AES) and stream cypher, the pixel correlation remains. Data extraction and picture recovery may be accomplished by employing correlation. By computing the local standard deviation of encrypted blocks, the original picture is recovered.

In recent years, homomorphism-based approaches that can directly act on encrypted images to obtain the required effect have been developed. In general, homomorphic encryption is used to encrypt the original picture, and then homomorphic property is used to insert a secret message within the encrypted image. Finally, data extraction and picture recovery are accomplished by determining a specific connection between the directly decrypted image and the original image.

RDH-EI approaches based on secret sharing were established to decrease data growth and computational complexity. Wu et al. developed a secret sharing-based RDH-EI approach in [8], which encrypts the original picture to produce encrypted images using Shamir's threshold secret sharing [9], and then distributes the encrypted images to a data-hider for data hiding. In the best-case scenario, the encrypted photos are just twice the size of the original image.Another RDH-EI approach based on secret sharing was proposed in [10], in which an original picture is turned into an encrypted image and the encrypted image is transferred to a data-hider for data concealment. Because the resulting encrypted picture is the same size as the original image, data expansion is avoided, and computational complexity is reduced.

However, the majority of known RDH-EI approaches use either a single data-hider or a multiple data-hider model. The original image cannot be reconstructed from the designated encrypted photos once the data-hider has been subjected to possible harm, such as faulty administration by itself or hostile assault by an opponent. In this paper, we propose a novel approach to safe picture encryption utilizing a single data hider is shown by the newly suggested method for reversible data hiding in images. Each manageable piece of the source image is encrypted with the AES encryption algorithm, a commonly known symmetric encryption method. The data hider processes the encrypted picture blocks, each of which holds a piece of the source image data and inserts a hidden message to create a labelled encrypted image.

The encrypted picture blocks are decoded at the receiver using the AES decryption technique and the same symmetric key. This permits the concealed data to be extracted using a key (kh) and the real picture to be recovered by reassembling the encrypted image blocks.

This method is particularly useful for industries like the military and medicine that require high degrees of

anonymity and data protection. Three people are involved in the process: the receiver, the data hider, and the picture provider. The receiver receives the secret key from both the image provider and the data hider, which boosts security by using the same key for both encryption and decryption.

II. PROPOSED ALGORITHM

Figure 1 illustrates the secret sharing paradigm put out by Wu et al. for RDH-EI (b). To hide the data, the resource owner separates the actual image into ‘n’ number of blocks, which are then distributed to the data cache and encrypted using the AES algorithm and the encryption key "ke."

The vault has a control center in this architecture that handles the distribution and collecting of encrypted photos, as well as decrypting the source images and extracting the secret message.

The suggested secret sharing paradigm with multipart encryption blocks is depicted in Figure 2 below and consists of three steps: image encryption, data concealment, and data extraction and picture recovery.

Unlike previous designs, the entire image is encrypted and sent to the data cache, while the proposed mode contains multiple part data image blocks that are sent to the data cache. Next, we present each step of the formally proposed model. In the image encryption step, the actual image is divided into ‘n’ number of blocks each of which gets encrypted. Each byte array read from the source image is then represented in a block, which is then encrypted with the encryption key that, and each encrypted block is placed into a single cache. The source image encryption procedure is formatted with,

$$\left(E^{(1)}, E^{(2)}, \cdots, E^{(n)}\right) = Enc_{ke}(I), \qquad (2)$$

where E(t) 1<t<n is the block encrypted in ‘t’ and Encke(I) is the source image encryption technique using the encryption key. The data hider then receives E(t) to conceal the data. The data of the encrypted image block E(t) can be included in a data hider with a data hiding key kht. The number may be used to get the linked tagged encrypted picture.,

$$EM^{(t)} = Emb_{kh_t}\left(E^{(t)}, D\right), \qquad (3)$$

Where 'D' represents embedded data, EM(t) represents the tth indicated encrypted image block, and Embkht (*) represents the data hiding technique with data hiding key kht. When there is k (2 k n) or more specified encrypted pictures, the receiver may retrieve both the original image and the k or more embedded data. Let EM(t1), EM(t2), and EM (tr) be any k or more marked encrypted image blocks, with 't1', 't2', 'EM(tr)', and 'n', 'k', and 'r' being integers.

Depending on whether the data concealing key khte, 1 er is required in the source image recovery procedure, the data extraction and picture recovery operations can be characterized by one of two scenarios:

$$\begin{cases} D = Ext_{kh_{t_e}}\left(EM^{(t_e)}, kd\right), 1 \le e \le r, \\ I = Rec_{kd}\left(EM^{(t_1)}, \cdots, EM^{(t_r)}\right), \end{cases} \qquad (4)$$

where Extkhte (*) is a data extraction method with the data hiding key khte, Reckd (*) is a source image recovery algorithm with the decryption key 'kd', and 'D' is the extracted data This new model is summarized below based on the aforementioned study.

RDH-EI uses the idea of secret sharing, which allows the resource owner to share encrypted image blocks to hide data in a single data cache. Thus, the source image is more protected, and an unauthorized user cannot decrypt the actual image. Each image block is embedded with secret information, making it much more secure.

Each encrypted image block can have an arbitrary number of bits embedded in it, and each cache has a different labelled encrypted image block, and the receiver requires k labelled encrypted image blocks to recover the actual image, which means that even if the labelled encrypted image block k1 caches leak, the actual image will not be leaked. As a result, the suggested strategy can effectively limit the likelihood of real image leaking. We may lessen the risk of the original image being leaked by using the recommended approach.

III. CONCLUSION AND FUTURE ENHANCEMENT

When we examined the previous system, we noticed flaws, such as the encrypted image being decrypted, but by implementing the newly presented ideas, we can limit the risk of the actual image being revealed.

Finally, this work presents a novel model for secret sharing that uses a single data hider and converts the original picture into numerous encrypted image blocks, which are then sent to a single data hider for data hiding. The receiver then pulls actual data from the image blocks that have been tagged while recreating the actual image.

As a result, the suggested technique has a lower likelihood of reconstructing the actual image than the present method, which employs a single encrypted image.

Future work: In the proposed method, we use a very single encryption key to process multiple blocks of the source image. In the future, there may be a series of encryption keys that can be used to encrypt the set blocks, and each block can carry its pretty own encryption key identifier, which will kind of be used by the recipient to decrypt the appropriate key for the source image set in a subtle way.

Online System for Monitoring Water Quality, Leaks, Contamination and Managing Pipeline Network

Raj Salvi, Sachet Engineer, Namdeo Badhe
Thakur College of Engineering and Technology Mumbai, Maharashtra, India
Rajsalvi917@gmail.com, Sacheteng711@gmail.com, namdeo.badhe@thakureducation.org

Abstract **- Online system for monitoring water quality, leaks, contamination and managing pipeline network entails several steps, including establishing admin login, comprehending the nature of managing pipeline network activities, and ensuring the legitimacy of the leaks and contamination. We have a portal in this project where clients can upload reports or mail in of themselves saying all their information, and it then helps in functioning correctly of the required standard operating procedure. This is done to increase the possibility of monitoring water system efficiently. It also ensures the veracity and authenticity of the information presented.**

Keywords – monitoring water, leaks, contamination, pipeline network.

I. INTRODUCTION

The system is simply all about management of the network and other factors. The working and important parts are the way we make it to communicate in easiest way possible. the problem is to manage the network, leaks, and contamination and above all is monitoring it as it can be costly if high-tech sensors and other tracking devices are used. Stating that pipeline networks are generally spread vast. This is important to keep in mind that any idea that can solve these issues must know that it must not be costly that it makes it difficult to apply and solve the issues efficiently. Managing water system being a challenging task since ages, but always has been evolved and will be using multi-level technologies and technologies evolving everyday makes it more possible to be managed accurately. It has been observed that managing water pipeline network has been a task for a while. Hence managing it has now been possible due to new technologies like IOT or electronic tracking devices which are connected to a neural network of computers. There are different aspects and parameters which make it difficult and so to manage well. In this project we have tested the problems and solution those which can be simple but need proper responses and risk management has been kept on priority. The pipeline network is complex in metropolitan cities and multilevel infrastructure, population, commercial sectors and, and housing affects managing it. Water leaks are one of the problems that need physical attention even as normal pipeline networks are over acres or kms. Monitoring them is a task and needs to be done on field but here the solution is not found. the solution is applied using the computers even if in this generation we have phones. The word management itself states its importance but when it comes to water management which have specific problems apart from awareness it stands apart from regularly faced issues. Water leaks can be a serious issue as it wastes water which is an essential for human being and other purposes. The contamination of water is more serious than just wasting water. There are several serious diseases that come to the picture when it comes to contamination. Human life can be seriously affected if consumed contaminated water. Lead, PH level and other contaminants can prove to be harmful to human life if not treated well. Keeping a track or monitoring it has been an important part in management of the water system. Water system clearly states that it must be just not be treated well but also can be managed using traditional as well as modern technology. Commercial sectors have contaminated the water and not keeping a track of how much MLD water is contaminated and its treatment must be to the water is not task but duty.

II. RELATED WORKS

A literature survey has been conducted for the related title of this project. In that Methodology used, results and the gaps must be found. The gaps that would be found will be trying to implement that in our project.

[1] Dipanjan Rakshit, et al. “Water level indicator” International Journal of Scientific & Engineering Research, Volume 7, Issue 4, April-2016 7 ISSN 2229-5518 IJSER © 2016 have a dynamic system but not fulfilling the requirement completely. The accuracy has been 95% as it is not cost friendly and lacks the current requirement.

[2] This paper uses Danve S and Barabde M 2015 Real Time Water Quality Monitoring System Int. J. Innov. Res. Comput. Commun. Eng. 3:6 pp 5064–5069 the perfect requirement and is best to learn from giving the accurate idea and the accuracy is as much as 95% to the project been made.

III. PROPOSED WORK

Admin portal: the admin portal is going the be the head of this project as it will be monitoring overall activities and the flow of the system. It will be the brain or can be

said the headmaster of this system. Client login: This will be the actual working part where people will be logging in to share queries and help in to monitor or will be making a two-way communication system. Pipeline network map: This is to show complete network in subdivisions when put into search nav bar. Contamination report portal: In this portal daily updates from the testing center will be updated about the contamination from sources of water to storage houses and use. Leaks report portal: this will the portal where the official or the workers and people can report about leaks of the pipeline and history and future repair data can be maintained, and work accordingly can be assigned to whomsoever concerned.

The main aim is to develop and constantly improve a comprehensive online water management system system that works with any type of monitoring, contamination monitoring, leaks monitoring.

Firstly, we will collect data. And apart from just collecting data understanding the need of such system is necessary or else working of this system will become hectic and difficult. Planning of pipeline network must be prepared after checking on the database which will become more efficient to use after gaining knowledge of past network and then work on new network required. Then we can monitor the network and all aspects of it.

The contamination is part where right reports and test that have been conducted the validation of test and its reports is a task and must be focused on. The contamination can be from the natural source or pipeline of the source or the storage house hence taking it into account 2 step contamination tests and its treatment must be done. One from the natural source of water and next before pumping from storage houses. This will make the physical part easy.

Monitoring leaks are easiest as they are all about constant physical monitoring which can be scheduled using database. The leaks and its repairs can be monitored here we can do it with use of data base as we will have the history of repairs and from there, we can schedule next repair and constant monitoring for the team which can do physical checks this will make their time efficient as they won't have to be constantly visiting the place or pipeline network again an again. The ground team cam work using the reporting systems and can visit the location using the reporting system between client login and admin login portals.

IV. SOLUTION

Here a simple website has been made to ease water management as it gives us more options where we can get updates on contamination and articles related to it. Bringing more awareness among people and is efficient in terms of keeping people away from falling into disease related to it.

The primary focus of the website has been to make sure that water management finds new ways to communicate and minimize management issues. From giving updates to taking in complains and giving out knowledge of pipeline and many other things. This brings in new experience and practices in the field of management that are concerned with water management.

The secondary focus is on the usability and true purpose of the website where in it is expected to offer more about how the contamination is contained and leaks are managed and what do we exactly give knowledge about the pipeline network in his/her town or city.

V. TECHSTACK

Language: HTML
CSS
PHP
SQL

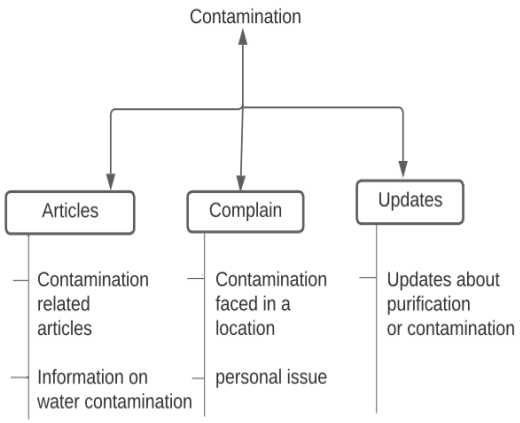
Software: Visual Studio Code

VI. WORKING

This project is a platform designed to cater information regarding to contamination, updates on leaks and repairs, also giving host of information on pipeline system. Here the login section gives option of two login ID. One for the admin that means the officials and one for the users. The project has been divided into three parts : Contamination , leaks and pipeline network.

Starting with part one: Contamination

In contamination , we have put in three sub sections: articles complains and updates. The article section contains contamination related articles wherein people will be aware about the causes of water contamination, what makes the water unfit for use and how one can make contaminated water fit for drinking. Here, the people will be made aware about the side effects of drinking contaminated water. The complain section is used to lodge a complain faced by the users. Here there will be a dialogue box where the individual can lodge any type of complain faced by himself in his locality. Another section is for updates where one can have a look about the updates about purification.



The second part is Leaks:

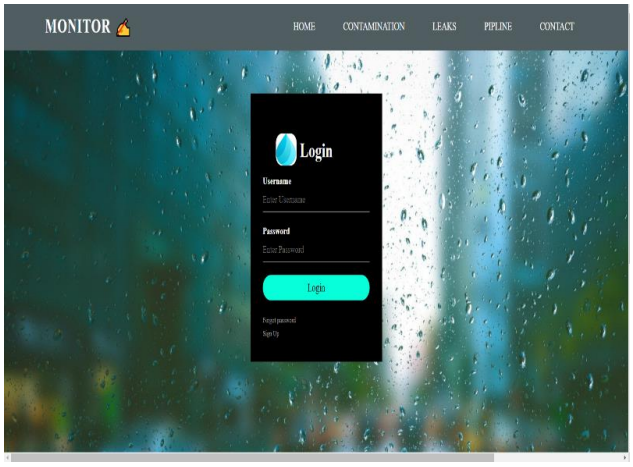
There are two subsections in Leaks: First part is reports where the consumer can report any leaks that occur in their societies or in corporations. The second part is updates where the people can see the current information about the leaks. Also, the previous history of repairs in the locality can be seen in this tab. Also, any further repairs can be seen under this banner. Any other maintenance about the leaks can be seen here.

The Third Part is Pipeline networks:

Here we have a search nav bar, where we can select the desired city or area and we can have a look of a pipeline network. This helps in giving knowledge on status of pipeline passing through city, locality, specific location. Putting these things all together new pipeline network can be planned well and strategic planning for repairs as well as better connectivity to the user can be planned.

VII. RESULTS

The image shown below depicts the exact view of our website that has been made.



VIII. CONCLUSION

The project of the online water management system has been successfully managing the water system well and monitoring the contamination, leaks and more importantly the pipeline network which in most important factor in today's world with growing population and rapid growth in modern infrastructure. The objective of test to contamination, planning of pipeline network and leaks if managed by the system with standard operating procedures and newly reporting system and feedback system which more often helps in monitoring and managing. Proving into real growth of managing water systems which has taken new turns into conservation and saving reserves of water and biotic life.

IX. FUTURE SCOPE

Our main aim of the project is to develop a system wherein the management of the system be it commercial, domestic, drinking or any other purpose must be clearly controlled and monitored thoroughly and treated In a manner that the water must not cause any more contamination but can be reused managed by the system and monitored as well and new can see the basic problems of managing water system has been done in the project using fusion of traditional and modern systems that can give great results in managing and monitoring the system. Eaze in management of online water management related to context of leaks, contamination.

Lightweight Cryptographic Algorithms

Akarsh Singh, Sahil Thakur, Avinash Singh, Raj Thakur
Information Technology TCET, Mumbai, India

Abstract— **This study examines Internet of Things (IoT) lightweight cryptographic solutions (IoT). This review includes a full range of security measures, from comparisons of various block cyphers to Lightweight Cryptographic solutions. Additionally, it compares hardware and software solutions, as well as many modern architectural variants of the most well- known and extensively studied block cypher, Advanced Encryption Standard (AES), as well as attacks for IoT security. The study found that lightweight AES worked well as a security solution for IoT devices with limited resources.**

Keywords— Internet of Things, Lightweight Security Solution, Block Cipher, Advanced Standard Encryption, Hardware Attack

I. INTRODUCTION

In recent years, the Internet of Things (IoT) has become a topic of discussion that is both theoretical and practical. The Internet of Things (IoT) is a concept that integrates common objects with the ability to perceive and connect with other devices online. More devices and sensors are connecting to the broadband Internet as it becomes more widely available and its cost of connectivity decreases. Such circumstances are creating favourable conditions for the development of IoT. The IoT is incredibly complex because we want to be able to interact with every thing from anywhere in the world. The physical objects that surround us are equipped with sophisticated electronics and sensors that communicate important data. Internet of things (IoT) consists of several interconnected devices which continuously share information and data among each other. To protect that information, we need to know the basic characteristics of security for IoT devices:

- Confidentiality- We need to make sure that the information is only available to the authorized users.
- Availability- Multiple devices are connected, we need to make sure a device gets its required data when it needs.
- Integrity- We need to make sure that the data is accurate.
- Authentication- This is an important characteristic yet difficult to implement from IoT perspective. In IoT, we

have different entities connected which have different purposes and levels in the whole structure.

- Key Encryption- This is the most important step. To ensure a secured connection, the devices and the other entities need to have a lightweight key management system.

The devices themselves must safely communicate with the IoT platform to start the process of sharing such a massive volume of data. To share the most important data with the apps, this platform combines the data from numerous devices and applies analytics. As everything will be connected to the internet, the IoT is elevating the traditional internet, sensor network, and mobile network to a new level. The difficulties relating to confidentiality, data integrity, and authenticity that would arise as a result of security and privacy must be taken into consideration as a subject of concern.

In this report, we reviewed recent research on several IoT security solution phases. We thoroughly addressed the progression of security measures, from Lightweight Cryptographic solutions through a comparison of various block cypher variants. Additionally, we compared the most well-researched and reliable block cypher, Advanced Encryption Standard (AES), with several modern approaches for IoT security.

The sections of the paper are as follows: Asymmetric and symmetric cryptography, two major categories of cryptography, were covered in Section II's discussion of lightweight cryptography. Additionally, we talked about and gathered many Stream Cipher and Block Cipher types that may be appropriate for IoT applications.

The most well-researched and reputable block cypher was the Advanced Encryption Standard, which was covered in part III. We made an effort to compile numerous recent studies on AES for IoT in accordance with diverse criteria.

II. LIGHTWEIGHT CRYPTOGRAPHY

To protect our sensitive data, a variety of cryptographic methods are available, but sadly not all of them are appropriate for contexts with limited resources, such as IoT devices

In order to provide a system that is both space and power efficient, lightweight cryptography techniques are being intensively investigated. Industrial and commercial IoT devices are also susceptible to IoT-specific attacks [1]. We will soon be faced with a security catastrophe if we keep using the current IoT device design cycle. Two categories can be used to categorise the present cryptographic primitives. There are two types of key encryption: symmetric and asymmetric.

A. Asymmetric Key Cryptography

A pair of public and private keys are required for asymmetric key cryptography, also known as public key cryptography (Fig. 1). Asymmetric key cryptography has received more attention recently than symmetric key encryption, however the results are not yet as consistent and productive. The operation of lightweight asymmetric algorithms is complicated, and they are not time-efficient. These algorithms are also weak because of the size of the operands and the relentless development of

attack models. Here are a few of the most significant asymmetric algorithms:

Rivest-Shamir-Adleman (RSA), Diffie-Hellman, Digital

Signature Algorithm (DSA)

• Rivest-Shamir Adleman (RSA) – An attacker would have a very tough time performing the reverse procedure and creating the private key from the public key. Therefore, even though key generation is complicated and time- consuming, this method is exceedingly secure.

• Diffie-Hellman – The process is quicker because the private key is so short. Short private keys make it more vulnerable to attacks, and man-in-the-middle attacks can also be used against the process.

• Digital Signature Algorithm (DSA) – The digital signatures have a limited lifespan, and the sharing is difficult, but this method is quicker and more advantageous than other asymmetric algorithms.

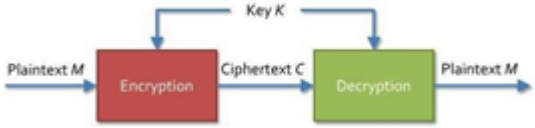

Fig. 1. Asymmetric Key Cryptography

A comparative study was done among RSA, Diffie-Hellman and Elliptical Curve Cryptography with Diffie-Hellman (ECDH) and they have found ECDH is better than other algorithms in terms of power and area.

B. Symmetric Key Cryptography

Secret key or shared key cryptography are other names for symmetric key cryptography. Through covert communication, the sender and the receiver in this procedure share a common key for both encryption and decryption. Due to its quick operations, which are mostly XOR and permutations, symmetric cryptography is better suited for IoT applications. They use fewer resources and absorb information more quickly.

The difference between stream and block cyphers in symmetric algorithms is crucial. A key used by stream cyphers has the same size as the data. In this procedure, plaintext is processed "bit by bit" to create the encrypted text. Despite having a poor throughput, Grain 128 is one of the most popular and appropriate lightweight cyphers for restricted devices. The lightweight cyphers below 1500 GE are reported to be the fastest with Espresso being the fastest.

Block cyphers use several phases of transformation that are determined by a symmetric key and have a set number of bits. The versatility of block cyphers is particularly advantageous from an IoT perspective. Another benefit is that the encryption and decryption techniques used in this procedure are nearly identical. Therefore, it might perhaps be done with minimal funding

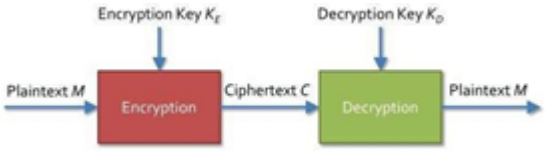

Fig. 2. Symmetric Key Cryptography

TABLE I. COMPARISON BETWEEN ASYMMETRIC KEY CRYPTOGRAPHY AND SYMMETRIC KEY CRYPTOGRAPHY

Symmetric Key	**Asymmetric Key Encryption**
It only requires a single key for both encryption and decryption.	It requires two keys, a public key and a private key, one to encrypt and the other one to decrypt
The size of cipher text is the same or smaller than the original plain text.	The size of cipher text is the same or larger than the original plain
The encryption process is very fast.	The encryption process is slow.
It is used when a large amount of data is required to transfer	It is used to transfer small amounts of data
It only provides confidentiality.	It provides confidentiality, authenticity, and non-repudiation
The length of key used is 128 or 256 bits	The length of key used is 2048 or higher
In symmetric key encryption, resource utilization is low as compared to asymmetric key encryption.	In asymmetric key encryption, resource utilization is high
It is efficient as it is used for handling large amount of data.	It is comparatively less efficient as it can handle a small amount of data.
Security is less as only one key is used for both encryption and decryption purpose.	It is more secure as two keys are used here- one for encryption and the other for decryption
The Mathematical Representation is as follows- P = D (K, E(P)) where K –> encryption and decryption key P –> plain text D –> Decryption E(P) –> Encryption of plain text	The Mathematical Representation is as follows- P = D(Kd, E (Ke,P)) where Ke –> encryption key Kd –> decryption key D –> Decryption E(Ke, P) –> Encryption of plain text using encryption key Ke . P –> plain text

Block cyphers are the most studied and changed IoT security solutions, despite their short latency. The Advanced Encryption Standard (AES), Data Encryption Standard (DES),

3DES, Blowfish, and Twofish are only a few examples of the various types of block cyphers. Researchers have used a variety of strategies to make these block cyphers acceptable for IoT and lightweight.

Various efforts to standardise cryptography take into account the security of both software and hardware. A comparison of a few lightweight block cyphers' software and hardware implementations was conducted.

Different metrics apply to software and hardware security solutions. Hardware measurements include throughput, area,

and throughout-area ratio, whereas software metrics include cycles, memory, and cycle per byte. Getting a straight

comparison between these two is challenging. By using a specially designed, lightweight reconfigurable CPU, the

authors were able to compare. They compared the size, throughput/area ratio, and hardware and software

implementations of AES, SIMON, SPECK, PRESENT, LED, and TWINE. Both in terms of hardware and software

performance, SPECK, TWINE, and PRESENT did well. Hardware and software security solutions are compared on a basiclevel.

It is significant to note that AES (Advanced Encryption Standard) is the most extensively researched block cypher algorithm out of all of them. To make AES lightweight and IoT friendly, several experiments have already been conducted on it, and more are being conducted right now.

III. ADVANCED STANDARD ENCRYPTION (AES)

1. The National Institute of Standards and Technology (NIST) standardised AES in 2001, and experts have since thoroughly examined it. It's probable that different devices will need varying levels of protection, as well as varied power budgets and throughputs, when it comes to security.

2. If we approach security from the level of the algorithm, it will rely on how the algorithm is built and how long the key is. Three distinct key sizes for AES offer three different levels of protection. To the best of our knowledge, it has security that has been proven, and it is frequently used for security measures and data encryption. AES has a high level of security and little complexity. AES core is split into halves : Key expansion path and the data encryption path. AES includes four meaningful rounds in total.

3. Key Expansion: Round keys are derived from the cipher key. This step has three rounds itself, Rotate, S-Box, and Rcon .

4. Initial Round:

Add Round Key: Each byte of the state is combined with a block of the round key using bitwise XOR.

5. Rounds:

a. Sub Bytes: A non-linear substitution step where each byte is replaced with another according to a lookup table.

b. Shift Rows: A transportation step where the last three rows of the state are shifted cyclically a certain number of steps.

c. Mix Columns: A mixing operation which operates on the columns of the state, combining the four bytes in each column and Add Round Key.

6. Final Round: All three rounds except Mix Column

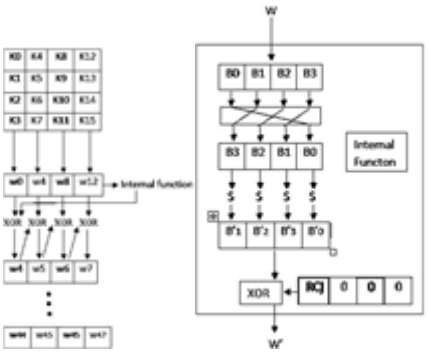

Fig. 3. AES – Key Expansion

TABLE II. PROPERTIES OF DIFFERENT BLOCK CIPHERS

Block Cipher	***Key Size (bit)***	***Block Size (bit)***	***No. of Rounds***	***Characteristics***
AES	128,192, 256	128	10, 12, 14	Excellent security,
DES	64	64	16	Not very secure but
3DES	112,118	64	48	Good security,
Blowfish	32-448	64	16	Excellent security, flexible
Twofish	128,192, 256	128	16	Can't be broken remotely
Humming Bird	256	16	4	Suitable for RFID tags or Wireless Sensor Network, Low power
SIMON	64~256	32~128	32~2	Excellent performance, easy
TWINE	80,128	64	36	Ultra-lightweight,Enough speed
LED	64, 128	64,	-	Efficient hardware implementation,

AES has a block size of 128 bits and key sizes of 128,

192 and 256 bits.

- For a 128-bit key 10 rounds are required.
- For a 192-bit key 12 rounds are required.
- For a 256-bit key 14 rounds are required.

Block diagram for 10 rounds of AES-128 is shown in Fig.

4. The total number of rounds is calculated by counting the most rounds for which shortcut attacks have been discovered and a sizeable security margin has been applied. An assault that uses shortcuts is more effective than one that does a thorough key search. No shortcut attacks for AES with block length and key length of 128 bits have been discovered for scaled-down versions with more than 6 rounds. Added as a security margin are 4 rounds. This is a cautious course of action. rounds. 4 rounds are added as a security margin. This is a conservative approach .

A. Recent Research Work on AES for IoT

The research on lightweight AES for IoT is still challenging. For IoT devices with power constraints that are implemented on UMC 130 nm technology, a power-efficient AES Core was described. The AES algorithm was provided with a completely asynchronous, quasi-delay-insensitive (QDI) implementation. For the AES 32-b datapath, many

cost, high-throughput, low-power, and energy-efficient design with numerous degrees of security. a brand-new AES microarchitecture with a 32-bit datapath that is geared for Internet of Things applications that use low power and low energy. AES circuit design that is ideal for Internet of Things applications was suggested as being small and light. Results for AES ideas were quite appealing. Also investigated was the energy efficiency of several block cyphers, including

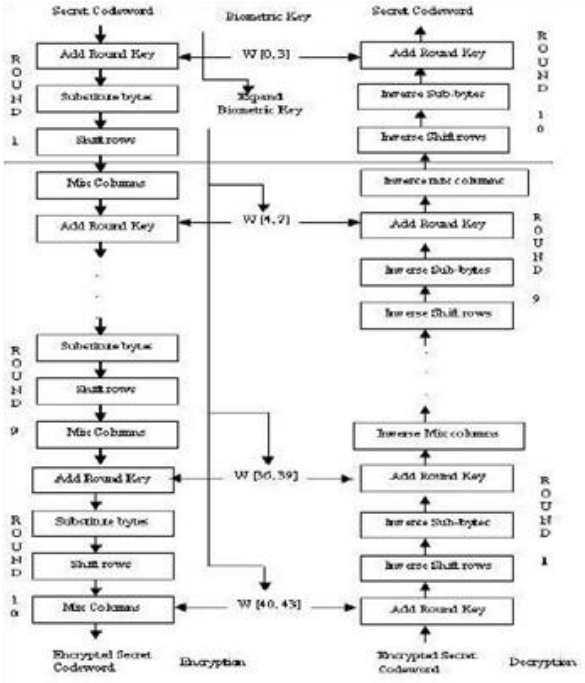

Fig. 4. 10 rounds of AES – 128 (Block Diagram)

B. Recent Research Work on AES for IoT

Mix-column round and S-box are the two main obstacles to an AES implementation on hardware. The primary objectives of the researchers are to decrease both the area and the delay of Hardware implementation of AES. To develop a lightweight AES that is appropriate for the Internet of Things, researchers have been working. Mix-Column and S-box have been the subject of research efforts up to this point

Utilizing the high performance Mix-Column and inv-Mix- Column approaches, which take advantage of the characteristics of binary computation, a novel FPGA implementation of AES was developed. Comparing the final design to the initial AES design, the area is reduced by 12% and the speed is increased by 20%. In a different publication, Mix-Column was also improved for speed and simplicity. In comparison to other similar studies, their results display less complexity and a smaller number of gates.

AES to become a compact and appropriate block cypher for the Internet of Things, S-boxes and Mix-Column rounds are two crucial issues. Regarding AES's level of security, there is no debate. A portable AES can protect the exposed IoT network. To accomplish the desired result, researchers have been putting out novel architectural designs and working on Mix-Column and S-boxes.

Attacks on AES

IoT hardware security attacks may target AES hardware implementation. Finding answers while keeping an eye on the attacks is crucial. Below are some current research articles about AES attacks.

It was established that the suggested Differential Fault Analysis Attacks for AES decryption were effective. Along with a relative key impossible differential attack on

7 round AES 192, a wireless interceptive Side Channel Attack technique was also suggested by to expose the secret key of the AES-128 encryption algorithm for IoT applications. A fake key and XOR gates based on Wave Dynamic Differential Logic were suggested as a defence against Correlation Power Analysis assaults.

IV. DISCUSSION

The key topic of interest for IoT researchers has been security. Finding a single, concise strategy that works for all IoT applications is challenging. In an IoT network, various types of devices are connected. Most IoT devices are resource constrained, however some may afford to have a heavyweight and a high security technique. They require a quick-acting security solution. It also needs to be more adaptable and less complicated.

We started our investigation by investigating lightweight cryptographic techniques. We have researched the use of symmetric and asymmetric keys in cryptography. We came to the conclusion that symmetric cryptographic methods have the speed and simplicity we require for the Internet of Things.

The two most significant symmetric cryptographic cyphers, stream cyphers and block cyphers, were further investigated and explored. Because block cyphers are more adaptable than stream cyphers, academics have developed a number of simple block cyphers that are suitable for IoT.

Finding the most reliable and well-researched block cypher was our next objective. We came to the

conclusion that Advanced Encryption Standard (AES) is the most reliable and thoroughly studied block cypher that can protect the world from the Internet of Insecure Things after reading and analysing numerous research papers. The problem with AES is that it wasn't intended to meet the block cipher's lightweight requirements when it was first proposed.

We also included a comparison of hardware and software security solutions in this article, and we came to the conclusion that we currently need to find a hardware solution for IoT.

Our next objective was to compile research on lightweight AES. We discovered various efforts to lighten the AES design. We also came to the conclusion that the complexity of AES is due in large part to two crucial components: Mix Column and S-box. We also reviewed previous studies that addressed similar topics.

Finally, we have provided the research on several AES attacks. This survey covered every avenue of potential security solutions, and based on our investigation, we came to the conclusion that lightweight AES can be an effective security option for restricted IoT devices

V. CONCLUSION AND FUTURE RESEARCH

In this survey, we discussed comprehensively a flow of lightweight security solutions for Internet of Things. We surveyed research work on Asymmetric cryptographic algorithms and Symmetric cryptographic algorithms (Stream Ciphers and Block Ciphers) for IoT. We also surveyed very recent research work (2015-2018) on AES for IoT in terms of architecture, Mix-Column/S-box modify strategy and attacks. According to our study we conclude, lightweight AES can be a very good security solution for constrained IoT devices. .

AES block cipher is the most researched and trusted block cipher. Researchers are still working on making AES lightweight and suitable for IoT. For our future work, we will work on AES architecture with a goal of proposing a lightweight solution for IoT.

Lightweight Cryptography in IOT Devices

Hardik Ramparia , Utsav Rana, Anand Thakur
Information Technology TCET, Mumbai, India

Abstract – **The Internet of Things comprises devices that have low or constrained resources and are rather portable. These devices communicate with each other viathe Internet to exchange data. Some examples of such devices are Sensors, Integrated Circuits, small single chipcomputers and many more. Due to the inadequate resources available on such a device, applying traditionalcryptographic techniques is infeasible. There are many comparisons of cryptographic algorithms for devices which have plentiful resources but those are bulky and cannot be applied for a more mobile usage. Developing lightweight algorithms for devices that are memory efficient, portable and easy to attach is the need of the hour. This paper talks about one such application and its comparison with traditional lightweight algorithms that are used currently.**

Key Terms - Internet of things, Cryptography, lightweight Machines

I. INTRODUCTION

Many restricted devices are connected to the Internet via a new computer environment called "Internet of Things (IoT)" or "Smart Object" networks. Through the network, the devices communicate with one another and give us fresh experiences. To take pleasure in this novel setting, Constrained end node security is crucial. The network would be compromised if one of the nodes could sustain catastrophic injuries. However, implementing sufficient cryptographic methods is difficult. on restricted devices as a result of the resources available to them.

What is lightweight cryptographic:

The field of cryptography is developing, and new methods of attack, design, and implementation are being thoroughly researched. The state-of-the-art method known as "Lightweight Cryptography (LWC)" is one of them. A cryptographic technique or protocol called "lightweight cryptography" is designed for use in limited situations, such as those posed by RFID tags, sensors, contactless smart cards, medical equipment, and so forth.

In ISO/IEC 29192, ISO/IEC JTC 1/SC 27 has already covered the characteristics of lightweight cryptography. A brand-new effort to standardise lightweight cryptography, known as ISO/IEC 29192, is currently under way. Based on target platforms, lightweight features are outlined in ISO/IEC 29192. Chip size and/or energy usage are crucial metrics for assessing the lightweight properties in hardware implementations. The lower the code and/or RAM space, the better for software implementations.

Challenges faced:

Coordinating several innovation networks into a typical all- IP system to ensure that communication systems have unwavering quality and variety is the main problem of ubiquitous deployment. IoT is therefore dependent on the communication's availability and dependability on future internet engineering and the IPv6 convention, which meet the requirements of care and variety. The assurance of security, protection, data reliability, and user confidentiality represents the second challenge. Additionally, crucial and significant IoT applications provide a challenge to the system that handles key management, access control, authentication, and authorization. Furthermore, it is critical to strengthen the security of edge systems for the global network as the capabilities of forced devices that may interface with the Internet are degraded.

II. IOT SECURITY

It is clear that the disadvantages related to security, privacy, and vulnerability concerns are one of the main obstacles IoT must overcome. IoT systems have a significant SPF risk because of their centralised cloudbased setup. Data confidentiality and device authentication are additional issues with IoT. IoT systems can be hacked and misused if the right security measures are not in place. IoT systems need to be secured against DDoS and injection attacks, among other threats. For any real-time and life-critical applications, such as healthcare, transportation, and telecommunications, both availability and data integrity are crucial Through (device) authentication and (data) hashing techniques employed in blockchain ecosystems, blockchain can provide IoT with the necessary mechanism to provide publicly verifiable audit trail. Thus, this can significantly contribute to the solution of the non-repudiation problem.

III. LITERATURE REVIEW

Techniques	Year	Main focus	Results
PRESENT a benefit milestone in LWC with several light-weight designs	2007	Light-weight cryptography implementations	development of the light-weight block cipher
ECC based cryptosystems	2014	satisfy security and efficiency requirements	inspire other researchers able to classify challenges over Secure cryptosystems or light-weight ones
Chaotic map and genetic operations	2014	Light-weight encryption scheme	Secure and light-weight encryption scheme
Blow Fish algorithm on FPGA	2014	Application of Data Encryption for IOT	Using(FPGA) implementation is cheap, simple to implement, reprogrammed and high speed
the operation for 128bit plain text with 128bit key and corresponding output text Each algorithm performs	2016	Light-weight encryption	design of hybrid light-weight and secure encryption system
AAβ Encryption Scheme on Embedded Linux for IOT	2016	analysis of light-weight asymmetric encryption	99% improvement on encryption time and improvement of 94% on decryption time for 2048-bit primes.
CP-ABE scheme	2016	Light-weight Attribute-	Pre-computation technicality reduces

		based Encryption	the cost of(CP-ABE) encryption	
KLEIN-80, TWINE-80, Piccolo-80, SPECK (64,96) and SIMON(64,96)	2017	evaluation of light-weight ciphers	The evaluation show that the SPECK(64,96) cipher has been the best value of the perspective of energy and is appropriate for wireless sensor networks	[12]
block cipher including AES (Rijndael)	2017	Secure IOT (SIT)	Development a light-weight algorithm that presents substantial security in(IOT) environment	[13]

IV.APPLICATIONS OF LWC IN IOT DEVICES

Most popular applications of LWC in IoT appear to falls into three major categories as follow Controlled Lab Experimentation Infrastructure Initially, algorithms were evaluated within a controlled test bench comprised of Raspberry Pi devices. Specifically, Raspberry Pi devices were used in all experiments within the test bench. We evaluated algorithm performance using a real-world message broker, MQTT, that is used in many IoT networks to send and receive short messages.

To reiterate, the MQTT natively does not encrypt data being sent/received . Experiments were run on a Raspberry Pi Zero with a 1 GHz, single core CPU and 512 MB of RAM. Raspberry Pi 3 and 4 sets were also tested. Experimental setup included two Pi's connected via Wi-Fi. The results were collected based on a roundtrip timing approach where the times reported are the total time to send a message, receive the message, decrypt, re-encrypt, send back, and finally decrypt the message. This roundtrip time measurement provides an exemplar use case to measure the impact of these algorithms on IoT device communications. Messages are comprised of a randomly generated string of characters. The message lengths of 10, 100, and 500 bytes were determined using common message lengths within the test bench setup.

Weather Messaging System

The weather messaging system provides real-time weather metrics/readings of anoutdoor drone airfield located at the US Air Force Academy. The weather messages vary in length and provide insight into potential flying conditions. The weather data messaging system is critical to the USAFA given their real-time requirement for localized weather awareness and understanding to inform key and essential flight aviation operations. Given the USAFA campus is located at the foot of the Eastern Range of the Rocky Mountains, large variances of campus weather conditions as compared to weather reported at other nearby airfields requires additional monitoring capabilities and reporting performed using sensors located directly at the Stillman field drone launch area. Key weather data (wind speed, direction, temperatures and pressure) from numerous sensors is available to inform faculty and students of the necessary, safe conditions at their aircraft launch and recovery. Figure 2 provides an OV-1 model style overview of the IoT testbed at USAFA that includes the weather station for drone operations. Exact locations are not represented in the figure.

E-Iink displays are powered by Raspberry Pi devices that subscribe to these topics and display the stored weather messages. This provides cadets and instructors with real time weather measurements, giving them the ability to determine if conditions are safe and suitable for flying. Figure 33 below provides the general workflow for the weather messaging system's:

V.CHALLENGES IN LWC

1. Software and firmware vulnerabilities Ensuring the security of IoT systems is tricky, mostly because a lot of smart devices are resource-constrained and have limited computing power. Thus, they can't run powerful, resource-hungry security functions and are likely to have more vulnerabilities than non-IoT devices. Lack of computational capacity for efficient built-in security

2. Insecure communications Most existing security mechanisms were initially designed for desktop computers and are difficult to implement on resource constrained IoT devices. That's why traditional security measures aren't as efficient when it comes to protecting the communication of IoT devices.

3. Data leaks from IoT systems We've already established that by capturing unencrypted messages from your IoT system, hackers can get access to the data it processes. This might include even sensitive data like your location, bank account details, and health records. However, abusing poorly secured communications isn't the only way attackers can gather valuable data.

4. Malware risks A recent study by Zscaler found that devices most at risk of being hacked by a malware attack were set-top boxes, smart TVs, and smartwatches.

VI.CONCLUSION

Due to the exponential growth in the number of IoT de-vices in various domains, IoT security is one of the main concerns and as a consequence, there is need of lightweight algorithm(s)

with strong security and right balance of cost and performance metrics. For resource constrained devices, in particular IoT devices, lightweight cryptography is an effective way to secure the communication by transforming

the data. The well-defined LWC characteristics (cost, performance and security) by NIST are compared and further research gaps and open research challenges are highlighted in this paper. From the literature review, AES, PRESENT, CLEFIA and lightweight versions of DES are the most experimented and widely accepted block ciphers. However, new attacks are reported with the growth of new LWC algorithms which is inevitable and never ending process. The war between cyber security experts and attackers always opens a door of opportunities for new research in the field of cybersecurity, especially lightweight cryptography.

VII. ACKNOWLEDGEMENT

I pay gratitude to my supervisor Ms. Rahul Neve for guidance, support, patience and understanding throughout the research period, also my sincere gratitude goes TCET

Online Student Evaluation and Assessment: Improving Student Performance through Technology

Shaurya Sharma, Mihir Tayshete, Aditya Sharma, Pratibha Prasad
Thakur College of Engineering and Technology, Mumbai, Maharashtra, India
shaurya064@gmail.com, mihirtayshete@gmail.com, adityaraysharma@gmail.com, pratibha.prasad@thakureducation.org

Abstract— **Online learning has become a widely adopted mode of education in recent years, and with it comes the need for a reliable and efficient evaluation system. In order to address this need, this project aims to improve the assessment process for teachers and students. It provides a simple and effective way for teachers to assess student performance and for students to receive necessary tools and resources for their assignments. The system keeps students engaged with interactive features and performance analysis. Additionally, it delivers a more comprehensive evaluation of students' performance by considering different elements such as class participation, group work, and assignments. To maintain the authenticity of the finished assignments, unique certificates would be generated. This platform also implements measures to prevent instances of cheating among students. This enables teachers to have a better understanding of a student's overall competence.**

Keywords—assessment, student, certification, analysis

I. INTRODUCTION

The main aim of this project is to bridge the gap between student-teacher interaction in the online mode. To achieve this, separate modules have been created for both teachers and students, each with unique functionalities. Both the teacher and student have individual login systems for secure access. Teachers can create courses that students can join, and the teacher or faculty in-charge can assign different tasks and assignments that are time-based. To prevent cheating during exams, the system has been designed to be tab-restricted, which means that students will receive a warning each time they switch tabs, and time will be deducted accordingly. Professors can also award students with certificates based on their performance in specific activities. These certificates can be verified using an ID generated during the certificate creation process.

In addition to promoting student-teacher interaction, the project also prioritizes students' access to proper learning resources. With this in mind, a note sharing feature marketplace has been implemented, where students can access and share learning materials. The website has been designed to be dynamic and user-friendly, incorporating modern technologies.

II. COMPARITIVE STUDY

The demand for effective online evaluation has significantly increased in recent years, as the recognition of distance learning and online education has led educational institutions to revamp their delivery methods, teaching strategies, and learning environments [1]. Online delivery has the potential to offer numerous benefits in promoting sustainable education, such as offering academic opportunities to students from diverse backgrounds, and broadening the dissemination of education [2].

However, the current online assessment system for students is outdated and does not offer the same benefits as the traditional offline system. Most online evaluations only provide a general overview of a student's performance, without highlighting their mistakes, and do not offer any opportunities for interaction with the teacher. Additionally, the online system is prone to cheating as students can easily switch tabs and access external resources. Table 1 shows the acceptance rate of an online e-learning platform Google Classroom for a dataset of 305 people [3].

Table I

Students Acceptance of Google Classroom

Attribute	Values	Population	Percentage
Gender	Male	78	26%
	Female	227	74%
Age	18-22	242	79%
	23-28	35	12%
	28+	28	9%

Education is a crucial aspect of an individual's growth and development, and it is essential to have a system in place that promotes a culture of learning, generates genuine interest in the subject matter, and provides students with the necessary resources to succeed [4]. With the vast amount of information available online, online learning has tremendous potential to positively impact the future of ed-tech. Improving online learning and assessment would play a significant role in shaping

this future, and making the necessary enhancements to an already expanding system is vital [5]. Effective teaching techniques are crucial to a student's ability to absorb and understand the information being delivered, and good instructors create an environment that supports this learning.

The most noticeable issue found in the current system, as revealed by the comparative study, is the lack of a suitable learning environment for students and inadequate assessment system. To address this, the ideal solution would be a system that facilitates student learning and resolving doubts, with a user-friendly grading system.

III. TECHNOLOGIES USED

The website has been developed using the latest technology stack to ensure a seamless user experience. For the front-end, the proposed system has utilized ReactJS and Material UI. ReactJS is a highly effective JavaScript library that makes front-end development easier, and its component reusability and state handling capabilities making it the ideal choice. Material UI, a library of functional components, has further enhanced the user interface, making it visually appealing and interactive.

The back-end of the website has been built using NodeJS and ExpressJS. NodeJS is an event-driven asynchronous JavaScript runtime that is designed for building scalable network applications, making it perfect for the use case. ExpressJS is a minimal and flexible web application framework that provides a robust set of features for web and mobile applications, making it an ideal choice for the project requirements.

To store the data required by the application, MongoDB, a NoSQL database, and Firebase, a cloud-based database has been utilized. MongoDB provides a flexible database schema, which makes it an ideal choice for the proposed application. However, as MongoDB only allowed for video storage in chunks, Firebase was used to store the video lectures in their entirety. Firebase provides a range of features, including messaging, authentication, and storage, making it the ideal choice for this purpose. For testing the post and get methods, Postman has been used.

IV. WORKING & CHARACTERISTICS

The website has been designed and developed with three key modules in mind, each serving a specific purpose. These modules include the Student Module, Teacher Module, and Certification Module, each of which has been equipped with various functionalities to meet the specific needs and requirements. The website encompasses several key features, including:

- Login system: The website boasts a sophisticated login system that elegantly separates the set of features intended for students from those for teachers. This segregation is achieved through the utilization of a classifying attribute known as "type," as depicted in Fig. 1. To ensure the appropriate level of access, separate login credentials have been created for each group. The login system has been implemented using PassportJS and a session management mechanism, which securely stores the user's information. This information is then used to authenticate and validate each user's access to their respective modules.

The website's design considers the need to maintain a clear distinction between the student and teacher modules. This is to prevent unauthorized access and ensure that the website is used in an orderly, ethical, and organized manner. As a result, students cannot access the teacher module, and teachers cannot access the student module. This clear assignment of roles and responsibilities helps maintain the integrity of the learning community and reduces the potential for confusion or hastiness.

- Creating & joining courses: This platform aims to provide a comprehensive and organized learning experience for students and teachers alike. With its course creation module, teachers have the ability to create subject-specific courses that students can enroll in. These courses are designed to help reduce the amount of paperwork involved in the education process and provide an efficient means of grading and assessment.

The teacher is responsible for assigning tasks and assignments to students within the course. To prevent multiple entries from the same student, a unique course code is generated upon course creation and is distributed to students for enrollment purposes. This code is then used to verify the student’s identity and grant access to the course.

The implementation of course-based classrooms helps streamline the organization of coursework, allowing teachers to focus on lesson planning rather than administrative tasks [6]. The digital grade book reduces the need for physical paperwork and eliminates the repetition involved in manually grading several assignments. It also prevents the physical strain associated with manual grading.

Inclusion of assignments in these courses is a crucial aspect of the platform. Assignments promote independent learning, as students are encouraged to work their way around the questions and overcome difficulties. Each time a student completes an assignment, they become more capable of independent learning, which is a valuable life skill.

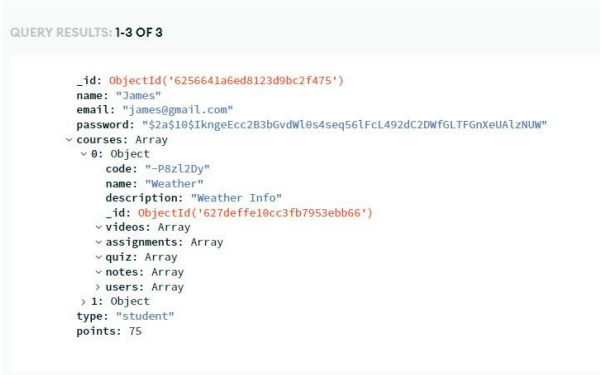

Fig. 1 User Schema Example

• Video lectures: The platform includes a video lecture feature, which is particularly beneficial for students who miss classes. The flexibility of the video lectures allows students to learn at their own pace and revisit certain concepts if they haven't understood them, promoting self- learning [7]. The combination of body language and tone of voice in video lectures makes the learning experience more engaging and impactful compared to the written word. Research has shown that video learning is beneficial for students in many ways, including motivation, learning depth, and critical thinking skills.

In a flipped classroom, students view video lessons as homework and engage in discussions with teachers during class time. The use of visual and aural clues in video learning enhances students' understanding and retention of new information. James McQuivey, an analyst with Forrester Research, states that one minute of video is equivalent to almost 1.8 million written words. Studies show that the combination of visual and audio learning leads to high engagement and improved outcomes [8].

The video lecture feature also enables the dissemination of educational knowledge to classrooms around the world [9]. A teacher from the comfort of their home can easily create a video tutorial for students, promoting cultural understanding and social empathy through information sharing. The platform's video uploading feature is an important tool for facilitating this type of global education.

• Time Based Assignments: Additionally, the platform's time-limited assignment feature as seen in Fig. 2, further promotes the integrity of the evaluation process. By setting a deadline for submission, the teacher minimizes the opportunity for students to engage in copying or cheating behaviors. Once the time limit has passed, the assignment is automatically submitted, and all marked answers are saved, providing a precise evaluation of the student's understanding and abilities. This feature not only ensures the validity of the evaluation process but also encourages students to prioritize their time and focus on their coursework.

Fig. 2 Time Based Assignments

• Anti-Cheating System: Platforms like Swayam provide intuitive assignments to students, but they lack anti- cheat measures [10]. To counter this, the platform has measures in place to prevent cheating during online exams The students are warned a few times against changing tabs during the exam, and after that, any violation of this rule would result in a penalty such as deduction of time or reduction of scores. These measures aim to create a fair and equal evaluation process for all students, ensuring that their performance is based on their own abilities and understanding of the subject. The platform also promotes academic integrity and helps prevent any kind of unethical behavior. This way, students are encouraged to perform to the best of their abilities and achieve their full potential.

Fig. 3 Certificate on Course Completion

• Reward System: Rewards play a crucial role in an efficient behavior management method in the classroom. Both intrinsic and extrinsic motivation are important for driving students to perform well and follow expected behaviors.

Intrinsic motivation is when students find pleasure in their work and engage in it simply because they enjoy it. This can be fostered through compliments, individually demanding assignments, and completing academic work purely out of a desire to learn. On the other hand, extrinsic motivation involves providing more tangible

rewards such as pencils, erasers, stickers, and even candy. It's important to provide rewards that are fair and consistent for all students, and also unique for each assignment. Extending rewards to students helps to promote positive and appropriate behavior in the classroom. Students are encouraged to follow class rules, be kind to each other, and prioritize safety, among other positive behaviors. With appropriate student behavior, teachers are able to focus on lesson content and interactive activities, rather than spending time on classroom discipline. Offering rewards also motivates students to give their full effort when attempting class projects, assignments, and various tasks. When a reward system is in place, students tend to show increased interest and participation in everyday classroom activities. The goal of assigning homework is to reinforce the subject matter, and without homework completion, students are not able to practice what they have learned. By rewarding students for completed projects and homework assignments, both in groups and individually, the teacher can promote a better understanding of the lesson. Finally, it's important to note that after the student completes a set of assignments, they can be rewarded with a certificate. The certificates can be auto-generated and will contain the student's name, course name, date of completion, email address, and a credential ID as seen in Fig. 3, which can be used to verify the credibility of the certificate. This helps to remove any concerns regarding the creation of fake certificates, as they cannot be validated.

Overall, a reward system is an effective tool for promoting positive behavior and encouraging students to be more productive in their learning.

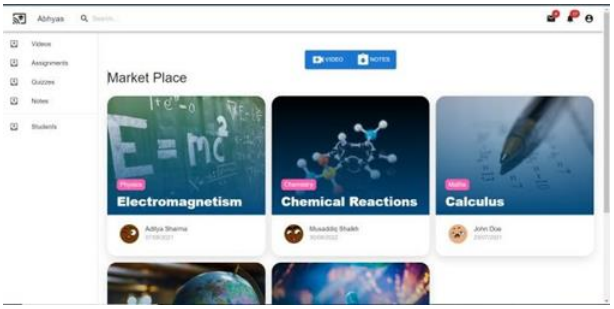

Fig. 4 Marketplace for Sharing Resources

• Marketplace: This helps students who do not have access to schools or colleges to get hands-on high-quality notes for further education and expand their knowledge base, as these notes can be accessed from anywhere with an internet connection. This also helps to bridge the gap between students from different socio-economic backgrounds, as all students will have equal access to the resources shared on the platform.

In addition, having a library of resources and study materials readily available can greatly benefit students in the long run. It can save students time and effort in searching for resources, and it also provides a platform for students to share their own resources with others. This not only supports student learning but also encourages collaboration and teamwork, which are crucial skills for success in both academic and professional settings.

In addition to notes, students can also share study tips, learning techniques, and other resources that have helped them excel in their studies. This can help create a supportive and collaborative learning environment where students can share their experiences and help each other grow.

Overall, the marketplace provides a unique opportunity for students and teachers to collaborate, share, and grow together, making the process of learning more efficient and enjoyable. An example of the mentioned feature can be seen above in Fig. 4.

• Interactive whiteboard: Interactive whiteboards are transforming the way education is delivered in the classroom. In addition to the many benefits, such as increased engagement and better learning experiences, there are even more advantages to using an interactive whiteboard in the classroom.

Firstly, interactive whiteboards promote collaboration between students and teachers. Fig. 5 shows both teacher’s and student’s perspective while using the whiteboard feature. With the use of interactive whiteboards, teachers are able to present learning materials in a more interactive way, allowing students to participate in the learning process by asking questions, providing answers, and working together on projects and assignments. This type of collaboration fosters a supportive learning environment, where students feel comfortable to engage with the material and each other, resulting in a deeper understanding of the subject.

Moreover, interactive whiteboards allow for immediate feedback and assessment. With the use of technology, teachers can quickly assess students' understanding of the material through interactive activities, polls, and games. This type of assessment not only helps teachers gauge students' learning but also provides students with instant feedback, allowing them to address any misunderstandings and reinforce their learning [11].

Interactive whiteboards also make it possible for students to save slides, which can be easily reused and adapted for future classes. This not only saves time but also ensures that all the lessons are consistent and up to date. Interactive whiteboards are cost-effective and eco-friendly. As mentioned earlier, the use of interactive whiteboards reduces the need for traditional teaching supplies, such as paper and markers, reducing the overall cost of running a classroom. Furthermore, the use of technology also reduces the use of paper, which is not only good for the environment but also saves schools and colleges money on printing and purchasing resources.

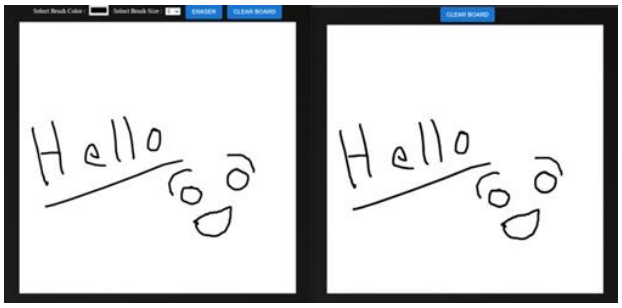

Fig. 5 Interactive Whiteboard for E-Learning

• Analytics Dashboard: One of the key features of the project is the Analytics Dashboard. This dashboard provides an in-depth analysis of the student's performance and their engagement with the course material. The Analytics Dashboard provides a comprehensive overview of the student's learning progress and provides insights into their strengths and weaknesses. The dashboard also helps teachers to identify the areas in which the student needs improvement, enabling them to customize their teaching approach accordingly. The analytics dashboard allows teachers to track the progress of each student in real-time and make data- driven decisions to enhance the learning experience. This feature provides teachers with the necessary information to create a personalized learning plan for each student, helping them to achieve their learning objectives and reach their full potential.

V. FLOWCHART

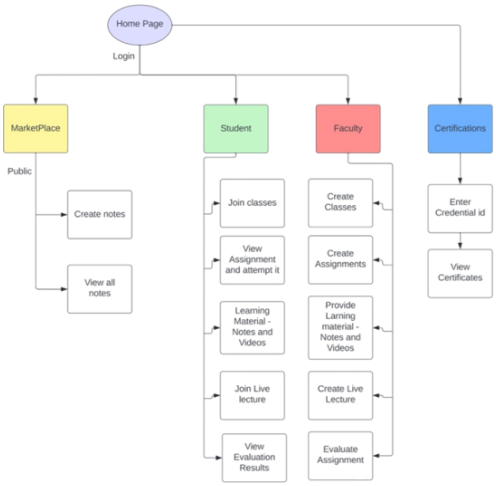

Fig. 6 Basic Architecture of the Project

Abhyas is a comprehensive platform for learning, teaching, and sharing knowledge that offers numerous features and benefits for both students and teachers. As mentioned in Fig. 6, here are some additional details about each of the four main modules:

1. Marketplace:

The marketplace is a platform where users can share their knowledge by uploading and selling their notes, video tutorials, and study materials. This platform serves as a hub for students and teachers to access a wide variety of resources and learning materials, making it easier for students to find the information they need to succeed in their studies. In addition, it also provides an opportunity for individuals to monetize their knowledge and skills by selling their materials to other students and teachers.

2. Student:

The student module is designed specifically to support students in their learning journey. This module includes a personalized profile that displays the student's certifications, as well as a dashboard that allows the student to access their enrolled courses, assignments, notes, live lectures, quizzes, and pre-recorded videos. With this module, students have everything they need to study effectively and efficiently, all in one place.

3. Faculty:

The faculty module is designed for teachers to create classes for their students, manage course materials, and assess students' progress. With this module, teachers can easily create classes, add assignments and quizzes, and keep track of student progress. Teachers can also assign certificates to students to recognize their achievements and progress, providing motivation and encouragement for the students to continue their studies.

4. Certifications:

Certifications are an important aspect of Abhyas, as they serve as a validation of the student's knowledge and skills. Certifications can be created by teachers, or they can be earned by students by completing a set number of quizzes from a particular class. Each certification includes a unique credential that can be used to verify the authenticity of the certificate, along with other relevant details, such as the student's name, course, and date of completion.

In conclusion, Abhyas is an innovative platform that provides students and teachers with a comprehensive solution for learning and teaching. With its numerous features and benefits, Abhyas makes it easier for students to access the information they need to succeed in their studies, and for teachers to create and manage effective learning environments.

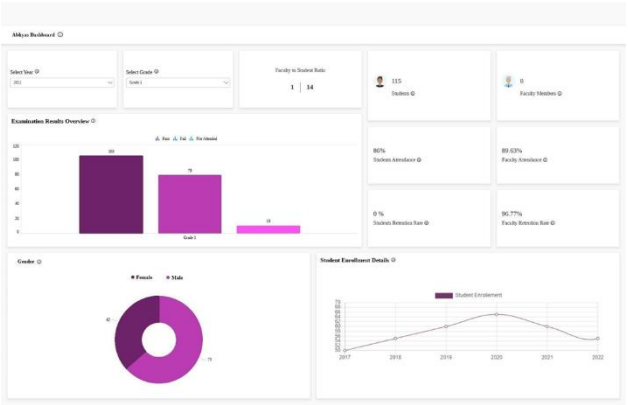

Fig. 7 Dashboard for Student Analytics

VI. CONCLUSION

With a thorough consideration of the various factors that greatly impact the current system of online learning, a meticulous study of the different methods and approaches in place has been conducted. Through this, several areas for improvement have been identified and necessary innovative and practical features to enhance the existing model of online learning and assessment have been developed. The proposed system aims to offer a comprehensive solution that meets the needs of both students and instructors, providing a seamless and efficient experience for all parties involved. The implementation of this project will be instrumental in furthering the advancement and success of online education.

VII. FUTURE SCOPE

The evaluation of performance in a test is an important aspect of any educational system. It helps students to understand their strengths and weaknesses and work towards improving in areas where they may be lagging behind. By feeding the results of these tests into a machine learning algorithm, the system can more accurately identify weak subjects and provide personalized recommendations for improvement. This can be a valuable tool for both students and educators alike. To make the system even more accessible and user-friendly, it can be ported into a mobile application that is easily loaded and used on the go. Additionally, a reward system can be implemented to encourage students to actively participate in the platform. This reward system can recognize not just the completion of assignments but also the most active contributors and resource sharers in the marketplace. This will create a sense of community and encourage students to collaborate and share resources with each other.To further enhance the system, the question sets in the assignments section can be broadened to include preparation for interviews and competitive examinations. This will not only help students to prepare for these important events but also give them a sense of the types of questions they may encounter in the real world. To keep track of individual performance, charts and graphs can be used to represent the academic growth of each student for each subject. This will provide a visual representation of progress over time and allow students and educators to track their success.

VIII. ACKNOWLDEMENTS

We are deeply grateful to our guide, Mrs. Pratibha Prasad, for imparting her vast knowledge and expertise, providing valuable feedback and mentoring us every step of the way. We would also like to thank our principal, Dr. B.K. Mishra, for providing us with the resources and facilities necessary to carry out our research. Finally, we are thankful to Thakur College of Engineering and Technology for providing us with a nurturing and dynamic environment where we could thrive academically and intellectually.

Sure Help

Jhanvi Pandya, Meera Prajapati, Sumit Singh, Dr Kamal Shah
Information Technology Thakur College of Engineering and Technology, Mumbai India
jhanvipandya325@gmail.com, meerajyotiprajapati@gmail.co m, tok2sumit@gmail.com, kamal.shah@thakureducation.org

Abstract: **SureHelp is a system that eases the day to day life of the elderly society. The technological challenges that were faced while an analyzing and designing the system is to first consider every feature that might make an elderly person's daily life easier and to inspect if any such applications exist in the market. And if any such application or paper does exist what are their gaps and how can the system overcome them. The second difficulty was that how can the system be easy to use for an elderly, whether it be multilingual, choosing the colors which are easy to see for them, choosing the correct font, to think of adding speech to text feature, audio search feature etc. The major aim of this app is to make it as elderly friendly as possible and that's why the main technical parameter is to keep a check on its Graphical user interface (GUI) so that it is easy to use, and to see how conveniently the features can be used by them. The result achieved till now is to study the resources needed to plan the idea. Literature survey was done and gaps were identified which SureHelp aims to overcome. Finally, an android mobile application is developed which consists of the various features like medicine reminder, yoga/workout, view nearby hospital, learn technology, government facilities, and send location to emergency contacts.**

I. INTRODUCTION

All of us might have had experiences of our grandparents asking for our assistance in running a particular application or a highlight on the mobile phone and we tell them once or twice but they fail to figure it out and we become annoyed. It gets challenging for older individuals to follow such applications instantly or in one go as there are many mental and natural changes that they go through as they age. Their handle on it isn't on par with their ability to get a handle on it.

SureHelp is basically an application that is designed for aged people who belong to the age group above 60. This project intends to help elderly individuals. Old people have trouble keeping up with latest technologies. Currently, not many apps are in market for senior citizens. it allows the user to access all important government facilities and eases day to day activities. the main focus is to create an application with all unified features. the day-to-day activities of the older generation are made easier by this project. It is done by helping them with everyday activities like reminding medications, providing all information whether, legal or financial which is easily

accessible. Letting their dear ones know about their condition and location. Therefore, it is essential to ensure that they experience an effortless day in which they can be independent and exist with assurance.

II. IMPORTANCE OF THE PROJECT

Adopting such senior-friendly applications is a blessing for individuals suffering from fitness problems like sight impairment or memory deterioration. Let's review some of the perks of advancing senior-friendly apps.

1. Such applications will serve in staying in touch with their family.

2. Handy and connection to governmental assistance.

3. It provides them a sense of living independently.

4. It additionally improves self-confidence and gives them a feeling of accomplishment by acquiring new cognitive abilities.

III. PERSPECTIVE OF STAKEHOLDERS AND CUSTOMERS

The population is growing older, and according to UNO estimations, the number of individuals above 60 will touch more than 2 billion people by 2050. For advanced Western countries, this drift is particularly applicable.

Elders of the new world require technological solutions in various fields, from health supervising to retirement provision planning. More exceeding are sincerely engaged in designing apps particularly for those over 60 years old, and shareholders display considerable enthusiasm in such ventures. In advanced countries like the US, senior residents are progressively maturing a significant part of the audience for the industry. They are financially stable, have plenty of unoccupied time, and have already moved the responsibility of being parents.

As per a Pew Research Center, 74% of individuals matured 50 to 64, and 42% of individuals more than 65. An ever-increasing number of clients, remembering those for the 60+ class, use applications for all everyday issues. New companies that cover various spaces of senior residents' lives have been put in motion all over the world. The normal change of clients from moderately aged to old age involves the development of new necessities from applications. A wide scope of reasonable advanced cells and tablets invigorates the development of this high-likely market.

Developers have lately intensified their concern in this crowd. Nevertheless, in almost every mobile application

division for the senior age, conflict is currently truly less. This is a huge, however underrated industry.

IV. OBJECTIVES AND SCOPE OF THE PROJECT

Main objective of this system is to make life of elder people easier. Most applications are constructed, identifying the age group of 15 to 34. Applications are executed as per convenience while elder people don't have that much knowledge about technology, these applications are quite complex for them to learn. Mobile app developers believe that the broader audience adopting smartphones is the younger group, and creating applications as per their requirements will produce them gains.

Main features of this Application include:

- Government facilities notifications
- Medicine Reminder
- Handy technology manual which comprises of information regarding payment facilities, social media, etc.
- Speech to text search
- User-friendly UI
- Yoga/ workout
- Location Tracking - Notify dear ones about
- View nearby hospitals

V. PROBLEM DEFINITION

This project named Sure Help aims to make the day to day lives of elderly individuals easy by providing them with the features necessary for them and with an interface which is easy for them to use.

- According to the Pew Research Centre's Mobile Fact Sheet, older adults who are 50 and above are frequent smartphone users.

- With the advancement of technology, more and more seniors (aged 50 to 64) are purchasing smartphones, with the percentage rising to over 74%

- This demonstrates how elderly consumers represent a sizable population segment that mobile app developers should take in mind. After coming to a conclusion by reading several papers and also going through many apps on the android platform, a conclusion was made that there still aren't many apps which target this problem, which is why it gives this project a unique stand.

VI. ANALYSIS

Product Backlog for SureHelp App			
Story ID	**Story**	**Story points1**	**Priority**
1	As a app user, I want to Register and Login to the system.	1	1
2	As a app user, Once I logged in, I want to seeall the features of the app.	1	2
3	As a app user, I want to set a pill remainder.	2	3
4	As a app user, I want to see all the government facilities.	2	4
5	As a user, I want to a tutorial on yoga/workout.	3	5
6	As a user, I want to learn the trending technology.	5	6
7	As an app user, I want to see all the nearby hospitals/chemists.	8	7
8	As an App user, I want to notify my dear ones about my location when required.	8	8
9	As an App user, I want to give commands through voice.	13	9

VII. FLOWCHART

The flowchart of the project is as given below.

VIII. PROJECT PLANNING

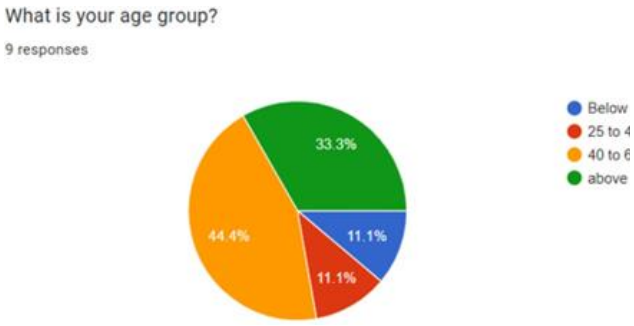
Tools used:

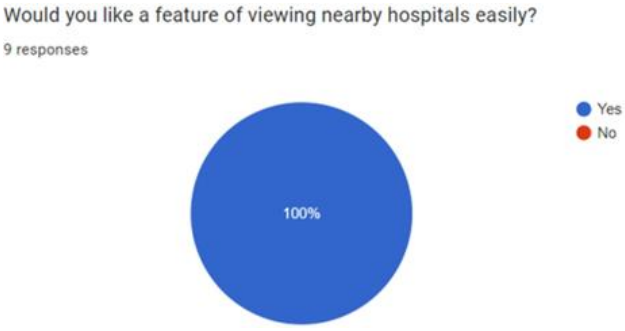
Figma – for making project prototype.

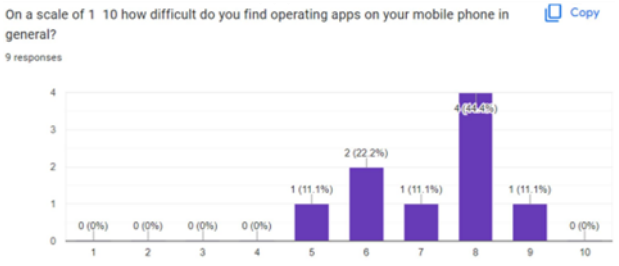
1. Android Studio
2. Build-in APIs
3. Java/Kotlin
4. XML
5. SQLite Database/Firebase.

IX. OUTPUTS

The idea generation started by recognizing social issues. After finding out that there were not many apps for elder part of the society, Soon, analysing and reading various papers and research about this particular topic began. Then, the idea was presented to the assigned mentor. She gave her inputs in return and showed great interest in this topic. After this, literature survey was completed and features of the project were established. The design of a basic prototype of the application like homepage, login, signup, features, etc. were done through Figma tool. A survey was taken where mostly people of age above 40 took part and their feedback was taken into consideration. The current phase at which the project stands is the successful implementation of features like sending location to emergency contacts, yoga and workout, medicine reminder and view nearby hospitals.







X. CONCLUSION

The undertaking is expected for more established individuals, mature 65 and over, who approach

innovation and use gadgets like PCs and touchscreens consistently.

This project includes some of the basic and important features like pill remainder, getting notifications for the government facilities provided them , yoga/workout needed for their age group , searching for nearby hospitals around them , text to speech , etc.

The elderly are, as of now, a dismissed section of the populace. Such a portable application for seniors has been created which will assist them with utilizing the innovation helpfully. These senior-accommodating applications will assist them in managing the huge issues that they are confronting. These applications will help their certainty and give them a feeling of fulfillment.

Disha: A Module for Visually Impaired to Fill the forms by Voice

Himanshi Jain, Megha Jain, Sejal Jain, Ms. Afreenzehra Sayed
Department of Information Technology, Thakur College of Engineering and Technology, Mumbai
jain29himanshi@gmail.com, meghajn141@gmail.com, sejalrj.26@gmail.com, afreenzehra.sayed@tcetmumbai.in

Abstract: **As per the research, the world's visually impaired population is estimated to be around 2.2 billion people. These people face a lot of issue when it comes to filling out a form in several places such as banks or hospitals. They are also unable to access the services offered by various organizations via their websites. Many voice-based assistant systems are available, but they have limitations when it comes to filling the forms. To address this issue, DISHA, a module for filling out forms by voice, offers visually impaired people an experience that allows them to fill out forms online interactively on any portal that has the module integrated. Thereby, increasing the overall engagements and adding multiple other facilities focused on easing the tasks of visually impaired individuals. DISHA provides a fully voice-operated system that supports voice-based form filling by utilizing the concepts of Speech Synthesis (Text-to-Speech) and Automatic Speech Recognition (ASR). This system will make it simpler for those who are blind or have other reading and writing disabilities to fill out forms.**

Keywords –Text to Speech (TTS), Automatic Speech Recognition (ASR), Voice Recognition

I. INTRODUCTION

Voice-based form filling systems using automatic speech recognition (ASR) and speech synthesis are advanced applications that allow users to complete forms using their voice rather than manual data entry. These systems use cutting-edge technology to automatically recognize and transcribe spoken responses, and then convert them into text for form filling [1]. The synthesized speech then reads back the form fields to the user for verification and submission.

These systems are designed to improve accessibility and efficiency, particularly for individuals with limited mobility or vision impairment. With voice-based form filling, users can simply speak their responses, which are then transcribed and filled into the appropriate fields. This eliminates the need for manual data entry and can reduce errors that can occur with traditional form filling methods [2]. The voice-based form filling system is powered by advanced automatic speech recognition (ASR) technology, which can recognize and transcribing natural language speech. This technology is paired with speech synthesis, which uses artificial intelligence (AI) to produce natural-sounding synthesized speech for form field reading. Voice-based form filling systems can be implemented in various settings, such as healthcare, banking, and government services. By providing an accessible and efficient form filling solution, these systems can improve user experience, save time and resources, and enhance overall productivity. Overall, voice-based form filling systems using automatic speech recognition and speech synthesis are valuable tools for making form filling more accessible and efficient for users with varying abilities [3].

II. BACKGROUND

A. Speech Recognition systems

Speech recognition systems have been developed since the early 1900s. The first automated speech recognition system was created in 1952. In the following decades, speech recognition research advanced, driven by the military and medical fields. In the late 1990s, advances in digital signal processing and machine learning enabled speech recognition to become practical for consumer and commercial applications, such as voice-activated personal assistants and automated call centers. Today, speech recognition systems are integrated into a wide range of devices, including smartphones, smart speakers, and automobiles, and continue to evolve with improved accuracy and functionality. For more than 50 years, technology for speech processing has served as a foundation for research. The need for accessible computing solutions for people with disabilities and the early days of computer technology can be traced back to the development of voice-based form filling systems for visually impaired individuals. As early as the 1970s, researchers and computer engineers began experimenting with voice recognition technology to create assistive systems for people with visual impairments.

B. Voice based form filling systems

One of the earliest examples of voice based form filling systems was the Kurzweil Reading Machine, introduced in 1976, which utilized voice recognition technology to read aloud text from printed materials. Over the years, this technology has continued to evolve and has been integrated into a wide range of assistive technologies, including form filling systems. More advanced voice-based form filling systems that are able to comprehend and interpret natural language inputs have been developed in recent years as a result of the rise of artificial intelligence and machine learning.

Today, voice based form filling systems for visually impaired individuals are widely available and are used by individuals, government agencies, and businesses around

the world. These systems provide a critical tool for visually impaired individuals to access information, complete online transactions, and participate in daily life activities with greater ease and independence. The development of systems that are able to comprehend, generate, and code speech in a variety of human-to-human and human-to-machine interactions is the primary goal of speech research. Speech synthesis (also known as text-to-speech, or TTS) and speech recognition (also known as automatic speech recognition, or ASR) are the NLP technologies that are least readily available for indigenous and low-resource languages. Regarding the creation of linguistic instruments for these languages, the major hindrance is a lack of computing and data resources. We provide a methodology that does not demand massive GPU and target data resources while yet ensuring pretty decent end-product performance. In this paper, we use a low-resource configuration to connect TTS and ASR models and have them learn from each other.

III. LITERATURE SURVEY

H. Chen, X. Liu, D. Yin, and J. Tang in "A Survey on Dialogue Systems: Recent Advances and New Frontiers" (2017) provided a comprehensive review of recent developments in dialogue systems, covering a range of perspectives and suggesting possible areas for further research. The authors classified existing dialogue systems into two categories: task-oriented and non-task-oriented models. They also discussed how deep learning techniques have been used to enhance these models, providing specific examples of representative algorithms. The authors pointed out that designing an intelligent dialogue system can be challenging, particularly when attempting to imitate human responses. This is especially true when working with limited dialogue data in a specific domain. [4] Caranica Alexandru, Cucu Horia, Burileanu Corneliu, François Portet, Michel Vacher in "Speech Recognition Results for Voice- controlled Assistive Applications" (2017) conducted a usability test on the most popular speech-based systems used worldwide, including Alexa, Siri, Cortana, and Google's system. The authors identified several major issues with these systems, including a limited focus on addressing common problems, reliance on Internet and cloud services, complexity, and a lack of integration with third-party systems. Another key concern was the insecurity of personal data associated with these systems. [5] S. O. Arik, M. Chrzanowski, A. Coates et al in "Deep voice: Real-time neural text-to-speech" (2017), proposed a real-time neural text-to-speech (TTS) system in which every component of the TTS pipeline is replaced by a corresponding deep neural network (DNN). While this approach has several advantages, including real-time processing and high-quality synthesized speech, the authors noted a major disadvantage: since each component of the TTS system is trained independently, any errors that occur can accumulate and result in synthesized speech with errors. V. Ajith Mani, A. Dhanalakshmi, S. Dharani, B. Bharati in "Speech Enabled Automatic Form Filling System" (2021) proposed a system for filling forms in one language only i.e., English for preliterate and senior citizens using Hidden Markov Model Toolkit (HTK). This system was confined to a particular language and was accessible by the individuals known to that language. [7] S. Usharani, P. Manju Bala, R. Balamurugan in "Voice Based Form Filling System for Visually Challenged People" (2020) developed a system that enables the user to take a print of the form using OTG adaptor after filling the form. The outcome is an independent system to fill the forms for a particular organization and was also confined to English language. [8]

IV. SYSTEM REQUIREMENTS

The module has basic three requirements so that it runs smoothly without any hesitation. Firstly, a software tool named IDLE (Integrated Development and Learning Environment) is required as an integrated development environment (IDE) for Python. IDLE comes along with the Python installer for Windows as a default module. It serves as an alternative to Python Shell and allows the execution of single statements, writing, editing, and running Python programs. IDLE provides a comprehensive text editor with features like syntax highlighting, autocompletion, and smart indent for coding in Python. Additionally, it contains a debugger that includes stepping and breakpoints. Secondly, Google APIs, which are application programming interfaces (APIs) that help communicate and integrate Google Services with other services. These include Google Search, Gmail, Translate, and Google Maps, as examples. Lastly, to operate the module, a Windows 10 operating system and a stable internet connection is required.

V. METHODOLOGY

A. Model Architecture

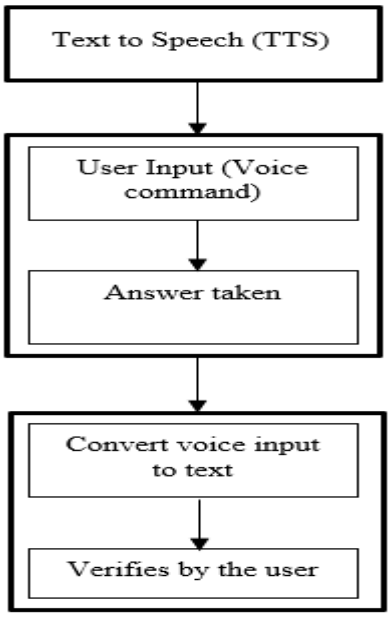

Fig.1. Model Architecture

The architecture includes the module's key components, which are shown in Fig. 1. The Text-To-Speech (TTS), Speech Synthesis, and Automatic Speech Recognition (ASR) components comprise the module. The organization's text instructions, which must be followed when filling out the form, are converted to speech by the TTS component. Speech Synthesis component further consists of User input which is voice based and the answer are recorded accordingly. The final element is the ASR component, which turns speech input into text and also allows for user validation by having the user confirm the input.

B. Working

Initiation of the module is done by providing the user with the instructions about the form. These instructions consists of the field inputs that the user inputs through spoken language. The basic flow of the system is to first take the speech input of the user and convert it to text using the Speech Recognition library in python as mentioned above in Fig.2. Further to validate and verify the recorded audio of the user, the pyttsx3 library is used which will convert the text into speech form and take the validation of the user according with a yes or no input.

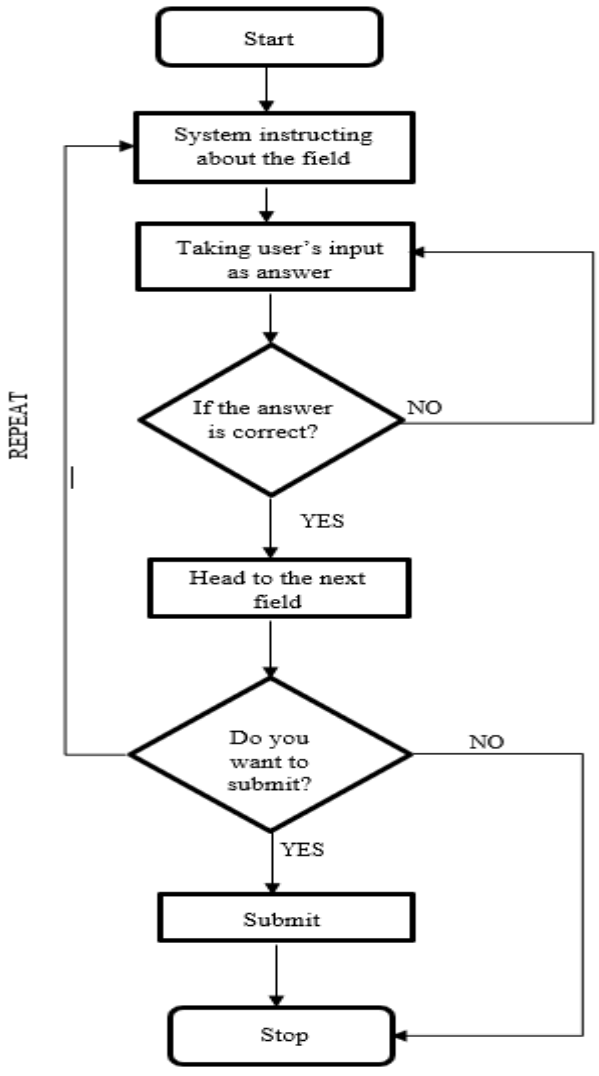

Fig.2. Flowchart

Disha is based on two fundamental technologies: TTS (Text-to-Speech) and ASR (Automatic Speech Recognition). This will allow the visually impaired user to communicate with the system as well as fill out forms. The process of converting written text into speech is known as text-to-speech (TTS) [9]. This technology collaborates with other language technologies, such as speech recognition, that seeks to transform spoken words into written text, and machine translation, that aims to convert either written or spoken language from one language to another. The Disha module employs TTS to convert system outputs into user understandable speech form; these are simply the system's speech instructions. ASR is the process of converting an individual's speech into readable text format using Machine Learning or Artificial Intelligence (AI) technology. This will help the system to interpret the user voice input by converting it into the text form which is human readable. To build the overall voice-based form filling module, Python is used. The speech recognition library in python is used to convert speech to text. Speech Recognition is a machine's ability to listen to and identify spoken words. Speech recognition technology is employed to transform spoken language into written text, inquire about something, or give a reply. This is achieved by computer programs that receive audio input from a microphone, process it, and convert it into the required format. Whatever speech the user gives will be recorded and captured using Python's pyaudio library. After recording the audio, it is converted to text using Speech Recognition and displayed on the output screen. The pyttsx3 library is used to validate the displayed text from the user. Pyttsx3 is a Python library that is used in this system to convert text to speech. It works offline and is a simple tool that converts entered text into speech. The module can also be used for different Indian languages such as Hindi and Marathi along with English so that it becomes convenient for the users to use the module.

VI. RESULT & DISCUSSION

```
🔊 This is a simple college feedback form. Say yes whenev
er you are ready

A voice-based form filling system is a technology that allows users to fill out forms using voice commands

rather than typing. Fig. 3 displays the output of the voice-activated computer program's instructions simultaneously with the user's input into the necessary form fields.

Fig.3. Demonstration of Module outcome

This technology aims to eliminate the need for typing or handwriting when filling out forms. Through the use of machine learning, there can be significant advancements in speech recognition and text-to-speech synthesis, which are essential speech-related technologies. The results of implementing such a system can be seen in the following ways:

- Increased efficiency and speed: Voice commands can be processed faster than typing, leading to a faster completion of forms.
- Improved accessibility: People with disabilities or mobility issues can benefit from using a voice-based form filling system, as it eliminates the need for typing.
- Enhanced user experience: Voice-based form filling can make the process of filling out forms more convenient and enjoyable.
- Reduced errors: Typing errors can be reduced, as users can dictate their answers rather than typing them.
- Increased adoption: A voice-based form filling system can attract more users, as it offers a more user-friendly experience.

VII. CONCLUSION

The software will help with filling out forms and make the process less boring. It is designed to primarily use speech communication, which means it can help bring the benefits of current digital strategies to people living in rural areas and those who are visually impaired.

VIII. FUTURE SCOPE

The module currently interprets three different languages i.e. English, Hindi and Marathi. More native languages can be added. Further the captcha system can be included in the module for verification purpose. These captchas will be based according to the visually impaired users so that the user can respond with ease.

IX. ACKNOWLEDGMENT

We express our gratitude to Afreenzehra Sayed, our guide, for providing us with continuous guidance and support, as well as keeping us on track. We would also like to acknowledge the project coordinators for facilitating the necessary resources to conduct our project. Our thanks also go to Dr. Sangeeta Vhatkar, the HOD, Dr. B. K. Mishra, the Principal, and the college management for their unwavering support.

Sentiment Analysis of Charging Stations on Multiple Reviews

Ajay Gadicha, Zeeshan Alvi, Mohammad Zuhair
P.R. Pote Patil, College Of Engineering & Management Amravati Maharashtra, India

Abstract—**The phrase "sentiment analysis" refers to a method of analysing online text in order to ascertain the author's intended mood. Text sentiment analysis entails dividing author's feelings about a topic into positive, negative, and neutral buckets. It goes by a few different names: subjectivity analysis, opinion mining, and value judgement extraction. Learning how buyers react to a product is crucial for any company looking to expand. Sentiment analysis plays a key role when trying to understand consumer opinion on a certain issue.The existing charging station requires us to charge by waiting in line, which is one of the most inconvenient aspects of auto ownership. The growing length of these lines is a major inconvenience for customers. The purpose of this system is to simplify the process of charging vehicles by keeping a virtual queue, and after a user has finished charging, they will receive a notification with a link to leave a review based on certain qualitative and quantitative feedback parameters concerning the station's service. Charge times, employee friendliness, security measures, wait times, and general remarks are all acceptable forms of feedback. We will use this information to compile a rating score for each charging station and then arrange them in order of this score. Whether a remark is favourable or negative may be determined by utilising the Naive Bayes Algorithm, the Logistic regression Algorithm, or the Support Vector Machine Algorithm. Each remark is read three times, and the overall score for comments at each station is updated after each round of analysis, taking into account whether the comment was favourable or negative. In order to get the average rating for charging stations, we first find the proportion of favourable comments for a certain charging station and then translate that percentage into a rating of 5.**

Keywords—Sentiment Analysis, Customer Review,Naïve Bayes Algorithm, Charging Station

I. INTRODUCTION

Sentiment analysis is a method for detecting ambiguity in written or spoken expressions of thought or feeling. The term "opinion mining" describes a similar practise. How a spokesperson and a user feel about an issue is revealed through sentiment analysisThere has been a flurry of algorithmic presentations recently aimed at analysing, anticipating, and evaluating attitudes in text data, such as product or customer reviews. The process of sentiment analysis has the potential to be very helpful in polarity detection. Spam and false information, domain-specific problems, negation, the computational burden of natural language processing, bipolar terminology, and a large vocabulary are further obstacles. If we want to see improvements in data mining's efficacy and efficiency, we must address the issues we've already discussed. After realising the significance of sentiment analysis, the system helps to improve the process of sentiment analysis in web-based daily life. The proposed approach yields superior or identical answers with the maximum degree of confidence and the least amount of processing complexity [8]. Data cleaning, normalisation, hashtag removal, punctuation removal, text to lowercase, and tokenization are just some of the pre-processing chores we've explored and investigated to see how they affect user evaluations. Data selection, pre-processing, and classification were all areas that saw significant improvements because to this study's contributions.

II. LITERATURE REVIEW

[1]. In this study, we focus on the problem of noisy, irrelevant, and redundant qualities that arise when using huge collections of different n-gram features for sentiment categorization. Due to these factors, it may be challenging to fully utilize the increased discriminating power that comes with using expanded feature sets. To this end, In this work, we introduce Feature Relation Network (FRN), a rule-based multivariate text feature selection approach that uses semantic information and the syntactic relationships between n-gram features. The purpose of FRN is to increase the precision of sentiment analysis by enabling the efficient assimilation of large, heterogeneous n-gram feature sets. Experiments were conducted using three different online review testbeds to evaluate and compare different methods of classifying reviewers' emotions. Because it can choose qualities that lead to considerably greater classification accuracy regardless of the feature subset sizes, FRN outperforms competing univariate, multivariate, and hybrid feature selection approaches. FRN is also able to choose features in a more computationally efficient manner than many multivariate and hybrid algorithms because it incorporates syntactic information about n-gram associations.

In this study, we explore the use of a rough k-Nearest Neighbor (k-NN) classifier and a method for increasing the size of the training set by creating artificially generated handwritten capital letters through the distorting of genuine photographs (see [3]). [4] The study argues that one has to do more than look at the words in an expression to figure out which way the feeling is leaning. In example, the polarity of a phrase can be influenced by the interplay of its individual words or components. This study takes a compositional semantics perspective on such subsentential interactions, and presents a unique learning-based technique that includes compositionally-motivated structural inference into the learning process. It turns out that (1) compositional semantics-based heuristics can outperform learning-based approaches that don't include compositional semantics (89.7% vs. 89.1% accuracy), but (2) a method that incorporates compositional semantics into learning outperforms all other options (90.7% accuracy). Our research also reveals the significance of "content word negates," which have been

underutilised in prior studies, in establishing polarity at the expression level.

[5] Based on the amount of detail they examine, sentiment analysis tasks can be categorised as either document-level, sentence-level, phrase-level, or aspect-level. By concentrating on sentiment analysis at the phrase/sub-sentence level and the aspect level, Wilson et al. investigated the repercussions of complex polarity change. They began with a glossary of words that were previously assigned polarities in order to identify the "contextual polarity" of phrases. Choi and Cardie [4] used numerous compositional semantic models, both heuristic and machine learning-based, to improve subsentential sentiment analysis by coupling multiple negators with lexical polarity When it comes to the challenging work of word sense disambiguation, Agirre and Martinez [2] suggested employing a Web search using monospermous synonyms or unique phrases in definitions from WorldNet to increase the amount of labelled data

III. MOTIVATION

There are several potential downsides to using BOW, despite the fact that it is one of the most often used feature extraction approaches, when it comes to learning from textual cases. In particular, a word may have varied meanings depending on the context, which might result in the situation where the same term is highly significant to the positive class in some circumstances but very relevant to the negative class in others. Students who put in extra effort can be told things like, "You completely deserve the success," whereas others who weren't as motivated could be told things like, "That is what you deserve." From a syntactic point of view, the same word can function as several nouns, verbs, adjectives, and adverbs. Consider the term "approach," which may function as either a verb or a noun, and the resulting differences in semantic discrimination. When employed as a verb, the aforementioned term might have an unfavourable meaning, as in "I approach you to perform something for me." As a noun, however, the connotation is less clear and more neutral. The two examples given above show that it is inappropriate to consider a word as if it only had one attribute when that word also serves as another element of speech or has several meanings.

IV. PROBLEM DEFINATION

One of the most fundamental jobs in sentiment analysis is to classify if the expressed opinion in a document, phrase, or entity feature/aspect is positive, negative, or neutral. "Beyond polarity" sentiment analysis takes into account more than just happy and sad feelings. What we need is simply this. In other words, if a consumer says something like "I've used your product XXX and I haven't been disappointed, only the contrary!," we may assume that not only is the client satisfied with the product, but so are hundreds or thousands of other customers. Unfortunately, many rule-based or keyword extraction approaches for sentiment analysis misclassify the overall tone of the text as neutral or negative because they ignore positive terms like "happy," "lucky," and "good" and focus instead on negative words like "disappointed" and "haven't." To avoid these and other problems, we can use cutting-edge machine learning strategies.

V SIGNIFICANCE OF PROPOSED WORK

Any company has a responsibility to learn about its customers and to respond to their wants, concerns, and overall levels of satisfaction. In the case of huge web-based firms, we need to analyse hundreds of thousands, if not millions, of responses about various items; and it is not sufficient to search for predefined "good" or "poor" terms in the comments. In recent years, thanks to advances in machine learning—and more specifically, deep neural networks and sentiment analysis—the challenge of identifying a text's underlying emotional tone has been effectively addressed. In this research, we want to demonstrate the state-of-the-art solution to this issue by using word representations and the Naive Bayes Algorithm to categorise positive, negative, and neutral sentiment.

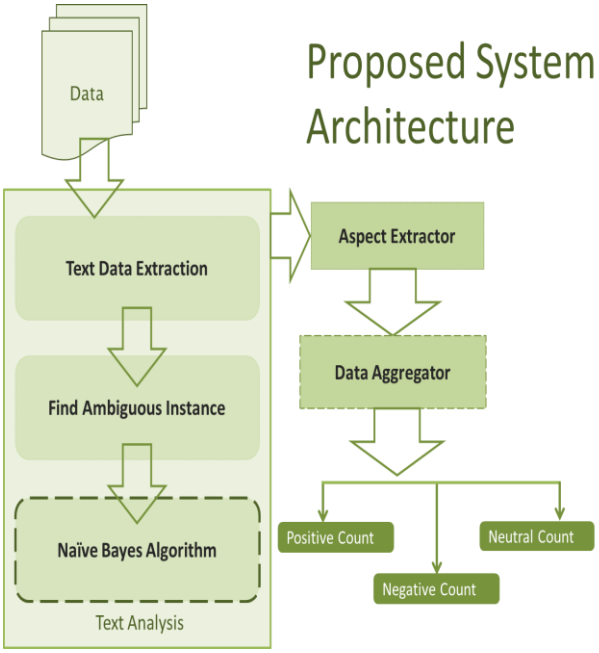

Fig. 1. Proposed System Architecture

VI. METHODOLOGY

Naïve Bayes Algorithm: Naïve Bayes algorithm is a supervised literacy algorithm, which is grounded on Bayes theorem and used for solving classification problems. It's substantially used in textbook classification that includes a high- dimensional training dataset. Naïve Bayes Classifier is one of the simple and utmost effective Bracket algorithms which helps in erecting the fast machine literacy models that can make quick predictions

Deep Learning-Based Classification of Bayes Algorithms : During this phase, the intermittent neural network- grounded LSTM classifiers are used for the task of bracket. Three different types of models were developed by changing network armature and parameters. These models are considered Model 1, Model 2, and Model 3, independently. In our studies, a corpus of reviews was considered for the training dataset, and the remaining,016 reviews were used to

assess the performance of named classifiers. Training and testing portions of the data were divided into two separate groups. The bracket algorithms were trained and estimated doubly for each analysis, formerly on the training and formerly on the testing

section reviews. In the posterior step, the review textbook was decoded into a numerical point vector before being taken care of by any bracket algorithm.

DataPre-processing: Datapre-processing is a crucial phase in textbook data analysis. Due to the reiterations and redundancies in tweets, blogs, reviews, and other types of textbook, textbook data come more complicated. Data normalization uses datapre-processing as a filtering system. The normalization, word tokenization, removing stop words, removing redundant spaces, padding, changing the textbook data to lowercase, and removing hash trailing are exemplifications of datapre-processing, etc.

VII. RESULT

Sr. No.	Charging Station	City	Area	No. of Chargers	Reviews	Recommendation
1	A1 Station	PQR	A Street	02	05 Positive 00 Negative 10 Neutral	Recommended
2	A2 Station	PQR	A Street	05	10 Positive 12 Negative 02 Neutral	
3	A3 Station	PQR	B Street	03	10 Positive 2 Negative 0 Neutral	Recommended
4	A4 Station	PQR	C Street	05	5 Positive 0 Negative 0 Neutral	Recommended
5	A5 Station	PQR	D Street	10	0 Positive 5 Negative 15 Neutral

12	A12 Station	PQR	J Street	08	27 Positive 0 Negative 15 Neutral	Most Recommended

TABLE I. RESULT IN TABULAR FROMAT

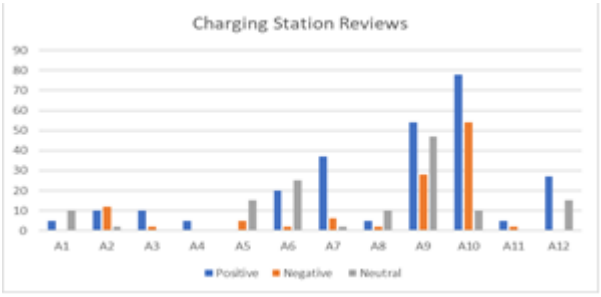

FIG.2 BAR GRAPH

VIII. CONCLUSION

Sentiment Analysis is considered as one of the most research topics in the sphere of knowledge discovery. Large quantum ofonline data is being added on weekly basis ranging from socialmedia posts and to movie reviews. Byusing sentiment analysis ways, these data sources can beused to cost theimportant information such as: getting user's feedback about any software,carrying public opinion before launching a new product etc.

IX. FUTURE WORK

In future,we will find out how this method can be used as further general system when applied to client reviews, product reviews etc. Focus will be on enhancement and more accurate results for sentiment analysis. Efforts will be made to add some fresh features in Naïve Bayes classifier algorithm so that it can be used to develop a farther general system.

Expert Connect

Raghavendra Pandey, Mohd Anas Shaikh, Musaddiq Shaikh, Rahul Khokale
Thakur College of Engineering and Technology, Mumbai, Maharashtra, India
raghavp0702@gmail.com, mdanassk707@gmail.com, musaddiqshaikh42001@gmail. com, softrahul2018@gmail.com

Abstract: Expert Connect is a website for connecting professionals working in the same field and helping them to build a community. It enables a professional to network and build connections with people and organizations in the technical industry. In this, users can add articles which can help produce information for potential audiences around the world, leave comments and likes, find similar articles, connect sections which will help users to see their connections and will be recommended to users with similar interests and skills. This is achieved by separating the project into two parts, the posting and the networking fragments, each of which with its own set of features. The posting part focuses more on technical readers and gives them valuable information. It can discuss new innovations, new projects in development, solve problems and provide more relevant information. In today's scenario, you have a choice of different blogging platforms such as WordPress and Blogger. However, there are a number of drawbacks, including the inability to customise the software to suit your needs and the impracticality of this website providing a specialized blogging environment for every organisation. The proposed work is being created using ReactJS, a JavaScript framework for frontend development which helps in creating a single page application. A single page application is comparatively faster and quicker to load as compared to traditional websites. For Backend, Express JS, a module for NodeJS is being used to handle the server-side scripting. MongoDB. A NoSQL database service handles the backend database in the proposed work.

Keywords- professionals, connections, articles, organizations, community.

I. INTRODUCTION

With technology evolving in each and every aspect, there arises a need of guidance and a community where one can interact, clarify doubts and grow individually or as a team. bridge the gap between the professionals working in the same field and help them to build a community in such a way which will help them learn and grow together. This is achieved by separating the project into two parts, the posting and the networking fragments, each of which with its own set of features. ExpertConnect enables you to build a network with people and professional organizations in your industry. This can prove to be a great way to stay up to date with the latest developments, and to share information with others in your field. The proposed work serves as platform where a user can with a professional with similar interests. When a user visits the portal, they can either signup or login if already signed up earlier then they can either read the blogs uploaded by other individual or either post the blog in the form of images, videos and in text format. The user also has a profile section where they can update the skillset, education details and their workplace. Also, user has a Connect section where they can connect with the professionals of similar interests. While the networking section focuses on building relationships between professionals in a healthy and learning environment. This can be extremely beneficial as they can exchange ideas, learn from each other and build business relationships with people that can lead to future business opportunities. It also includes a comprehensive profile system that allows users to list their skills, experience, education and contact details. The users can also search for other users based on specific criteria, such as job title, company or location.

II. IMPORTANCE OF THE PROJECT

Majority of the websites or applications do not provide the proper mapping system such that similar interest professionals can connect. Proposed work fills all the gaps & has created the project keeping that in mind all the aspects are covered and the recommendations are also of one's genuine interest. Many research papers & websites have failed to identify the existing problem. A user can connect with the professionals working in the same field and help them to build a community in such a way which will help them learn and grow together. Our website aims to bridge all these gaps which will help in efficient, and less time of user being used in performance redundant tasks.

III. PERSPECTIVE OF STAKEHOLDERS AND CUSTOMERS

According to literature survey done by our team, there hasn't been any technologically advanced solution which focuses on community building along with the blogging section, hence market potential for an idea which is relatively new and unthought of is on the positive side.

IV. OBJECTIVES AND SCOPE OF THE PROJECT

The objective is to create a website or an application with all the facility where one can groom himself along with the community and with lot of features right from connecting with the professional of similar interest, updating profile along with each milestone achieved to the posting or reading of blogs to gain or share knowledge of genuine interest. Along with the professional aspect, our objective is to inculcate a certain set of value in the person's personality which will make him groom in all the aspects and help him in becoming a better a better individual.

Main features of this Application include:

- To gain and share knowledge.
- Network with complete strangers who you feel you can learn a lot from.
- Navigating professional life including small business owners, students, and job seekers.
- Used for seeking employment and being found by the recruiters.
- For advertising jobs and headhunting suitable candidates.
- Advancing the company's profile and Gaining visibility in content marketing.
- Connection to professionals for business and harnessing the professional network.
- Connection with like-minded people and reaching out to old colleagues and classmates.
- Making connections for generating leads.

V. PROBLEM DEFINITION

The post on the website has mixed content so it makes user difficult to search post which related to technical content. It can be very frustrating to dedicate time creating a blog post, only to sit and wait for comments that never come. The interactive aspect of blogging is what draws many people to get started with their own blog, but in reality, many new blogs have trouble attracting comments. If you find that your blog posts don't usually get the attention or feedback that you had hoped for, you're not alone. In some website information of the user's professional skills and interests is not available. Saving or adding post to favourites is not available in the websites. Possibly the most frustrating challenge for many users is trying to attract more visitors. In fact, most users don't give very much thought to how they will attract visitors until after the blog has been launched and they find that not many people are visiting. Regardless of how much traffic you have, you'll always want more.

VI. ANALYSIS

A. Existing System

The significance of blogs in online applications and how to communicate with other users. Through blog websites, we can also obtain information and knowledge [1]. Blogs can also aid students in developing their writing abilities. Additionally, it can increase pupils' self-confidence, which will benefit them in the long run [2]. Blogs based on certain themes are popular in today's world, also blogs have been found to have influence on media coverage of politics [3].In the current scenario, the blogging system doesn't have filters for accessing a particular blog on particular subject. Also, there is no way of connecting the peers of the same field. In existing system. There is no readability which does not attract viewers. Also uploading video of large size is not supported on the existing blogging websites.

Blogging within an organization to share information has also taken centre stage in recent times [4]. A website can assist students in honing their writing abilities through the use of blogs. Additionally, it can increase pupils' self-confidence, which will benefit them in the long run [5].

B. Proposed System

With the proposed system, students in the various domain who are confused by their career path can connect with the individuals of the same domains. This system is to help such students reach, connect individuals, make a network and get guidance. Also, individuals can post, read a blog along with the functionality of uploading images, videos and text format. With the favourites section functionality, students can put a particular blog in this section for future reference.

VII. FLOWCHART

The flowchart of the project is as given below.

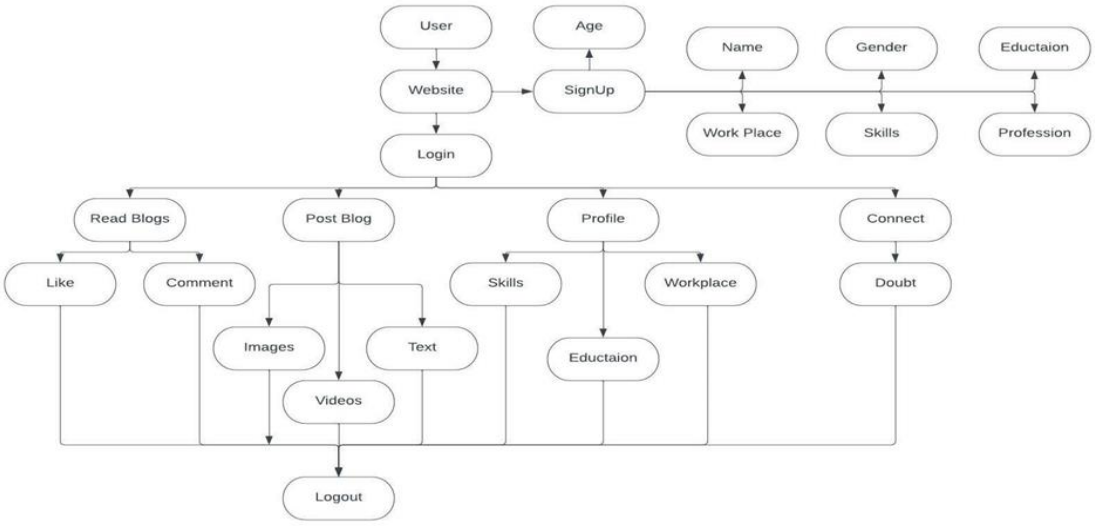

Fig 1: Flowchart.

VIII. PROJECT PLANNING

Tools used: Lucid Chart – for making project prototype.

1. HTML, CSS
2. React JS
3. MongoDB
4. Express JS
5. Node JS
6. Firebase

IX. OUTPUTS

The intent of the project is clear to give a simple and attractive application to simplify the work of going through all the information about posting, reading blogs and connection with the similar professionals, to eliminate the hassle of using separate platforms for each task and also instead of searching similar interest people to getting auto recommendation. This is a type of website that allows many records of members of an institution. Writing articles is a great way to learn how to start your own post This website is free and allows anyone to manage their own articles with the help of images and videos, conduct polls, ask doubts and form relationships with professionals with similar interests and skills. Proposed platform can provide user with the information to guiding someone, building a community for all technology aspects. It will also provide a feature of commenting on a particular post so that people can share their views on each and every post.

X. CONCLUSION

ExpertConnect has a huge scope in not only in specific area, right from the educational purpose to individual helping them in getting blogs and connecting with the professional in a specific category. Blogging had seen an upward income trend as monetizing articles is becoming easier as consumer purchases and business processes increasingly move online. Covid-19 has further helped to accelerate this trend. Our important feature is that it allows the user to read, write articles, add skills and connect with the individual with similar skills thereby giving the user a complete end to end solution. ExpertConnect will help the individual in shaping the personality and thereby guiding him the correct path. The purpose of this paper is to explain the need for blogging and forming relationships together. This is a type of website that allows many entries from members of an organisation. Writing articles is a great way to learn how to start your own post. This website is free and allows anyone to manage their own articles with the help of images and videos, conduct polls, ask doubts and form relationships with professionals with similar interests and skills.

As an add-on a feature called “Connect” is being provided so that a user can directly connects with the professionals of the same field. Also, we are bringing the awareness among community to help to build a community of each and every technical field so that there is a roadmap for each sector, thus helping the entire technology person who would like to pursue in a particular field is getting helped. Other additional features have been included in the proposed work to further improve the pace of eliminating this plaguing disease among the society.

Educational Game Application

Neha Kapadia, Anurag Pandey, Deepak Gupta
Thakur College of Engineering and Technology, Mumbai, Maharashtra, India
neha.kapadia@thakureducation.org, pandeyanurag1903@gmail.com, deepakgupta0002@gmail.com

Abstract: **As per the research, School shutdown due to the COVID-19 pandemic has resulted in a complete break from education for the vast majority of children or inadequate alternatives like community-based classes or poor alternatives in the form of online education options, including mobile phone-based learning. Students need assistance in completing their academic course and earning acquiring credentials. during this extraordinary crisis. To address this issue, educational game application helps students to learn at their own pace, helping students understand their strengths and weaknesses. Students can be more participate in their learning thanks to quizzes, games, polls, video content, and other media. Subjects that students typically find uninteresting can become more interesting. Remote learning and working are the main COVID-19 applications in the field of education. Advising systems, degree progress tracking, and other technologies to support student enhance student achievement will be equally important to help student's complete courses and attain credentials.**

Keywords – Educational game application, pandemic, technology learning,

I. INTRODUCTION

A sport is a sort of play where individuals follow described rules discusses instructional video games because the usage of video games to help coaching and getting to know. Games maybe used as a help tool to complement conventional teaching strategies to improve the studying experience of the inexperienced persons even as additionally teaching other skills together with following regulations, edition, hassle solving, interplay, crucial wondering skills, creativity, teamwork, and precise sportsmanship. Learning have to not feel stupid and it must no longer best suggest rote memorization wherein students learn and grasp concepts through repetition or cramming. Teachers can take gain of the strength and innovative thinking that is provided through the use of era in mastering to improve scholar performance.

II. OVERVIEW OF GAMES IN EDUCATION

Many exceptional styles of academic games are being implemented and utilized in academic institutions, faculties and homes. Using video games in schooling in most cases focuses on improving essential wondering talents at the same time as coaching a particular challenge, by means of allowing students to think out of doors the container as they follow policies. There are other video games that can be used which limit to improving know-how in a specific situation and the maximum famous ones are math games. (Yue, & Zin, 2009) discussed that games like chess cannot be viewed as educational video games as these improve logic skills, reasoning, and different traits valued in education however they're no longer taken into consideration educational due to the fact they do not deliver content material or relay curriculum fabric. Games that contain curriculum content or other academic fabric are known as instructional games (Michel, 2016).

III. PROBLEM DEFINITION

School shutdown due to the COVID-19 pandemic has resulted in a complete break from education for the vast majority of children or inadequate alternatives like community-based classes or poor alternatives in the form of online education options, including mobile phone-based learning. Students need assistance in completing their academic course and earning acquiring credentials. during this extraordinary crisis. Skill sets and dispositions embedded in well-designed games are a good match for the contemporary, technology-rich worlds students inhabit. They accommodate various learning styles and promote a complex decision-making context. Games have the potential to promote the 21st century skills recognized as critical for all citizens.

IV. ADVANTAGES OF USING GAMES IN EDUCATION

i. Engage students The main role of applying generation is to interact students and to encourage students to participate. The use of games in schooling performs an essential function in enticing students by encouraging a hands on technique.

ii. Help students remember The use of video games in education goals to assist college students recollect what they have got learnt as active participation is recommended. Learning have to not imply rote memorization but students can use games to keep in mind the vital points which they could observe in their examinations in addition to in real-global conditions.

iii. Visual and computer literacy This is something which is vital in mild of the truth that we stay in a international that is dominated by way of innovation. By playing video games, students benefit visual and computer literacy abilities if you want to put together them for the world of work.

iv. Rule following and problem-solving skills Game drills are primarily based on rule following and students are required to follow policies that allows you to acquire a excessive score and pass to the following level.

Students can without difficulty practice this understanding in actual international conditions as they may be endorsed to suppose outside the field.

v. Teach other skills Game drills are based on rule following and students are required to comply with policies so that it will reap a high rating and pass to the next degree. Students can without problems apply this knowledge in real international situations as they're advocated to assume out of doors the field.

V. DISADVANTAGES OF USING GAMES IN EDUCATION

However, gaming in schooling has setbacks which want to be addressed.

i. Providing a platform for college kids to play revision video games will become a assignment when teachers or instructors can not manage such an environment. Students could have get entry to to different platforms which might be harmful.

ii. Students who depend upon games are often secluded from real existence interaction.

iii. Using computers and different digital gadgets can purpose health risks such as eye strain and other bodily problems.

iv. The technologies required for full participation can be quite luxurious and this will create an opening between the scholars who have get admission to the technology and those who donow not have access. The diagram below summarizes the role of games in education.

VI. TOOLS USED

1. Android Studio will help you develop your app in a more productive way at scale. Android Studio provides the fastest tools for building apps on every Android device. Code with confidence. Eliminate tiresome tasks. Building without limits. Build rich experiences.

2. Sublime Text is a commercial source code editor. It natively supports many programming languages and markup languages. Users can expand its functionality with plugins, typically community-built and maintained under freesoftware licenses.

VII. CONCLUSION

The application of serious games and simulations for learning provides an opportunity for learners to apply acquired knowledge and to experiment, get feedback in form of consequences thus getting the experiences in the “safe virtual world”. There are specific educational domains where game-based learning concepts and approaches have a high learning value. These domains are interdisciplinary topics where skills such as critical thinking, group communication, debate and decision making are of high importance. Such subjects, if learned in isolation, oftencannot be applied in real world contexts.

Leveraging E-Healthcare for Improved Healthcare Services in Rural India: An Assessment

Inaaya Khan, Aman Singh, Anmol Goyal, Anil Vasoya
Thakur College of Engineering and Technology, Mumbai, Maharashtra, India

Abstract - **In developing countries like India, access to healthcare services remains a challenge, particularly in rural and remote communities. With over 800 million smartphone users and 227 million internet users in India, utilizing e-health solutions can help bridge the gap in healthcare access. This paper aims to evaluate the potential of e-health in providing healthcare services to rural communities in India. A survey was conducted to gather public data and opinion on the subject, exploring existing healthcare applications and analyzing the issues faced by civilians. The results of this study indicate the need for improved e-health solutions to enhance healthcare access in rural areas. The findings provide valuable insights for further development and implementation of e-health solutions in India. The actual impact on the doctor-patient ratio will depend on the effective implementation and adoption of the proposed e-healthcare system.**

Keywords – healthcare, artificial intelligence, rural healthcare, online healthcare, e-health, chat bot, medicine

I. INTRODUCTION

The provision of quality healthcare services in rural and remote areas of India remains a challenge, with limited access to healthcare facilities and medical professionals being a major issue. The objective of this project is to develop an application that can help address these challenges by providing healthcare services to individuals in rural areas through their smartphones. The main problem faced in rural areas is limited internet connectivity and slow internet services, along with a lack of awareness about the use of healthcare applications on smartphones. The aim of this project is to bridge this gap by spreading awareness and making the application easily accessible to every individual in rural areas. The application will connect rural populations with nearby doctors, as well as with doctors located in urban areas. This will not only improve access to healthcare services, but also increase the availability of medical professionals in rural areas, thereby improving the overall health of the population. The goal is to create a solution that is affordable, scalable, and easily configurable, making it accessible to everyone in rural areas.

II. BACKGROUND

In developing countries like India, access to quality healthcare remains a significant challenge, particularly in rural and remote areas. The majority of the rural population is unable to access quality healthcare services, leading to poor health outcomes and an increased burden on the healthcare system. With over 800 million smartphone users in India, accounting for approximately 57% of the population, and with around 25% of the rural population being smartphone users, the use of mobile health (mHealth) solutions has the potential to greatly improve access to healthcare services in rural areas. According to the Internet & Mobile Association of India (IAMAI), there are 227 million internet users in the country. The widespread adoption of smartphones and the internet presents a unique opportunity to deliver healthcare services in rural areas using e-health solutions. By leveraging emerging technologies, healthcare professionals and industries can shift towards more accurate, prompt, and real-time treatment of patients. The development and implementation of a cloud-based e-health solution has the potential to improve healthcare delivery in rural areas by centralizing and managing patient data, making it easier for healthcare providers to access and share information in real-time. Additionally, the use of cloud technology can reduce the cost of healthcare delivery, making it more affordable for rural populations. The goal of this project is to develop and evaluate a context-sensitive cloud-based e-health solution for rural communities in India, with a focus on improving healthcare delivery and increasing access to healthcare services.

III. LITERATURE REVIEW

E-health solutions, including telemedicine and mHealth, have gained significant attention in recent years as a means of improving access to healthcare services and improving patient outcomes. A number of studies have demonstrated the effectiveness of telemedicine and mHealth solutions in rural areas, particularly in increasing access to healthcare services and improving patient outcomes.

In 2006, Mrs. Gurujit Kaur and Dr. Neena Gupta published a paper on "E-health: A New Perspective on Global Health"[1]. The key findings of the paper highlight the potential of e-health to allow patients to maintain their independence longer and for healthcare providers to monitor conditions more closely. However, the authors also describe the barriers and challenges that

exist in the adoption of e-health and provide an overview of the current status of e-health globally, including an examination of the e-health scenario in India. One of the gaps identified in the paper is that, while an electronic health record system can provide patients with access to their medical data, it can also lead to misinterpretation of information and cause unnecessary alarm or panic. In the study, "eHealth in India Today: Nature of Work, Challenges, and Finances" by Szymon Jaros Awski and Gayatri Saberwal (2014), a qualitative approach was taken to understand the current state of eHealth in India through interviews with a diverse group of stakeholders [2]. Thirty interviews were conducted with individuals from 28 organizations involved in the implementation, design, evaluation, and provision of eHealth programs. The study found that a range of programs, such as point-of-care in both rural and urban areas, treatment compliance, disease surveillance, and distant medical education, are being run in India. However, the major challenges faced by these programs include a shortage of suitable health personnel, especially in rural areas, and financial sustainability concerns. The findings highlight the need for addressing these challenges to further the growth and impact of eHealth programs in India.

The study "Private Cloud Solution for Rural Healthcare" by Mrs. Deepa Lakshmi in 2016 aimed to improve access to healthcare for rural populations through a mobile-based application [3]. The project analyzed doctor-patient conversations to develop a chatbot that could provide medical advice. The study identified several challenges including compliance with ethical and privacy laws, ensuring data security, the potential for loss of connectivity, and difficulties in integrating with other platforms. Additionally, a lack of standards in the field was also identified as a gap.

The study "Exclusive E-Health Care using Centralized Health Management System" was conducted by Mrs. Arthi CI and Mrs. Priya RL in 2016 [4]. The methodology involved the construction of a nationwide health database system that would provide access to detailed patient records and help medical personnel perform technical tasks more efficiently. The system aimed to streamline healthcare processes and improve patient outcomes. However, the implementation of such a system required a significant amount of time and effort, particularly in regards to moving to a centralized access service. This process was found to be challenging, as a considerable amount of time had to be spent dealing with daily bed management problems and sometimes repeating the same events as the day prior.

In "Contexts and Opportunities of e-Health Technology in Medical Care" by Mr. Sojib Bin Zaman, Mrs. Naznin Hossain, Mr. Shad Ahmad, and Mr. Zubair Ahmed, published in 2017, the authors explore the potential benefits and challenges of eHealth technology in the healthcare sector [5]. The key findings of the study indicate that eHealth has the potential to be a game-changer in the medical care system if it is properly integrated with the traditional medical system. The authors emphasize the need for more strategic planning, development, and evaluation of eHealth to fully realize its benefits. They also discuss the existing and future opportunities of eHealth in health support systems. However, the authors also identify several challenges, including concerns about electronic and internet-based data transmission, data storage, data safety, and confidentiality. These issues highlight the importance of careful consideration and implementation of eHealth technology to ensure its success.

"Health Monitoring using Cloud-based Processing" is a research study by Mrs. Alex Page in 2017 [6]. The study adopted a methodology to examine the current state and future potential of remote health monitoring technologies in medical care. The study found that the system allows users to receive health care services anytime and anywhere, realizing the purpose of remote health monitoring. However, the study also identified several challenges in the areas of sensing, analytics, and visualization that must be addressed to ensure seamless integration into clinical practice. Applications of Cloud Computing in Health Systems" by Mr. Hamid Moghaddasi, 2018, is a study that explores the potential of incorporating cloud computing in healthcare to enhance patient care [7]. The key findings highlight the benefits of implementing cloud computing systems in healthcare and the positive impact it can have on patient care quality. However, the study also identifies a gap in the need to synchronize these systems with other external systems to ensure seamless maintenance and continuity of care. In 2019, Mrs. Repu Daman conducted a study on the application of Cloud Computing in the medical field [8]. The methodology involved using the web service method to pack the data access interface of the medical data service layer. The key findings of the study revealed that implementing cloud computing in healthcare could lead to cost-effectiveness, energy savings, and improved collaboration between hospitals. However, a gap was identified in the form of limited access to the cloud only through high-speed internet. Cloud Computing in Healthcare Industry" by Mrs. G Nikhita and Reddy Vanga in 2020, utilized the Alma-Ata declaration to approach primary healthcare as the basis for their study [9]. The methodology focused on presenting essential healthcare through practical and scientifically sound methods and technology. The key findings of the study showed that cloud computing can help physicians effectively communicate and examine their patients. However, the study also identified that cloud computing is still a developing technology in the healthcare industry. Chatbot for Healthcare System Using Artificial Intelligence" is a study conducted by Mrs. Lekha Athota, Mr. Vinod Shukla, Mr. Nitin Pandey, and Mr. Ajay Rana in 2020 [10]. The methodology used involved having the client input a question into the user interface which then sends it to the chatbot application for processing. The

preprocessing steps include tokenization and removal of stop words, followed by feature extraction using ngram, TF- IDF, and cosine similarity. The chatbot retrieves the answers from its knowledge database. The key findings of the study include the development of an application that provides quality answers in a short period of time and reduces the burden on the answer provider by using an expert system. However, one of the gaps identified is that the chatbot's inability to take into account all the personal details associated with the patient may lead to inaccuracies in medical practice, raising medical liabilities and new ethical issues.

In India, telemedicine and mHealth solutions have been implemented in rural areas with a focus on providing healthcare services to remote and underserved populations. Despite these efforts, the adoption of e-health solutions in rural areas remains limited due to various challenges such as limited internet connectivity, lack of awareness about the use of healthcare applications, and limited access to healthcare services.

Cloud-based e-health solutions have the potential to overcome these challenges and improve healthcare delivery in rural areas. The centralization and management of patient data through cloud technology makes it easier for healthcare providers to access and share information in real- time, improving the accuracy and promptness of healthcare delivery. Furthermore, the cost-effectiveness of cloud technology can make healthcare delivery more affordable for rural populations.

IV. METHODOLOGY

To develop and evaluate our e-health solution, we will conduct a study in rural areas of India. The study will include a survey of healthcare providers and patients to understand their needs and preferences, as well as to identify the challenges they face in accessing healthcare services. We will also conduct a user-centered design process to develop the e-health solution, taking into consideration the needs and preferences of healthcare providers and patients. The e-health solution will be tested and evaluated through a pilot study in rural areas of India, and the results will be used to make improvements and fine- tune the solution.

V. PROPOSED SYSTEM

The proposed system is an e-health solution that aims to provide healthcare services to rural communities in India. The system consists of a user-friendly mobile application that connects patients with healthcare professionals, providing them with access to medical information, diagnosis, and treatment. The application also provides a platform for online communication between patients and healthcare professionals, enabling real-time consultation and monitoring of treatment progress.

The system is designed to address the unique challenges and limitations of rural healthcare in India, including low levels of digital literacy. The proposed system features a user- friendly mobile application with multilingual functionality, allowing patients to use the application in their preferred regional language. The system is scalable and configurable, allowing it to adapt to changing needs and requirements over time. It is also designed to be secure, ensuring that sensitive medical information is protected and maintained confidentially.

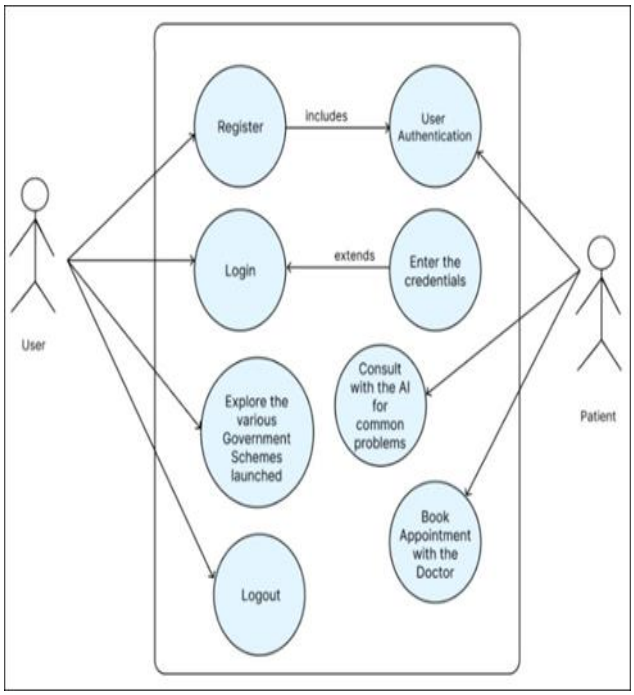

Fig.1 Use Case Diagram

As shown in Fig.1, the proposed system aims to revolutionize the delivery of healthcare services in rural areas of India, by connecting them to certified doctors. By using innovative technology and design, the proposed system aims to close the gap in healthcare services between rural and urban areas and to provide improved health outcomes for rural communities in India.

VI. MODULE DESCRIPTION

The system consists of four key modules: the admin module, the Patient module, the Doctor module, and the Health Bot (Chatbot) module.

6.1 Admin Module

The primary role of the administrator is to maintain the functionality and updates of the application. This includes adding information about nearby medical facilities and laboratories, as well as updating information about government-sponsored campaigns and schemes. The administrator is also responsible for monitoring the performance of doctors and analyzing patient feedback to ensure the quality of care provided. The administrator also has the capability to block users who are booking fake appointments with doctors.

6.2 Patient Module

Patients have the ability to communicate their healthcare concerns to the HealthBot through a chat interface. The chatbot is designed to provide instant remedies for

common health problems, such as fever, colds, and headaches. Additionally, patients can seek assistance from doctors through the application using a text message or video call feature.

6.3 Doctor Module

Doctors can respond to patient inquiries and provide care through the application. They can also interact with patients through video calls if necessary. Doctors have access to a patient's medical history, which can aid in their understanding of the patient's healthcare needs. In emergency situations, doctors can also communicate with the patient's circle of care.

6.4 Artificial Intelligence Chatbot Module

Artificial Intelligence (AI) refers to the development of algorithms that are capable of performing tasks typically associated with human intelligence, such as learning, problem solving, and decision making. In the context of this application, AI is utilized to create a Health Bot, a chatbot that provides patients with instant remedies for common day-to-day healthcare issues. The chatbot was trained using a dataset specifically designed for disease and their symptoms, sourced from the well-known Kaggle Healthcare Analytics platform. The dataset contains comprehensive information on various diseases, their symptoms, and other relevant data, which was leveraged to train the chatbot to accurately identify and diagnose different health conditions. By utilizing this comprehensive dataset, the chatbot is equipped with the knowledge and insights necessary to provide reliable and efficient healthcare solutions to users.

VII. STRUCTURE AND IMPLEMENTATION

The flowchart in Fig.2 provides an overview of the functioning of the application. Patients and doctors can register on the application or log in if they have already done so. Both will have access to a menu with all the features available in the system. The patient can choose to receive assistance either from the HealthBot or from a doctor. If the patient chooses to communicate with the HealthBot, they will be asked to provide information about their symptoms, and the chatbot will offer a remedy or suggest that the patient contact a doctor. If the patient decides to see a doctor, they can book an appointment and conduct a video call with the doctor, who will provide a prescription and receive feedback from the patient. Users can also stay informed about various healthcare activities and avail of opportunities, such as free eye cataract campaigns and yoga training sessions. The map feature allows users to locate nearby healthcare facilities, such as hospitals and medical shops.

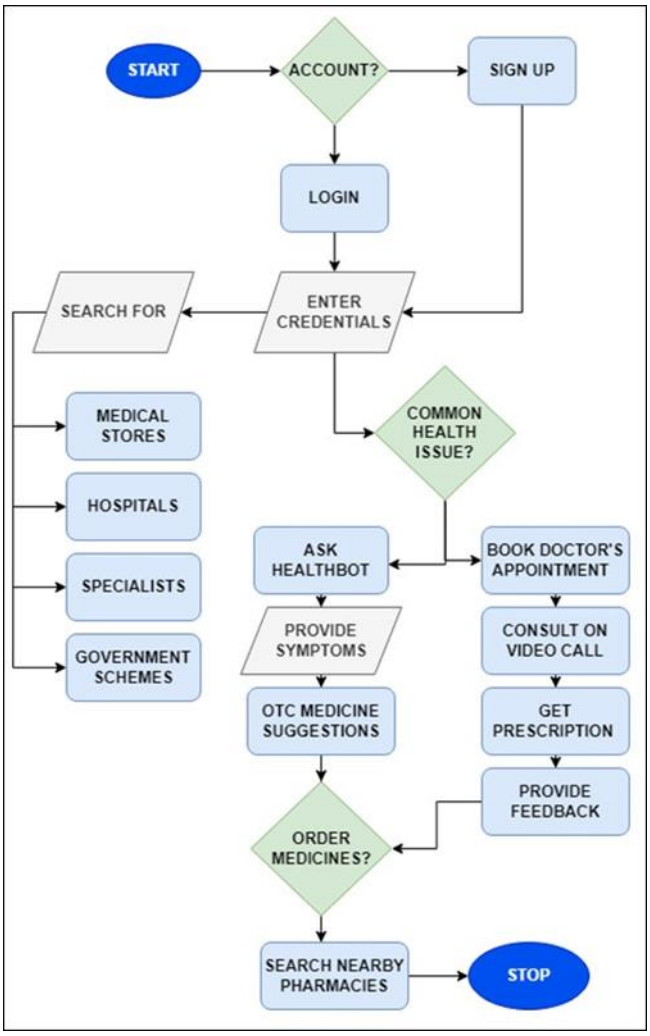

Fig.2 Flowchart

VIII. FUTURE SCOPE

In this age of technology, there is a need for making healthcare more accessible and convenient for individuals. The proposed mobile application-based health care system aims to provide a comprehensive solution for the masses by offering various conveniences during emergencies. The future goal of the system is to integrate Artificial Intelligence to enhance disease detection accuracy and make the application more reliable, efficient, and user- friendly. To further enhance the experience, the system will also be integrated with appointment booking automation to save the user from manual data entry. The development team also plans to connect with more hospitals and use API integration for real-time information regarding bed and operating room availability. In addition, the system will be customizable to meet individual requirements and provide an all-in-one medical service. Lastly, the plan is to integrate a chatbot to offer initial support to users before the ambulance arrives.

IX. RESULT AND DISCUSSION

Based on the survey results, we gained a deeper understanding of the current state of healthcare services in both urban and rural areas. Our ultimate goal is to

bridge the gap between the two and provide the same level of care and access to healthcare services in rural communities. Our aim is to prevent avoidable deaths due to a lack of basic healthcare facilities in these areas.

We realized that many people in rural areas avoid routine check-ups, so our application will allow them to consult with doctors virtually and maintain their health and well-being. According to the survey, many participants believe that AI chatbots have the potential to solve common health- related issues. One of the most pressing needs identified was the availability of doctors when needed, and our application aims to address this issue.

Fig.3 Login page

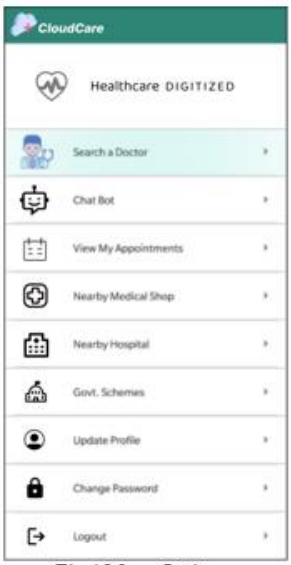

Fig.4 Menu Options

Fig.5 Book Appointment

Fig.6 HealthBot

We successfully introduced an innovative healthcare solution for rural areas, as shown in Figures 3 to 6. Our user- friendly interface is easily navigable for both doctors and patients, ensuring a smooth experience. To guarantee accuracy, we conducted thorough testing of our system. As a result, our application is functioning seamlessly, with all data being accurately recorded in the database and the user interface operating optimally.

X. CONCLUSION

The increasing advancements in science and technology have made it easier for people to find solutions to their everyday problems. In particular, the healthcare sector is attracting the attention of engineers and researchers who are developing innovative systems to improve lives and health outcomes. This paper presents a mobile application-based healthcare tool that aims to provide users with convenient access to health services. The app offers a range of features that can simplify and streamline emergency response, reducing panic and allowing for quick and effective problem-solving. In the future, we plan to continue developing this technology to provide even better support to individuals, especially those in underserved communities. Additionally, we hope to leverage artificial intelligence to improve the accuracy of disease detection based on symptoms, making mobile healthcare a crucial aspect of daily life for all.

Alumni Connect – TCET

Chirag Jain, Pritam Pashte, Prince Jain, Dr. Anil Vasoya
Dept of Information Technology, Thakur College of Engineering and Technology ,Mumbai, Maharashtra, India

Abstract - **Today's this type of portal is useful for various colleges to manage their pass out student. In this portal administrator verify and authenticate the alumni's, manage events, notices, achievement and approve register student. Pass out student register in this portal and view all type of event and participate in this. Student have secure login with OTP verification to access the events and achievement updates. The proposed system will be web based applications so it can be accessed by alumni and students with the help of admin. It enables quick and easy communications. Each user will be responsible for updating their own information's. Alumni will be able to organize meetings and find out about job opportunities using this system. This system will help the students to connect with their seniors which will help them in their doubt solving or attending any event regarding to higher studies or placements.**

Keywords – Alumni Connect, TCET, Technology, Alumni, Alumni events, Mobile Application

I. INTRODUCTION

The greatest asset any Institution can have is the Alumni system. Alumni are the people who represent the Institution in the real world. Many institutions manually maintain student data.

Efficiency is not possible in this. There are certain downsides to the conventional approach to managing student and alumni data and issues. These paper record keeping methods' shortcomings include:

1. The typical method of transferring the material to the students involves a longer delay. At first, it must be pasted on the notice board, and students must view the notice board in order to learn the news[7].

2. It is difficult to keep and update the values in paper records, and they are prone to harm. To store the paper records, a sizable storage space is required[6][3]. Especially in a country like India, efficient management institutes with the practiced industry institute-alumni interface have always been the inspiration to engage, consult and communicate effectively in helping them develop and succeed in a new outlook[4].

We are developing the best alumni portal to provide efficient connection between the institute's three stake-holders - TCET-College, College students, and Alumni through online chatting, profile viewing, and personal messaging. This portal emphasizes the ability for current students to communicate with college alumni in order to receive various updates on current business trends, internship opportunities, sponsored projects, and numerous referral opportunities in the corporate sector. Alumni and students can sign up on their own, and with the administrator's approval, they can log in to their accounts and update their profiles. The alumni portal's significance comes from the fact that it automatically takes care of a problem that is more vital and significant for the wellbeing of the university.

II. BACKGROUND

The existing system is built with numberless excel sheets that are created by each user. These sheets may be collated by an alumni organization and shared with all the alumni but this activity may not be frequent.

The system has privacy difficulties and is difficult to maintain on a regular basis.

- It is not intended for frequent use.
- This system cannot be frequently maintained; data loss is a possibility.
- There may be issues with privacy and security. The procedure of maintaining all user information is extensive.

The suggested system will be a web-based application, allowing alumni and students to use it with the support of administration. It makes communication simple and rapid. Each user is in charge of maintaining their own information. The proposed system will assist former students and the concerned institution in forging close connections through sharing their perspectives, ideas, direction, inspiration, and methods[14] .Information about alumni is freely accessible to users and administrators. Once a student has graduated from the institution, they can pursue higher education in their professional lives or careers. playing a significant part in developing one's professional reputation[14].

III. ADVANTAGE OF PROPOSED SYSTEM

•It is very easy to manage historical data in database.

•It is very easy to record the information of the colleges and about the students in the databases. This system is secured.

•This system provides a single point of network as they connect all the people connected to the university at a single place allowing interactions, exchange of ideas and other information.

•The system is an application for managing and accessing Alumni information regularly.

IV. LITERATURE REVIEW

Alumni Re-Union Using Android Application- Many people are using mobile phones but non-communication between their school and college friends and staffs

because they forget their contacts [5][8]. To overcome the above issues this android application is used for the reunion of alumnus and connect alumni members regularly, to displays, share recent news and photos, offline alert, inaugurate forum, video streaming, online seminar talk [5]. In the proposed system, the app allows students to register and then search the database on different criteria. Then include video streaming, online seminar, event management, gallery. This does not allow efficient data management and retrieval process. It is complex and time consuming

Alumni Smart Connect through Android Application- This system makes an effective communication among different batches of graduates from the same institution[3]. The purpose of this connect application is to provide a mobile user interface, which facilitates a data storage, authenticate a user and provide different services[3]. The services includes connect and communicate an individual alumnus. In this there is no video streaming. There is no section for the ongoing or upcoming cultural events.

Harvard Alumni- Front page of this portal shows the features like login tab so that the alumnus can login easily, ways to connect for connecting the junior and the pass out students, make gift for various occasions like birthdays or anything else [2]. With that Harvard provides Features News for surrounding information's ,Lecture details which describes the schedule , events and the Notice are displayed on home page itself with the present event [2]. Also gives the Donor Initiative Chance for the scenario when the alumni student he/she feels that they can help the college in terms of donation so that will be possible with this[2]. With all this we have observe the unique feature that , it provides the clubbed video on the home page and this thing makes the whole portal very much attractive [2].

IIT Kanpur Alumni- IIT has Gallery with many images, Lectures details with Specific day and time , contacts which shows whom all are Connected with this portal, woman alumni convention as Separate for the woman only on the Home page [9][13]. Features Are Gallery present on the home page , visit for guide Allocations is given so that the junior student can get the Solution or the advice for their difficulties [9]. Notice with Highlighted form is shown for better visualization . also gives The Donor Initiative Chance [9]. IIT Kanpur shows information Events about present on every page where the current events are Highlighted also there is a separate women alumni convention And that is the unique feature [9][13].

Alumni Princeton University- This portal has different things in their front page like Calendar for the current and the in coming occasions and in Order to get about their own information there is a tab i.e. About us [10]. This portal is provides the features that is same as The IIT KANPUR like Gallery present on the home page , visit For guide allocations is given so that the junior student can get the solution or the advice for their difficulties [10]. But the different thing is that this portal provides the scholar ship in terms of donor initiative for the collage requirement purpose [10]. Providing the unique feature like the alumnus are categorized on the basis of regions communities of networks so that the students who belongs to the same area will get listed together [10].

ITMB Alumni Association -In the home page this portal shows the search tab for searching the alumni student whether he/she is connected in the portal or not [11].The notice are present in the highlighted form not only for the better visualization but also for making the portal active[11].And the unique feature which makes ITMB Alumni Association more unique is the search tab which is shown on every page[11]. Also provided Donor initiative for college[11].

UCLA Alumni- The UCLA Alumni Portal's home page layout is very much attractive , shows the similar features like all the portal which we have discussed yet [12] .But unfortunately there is no notice section because of that the portal not shows any surrounding information[12]. And also the donor initiative is present in the form of scholarship but the basic concept is same[12]. Here the alumnus are connected by the social networks which reduce the distance between the pass out and the junior students and that makes the portal unique as compare to the other portals[12].

Commonly Identified Weaknesses- Majority of the alumni portals do not provide the feature of direct communication of the students with the alumnus although the institute remains in direct contact with the alumni. And also the conservation is hidden or not displayed from the other student who all are connected with that particular portal[1]. No chat rooms specific to topic/ interest / domain. No direct registration

V. MODULE DESCRIPTION

The system after careful analysis has been identified to be presented with the following modules User, Admin.

User

- Register – User has to register their basic details to get access with this application service.
- Authenticate
  - SMS OTP will sent to the user registered mobile number
- Security – MD5 Hash
  - Encrypt the password using md5 hash function
- Login – Once they have registered admin will approve the account for login to avail the service at the needy time.
- Publish Event Details – Logging in with the application will provide you to publish the events.

- Publish Achievement Details – Logging in with the application will provide you to publish of achievement that have the approval of the application.
- Search records – So that the users can search the details among the list according. Administrator
- Provide Approval – Administration has to give approval to the registering user after verifying their details.
- Login –Can login their accounts.
- Search records – So that the users can search the details by year among the list according.
- Publish Event details – Here admin have to post their details of event for the alumni
- Publish Achievement details – Here admin have to post their details of Achievement details of the alumni students.

VI. STRUCTURE & IMPLEMENTATION

An alumni connect app is a platform for alumni of a specific institution to network, communicate and connect with one another. The app typically has features such as:Profile creation: Users can create profiles and update their personal and professional information. Search: Users can search alumni based on criteria such as graduation year. Communication: The app provides a platform for alumni to communicate with each other through messaging and notifications. Events: Alumni can be informed of and RSVP to upcoming events and reunions organized by the institution or alumni community. The goal of an alumni connect app is to create a centralized hub for alumni to stay connected, engaged, and involved with their alma mater and with each other[7].

Fig 1 shows the architecture of our application

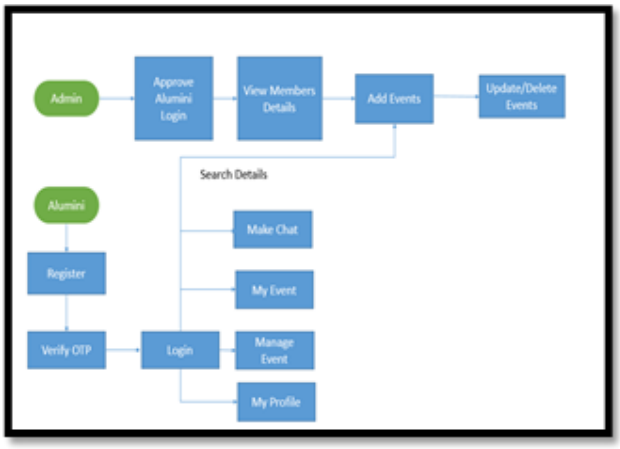

Fig 1. Model Architecture

The architecture of an alumni app is frequently used as a first step to create an overview of the alumni process without going into too much detail, which can then be explained. It includes the user flow and all of its components, such as login, admin, chat, events, profile, etc.

Fig 2 shows the work flow of our application

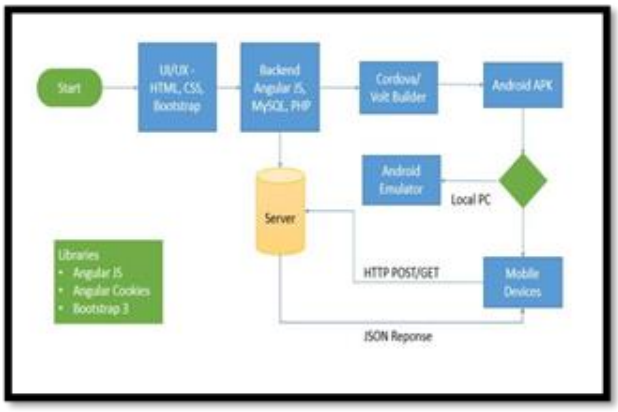

Fig 2. Work Flow Diagram

A work flow diagram of the system's features and functionality provided a description of the system. In order to build the overall system architecture, the system was then designed to match the requirements to the hardware or software system. The programme design that depicts a software system's functionality in a way that allows the user to engage with it and determine how well it satisfies their needs.

Fig 3 shows the Entity Relationship of the objects entity in our application.

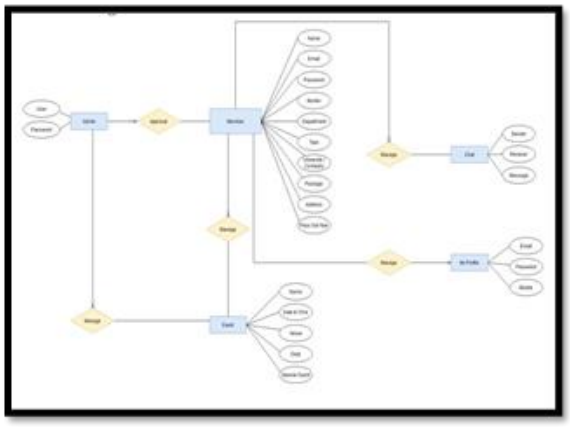

Fig 3. ER Diagram

The Alumni app's entity-relationship diagram displays every visual representation of database tables as well as the connections between colleges, social networks, alumni, alumni news, etc. To describe the relationships between structured data groups of the Alumni app features, it used structure data. The database, college news, chat, events, and admin and user logins are the key components of the alumni app.

The ALUMNI CONNECT – TCET mobile application has been developed with the following section.

5.1. Admin Login
5.2. User Registration
5.3. User Login

Fig 4. Home page of application

Here user gets an option to select any one of the three options as per their requirements and proceed further.

5.1 ADMINISTRATION LOGIN

This module is developed to create user interface to get the administrator in the application with the help of admin login. Admin can login with help of email id and password. The module allow the admin to create an account, view profile, alumni members, publish events, view events, view user. The admin login process is very simple and easy to use. After admin login , admin can view the home page as in fig5.

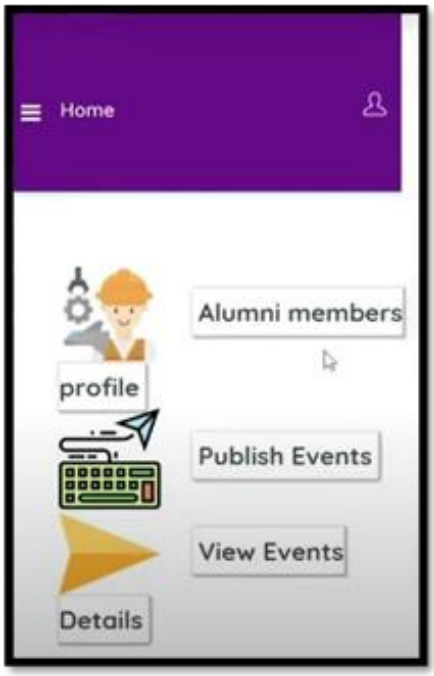

Fig 5. Home page of Admin

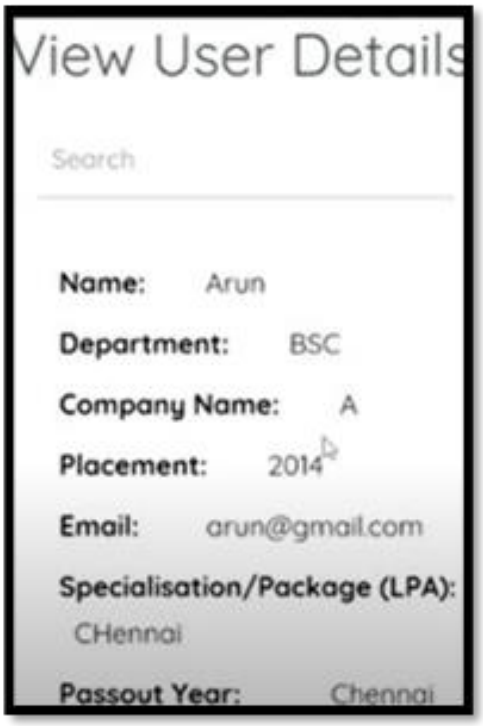
Admin can view all the details of users and has feature to search the user with help of any user detail.

Fig 6 shows the users details that can be viewed by administrator.



5.2 USER REGISTRATION

This module is designed to build a user interface for entering a user's fundamental registration information into the system. The module gives the user the option to register before entering any personal data. The process for creating an account is incredibly easy to use and understand. While registering user has to fill the details such as name, Reg no, email id, password, contact no, department, placement type, pass out year, etc

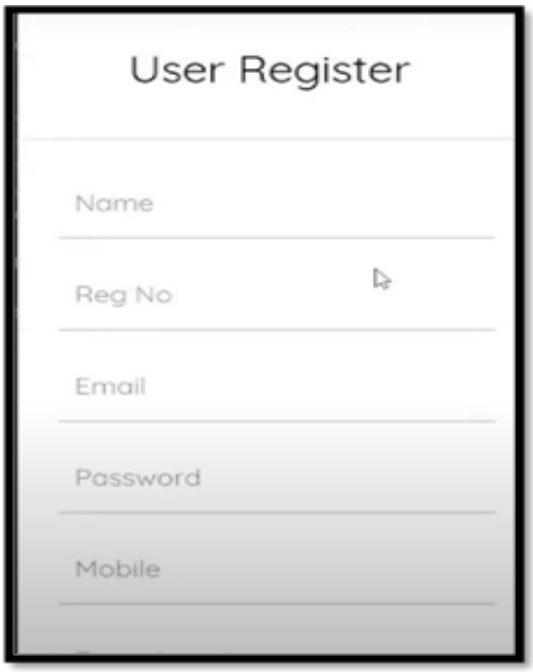


Fig 7. User Registration1

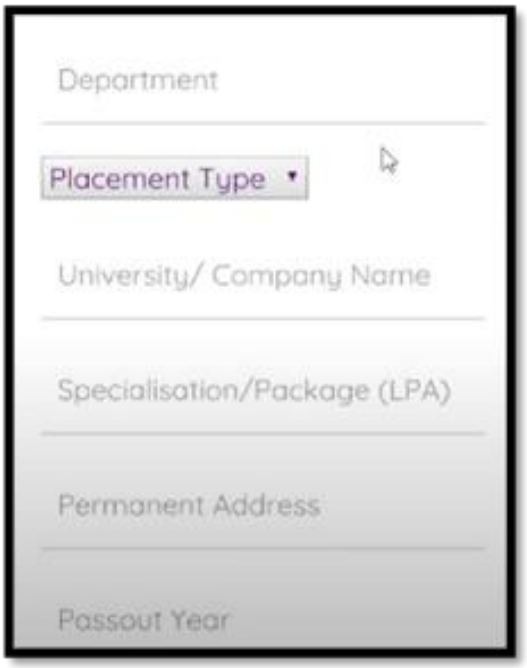

5.3 USER LOGIN

A user login feature in an alumni connect app enables alumni to register for an account and sign in to use the app's features. Typically, the procedure entails providing a special username, email address, and password that are checked against the app's database. The user is given access to the app's capabilities after successfully authenticating themselves, including the ability to read their profile, interact with other alumni, access resources, and take part in activities. The user login contributes to the privacy and security of app users and their data

VII. FUTURE SCOPE

The project's explicit goal is to provide a user-friendly programme that will make tasks easier to complete offline, or via alternative methods, while also requiring less effort. In this application we will be able to save database of all current and past students. Login /registration Module, Chat System Module, Events News section ,Video streaming. If former college students who are members of the alumni website could get in touch with the alumni officer directly through the website, that would be very helpful. This functionality is not provided by the system that was put in place. However, the alumni officer's email address is simple to locate because it will be displayed on the website of the online community. Asp, which is also used to build the broadcast email capabilities that the alumni web site offers, might be used to implement the contact alumni officer capability with ease. If the website featured a forum where any topic that was relevant to a person's field may be opened, that would be another valuable feature from which the alumni members could profit.

7. CONCLUSION

Alumni Portal for any college website is very important. During covid pandemic ,when education was in online mode interaction of students with their seniors is almost none so it has been setup to increase interaction, knowledge sharing and networking among the alumni students and also focuses on bringing together alumni students of college and the primary goal of this report is to connect the alumni students with the college and existing college students with the help of alumni web portal where they can have communication with existing students and college.

VIII. ACKNOWLEDGMENT

We sincerely thank our guide Dr. Anil Vasoya for his guidance and constant support and also for the stick our backs. We also thank the project coordinators for [1] [2]arranging the necessary facilities to carry out the project work. We thank the HOD, Dr. Sangeeta Vhatkar, the Principal, Dr. B. K. Mishra, and the college management for their support.

The Impact of Personalized Fitness Applications on Physical Activity, Body Composition, and Health and Well-Being

Rushal Chikane, Prashant Chaurasia, Nachiket Kadkol, Apeksha Waghmare
Thakur College of Engineering and Technology, Mumbai, Maharashtra, India
chikanerushal@gmail.com, prashant18chaurasia@gmail.com, nachiketkadkol17@gmail.com

Abstract **Smartphones and tablets are slowly but steadily changing the way we look after our health and fitness. Today, numerous high quality mobile apps are available for users and health professionals and cover the whole health care chain, i.e. information collection, prevention, diagnosis, treatment and monitoring. There are thousands of fitness-related smartphone applications available for free and purchase, but there is uncertainty if these apps help individuals achieve and maintain personal fitness. This study aimed to investigate the factors that contribute to the success of personalized fitness applications and the user experience. The results showed that the key factors contributing to the success of personalized fitness applications are personalization, goal setting, and progress tracking. The user experience was also found to be positively impacted by these factors, as well as by the availability of resources such as workout plans. This study highlights the importance of considering personalization, goal setting, and progress tracking in the development of personalized fitness applications to improve user engagement and satisfaction.**

Index Terms - Personalized fitness application, apps, health, fitness, smartphone

I. INTRODUCTION

The use of technology to monitor and improve physical health has become increasingly popular in recent years. Personalized fitness applications provide users with personalized fitness plans, track progress, and offer incentives and rewards. The convenience and effectiveness of these applications make them an attractive solution for individuals looking to improve their physical health. However, little research has been done to evaluate the impact of using these applications on physical activity, body composition, and overall health and well-being. Through Using app, we can have young people involve in physical exercise. We Barely get any time from morning to evening to do some workout due to Extensive work and busy social life. Healthcare applications will encourage to Keep body fit and lead a healthy life through using it. Our aim will be to create App which we can update according to trends. Personalized fitness applications have become increasingly popular in recent years as a means of tracking exercise and promoting healthy lifestyles. With a wide range of features, including workout plans, nutrition tracking, and goal-setting tools, these applications aim to provide users with a customized approach to fitness and wellness. However, despite their growing popularity, there is limited research on the effectiveness of these applications in improving fitness outcomes and user engagement. This study seeks to fill this gap by examining the benefits and challenges of personalized fitness applications and exploring the key features that contribute to their success.

II. IMPORTANCE OF THE PROJECT

Fitness apps offers the freedom to work out anywhere as per their convenience. We all have different body types some have Endomorphs, some have Ectomorphs and some have Mesomorphs and substantially to know your type you just have to give some inputs to the operation like weight, height, etc and it'll show your body type and the required workout for that type. Fitness apps are like " anywhere, anytime " where your just need a Mobile Phone and Internet Connection and you can indeed download the Workout or Diet if you want to avoid using Internet Connection. So, whether you're on a business trip, family holiday, or out of the city for any other reason, you have no reason to miss your Workout. Those who are formerly-fit and want to maintain this fitness position can choose from hundreds of workout plans given in the fitness apps. Monitoring your Progress and Diet is veritably easy using fitness apps. Fitness apps are like a one- stop station where you can cover all your life parameters like step count, diet, water input, blood parameters and drill routine. You do not need to maintain different journals or books to keep a record of all these effects. Fitness apps help ameliorate your life habits, as they've a huge positive impact on your health. One of the most Important benefits of using fitness apps is ' Motivation '. Notification and Reminders from fitness apps keep reminding you about your health and Goals, therefore keeping you motivated. Fitness apps keep track of your goals and remind you to follow them. With the Perfect fitness apps, you can achieve your goals and stay healthy.

III. OBJECTIVES

The following are the objectives of this research on personalized fitness applications:

To determine the effectiveness of personalized fitness applications in improving fitness outcomes such as weight loss, muscle gain, and improved overall health.

To evaluate user satisfaction with personalized fitness applications, including ease of use, personalization, and overall enjoyment.

To identify the key features and functions that contribute to the success of personalized fitness applications, including workout plans, nutrition tracking, and goal-setting tools.

To understand the challenges faced by users in using personalized fitness applications, such as difficulty in adherence to workout plans and barriers to long-term engagement.

To provide insights into the current state of the personalized fitness application market and offer recommendations for future development.

To contribute to the existing body of literature on personalized fitness applications and their impact on health and wellness.

IV. SCOPE

The fitness industry is experiencing a steady pattern of growth, whether it's health clubs or fitness app development companies. One of the most important tasks of fitness app developers is protecting the user's data from being leaked. Pay close attention to the subject of data security. Another challenge is delivering exceptional user experience for the apps to be fast and easy to use. If you're not well- experienced in this business, you might find yourself in need of help from the team of UI/UX designers during this stage of fitness application development. Fitness industry trends reflect global trends in society. Technologies are seamlessly integrated into our lives. They are finding their place in people's fitness and health routines. Our aim will be to create app which we can update according to trends.

V. TECHNICAL KNOWLEDGE

The development of apps requires multidisciplinary collaboration with partners that have a background in software development. Such a team should include members capable of content design, software coding and usability testing of the product (e.g., alpha testing). Although it is possible for a mobile

app to be developed by a single individual, it is unlikely that a mental health provider will be able to individually develop a comprehensive app independently, especially given the advanced technical and programming skills required. The mental health provider may find it easier to collaborate with qualified teams of software developers to facilitate the technical components. The provider would offer expertise in content to guide development and communicate user needs, whereas the programmers would complete the technical components. However, it would be helpful for the mental health provider to possess, or involve other mental health professionals who possess, basic training in software design to facilitate communication with technical staff.

VI. APP MAINTAINANCE

New mobile technologies and evidence-based mental health care continues to evolve. As such, app developers and mental health providers should identify methods to maintain, modify and improve existing apps to incorporate these advances in technology and psychological research. These methods should include strategies to fix technical problems that arise as hardware and software systems are updated. Developers are encouraged to create a plan to maintain the app after the initial development is completed. Maintaining and updating an app can be challenging due to limitations in funding. Traditional research funding mechanisms, including multi-year research projects, are conducive to initial development, usability testing and preliminary evaluation but are limited in their ability to support continued revision. Fortunately, apps themselves are products and can be integrated into a self-sustaining business model. This approach would also promote the development of high-quality apps that are more likely to be used in order to generate such financial support. However, the need for sustained funding leads to challenges in identifying ethical and manageable revenue streams. The most common approach is to charge for the initial download of the app itself. Additional models include offering an initial free download and then selling supplemental content for the app. For example, a mood monitoring app could offer a supplemental feature that communicates with an external heart rate monitor for an additional fee. Alternatively, arrangements with a specific institution (e.g., a university or hospital) or health insurance agencies could be made to allocate funding to successfully sustain an app. Such an agreement islikely to succeed when the app offers direct benefit to the larger organization, such as coordinating care amongst disparate service centres. Although no one strategy has emerged as consistently successful, there is a continued need to identify approaches that balance costs of development and continued maintenance with wide-scale dissemination of such software.

VII. MOBILE DEVICE TRENDS AND HEALTHCARE

As described, mobile devices have numerous functions that are of direct utility to mental health treatment. The present discussion has highlighted the ability of such devices to asynchronously communicate with patients in specific contexts at all stages of the treatment process. Such functions rely on the expanded communication functionality of the mobile device (e.g., messaging, telephone conversations and video chat). Additionally, such devices offer increased functionality through integrated hardware (e.g., global positioning systems and camera) and supplemental hardware that connects to the device directly or wirelessly through Bluetooth.

Mobile devices contain a number of embedded sensors that can be used to improve the timeliness of a given intervention. These sensors include global positioning

systems capable of determining locations as well as movement in a given area, accelerometers capable of measuring movement of the device, microphones capable of recording sounds in the area, camera capable of video and pictures and Bluetooth sensors capable of identifying and communicating with nearby devices. These sensors can be used in conjunction with one another to obtain a comprehensive understanding of an individual's behavior at a given time and have the potential to predict subsequent behavior (Burns et al., 2011).

The future of mobile devices will involve advances to functionality within the device such as improving the breadth and precision of sensor capabilities, as well as enhancing interactivity with other devices. This interoperability includes seamless communication with other mobile devices (e.g., Bluetooth and near field communication), software systems (e.g., electronic medical records) and other hardware (e.g., actigraphy). These features are likely to improve opportunities for passive data collection, which requires minimal input from the user and reduces the overall burden of usage. The ability of the mobile device to communicate with other devices and

systems around an individual represents a potential shift in the functionality of the device from that of an additional tool to be used in treatment to the central device that manages the process of treatment outside of care. This feature will be increasingly important as high-powered wearable sensors become more prominent.

VIII. CONCLUSION

Health and fitness apps make it easier to motivate, track progress, and reach your goals. Today, there a ton of apps devoted to all kinds of workouts, from yoga and available, known Exercises For better Health and strength training sessions. We have started creating M-healthcare application for Mobile devices which will be Open source, User friendly, Helpful for many People.

Mobile applications that focus on mental health treatment can be used for a variety of purposes. They show great promise in promoting healthy behaviour changes, increasing adherence to treatment programmes, providing immediate psychological support, facilitating self-monitoring and reducing the demand for clinician time (Spurgeon & Wright, 2010). As mobile applications grow in popularity among the general public, so does the potential to increase the quality of care and access to evidence-based treatments through this technology. Mental health providers and researchers are encouraged to thoughtfully develop and evaluate mobile applications for use in clinical practice and research. As the mental health field continues to adopt new technologies to increase access and quality of care, it is imperative to investigate their effectiveness, feasibility, usability and acceptance in an effort to reduce the burden of mental illness, increase access to high-quality evidence-based treatments, bridge the gap between science and clinical practice and ensure that the mental health field remains at the cutting edge of new developments in health care.

Abstract— Health is the most important factor for anyone but maintaining it can be tiresome without any external advisory. Keeping track of one's sleep, calorie intake and their medicines is a task that becomes difficult for humans. The application that we intend to build solves these problems. A user of our application can set reminders for their daily or weekly medicines. Along with the zeal of curing people's health, technology has become a marvellous combination and has given rise to mobile healthcare apps. Recently, the entire world is struggling with an outbreak, and healthcare apps are playing a pivotal role to cure the patients via making them all alert about their diet and also make seekers connected to the doctors directly for the healthcare consultants. The most useful aspect of our mobile app is the patient and public app (which includes the health and fitness app), which is concentrated on primarily providing a rich experience to the common man by having the capability to perform a wide range of functions, such as sleep tracking, calorie tracking, scheduling medications, or booking doctor appointments as per schedule.

Keywords—m-health mobile app, Medicine tracker, sleep tracker, doctor appointment, chronic illness

I. INTRODUCTION

The main idea of medicine intake in most cases depends solely on memory. If the patient remembers to take the medicine, then they will, else there's a very high chance that one might miss out on doses and it can be dangerous in return when someone is on antibiotics or on doses of something powerful like insulin. This app will be like a digital caregiver to the users. It will help schedule medicines and doses at different times of the day. It will help the user track their sleep and calories all the press of a button. Further features like appointment booking with doctors via chat or direct consultation via video calls is on the table for debate.

This app works fine for medical providers like healthcare workers, physicians, pharmacies, chemists, nurses and assistants. Secondly, we have got hold of Special disease specific apps, using general medical knowledge accessible to all. We will make use of a Machine Learning model with higher accuracy of prediction and use it for different diseases like diabetes prediction or heart disease predictions. All these features will be very useful for anyone with a chronic illness or people for whom age is a problem, this app will help them regulate their medicines and make sure they don't miss a dose. It will also allow them to share their data with their family or friends via other existing social media apps so that they can keep track too. This application serves a broader purpose because we are high on safety and privacy conditions, the application doesn't track personal data from the user's device. Permissions will be taken at every step from the user and the function executes given all the permissions match. In times of global pandemic and health crisis, mobile apps like ours will help the people trust on one app instead of panicking with many sources confirming different needs.

II. LITERATURE REVIEW:

1. YEAR – 2014

AUTHOR – David B. Buller,Ann C. Brewer, Maged N. Kamel Boulos, Chante Karimkhani, and Robert P. Dellavalle

KEY FINDINGS – Experimented with the views of over 40,000 healthcare professionals as they mention the quality of many health apps. Finds out that most apps use the same list of benchmarking ideas which help in prediction.

RESEARCH GAPS – There are health apps for various domains but not one which caters to the needs of all

2. YEAR – 2016

AUTHOR – Syed Ali Hussain,Shaheen Kanthawala, Shupei Yuan & Wei Peng

KEY FINDINGS – Gives insights to a study that the users of mobile apps don't use the apps over a period of time Highlights a different perspective after research which is that a huge population is usually unaware of the existence of such apps.

RESEARCH GAPS – Restricted to apps that actually have good user interface or are marketed well for public usage

3. YEAR – 2017

AUTHOR – Stephan U Dombrowski Monika Oedekoven Julie L O´Sullivan Melanie Kanzler Adelheid Kuhlmey Paul Gellert ,Clemens Ernsting KEY FINDINGS – For people and the healthcare system, chronic diseases constitute a growing challenge. Smartphones and health applications are potentially effective tools for managing chronic diseases and altering health-related habits.

RESEARCH GAPS – Restricted only to the audience focusing on health apps for chronic illnesses.

4. YEAR – 2014

AUTHOR – Borja Martínez-Pérez, Miguel López-Coronado & Isabel de la Torre-Díez

KEY FINDINGS – Focuses majorly on collection and handling of personal information which is private to the users entered on health apps. Talks about how the app designers use the data to their own advantage.

RESEARCH GAPS – Focuses only on low security and insecure app connections which misuse user data. Focuses only on low security and insecure app connections which misuse user data

III. M-HEALTHCARE SYSTEM: ROAD SO FAR

E-Health services at the turn of the century finally woke up and expanded dramatically between 1999 and 2002. Its growth coincided with the quick development of ICT infrastructures and patient data access. Healthcare practitioners now have options that they never had before thanks to the Web 2.0 concept and the impending Web 3.0. Also, they cleared the way for the introduction of electronic health records, or EHRs, which have grown to be an essential part of healthcare systems (PHRs). Healthcare professionals typically monitor and preserve patient medical records. Patients, on the other hand, are asking for access to those records more frequently. Medical records, usually referred to as health records, make it possible for clinicians to swiftly learn details about a patient without having to speak to them directly. The support of e-health systems is frequently provided through EHRs. An electronic health record (EHR) system is a computerized database that contains data about a patient's or consumer's health records. A public EHR system can offer a public healthcare system several advantages, such as decreased and more effective management costs, improved management of large volumes of patient data, and integrated medical patient records.To provide healthcare via various communication technologies, many telemedicine and e-Health systems are being successfully built. In 2011, the World Health Organization (WHO) released a compilation of emerging health technologies that were either still under development or had already been commercialized. The various health-related technologies that could provide affordable answers to unmet medical needs are discussed in this study.The most widely used and commercialized e-Health technologies today include a fetal heart rate monitor, a portable hemoglobin meter, a self-powered pulse oximeter, a medical data communication system, mobile computing to connect patients to distant doctors, and a software application for monitoring treatment responses.The authors identified the most relevant technologies in development, to the best of their knowledge.

A fetal heart rate monitor is a mobile application that analyzes the fetus' heartbeat and calculates the heart rate using a beat-to-beat accuracy algorithm. A midwife can access these data via a Web browser after they have been uploaded to a database and kept there. A mobile health record system for minors with HIV is provided via a web-based EHR system that integrates a clinical decision support system with a comprehensive pediatric HIV knowledge base. Using this strategy, medical professionals may control HIV in minors at the point of care by using clinical data. Mobile phone camera image transmission for diagnosis: A mobile phone with a camera is used as an image transmission device. This technology provides a basic connection to more specialised healthcare facilities in far-off locations in the field of medical imaging diagnostics. Mobile phones get the photographs as MMS (Multimedia Message System) messages. A cell device with a pulse oximeter sensor analyses and displays data from a sensor that is placed on a finger. It can aid clinicians in identifying clinical events and rendering decisions. The term "portable telemedicine unit" refers to a device that combines a computer server with a mobile telemedicine system. They can communicate with each other through satellite, the Internet, GSM, and CDMA, among other channels.It can be used for a variety of health services, including teleconsultation, tracking and reporting, and healthcare services in remote or rural regions.

IV. M-HEALTHCARE SYSTEM ARCHITECTURE

The requirements that stakeholders in the health industry revealed in this study were taken into account while developing the suggested mobile health architecture. All linked entities of the architecture exchange information back and forth. As mentioned above, doctors, specialists, and patients/users all utilize their phones to access mHealth services via Message service or data connection. Communication between Mobile Equipment (ME), such as a cell phone, and the application server, must be routed through the mobile operator. Over the network of the mobile operator, HTTP is the protocol used for communication between the ME and the application server (HyperText Transmission Protocol). This is made possible via the GPRS functionality of a mobile phone and data services offered by the mobile operator, like EDGE and UMTS. The application server creates safe network connections with other organizations that use the platform to access data, like the Health Information System and NonGovernmental Organizations. When a patient enters the health center, the medical officer registers them in the M-Health system. After that, the patient will be able to use the M-Health system to both seek and receive information. Users will thereafter be able to send and receive educational text messages. When customers send the text messages, they will automatically receive a response stating that the system will respond to their question shortly. Thereafter, the mHealth system will text the patient with the pertinent response. Community workers can send data to the system and get SMS messages from Ministry of Health officers while on the job if they have enrolled with the system. They should state their work number, the area or location, and then the specifics.

V. ACQUISITION OF M-HEALTH DATA

Our project aims at providing practically useful services for users, we are engaged in developing an application that tracks the sleep, calorie intake and medicines. A user of our system may set alarms for their medicines and be reminded of them. The users will be asked to enter their details such as their height, weight, lifestyle, medicines, dosages, etc. which will be stored in our database. With the help of that data, the app will help the user achieve their goal. The users can schedule video call appointments with their doctors and avoid going outside in the pandemic and risk their health. This application will have many positive applications on society. It will enable users to manage their health-related concerns in an easy way. Those with financial problems will also find it helpful.

VI. APPLICATION OF M-HEALTHCARE DATA

Our app makes the management and records of all the medical metrics very easy and at your fingertips (heart rate, blood pressure, blood sugar levels, etc). This app can help you record daily fitness achievements like number of steps, number of km walked, calories burnt in a day, water consumed etc. Healthcare apps can help you control your diet and help you live a healthy life. Healthcare apps also help you in monitoring your drug intake and treatment management by simply entering the medicine and the dosage. The app will then remind you whenever it is time for your medicine. Taking advice from some professional doctors or surgeons through an interacting platform provided by the healthcare app is also another application of the project. It is useful for interacting with a medical centre or clinic and book appointments easily. Remote diagnosis and monitoring can be achieved by a video call feature where doctors or surgeons can directly interact with patients.

VII. SECURITY OF M-HEALTH SYSTEM

The individual is able to decide who has access to their private medical records. Therefore, it is essential that mobile health systems and gadgets are secure. Security, privacy, and confidentiality are three aspects of this issue. Professionals who have access to patient data or information have a duty of confidentiality to keep that information secret. The ability of a patient to control how personal data is disclosed is referred to as their right to privacy. Security refers to the physical, technological, or administrative means used to prevent unauthorized disclosure of identifiable health data. It is impossible to exaggerate the value of security, privacy, and confidentiality. A mobile health system uses the Internet to store and access data electronically. Your health information is vulnerable to intrusion if it isn't protected. It is highly advised that m-health data and equipment be HIPAA compliant. A foundation for protecting private patient data is established under HIPAA (Health Insurance Portability and Accountability Act). Any company handling protected health information is required to implement all essential physical, network, and procedural security measures. Following measures are recommended to ensure privacy, confidentiality, and security and m-health system:

1) Only permitted physical access to the data centre is protected by physical safeguards. Workstation and electronic media use and access policies must be in place at all HIPAA-compliant establishments. Transferring, deleting, discarding, and reusing electronic media and electronic protected health information are all examples of this (ePHI).

2) Technological safeguards restrict unauthorized users' access to computerized protected health data. Access control techniques include using a distinct user ID, a secure password, automated logoff, and safeguarded data storage and transport.

3) Audit reports are used to maintain track of actions such as user logins and logouts, data access, system messages, and so on. Audits are a great way to figure out where a security breach came from.

4) Technical guidelines must also specify integrity controls, or measures taken to guarantee that ePHI is not manipulated with or destroyed. IT disaster recovery and offsite backup are essential for ensuring that any errors or issues with electronic media are quickly fixed and that patient health information is accurately and damage-free restored.

5) A vital defense against unapproved public access to electronic health information is network security (ePHI). Network security refers to a network administrator's policies and procedures for preventing unauthorised use of the network and its resources, as well as its exploitation, modification, and denial. It encompasses all means of transmitting and receiving data, including email, the internet, and other channels.

VIII. FUTURE SCOPE

Due to the rise in smart devices and internet users, the m-health app market has experienced tremendous growth. Some of the most frequently used phone applications are those for tracking medication history, health records, and doctor and hospital appointments. The healthcare industry benefits greatly from these apps. Further future implementations:

1. Adding oxygen level monitoring.
2. Adding the diseases of people around you or someone the user had close contact with in a day so that the user can take the required precautions.
3. Doctor search -Incase of emergencies the user can type a keyword related to the problem and any doctor nearby can connect to the patient or the user himself and help the hurt.
4. Ambulance search - even though most private hospitals have their own ambulances most times they fail to reach the person on time, this feature will keep track not only of private ambulances but also of the ambulance

services provided by health care NGOs thus focusing that the help can be given to the patient as soon as possible.

IX. ACKNOWLEDGEMENT

A wholehearted thank you to our mentor, our guide Apeksha Waghmare. Thank you to all the student members

and other teaching staff of the IT (Information and Technology) department of Thakur college of Engineering and Technology (TCET) involved in this research.

Study on the Need of a Unified Stray Service Platform in India

Kailash Ahir, Hemin Dhamelia, Dhruvi Jivani
Information Technology Thakur College of Engineering and Technology Mumbai, Maharashtra India
kailashahir2801@gmail.com, heminpatel2002@gmail.com, jivanidhruvi19@gmail.com

Abstract - **With ever increasing numbers of stray animals in India there are comparatively less shelters to support the increasing number of strays. In India, there are no safe places for dogs to be, and these dogs have no true place in our society. Although more people are adopting stray cats and dogs, there are still too many unadopted strays roaming around on the streets who have little chance of finding a loving home. Shelter is necessary for these homeless animals to give them a chance of having a life again. Many shelters in India do not take in the strays because they do not have enough resources or space to keep many dogs at the same time. A few shelters do not even provide them with food or water, which is why most strays live on the street existing off scraps from dumpsters or rubbing shoulders with dangerous criminals who use them for target practice. Stray animals are a major cause of animal cruelty and suffering with the right steps being taken, there is hope for strays in society. Stray animals lack shelter, food, and water. To solve this issue, we need to increase the number of shelters throughout the world by making each shelter take care of at least one stray animal every day. By doing this we can decrease animal cruelty, increase their chances of being adopted or returned home and hopefully rid our world of stray dogs and cats once and for all.**

Keywords—Shelters, Stray, Animals, Sustainable, India.

I. INTRODUCTION

As the Indian population grows there is a lack of living spaces for humans. As humans struggle to find a roof above their heads there are millions of strays that must bear the wrath of nature no matter what the season, condition, or festival. Stray animals suffer in an unfriendly environment as they roam the streets for food and companionship. They are often victims of abuse, neglect, and fatal attacks from humans as well as diseases. Indiscriminate killing of stray animals often associated with high-speed road crashes, acts of terrorism and cruelty amongst humans is blamed as the main reason for the population explosion. Due to lack of shelters and treatment, many animals are forced to live in filthy conditions which often leads to chronic diseases and their death. People need to understand the importance of placing a shelter for these animals since they cannot survive on the streets. As India is facing a growing problem of stray animals, with limited resources and shelters available to support the increasing number. To tackle this issue, it is crucial to explore and implement sustainable solutions that can effectively address this problem. Some possible measures could include implementing spaying and neutering programs, promoting animal adoption, and increasing public awareness about the importance of responsible pet ownership. By taking a comprehensive approach, it is possible to make a meaningful impact on the lives of stray animals and the communities they live in.

II. CURRENT SITUATION OF STRAYS IN INDIA

Stray animals, particularly dogs, are a growing problem in many communities, posing risks to both public health and safety, as well as causing damage to community resources. The factors contributing to the population of strays are complex and multifaceted, including limited adoption programs, lack of management of the community cat population, and broader social issues such as poverty and unemployment. Additionally, some animals become strays due to neglect or cruelty at the hands of their owners, who may no longer be able or willing to care for them. Today there are 6.2 crore stray dogs and 91 lakh street cats in India. They are the most vulnerable of all animals. These animals do not have a place to call their own and they have nowhere to go. The government is wasting millions of rands each year on trying to control these animals through round-ups, baiting and snaring. As stray animals continue to proliferate across India, the plight of these animals has been neglected by the government and civil society. This problem has reached critical levels and is affecting communities throughout the country. While stray dogs may be seen as cute and friendly creatures, they need proper care and support to ensure their well-being. It is crucial for the government and society to take action to address this issue and provide support for these vulnerable animals, through measures such as adoption programs, community outreach, and education efforts. So there is a need to come forward with proper support in order to save their lives.

III. PROBLEMS FACED BY STRAYS DUE TO HUMANS

Strays also suffer from physical abuse at the hands of humans. Some people intentionally harm strays due to fear of diseases or fear of being bitten. This often results in injury or death of these innocent animals. In addition, strays are often malnourished as they are unable to find adequate food and water sources in their environment. This can weaken their immune system, making them susceptible to diseases. Furthermore, strays are at risk of

getting hit by vehicles on roads, leading to serious injuries or death.

The lack of facilities for strays and their increasing populations has become a serious issue that requires immediate attention. The problems faced by strays are numerous, and include:

a. Homelessness: Stray animals do not have a place to call their own and are forced to roam the streets in search of food, shelter, and protection. This leaves them vulnerable to extreme weather conditions, disease and abuse.

b. Neglect: Many stray animals suffer from neglect, as they are not given proper food, water, or medical care. This often leads to malnourishment, disease and death.

c. Cruelty: Strays are often subjected to acts of cruelty by humans, who may harm them for no reason. This can range from physical abuse, neglect, to intentional acts of cruelty such as abandonment and killing.

d. Disease: Stray animals are more prone to diseases than pet animals, as they do not receive regular veterinary care. This can lead to the spread of zoonotic diseases, which can be transmitted to humans.

e. Lack of Resources: With an increasing number of strays and limited resources, shelters are often overcrowded and under-resourced, leaving many animals without adequate food, water, or medical care.

f. Conflict with Humans: Stray animals can cause conflict with humans, as they may scavenge for food or damage property. This can lead to negative attitudes towards strays, resulting in acts of cruelty.

It is clear that strays face numerous problems due to humans. It is the responsibility of society to address these problems and provide strays with the proper care and attention they need to live healthy and happy lives.

IV. PROBLEMS FACED BY HUMANS DUE TO STRAYS

The problem of stray animals is very prominent in our society. Stray animals are not only a problem for themselves but they can also cause several problems for humans. They are are a major social problem in many urban and rural areas around the world, and they can pose serious risks to human health and safety. One of the biggest problems is the danger they pose to public health. Stray dogs and cats can carry diseases like rabies, which can be transmitted to humans through bites or scratches. This can be life-threatening, particularly for children and the elderly. Stray dogs cause more than 100,000 human deaths globally annually. There are an estimated 1 billion stray dogs worldwide. 99% of all dog bites involve a family pet or household pet. More than 300,000 people die annually from rabies. Rabid dogs have caused more than 40 million human deaths in the last 10 years. Human civilization has been unable to decrease this animal problem.

In addition, stray animals can cause damage to property and personal belongings. They can dig up gardens and lawns, get into trash cans, and cause car accidents. This can cause a financial burden for homeowners, property owners, and local governments. Moreover, strays can create safety concerns for people, especially those who are vulnerable such as children and the elderly. Stray dogs and cats can become aggressive if they feel threatened or are hungry, and they can attack humans. This can cause physical harm and emotional trauma.

Another problem is the impact that stray animals can have on the environment. Stray dogs and cats are known to cause declines in native species of birds, mammals, and insects. They can also create problems for wildlife populations by feeding on them or disturbing their habitat.

V. LACK OF FACILITIES FOR THE STRAYS

In India, there are no safe places for dogs to be, and these dogs have no true place in our society. Although more people are adopting stray cats and dogs, there are still too many unadopted strays roaming around on the streets who have little chance of finding a loving home. Shelter is necessary for these homeless animals to give them a chance of having a life again. Many shelters in India do not take in the strays because they do not have enough resources or space to keep many dogs at the same time. A few shelters do not even provide them with food or water, which is why most strays live on the street existing off scraps from dumpsters or rubbing shoulders with dangerous criminals who use them for target practice. That is why Lack of facilities for strays is a major problem facing society today. Stray animals, including dogs and cats, are often seen wandering the streets searching for food, water, and shelter. The lack of proper facilities for these animals has led to increased instances of animal cruelty and suffering.

The issue of stray animals is particularly prevalent in urban areas, where there is limited space for the animals to live and roam. Many strays are forced to live on the streets, where they are exposed to harsh weather conditions, disease, and predators. The lack of proper food and water also results in malnutrition and dehydration, leading to poor health and a high risk of death. In addition to the direct impact on the health and welfare of stray animals, the lack of facilities for strays also affects the community in various ways. Stray animals can pose a threat to public safety by attacking humans or causing accidents.

To address the lack of facilities for strays, various steps need to be taken to improve the lives of strays and reduce animal cruelty and suffering. Addressing this issue will have positive impacts on public safety, the environment, and the health of both animals and humans. This can include increasing the number of shelters and rescue

organizations that provide care for stray animals, and increasing public awareness about the importance of responsible pet ownership.

VI. RELATED WORK

1. Increasing adoption rates at animal shelters: a two-phase approach to predict length of stay and optimal shelter allocation (BMC Veterinary Research 2021) -

The data that is collected from the database and animal shelters included information such as animal type, intake and outcome date, gender, color,breed, and intake and outcome status. These records also included information on several types of animals, such as dogs, cats, birds, and rabbits. Nearly 3–4 million animals are euthanized out of the 6–8 million animals that enter shelters annually. Further observing the results, it is found that age for dogs, multicolor,and large and small size are important predictor variables. The only issue is that the focus is on dogs and cats situated only in California, Kentucky, Colorado,Arizona, and Indiana The research does not contain enough staff or resources

2. The Journal of Applied Animal Welfare Science (JAAWS) is a peer-reviewed scientific journal that focuses on the study of animal welfare. The journal was established in 1998 and is published by Routledge. It aims to publish articles that advance the scientific understanding of animal welfare, with a focus on applied research.

The journal covers a wide range of topics related to animal welfare, including:

- Animal behavior and welfare in captive and farm animal settings
- Animal welfare in laboratory settings
- Wildlife welfare
- Animal welfare assessment
- The ethical and philosophical dimensions of animal welfare

Articles in JAAWS typically take the form of original research studies, reviews of the literature, or brief reports. The journal is well regarded in the field of animal welfare and is considered a valuable resource for those working in academia, animal welfare organizations, and government agencies.

In recent years, JAAWS has published articles on a variety of topics, including:

- The welfare implications of different housing systems for farm animals
- The development of new methods for assessing animal welfare
- The impact of environmental enrichment on the welfare of captive animals
- The ethical and legal implications of animal experimentation

Overall, JAAWS is an important resource for those interested in the scientific study of animal welfare and its applications.

3. The Indian Veterinary Journal is a peer-reviewed scientific journal that focuses on the field of veterinary medicine. The journal is published by the Indian Council of Agricultural Research and is widely recognized as a leading publication in the field of veterinary medicine in India.

The Indian Veterinary Journal covers a wide range of topics related to veterinary medicine, including:

- Clinical veterinary medicine
- Pathology and diagnostics
- Animal husbandry and nutrition
- Animal genetics and breeding
- Animal production and management
- Livestock products technology

Articles in the Indian Veterinary Journal typically take the form of original research studies, reviews of the literature, or brief reports. The journal is an important resource for veterinarians, animal scientists, and anyone working in the field of veterinary medicine in India.

In recent years, the Indian Veterinary Journal has published articles on a variety of topics, including:

- The diagnosis and treatment of various animal diseases
- Advances in veterinary surgery
- The development of new animal vaccines
- The nutritional needs of different species of livestock
- The impact of climate change on animal health

Overall, the Indian Veterinary Journal is a valuable resource for anyone interested in the field of veterinary medicine in India.

4. The study "What Studies with Laboratory Animals Might Teach Us about Life in the Dog Shelter," published in the Journal of Animals in 2020, explores the potential benefits of applying research conducted with laboratory animals to the study of dog behavior and welfare in animal shelters. The authors argue that the use of controlled experimental studies with laboratory animals has contributed greatly to our understanding of animal behavior and physiology, and that these findings can be applied to the study of dogs in animal shelters.

The authors review the current state of research on dog behavior and welfare in animal shelters, and suggest that

many of the existing studies have limitations due to the variability of shelter environments and the difficulty of controlling extraneous factors. They propose that the use of laboratory animals can help to address these limitations by providing controlled environments and standardized methods for studying behavior and welfare.

The authors also discuss the potential ethical concerns associated with using laboratory animals in research and emphasize the importance of using appropriate welfare standards to ensure the ethical treatment of animals. They also emphasize the importance of translating findings from laboratory studies to practical applications in animal shelters, such as the development of new housing and enrichment strategies to improve the welfare of dogs in shelters.

Overall, the authors suggest that the use of laboratory animals can provide valuable insights into dog behavior and welfare in animal shelters, and that the translation of these findings to practical applications can contribute to the improvement of the lives of dogs in shelters. The study highlights the potential for interdisciplinary collaboration between animal behavior and welfare researchers, veterinarians, and animal shelter practitioners to advance our understanding of the lives of dogs in shelters.

5. "Animal Shelters and Animal Welfare: Raising the Bar" is a publication in The Canadian Veteran Journal that focuses on the issue of animal shelters and animal welfare. The article provides an overview of the current state of animal shelters and animal welfare in Canada, and highlights the challenges that these organizations face in providing adequate care for the animals in their care.

The article begins by discussing the history of animal shelters in Canada, and how they have evolved over time to become an important aspect of the country's animal welfare system. It then goes on to discuss the challenges that animal shelters face, such as limited resources, lack of public support, and a growing population of animals in need of care.

The article also highlights the positive impact that animal shelters can have on the lives of animals and the communities in which they are located. For example, animal shelters provide a safe and loving environment for animals in need, help to reduce animal homelessness and abuse, and promote responsible pet ownership.

In order to raise the bar on animal welfare, the authors suggest several strategies that animal shelters can adopt, such as improving their policies and procedures, increasing public awareness and education, and seeking more support from the community. The authors also highlight the importance of collaboration between animal shelters, animal welfare organizations, and government agencies to improve the overall quality of care for animals in shelters.

In conclusion, the "Animal Shelters and Animal Welfare: Raising the Bar" publication in The Canadian Veteran Journal provides a comprehensive overview of the challenges and opportunities in the animal shelter system in Canada. It is a valuable resource for animal welfare organizations, animal shelters, and anyone who is interested in improving the lives of animals in Canada.

6. A review of the stray dog population demographics in Jodhpur, India following a population control and rabies vaccination program is likely to provide important insights into the effectiveness of such programs in reducing the number of stray dogs and improving their health. The study would likely assess changes in the size and composition of the stray dog population, as well as the impact of the program on the incidence of rabies in dogs and the wider community. The results of such a study could inform future efforts to control stray dog populations and reduce the risk of rabies in India and other countries.

It is likely that the review would find that the population control and rabies vaccination program was effective in reducing the number of stray dogs and the incidence of rabies in the area. This may be due to a combination of factors, such as the sterilization of female dogs, the vaccination of dogs against rabies, and increased public awareness of the importance of controlling stray dog populations.

The results of the study could also provide insights into the most effective strategies for controlling stray dog populations, such as sterilization and vaccination programs, and the role of community engagement and education in promoting the success of such programs. Overall, the review is likely to highlight the importance of addressing the issue of stray dog populations in India and the role of population control and rabies vaccination programs in reducing the risk of rabies and improving the health and welfare of dogs and communities.

7. A review of community perception regarding rabies prevention and stray dog control in urban slums in India would provide important insights into the attitudes and beliefs of residents in these areas towards these important public health issues. The study would likely assess the level of awareness of rabies and the importance of stray dog control, as well as the attitudes and beliefs towards different control strategies, such as vaccination and sterilization programs.

It is likely that the review would find that there is a need for increased public education and awareness regarding the importance of rabies prevention and the role of stray dog control in reducing the risk of rabies transmission. The study may also highlight the challenges and barriers to implementing effective control programs in urban slums, such as limited resources, a lack of infrastructure, and cultural attitudes towards dogs.

The results of the study could inform future efforts to improve rabies prevention and stray dog control in urban

slums in India and other countries. This could include the development of community-based education and awareness programs, as well as the implementation of effective and sustainable control programs that are tailored to the needs and resources of urban slums.

Overall, the review is likely to highlight the importance of addressing the issue of stray dog populations and rabies in urban slums in India and the role of community engagement and education in promoting the success of control programs and reducing the risk of rabies transmission.

VII. PROPOSED METHODOLOGY

The need of a web service for stray animals. Shelter management is hard work and every day, they deal with the issue of strays, which they cannot handle on their own. A web service for stray animals could be a valuable tool in addressing the growing problem of stray animals in India. By providing a platform for shelters to manage and promote their animals, they can connect with potential adopters and help find forever homes for the strays in their care. This web service could also facilitate community collaboration, allowing individuals and organizations to come together to support animal shelters and their efforts to care for stray animals. With its ease of use and ability to reach a wide audience, a web service for stray animals has the potential to make a significant impact in reducing the number of stray animals in India and improving the lives of both strays and the people who care for them.

A web-based application or smartphone app for stray animals is indeed a great idea, as it has many advantages over traditional methods of managing and promoting animal shelters. By offering an easy-to-use platform, it can help simplify the complex tasks involved in shelter management, while also making it more accessible to a wider audience. The ability to give donations through the app or website can also provide a crucial source of funding for animal shelters, enabling them to continue their important work. Furthermore, with various options built into the service, users can customize it to meet their specific needs, making it a truly versatile tool for supporting stray animals. By leveraging technology in this way, we can make a meaningful impact on the lives of stray animals and the communities they live in.

Other than that, to address this problem, it is important to create more animal shelters, increase funding for existing shelters, and promote animal adoption programs. The government and local communities can play a crucial role in supporting these efforts. Additionally, spaying, and neutering programs can help to control the population of stray animals and reduce the number of unadopted strays. Education and awareness campaigns can also help to raise awareness about the importance of responsible pet ownership and encourage people to adopt and care for animals properly.

Fig.6.1: Analytical Research of the project

VIII. CONCLUSION

The lack of facilities for strays is a serious issue that requires immediate attention. To solve this issue, it is essential to implement effective measures such as spaying and neutering programs, promoting animal adoption, and increasing public awareness about the importance of responsible pet ownership. By working together, we can make a positive impact on the lives of stray animals and the communities they live in.

And as we progress, we have started encroaching on the lands that do not belong to us. And in the process, we have somehow made it difficult for the strays to live out on the streets. The stray problem is something that is not well managed throughout the country and the shelter system is quite unreliable due to the lack of number of shelters.

So to promote the welfare of both humans and stray animals a website/community to help each and every one is needed. We also need to increase the number of shelters available so that they can sustain and help more animals through their service.

Entrepreneurial Competencies, Economic Growth & Challenges: an Explorative Study on Women Entrepreneurs

Sarita Dhal, Nishikanta Mishra, Puspalata Mahapatra, Bhaigrathi Nayak
KIIT Deemed to be University, Bhubaneswar, Odisha, India
saritaatbbsr@gmail.com, nmishrafhu@kiit.ac.in, puspalatam2004@gmail.com, bhagirathi.n@srisriuniversity.edu.in

Abstract **Due to LPG and continued growth in the Indian start-up industry, an increasing number of women are coming forefront and adding to the entrepreneurship segment of India. Creating a business from the beginning stage of conceiving the ideas, till its final stage and also surviving in long run as a profitable venture is a challenging task basically for women. Again these entrepreneurs have to take care of almost all business activities by themselves which starts with starting from brainstorming and vetting potential ideas, setting goals, planning a project, analyzing a product etc. Women Entrepreneurs are seen as a key driver of the economic expansion of each country irrespective of their development status. Despite their significant contributions, it's most important that they remain a small subset of business owners. This investigation into minority groups like women entrepreneurs is an attempt to identify the driving forces behind the rise of female business owners and the challenges they faced and their significant contribution to achieving their economic growth. Descriptive statistics and ANOVA were used to pinpoint many factors that contribute to the success of women business owners of the Kandhamal District of Odisha. This study's findings can guide the government, other institutional networks and support agencies in developing a constructive plan of action and policies to assist women entrepreneurs to succeed in the future and to enhance their ability to overcome their challenges.**

Keywords: Women Entrepreneurs, ANOVA, Statistics, Govt. Policy, Primary Factors.

I. INTRODUCTION

Every country irrespective of their status of development feels the need for entrepreneurs as an important driver for economic development. Entrepreneur development leads to higher growth rates concerning GDP, Employment, Sensex, per capita income, the standard of living, infrastructure and reduction in inflation which in turn lead to the development of the Country as a whole. (Anandalakshmy & kumar, 2018). Due to LPG and continuous growth in the Indian start-up industry, a huge number of women are coming forward to add to the entrepreneurship segment of India. (Sunitha &Sudha,2020). Women's Entrepreneurship greatly upgrades women's position in society and makes them economically sound which in turn makes their families, community and whole country develop (Mishra & Kiran, 2014). In a growing country like India and with the presence of the male dominant society Women entrepreneurs need support and guidance from their families and spouse to become successful. Among many factors accountable for influencing a woman to become an entrepreneur the key reasons are a reduction in the number of jobs, a lifestyle change, an increase in expenses, Financial independence, increase in family income (Sunitha, 2020). With profound struggle when women are becoming an entrepreneur and start their businesses also face many challenges like gender discrimination, getting funds and financing, acquiring the key competencies, and getting access to technology to make their enterprise successful. Though the Govt. has taken many initiatives for extending help to women entrepreneurs in both rural and urban areas still it is not result-oriented and successful. (Sunitha,2020). As is suggested by many researchers that for overall economic development, the contribution from rural women entrepreneurs is equally needed. Women's entrepreneurship growth and development are correlated with women's empowerment which makes them financially independent, self-sufficient and socially and economically sound. For setting own businesses both men and women face many challenges but for women, the barriers are more than their counterparts and they are confronted with a lack of Govt. support, limited access to bank accounts, and less freedom to get credit and loans. They get less education, skill training and carrier guidance, (UNIDO, Gender, 2014). Cultural values also influence women entrepreneurs and family responsibility also creates challenges for them to become a success. The planning commission including the Indian Government perceives the importance and need of women for their contribution to economic development and as a strategic solution for poverty alleviation both in rural and urban areas (Sumana.M, 2015).

When the conditions are going in the right direction, people are more likely to take the initiative to start their new businesses, which in turn stimulates the economic growth of a country. Women entrepreneurs are essential for achieving the aforementioned goals like economic growth because their proportion is almost nearer half of our population. Here the researchers tried to study women entrepreneurs who face lots of challenges in the district of Kandhamal, one of the state's more backward regions. Women's entrepreneurship in this district has been

studied to determine under different socio-economic factors, such as age, education, marital status, and motivation to know whether these factors affect their success and growth or not. When it comes to a country's progress, it's crucial to invest in its women, as they account for nearly half of the population. On ethical and humanitarian grounds, women must take part in economic activities as an entrepreneur and should occupy an equal footing with men in every aspect. Worldwide, the number of unemployed women has been rising at a faster rate than that of unemployed men recently. Women have historically faced discrimination and a lack of opportunities in the business world. This was nothing new; just as the labour market had traditionally been male-dominated, so too had knowledge been divided along gender lines, suggesting that men and women should approach business in different ways (Labour bureau, 2015). Women have traditionally been under-represented in business ownership, in part because they hold fewer managerial positions than men, have less access to capital, and are more likely to be the primary caregivers for their children and the home. Women in traditionally patriarchal societies, such as those in Asia and India, rarely take part in decision-making involving issues outside the home. However, changes in educational opportunities, employment rates, and economic status for women have all contributed to a rise in female entrepreneurship in recent years. In recent years, more and more women have shown an interest in earning their own money, working for themselves, and starting their businesses. This paper mostly focused on identifying the major factors and their impact on the development and other challenges of the women entrepreneurs of Kandhamal Districts. The proposed paper has been structured as follows: Section-I gives a brief introduction about the key competencies of women entrepreneurs, the challenges they face and their contribution to economic growth which is the motivation of the study, Section II deals with previous literature related to growth, importance, and challenges they face and Section III covers conceptual explanation about women entrepreneurs, section-IV is devoted to used methodology and analysis with its findings followed in section -V which describes detailed discussions which were extracted form use of PCA and ANOVA. Section - VI is the concluding section that summarises the entire article and suggests a direction for further research.

II. LITERATURE REVIEW

Lerner and Almor (2002), examined and found a link between the skill, competencies and growth and performance of Women entrepreneurs[11]. Man and Lau, (2005) highlighted that Entrepreneurial competencies include many skills that are grounded and related to personal things like traits, personality, attitudes, and social roles and which can be achieved through education, training and experience [13]. Man et al. (2002), described that an entrepreneur to play his or her role properly and effectively in a responsible way needs ability like entrepreneurial competencies which are known as entrepreneurial skills [12]. Lerner and Almor (2002), while doing their study on women entrepreneurs came to know that managerial skills and entrepreneurial skills contribute significantly to their success of them. It includes finance, proper management of human resources, proper production and operation activities, creativity, innovations and marketing products [11]. Chandler and Jansen (1992), who did their study on the state of Utah, found that identification and prioritisation of entrepreneurial, technical and managerial functions are three areas the entrepreneurs must employ to become successful [5]. Mitchelmore and Rowley (2010) observed in their study and then suggested that managerial competencies which include functional and organisational competencies are very vital for the growth and long-term survival of entrepreneurs [15]. Satpal & Rupa (2014) & Orser, Riding and Manley (2006) suggested sixteen areas of similar expertise which include Marketing opportunities, Strategic Planning, and effective management which are very crucial among them for making entrepreneurs more successful in the long run [20][16]. Man et al (2002) under their study identified six competency areas like Opportunity, interpersonal relationship, organising, conceptual and commitment competencies which are key to their success.[12].

Jennings and Cash (2006) pointed out that there is a difference between male and female entrepreneurs concerning aspects like capital investment, thinking, perception, knowledge, technical skills, motivation, personal background, risk-bearing capacity and support from their family etc. [9] Carter and Shaw, (2006), talked that women business proprietors enjoy a lower status either concerning organising human capital, personal socio-cultural background and working experience or negotiation skills while managing their entrepreneur [4]. According to Driessen and Zwart (2006), the competencies and key skills of entrepreneurs include experience, knowledge, motivation, capacity and entrepreneurial features (personal qualities) for growth [7]. Cardella (2020) discussed the reasons that motivate them to choose entrepreneurial activities both for men and women. In general, male entrepreneurs give importance to reasonable incentives, job certainty, growth and development scope whereas female entrepreneurs prefer to make a better balance between work and family, use initiative and get recognition while pursuing an entrepreneurship carrier [3]. According to Pihie & Bagheri (2011), women entrepreneur's personal and functional competencies are made-up skills, attitude, knowledge and family support to make them successful [17]. Rotefoss & Kolvereid (2005) did a cluster analysis and found out that entrepreneurial education plays a crucial role in developing entrepreneurial intentions among women and bridging the gap between men and women [19]. In a study conducted by Dawson and Henley(2012), it was found that due to differences in risk

attitude, there is a huge gap between men and women entrepreneurs in starting an entrepreneurial carrier. Again women's less participation is due to fear of failure, less support from family and poor social networks [6]. Anandalakshmy. A (2018) told about the problems and challenges the women entrepreneur are facing in India to start and operate their businesses [2]. These are non-availability of adequate capital, dual role play, restricted freedom, less Knowledge of information technology and less awareness about different schemes offered by Govt.

As per the suggestion given by Mishra (2015) after analysing 48 articles suggested that self-confidence, institutional support, and the ability to avail the credit facilities and social networks play a very important role for an entrepreneur for long-term survival and achieving success [14]. Afsaneh & Zaidatol (2011), of them, highlighted that personality factors which include self-efficacy and risk appetite and contextual factors like social media are highly relevant and significant for the sustainable business of women entrepreneurs and to make them successful [1]. Kulkarni1, Srinivas (2020) has identified that nowadays Govt. has increased its assistance to women entrepreneurs to make them socially and economically well accepted. Though the growth and development of women entrepreneurs depend upon many socio-economic factors but Govt. policies play an important role and their development will no doubt raise the status of women socially and economically [10]. As per the united nations report (UNIDO) 2017, female entrepreneurs face many problems in getting loans to form financial institutions including Banks, even though their repayment rate is more than their counterparts [23]. This is either due to discriminatory attitudes or less faith in them for paying the debt. Women entrepreneurship highlighted that lack of knowledge for marketing the products, getting loans and subsidies, less awareness about Government assistance and lack of family support are important challenges faced by women entrepreneurs while pursuing and developing their businesses. Tlaiss (2014) talks about the obstacles women entrepreneurs are facing in many developing countries including India [22]. Women entrepreneurs lack to access finance from banks get proper relevant education and expertise, are overburdened with household activities, are incapable to get proper practical and self-employed training, attending meetings conducted by Govt. bodies etc. All these bottlenecks are limiting the capacity of women entrepreneurs to excel in their competencies in performing their responsibilities towards the development of business establishments.

Women Entrepreneurs, Challenges & Economic Development

As per the survey conducted by the sixth economic Census (Ministry of Statistics, 2021) that only 13.76% of women entrepreneurs out of the total entrepreneurs of India. Again 2.76 million work in agriculture and 65% approximately 5.29 million are workings in the non-agriculture sector out of total business establishments. Among the different states of India, Tamilnadu has the highest 13.5% followed by Kerala at 11.35% and Andhra Pradesh at 10.56%. While running their business women faces many obstacles and challenges which hinder their growth and success. These problems may be concerning Finance, Marketing, Health, Entrepreneurial Attitude, Technology Access, Availability of workspace and boost of confidence. Rakesh(2016), pointed out that for the growth of rural areas, there is significant growth of women entrepreneurs but their development is very low as they face many challenges & problems. Studies conducted by many researchers suggest that among many obstacles lack of education, knowledge & Skill, biased attitude, and poor infrastructure support, are the major barriers which restrict the growth and development of entrepreneurial activities of rural women entering into this segment. In some situations, it is also observed that psychological and physical pressure also acts against women entrepreneurs to proceed further.

Entrepreneurship is a human endeavour that significantly contributes to economic growth and one of the identified findings is that there is a strong correlation between entrepreneurship and of economic growth of a country. It's not hard to draw parallels between the role of entrepreneurs and the growth of economies. Generally, women enter into the entrepreneurship segment due to economic factors and the mindset to do something independently, (Shabunath,2021). The role of Women entrepreneurs in the economic development of any country needs to be considered for several reasons as reported by (Nicholas and Victoria, 2010). It has been observed that there is a positive connection between economic growth and women entrepreneurs as they help in accelerating growth through the creation of a job, increasing savings and thereby creating growth in the industry. Rural women entrepreneurs no doubt will contribute to the wealth improvement of their family and their nations, (Kiran 2014). For the improvement of the rural economy through rural development, rural entrepreneurship is very much needed and it works like a growth engine for the quality of life of rural people and their economic and sustainable development. (Raju & Bhubaneswar, 2014). Women are crucial to the success of the household economy. Govt Schemes, policies, & programmes have made the growth and development of women entrepreneurs across the Tamil Nadu state and their economic and social status has improved after entering into this profession, (Joseph,2020). Women's attitudes have undergone dramatic shifts due to the technological and industrial revolutions in the realms of education and social and economic necessities. The last decade has seen a rise in women's access to economic opportunities. Women's participation in the workplace is a relatively recent phenomenon. Women's emergence as business owners is a major step toward their economic independence and the recognition and respect they deserve in all spheres of society. Women's involvement in

business would bring a calming influence to today's troubled world, paving the way for more harmony and cooperation. Women in India are encouraged to pursue self-employment by both the government and private organisations in several different states, including Gujrat, Kerala, Punjab, Delhi, Karnataka, Andhra Pradesh, and Tamil Nadu. The growth of the women-owned business sector in the country is undoubtedly boosted. Women's entrepreneurship in India is typically associated with more traditional industries, such as the production and sale of papad, pickle, clothing production and so on. Manufacturing, exports, the service industry, businesses with high revenue generation, etc. are all areas where women are gradually being encouraged to start their businesses.

III. OBJECTIVES AND HYPOTHESES

The study tried to pursue the following objectives

- Identify the crucial factors/ Key Competencies accountable for the expansion and magnification of women's entrepreneurial occupation.
- Examine the relationship between Challenges faced by Women entrepreneurs and Govt. Policies
- Determine whether business networking influences the performance of women's entrepreneurial activities.

IV. HYPOTHESIS

- H10: There is no significant relationship between entrepreneurial activities and their contribution to the economical growth of women entrepreneurs.
- H1a: There is a significant relationship between entrepreneurial activities and their contribution to the economical growth of women entrepreneurs.
- H20: There is no significant relationship between Govt. policy and the economic challenges of women entrepreneurs.
- H2a: There is a significant relationship between Govt. policy and the economic challenges of women entrepreneurs.
- H30: There is no significant influence of business networking on the performance of women entrepreneurs.
- H3a: There is a significant influence of business networking on the performance of women entrepreneurs.

V. METHODOLOGY AND ANALYSIS

The following conceptual models proposed here require first being operationalized so that they can be empirically tested. Therefore, a set of indicators is required to evaluate the conceptual model's frameworks. Care has been taken in selecting parameters for overall satisfaction to fully exploit the theoretical constructions available. In the following paragraphs, researchers look at some of the possible applications of these frameworks.

Conceptual Framework of the Study

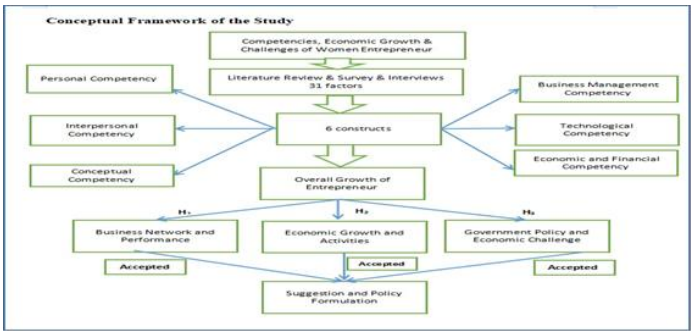

Figure 1: Conceptual Framework

This study involves the collection of primary data through our survey and interviews and secondary data from books, Journals and different reports. The researcher surveyed with our designed questionnaire from the women entrepreneurs, from the Kandhamal districts of Odisha which were collected from the sample size of 148 respondents as per random sampling. Our questionnaire is designed with six major parameters of Entrepreneurial Competencies i) Personal, ii) Interpersonal, iii) Conceptual, iv) Business Management, v) Technological, and vi) Economic & Financial Competencies. Each parameter are having five questions on a five-point Likert Scale. After collecting data, the empirical research provided an overview of data analysis and demonstrated the hypothesis through PCA and ANOVA. Statistical methods are the mathematical formulas, models, and techniques used to analyse raw study data statistically. The reliability of the findings can be evaluated with the help of statistical methods gleaned from survey data. Before conducting the pilot test and determining the sample size for our questionnaire, we performed a factor analysis to determine the relative importance of the factors under consideration. Then we used analysis of variance (ANOVA) to assess the economical growth and challenges of the key competencies of women entrepreneurs.

Data Analysis and proved hypotheses:

This empirical study explained the data analysis and proved the hypothesis in statistical analysis using PCA & ANOVA.

Eigenvalue			
Questions	Eigenvalue	Mean	Std. Dev
Q1	2.476	1.268	1.518
Q2	1.112	2.185	1.678
Q3	0.919	3.241	1.62
Q4	0.873	1.173	1.051
Q5	0.889	4.081	1.462

Table 1: Data Reliability of Hypothesis

After Principal Component Analysis (PCA), we can assess the validity of our data and the precision with which we measure it. Cronbach's alpha is 0.842, which indicates an extremely high degree of reliability of the data. All five questions are met by the eigenvalue Q1: 2.476, Q2: 1.112, Q3: 0.919, Q4: 0.873, and Q5: 0.889. So we can consider all questions for our analysis because all values are in the higher range and greater than 0.7 of the eigenvalue.

Hypothesis H1:

ANOVA TEST

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	16.9114198	4.2278549	5.62	0.0002
Error	715	537.8649691	0.7522587		
Corrected Total	719	554.7763889			

R-Square	Coeff Var	Root MSE	Score Mean
0.030483	27.28163	0.867328	3.179167

Source	DF	Type I SS	Mean Square	F Value	Pr > F
Source	4	16.91141975	4.22785494	5.62	0.0002

Table 2: ANOVA Table of Hypothesis H1. Fit Statistics

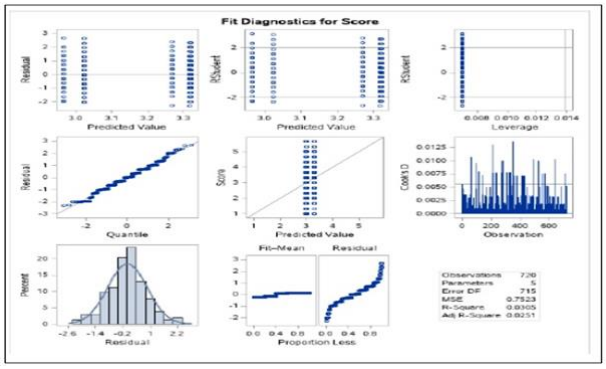

Figure 2: Fit Diagonestics of Hypothesis H1.

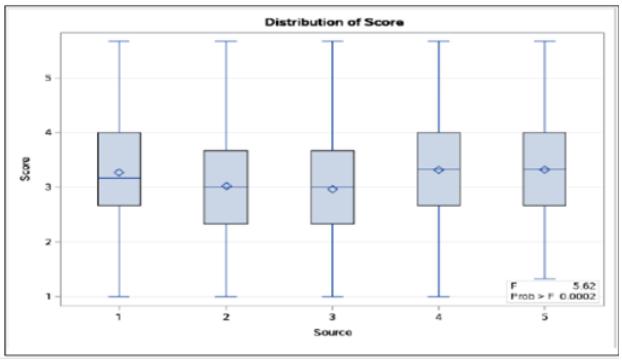

Figure 3: Box Plot of Hypothesis H1.

Table (1) shows the consistency of the eigenvalue, which is critical when verifying data. Each of the eigenvalues for each of the six criteria is larger than 0.7, which is a very good sign of the criteria's reliability. Since our data has high Cronbach's Alpha and eigenvalue reliability, we can conclude that our analysis is rigorous. Figures 2 provide clear depictions of the PCA scree plot and the component scores matrix, respectively.

Hypothesis H2:

Eigenvalue			
Questions	Eigenvalue	Mean	Std. Dev
Q1	1.326	3.028	1.218
Q2	2.128	1.131	1.718
Q3	0.983	1.541	1.612
Q4	0.975	2.124	1.271
Q5	1.299	4.081	1.241

Table 3: Data Reliability of Hypothesis H2

After Principal Component Analysis (PCA), we can assess the validity of our data and the precision with which we measure it. Cronbach's alpha is 0.802, which indicates an extremely high degree of reliability of the data. All five questions are met by the eigenvalue Q1: 1.326, Q2: 2.128, Q3: 0.983, Q4: 0.975, and Q5: 1.299. So we can consider all questions for our analysis because all values are in the higher range and greater than 0.7 of the eigenvalue.

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	98.0669753	24.5167438	36.82	<.0001
Error	715	476.0871914	0.6658562		
Corrected Total	719	574.1541667			

R-Square	Coeff Var	Root MSE	Score Mean
0.170803	26.79070	0.816000	3.045833

Source	DF	Type I SS	Mean Square	F Value	Pr > F
Source	4	98.06697531	24.51674383	36.82	<.0001

Table 4: ANOVA Table of Hypothesis H2

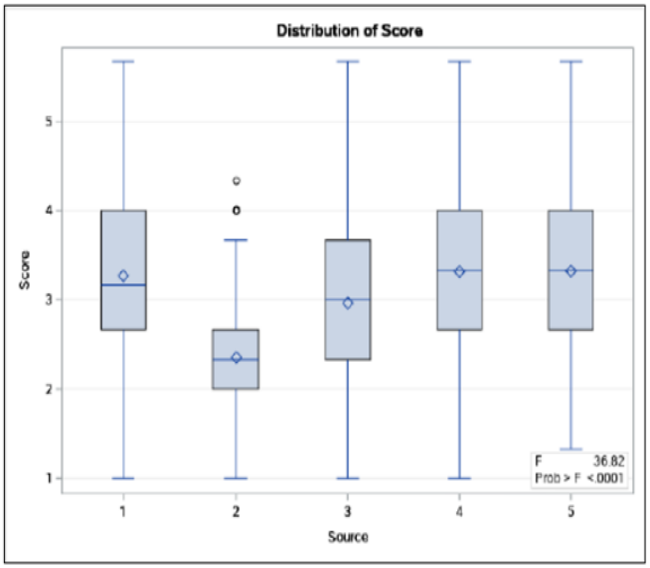

Figure 5: Box Plot of Hypothesis H2

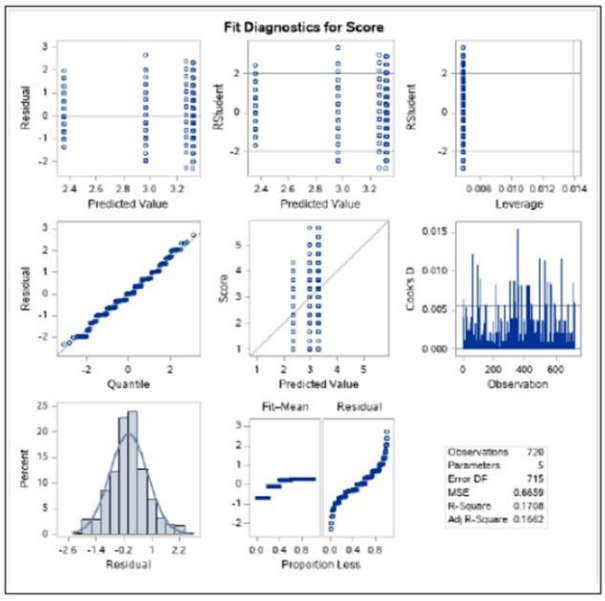

Figure 4: Fit Diagonestics of Hypothesis H2

The above ANOVA is applied to test the hypothesis. The ANOVA results as given in table 3, show that the calculated "F" value is (36.82), which is quite good and the "P" value is (0.0001), which is less than 0.05 of significance. Hence the null hypothesis H20: "There is no significant relationship between Govt. policy and the economic challenges of women entrepreneurs" is rejected, whereas the alternative hypothesis H2a: "There is a significant relationship between Govt. policy and the economic challenges of women entrepreneurs." is accepted. It is inferred that the Govt. Policy and schemes are most important to overcome the challenges faced by women entrepreneurs at different levels may it be Block, Panchayat, or District or State level.

Hypothesis H3:

Eigenvalue			
Questions	**Eigenvalue**	**Mean**	**Std. Dev**
Q1	1.219	3.218	1.118
Q2	2.273	2.132	1.653
Q3	1.325	1.441	1.204
Q4	1.649	2.024	1.381
Q5	2.173	4.691	1.412

Table 5: Data Reliability of Hypothesis H3.

After Principal Component Analysis (PCA), we can assess the validity of our data and the precision with which we measure it. Cronbach's alpha is 0.823, which indicates an extremely high degree of reliability of the data. All five questions are met by the eigenvalue Q1: 1.219, Q2: 2.273, Q3: 1.325, Q4: 1.649, and Q5: 2.173. So we can consider all questions for our analysis because all values are in the higher range and greater than 0.7 of the eigenvalue

ANNOVA TEST

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	133.7253086	33.4313272	45.74	<.0001
Error	715	522.6296296	0.7309505		
Corrected Total	719	656.3549383			

R-Square	Coeff Var	Root MSE	Score Mean
0.203739	29.83370	0.854956	2.865741

Table 6: ANOVA Table of Hypothesis H3

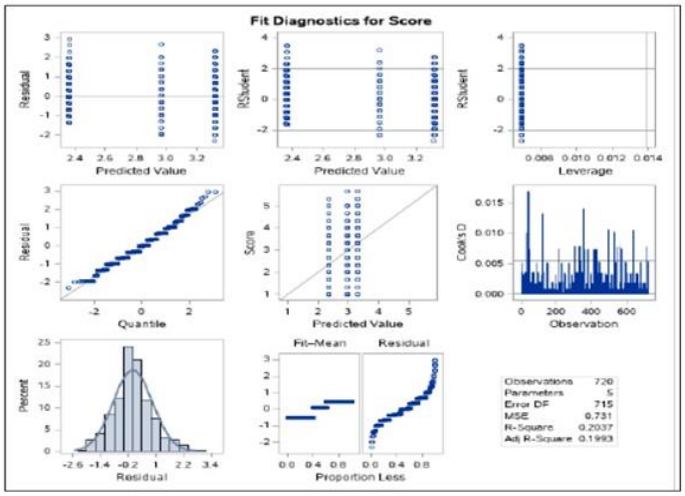

Figure 6: Fit Diagonestics of Hypothesis H3

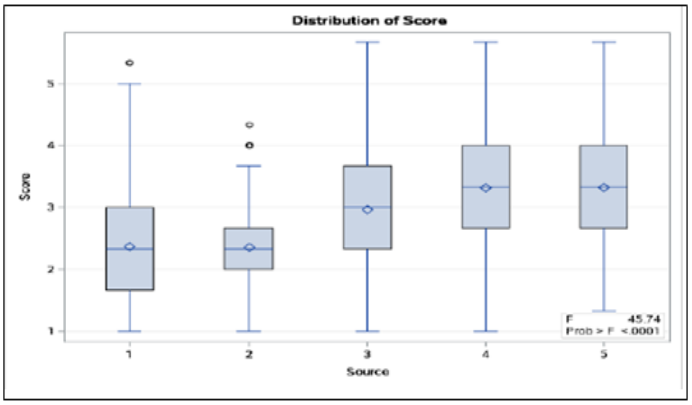

Figure 7: Box Plot of Hypothesis H3

The above ANOVA is applied to test the hypothesis. The ANOVA results as given in table 4, show that the calculated "F" value is (45.74), which is quite good and the "P" value is (0.0001), which is less than 0.05 of significance. Hence the null hypothesis H30: "There is no significant influence of business networking on the performance of the women entrepreneurs" is rejected, whereas the alternative hypothesis H3a: "There is a significant influence of business networking on the performance of the women entrepreneurs" is accepted. It is inferred that business networking is an art form, and one should be adept at it as an entrepreneur. Business

networking is all about bringing people together who can help each other's business activities and problems.

VI. FINDINGS AND DISCUSSION

This study tries to find out the key influential factors for the growth and success of women entrepreneurs and the challenges and hurdles they face during their entrepreneurship tenure. Again the study is interested to unveil the facts that starting their own business, influences the economic and financial condition of their family and country as a whole. There are many Govt. launched schemes which help them to face the challenges which generally restrict their entrepreneurial growth. The data analysis suggests that the key competencies which are responsible to make them successful and make them self-dependent are Personal Skills (1st), Economical & Financial (2nd), Business Management (3rd), Technological (4th) Interpersonal (5th) and Conceptual Competencies (6th) respectively. So it is well accepted that personal skills like Spotting Opportunities, Commitment to work, Motivation & Preservance, Self-efficiency & Self-confidence, Information seeking and Problem-Solving skills will make entrepreneurs more competent in doing their own business. The study also reveals that there is an influence of personal networking with the performance of the business owned by them and it has a significant impact on the success of entrepreneurial activities performed by women. It is inferred that business networking is an art form, and women should adopt it as an entrepreneur to survive and succeed in the long run. The networking will be beneficial to the rural women entrepreneurs in performing their enterprise-related activities like spotting business opportunities, getting moral support, enhancement of access to financial assistance, availing different Govt. schemes, acquiring technical support and understanding entrepreneurial orientation like creativity and innovativeness which will make them more proactive of success.

Concerning the fourth objective to conclude the interconnection between different Govt. Schemes and challenges faced by women entrepreneurs, it is explored there is a significant influence of the former to the latter. That indicates that if women entrepreneurs will be aware of many schemes launched to grow their small businesses both by Central and state Govt. like Annapurna Scheme for catering, Stree Shakti for (EDP), Dena Shakti (Manufacturing), Orient Mahila Vikas Yojana(Small Business) then the impact of challenges to them will reduce to a great extent. Other than these schemes Govt. have established many institutions to fulfil the needs of women business owners. The Platform for Women Entrepreneurship (WEP) is the WEP, which was launched by the NITI Aayog, and it aspiring and established women entrepreneurs in India. It's broken down into three sections and each one has different objectives like Iccha, Gyana & Karma Sakti for encouraging, educating and providing hands-on assistance to women entrepreneurs to expand their businesses. We found that if women will aware of and access all these schemes and facilities provided by different levels of Govt. automatically the effect of challenges will come down and they can overcome them.

VII. CONCLUSION

The study demonstrated that in rural areas like Kandhmala of Odisha, women enter into entrepreneurial activities by establishing their businesses due to many pull factors like exclusive accomplishments, responsibility towards family becoming self-sufficient & self-reliant and avail autonomy status. It is also noticeable from the study that a significant portion of women entrepreneurs became a success due to a combination of many competencies like self-confidence, strong willpower, determination, passion for their desired business and entrepreneurial spirit and tenacity. These competencies not only help them to become success also helps them to overcome the hard challenges during their entrepreneurship tenure. The findings of the study will enhance the personal and entrepreneurial skills of Women who have opted to take up business ownership status by providing new insight.

VIII. LIMITATIONS OF THE STUDY

The investigation here is limited to the women entrepreneurs in the Kandhmala district of Odisha but similar studies can be generalised further by doing it in other districts of Odisha and India and also by taking the other key competencies into account also. Here stratified sampling is adopted so that an overall view can be drawn from the studies but other studies can apply different sampling to pursue their study.

Ambulance Emergency Route Optimization (AERO)

Arya Dubey, Rachit Gupta, Sahil Patil, Mrs. Neha Kapadia
Information Technology, Thakur College of Engineering & Mumbai, Maharashtra India
aaryakdb@gmail.com, rachitgupta209@gmail.com, sahilpatil1792@gmail.com,

Abstract— **This research proposes an optimized routing system for ambulance using algorithms and data sets for a particular area. This study goes into great detail about the variety of routing issues, such as picking the quickest and best route to bring a vehicle to its destination in the shortest period of time while avoiding traffic jams. This research also discusses about how road networks are seen in relation to graphs and how techniques for traversal and path discovery, such as Dijkstra's algorithm and the A* method, can be used. In order to determine which areas have a greater or lesser need for ambulances and to allocate the appropriate number of vehicles, data sets from a region will be collected. Optimizing the route so that nearest ambulance can reach the required accident location as soon as possible.**

Keywords— Route Optimization, Allocation, Routing Techniques, Dataset Mapping.

I. INTRODUCTION

Human Nature involves movement from one place to another which increases traffic on the route of the movement, the increased traffic eventually leads to traffic congestion. Traffic congestion leads to long hours of waiting time to go from one place to another. To overcome this people often look for an optimized route which can take us to our destination in less time and through shortest distance. Most need for optimization route is during emergency. In India we don't have dedicated service lane for during emergency and due to congestion it leads to delay in reaching the accident location, which puts the patient at high risk sometimes causing death. Due to this route optimization and allocation is very necessary for ambulance system.

AERO is an ambulance emergency service application and website which will assist ambulances in determining the best and an optimized route to the accident place where the caller has requested for immediate assistance. Ambulance would be distributed with the help of the previously collected data of a particular region which will help us to plot a graph database. Accordingly, if a certain zone receives more emergency calls, we can allocate more ambulances so that they can use our application's route optimization to get there in the shortest amount of time.The user must register and verify himself so that we know the user is legit. The user will be able to view Google Maps using Google API and will be able to see the time required. When an emergency call is placed, the programme will look for the closest ambulance and notify the driver, allowing him to get at the scene as quickly as possible. The user would get the driver's contact information and his most recent location, which would be shown on Google API. With the aid of route optimization, the ambulance would be able to transport the patient to the closest hospital, and the time needed would be minimised to the greatest extent feasible, which is vital for the patient.

II. RELATED WORK

The ambulance routing problem is a well-known issue and numerous researchers have offered their own solutions using various routing strategies. One of the critical missions that ambulance services strive to provide is the ability to save injured or severely ill individuals and reduce mortality even in the event of a pandemic or a grave disaster, such as a volcano eruption, flood, storm, earthquake, etc. In other words, the main objective is to determine the most optimal route for the ambulance and get patients to the hospital in minimum time. This research has investigated different factors that several studies may have considered while devising a model for the route optimization.

A. Ambulance Allocation

The allocation problem has been extensively studied during the last few decades. Locating ambulances is a challenge for emergency service providers in order to properly meet any potential future demand. Ambulances should be stationed at predetermined areas so that in an emergency it will be easy to get to the patients quickly. (Brotcorne,2003) developed a mathematical model after thoroughly examining how ambulance location and relocation models have changed over the previous 30 years. (Gendreau,2001) looked into locating idle ambulances, examined the variations in rescue coverage, and presented a dynamic model and dynamic ambulance management system. incorporating real time traffic information and GIS data to dynamically update the suggested route while the user is really driving. The number of nodes used to determine the shortest path gradually reduces as the ambulance gets closer to the scene of the accident, reducing the computing time.between multiple points.

B. Optimal Route Selection

III. METHODOLGIES

I. VARIOUS ROUTE OPTIMIZATION TECHNIQUES A road network is viewed in reference to graph

theory as positive weights graph whose nodes correspond to junctions of the road and the graph edges are road sections (paths) between the junctions. The length (distance) of the road section represents the weight of the edge. Several algorithms use these properties and consequently are capable of computing the shortest path faster than the use of general graphs.

A. Dijkstra's Algorithm

The foundation of shortest path algorithm is the Dijkstra's algorithm. Dijkstra's algorithm computes the shortest paths from a particular node which is the source to every other available node. The nodes are visited in sequence following the shortest path from the origin by the algorithm. When all the goal nodes are visited, it stops the sequence. Dijkstra's algorithm resolves problem in single source shortest path and it is not available for graphs with negative edge weights.

B. A* Search Algorithm

A* search algorithm is an algorithm which is generally useful in graph traversal and path discovery. It is a technique for plotting a viable path connecting several nodes. Heuristics are used by A* to achieve better time performance. In order to achieve target it uses lower bounds on target distance to straight the search of Dijkstra's algorithm to the goal. The node is resolved in order of their provisional distance between the origin and plus the lower bound. The effectiveness of this approach depends highly on the lower bounds. The nodes geographic coordinates determines the simplest lower bounds in road network and this results to poor performance. A* algorithm and graph were used in the development of a novel algorithm for a self-aware route planning. The algorithm was able to forecast traffic and planned route for each car.

IV. PROPOSED WORK

Route Optimization is used widely for vehicle routing, geographical mapping, and various other routing application to give an optimized route with reduced travel time and least amount of hindrance which helps a business to stay cost effective. Our approach to the problem is divided into the following steps:

A. Allocating Ambulance Site

Using the local data, we will allocate various ambulance site in our application which will act as nearby source to the given destination. Our algorithm will use these sources as a starting point. It will also be useful for a variety of information, such as available drivers and ambulances.

B. Initiating requests

The user will need to start a request through our application in an emergency. This will search for any nearby free ambulance in a certain radius and the nearest vehicle will be reserved.

C. Processing Requests

After a request is initiated, the location of the user is sent to our application. Once this request is accepted by the driver or assigned to a driver by a hospital, the user's location is directed into our Routing application as the destination and an optimized route will be displayed on the driver's hardware. Here, we would only use Google Maps API's location service to track and display the appointed ambulance location on the user side and not for routing purpose.

D. After Pick-Up

After reaching the destination, if the patient condition is critical then an optimized route to the nearest hospital would already be calculated and all it would take is to press the emergency pop-up. If the condition is not critical then the route towards registered ambulance's hospital is selected by default.

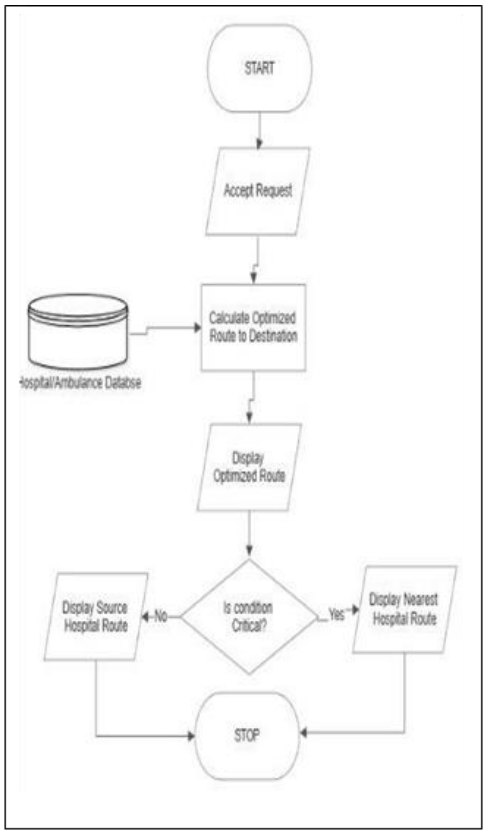

Fig 1: Step By Step Approach

V. RESULT AND DISCUSSION

The proposed methodology would likely help the ambulances reach on time and avoid any fatal situation which would probably occur if a unoptimized path was chosen. After going through various research paper and studying the techniques used for optimization will help to build a working model.

VI. CONCLUSION

The application aims to provide an optimized route for ambulances towards the requested location. Firstly, various ambulance sources will be mapped in our

application using local database. If requested, after reaching the location it will automatically provide an optimized route toward nearest hospital. For calculating the optimized route various algorithms like Dijkstra's algorithm, a* algorithm, Genetic algorithm, etc. will be used. For requesting ambulance, the application aims to provide a simple and clean UI which could be used by any age groups

VII. ACKNOWLEDGEMENT

This paper and the research behind it would not have been possible without the exceptional support of our teacher and project guide, Mrs. Neha Kapadia. This research was supported by Thakur College of Engineering and Technology. We thank our faculties from our institution who provided insight and expertise that greatly assisted the research. We would also like to show our gratitude to Mrs. Neha Kapadia for sharing her opinion and thoughts with us during the course of this research.

Rejuvenating The Pilgrimage Sector Using Information Technology

Arman Kazi, Nikhil Jha, John Sony,
Thakur college of engineering and technology, Mumbai, Maharashtra, India
armankazi02@gmail.com, nikhiljha03@gmail.com, johnsony04@gmail.com

Abstract— **This paper aims to cover the revolution that can be achieved by bringing the scopes of computing and IT in the pilgrimage sector. Pilgrimage till now is such a niche sector where the steps of starting till the end of the devotee's journey is whole and sole in the hands of the government. The devotee has to take a lot of efforts to register himself in the registry of government then using another technologies to see the better routes and stays are pretty much for the devote to handle. IT can be used to make the steps easy making it more of a comfort side for the devotee to be in. A separate IT software can be created in order to make a whole cluster of all the necessary steps to be taken. This paper aims to bring limelight to the development in the sector of pilgrimage as it can make the devotee's journey a lot more fulfiling. Our project looks after the problem that a pilgrim may suffer which can be reduced by our program. A tourist when decides to take on a journey he/she can get the safe and fulfilling steps to be taken due to various computing and it miracles. But specially for pilgrimage there is no single point of contact for the devotee/pilgrim to be in. Our program can looks after the easy registration of the pilgrims in the registry of the pilgrims. It can guide the pilgrims for all the precautionary steps to be taken by them. Our program looks after the problem of staying of the pilgrims while pilgrimage , our software can suggest the best inns and stays of affordable prices for the pilgrims. Our program can be a kind of tourist guide which will guide pilgrims to their destiny. Various technologies are used in order to create the interactive user interface of our program. Html, css, java, bootstrap, node, express and many more frameworks and tech are used in order to achieve our software. Our program also has database facility in order to get previous travel log of a particular pilgrim. Database technologies like MongoDB is used in order to keep track of all the steps and travel destination of the logged in pilgrim. Pilgrimage in its own is a vast sector to be in as it has various problems that can be identified and resolved. Our software can mostly resolve all the problems faced by the pilgrims. Problems like having the best stays, easy registration, easy routes to be in, easy travel partner to find like rickshaw and palkis in pilgrimage like Pilgrimage, having the climate conditions forehands to the users(as climate is a huge factor when carring on for the pilgrimage like Kedarnath) and many more. This review has examined the growth and development that can be brought in the field of religious tourism. This paper in turns highligh the problem that can be faced by the pilgrims and giving the utmost solutions to it. It also gives the government a better hand to handle the pilgrim registry problems. Hence our program has a scope of bring a kind of computing revolution in the field of pilgrimage.**

Keywords— IT, pilgrimage, registry, database, html, css, javascript, government, computing, revolution.

I. INTRODUCTION

Pilgrimage is an age old tradition that has been followed throughout all times. Recent tourism is an upbringing of this age-old tradition. Pilgrimage is such a niche sector in which IT has been brought but has never been flourished. There are various software related to various problems which are faced by tourist while undertaking a tourism. Problems like knowing better routes for the destination, knowing better hotels and its cost of living, knowing the best climatic condition to be in, knowing the best way to communicate with the guide and many other are resolved for the recent tourism sector, but when it comes to the pilgrimage, this gets diminished. A software can make a pilgrim to be self centric toward all the similar problem faced as followed above. Our software makes all this problems resolving in a self centric manner. Our software can guide the pilgrim just like a human guide can during their pilgrimage. Our software can guide then the better stays, better routes, better transport facilities(even in the terrain areas like kedarnath palkis system). Information technology can be embedded in the pilgrimage sector in order to create the same satisfaction that the tourist get when he/she uses the tourism related applications. The application uses various algorithms such as linear regression, rainforest algorithm in order to get the suitable inns/hotels in the route to the pilgrimage. Various climate detection algorithms like SACZ, Ocenic SACZ etc are used in order to provide the pilgrim with the most up-to- date climatic changes. All concepts of climate change that can be used for 'detection' and 'attribution' are as same as given in(IPCC, 2001; MITCHELL et al.,2001).

III. RESEARCH METHODOLOGY

Existing System Other existing applications are available in net which just gives a solution to a specific problem just like having best place to accommodate in or best transport to take from a specific point to a specific point. Applications are based on only one or maybe two problems faced by any tourist and for any tourism spot. But a tourist guide only based on pilgrimage is not available till yet. This problem of self centered pilgrimage application is been created by us. Basically we will include all the facilities that the existing system provides the tourists but being more self centered toward the pilgrimage pilgrimage. Also it will include all the process assistance that the tourist has to go through. The Existing system earlier consisted of following operations-

- Manually Searching the hotel or inns
- Getting data from respective hotels or inns.
- Getting data from third party websites which hardly considered the necessary parameters for the transport searching tool.

1).Absence of Recommendation System

The recommendation system is a very essential tool to provide list of hotels or ways of transport to the users which is evaluated automatically by the program based on the input data provided by the user after logging in the system

1. There are various sites which provide hotel or ponies finding finding facility but there are very few who provide recommendations to their registered users.

2. This system is necessary to reduce the efforts of the user for getting an insight of which conditions he can apply for and have chance for getting an ease toward it.

3. This system analyzes and generates the list of hotels/inns that a user can apply for based on his /her financial backgrounds.

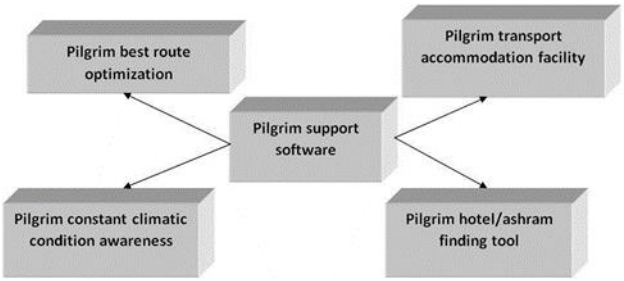

Figure 1: Attributes of the proposed system

IV. RESULTS AND DISCUSSION

To overcome the drawback of existing system we have developed new system, which is a web based application in which the tourist can simply search or explore the inns/ashrams anonymously. It also provides a special unit

which specifies various options for specially- abled provision as well. It is most reliable & time saving system for searching relevant and appropriate hotels from the comfort of your device. A.Architecture of Proposed System The components of the system are as explained below:.

Hotel Database: The database is a repository for storing the hotel details as well as user details. The user related details can be updated through logging in their account. • Inn Finder Website: The Website acts as an interface between user and database and helps to display information to the user.

• User: The user retrieves information from the database about hotel/transport data and manage their account.

• Administrator: The administrator updates the database as well as manage the users. B.Operations of Proposed System The proposed system has following operations as explained below:

1. Searching:- Searching of hotels/inns is used to find an appropriate accomodation quickly. This feature is used to give accurate search results. The user enters a keyword related to the inn and the inns satisfying that keywords are retrieved.

2. Filtering:- Filtering of hotels is used to find inns based on various properties. This feature is used to give relevant inn satisfying one or all the properties. The user enters options that they require (like….Location, Nearest walkway, etc).

3. Recommendation It helps to recommend hotels/transportation to user based on the input data provided by the user after logging in their profile. The data of what user expects in the data is saved on the database and the hotels satisfying the data are retrieved.

4. Registration ease: This window will help the tourist to even register him/herself for the respective pilgrimage plan as per the government guidelines.

V. ALGORITHMS FOR PROPOSED SYSTEM

1) Searching Algorithm:

The one thing that really annoys us when surfing around sites is searching on sites that give you irrelevant results. You can‟t help but think something has gone terribly wrong with the search script. With over 70% of users likely to just „bounce‟ off such a site after not being able to find what they were after immediately, we need to take a look into the why‟s of getting such irrelevant search results. The most basic search practice out there is to do something like:

• Break string into words.

• Compose the search query targeting known data fields like title, description, features, word by word, imploding into the query. At this point the where statement can look like „where (description like „%black%‟ or features like „%black%‟ or title like „%black%‟) and (description like „%pack‟‟)

. • Display the results and hope for the best. Its fair to say, certain words should not be used to score results, they are just too generic to be considered. Unless you are typing something like „the north face‟, „the‟ should be dismissed, in the same way as „this‟ should be removed. So, what is the alternative? Oddly enough, the most accurate search results are achieved via manual tagging and backed up by product knowledge. It goes like that:

• Assign tags to each product. You can build an aliases table for common tags and errors.

• Build the search algorithm to break down the string into parts and analyse them. Drop all common words that won‟t help and keep the „useful‟ bits only. What words you have left, treat as tags and fetch all tuples they have been applied to. Improved Querying tools that can be incorporated for search process –

• Keywords: Document creators (or trained indexers) are asked to supply a list of wordsthat describe the subject of the text, including synonyms of words that describe this subject. Keywords improve recall, particularly if the keyword list includes a search word that is not in the document text.

• Concept Search: A search that is based on multiword concepts, for example Compound term processing. This type of search is becoming popular in many eDiscovery solutions.

• Proximity Search: A phrase search matches only those documents that contain two or more words that are separated by a specified number of words; a search for "Wikipedia" WITHIN2 "free" would retrieve only those documents in which the words "Wikipedia" and "free" occur within two words of each other.

• Regular-Expression: A regular expression employs a complex but powerful querying syntax that can be used to specify retrieval conditions with precision. Fuzzy search will search for document that match the given terms and some variation around them (using for instance edit distance to threshold the multiple variation).

• Wildcard Search: A search that substitutes one or more characters in a search query for a wildcard character such as an asterisk. For example, using the asterisk in a search query "s*n" will find "sin", "son", "sun", etc. in a text

2) Sorting/Filtering Algorithm:

For Sorting/Filtering algorithms we can consider the shopping websites which provide sorting operations performed on products to show relevant results. On System websites, users can find hotels in two different ways: searching and browsing. Searching obviously means using the site search whilst browsing involves drilling down through the catalogue provided by the website. Getting sorting and filtering right improves

searching ability and allows users to find the product they want in less time, from this product listing. If users can't find the exact product they require in the minimal time, there's a good chance they'll go to another site where they can.

What is sorting and filtering? Sorting is a method of changing the order of any product listing, where by users can choose which criteria they want the hotels to be listed by. So, preconscious web users may choose to list the products in order of hotel fare, from cheapest to most expensive. Filtering is a way of reducing the number of products in a product listing. Users choose which criteria are important to them and view only relevant hotels. For example, price-conscious users may choose to view only inns having fare under 1 thousand rupees (thereby filtering out all products over 1 thousand rupees).

3) Recommendation Algorithm:

For getting accurate and relevant hotels as per users wish there is a need of Recommendation Algorithm to make the user experience much effective. The Recommendation algorithm helps to shortlist the hotels and transportation options based on individual users demand and thus provide refined results which really matter to users. This algorithm basically works on the input data provided by the users after logging in their account and completing their profile. The hotel/transport are recommended based on the details as given below:

- Fare for per night stay.
- Location
- Preferred transportation choices(likes ponies and palkies)
- Preferred hotels and transport(i.e ac or non-ac)

To achieve faster query results the ranking of accommodation fare is carried out. Like assigning ranks to hotels that fall in a certain range. For example: Let's consider the fare range being assigned position

. • Less than 5k fare > 1 place
- 5k-7k > 2 place
- 7k-10k > 3 place
- 10k-15k > 4 place
- Above 15k > 5 place

Now the hotel database values will be assigned these positions corresponding to the tourist given fare they require. Now when user selects the range in which their fare fall, the corresponding position will be assigned to the user and hence the user will be recommended with the hotels/inn that have position equal or lower corresponding to the user specified fare in the application. After filling such details they can get an estimate of which hotels they can afford for to get accomodated. This really helps to truncate down the search and provide minimal but optimal results quickly..

VI. CONCLUSION AND FUTURE SCOPE

This project assists in automating the existing manual system. This is a paperless work which can be monitored and controlled remotely. It reduces the man power required and provides accurate information. All years together gathered information can be saved and can be accessed at any time. Therefore the data stored in the repository helps in taking decision by management. So it is better to have a Web Based pilgrimage tourism guide system. Web based pilgrimage is of very useful nature as it can assist the pilgrim for any journey related issues to get resolved in his own hands. The project can make a big revolution to the way the pilgrimage is carried out from start till the commencement of its journey. The project can make the pilgrim a better understandable person to carry out the pilgrimage.

The web based pilgrimage application can be reached to all the religions though being major or minor. Database connectivity can be carried out in better way in order to get the data in all the structured manner. Situations like covid or any pandemic like situation can be a problem which can be resolved if we have te travel og of the pilgrims during their times.

In future the program can be supplied by various companies contract which have high range in that pilgrim areas. The program can be supplied by various ngos and other social service socities in order to carry out the pilgrimage for the poor dreaming people.

A Study of Teacher's Attitude with Trainees Towards Using Cyber Resources (ICT) in Their Teaching Learning Process

Lokesh Kumar Sahu
Mahant Laxminarayan Das College, Raipur (C.G.)

Abstract:- **Technology has dominated all spheres of life. The education is also one of the fields where we can see the impact of information technology. In this study the researcher tries to study the attitude of teacher trainee towards educational technology. To conduct the study the investigator select 600 B,Ed. Students from Raipur district, out of them 300 male and 300 female students .Through random sampling method the researcher select the sample .After analysis the researcher found that there is no significant difference between the urban male and rural male pupil teachers' attitude towards using cyber resources. Where in the 2nd hypothesis the investigator found that no significant difference between rural female and urban female pupil teachers' attitude towards using cyber resources. There was no significant difference in attitude towards using cyber resources among the pupil teachers irrespective of locale and gender. Hence training colleges should arrange, seminars & workshops for the pupil teacher so that they should be aware about the updated aspects of educational technology and use accordingly.**

Keywords:-Attitude, Cyber resources.

I. INTRODUCTION

The rapid advancement of information and communication technology (ICT) has brought a revolutionary change in the information scenario giving rise to a number of options to handle varied information sources conveniently and effortlessly as a result of which e-resources have become the most sought after modern library's reserves in satisfying varied needs of students, teachers, and researchers with minimum risk and time. Our educational system has been transformed owing to the ever-advancing technology. Teachers are the most dominating factors for contributing educational modernization. The teacher's effectiveness depends on the teacher's attitude, characteristics and classroom phenomena such as management, organization, classroom environment. If the teachers were motivated and inspired to use internet and other sources to make their teaching learning process most effective for their students then the teaching process and syllabus can easily fulfill the expected objectives. Hence this paper tries to study the attitude of B.Ed. students using cyber resources in their teaching learning process.

(Rajkumar, 2018) Did a study on "Awareness of educational technology among the B.Ed. trainees in Villupuram educational district". The investigators focused to study the level of awareness among the B.Ed. students on the basis of gender and their parental education. To collect the data from the samples (200 B.Ed. students) the investigator used survey method and a self made questionnaire. The investigator found that high level of awareness among the B.Ed. students towards educational technology. No significant difference between the male and female students, their parent's educational qualification does not affect their awareness towards educational technology.

(Chadha & Chhavi, 2018) Conducted a survey on the topic "A study of B.Ed. students' attitude towards using cyber resources". The main objectives of the study were (i) To assess the attitude of B.Ed. students towards using cyber resources. (ii) To compare the attitude of male and female students of B.Ed. students towards using cyber resources. (iii) To compare the attitude of B.Ed. students residing in rural and urban areas towards using cyber resources. The surveyor adopted normative survey method to conduct the study. The sample comprised of 120 pupil teachers, 60 males and 60 females selected randomly. The entire sample belonged to HNB Garwal University of Srinagar. To measure the attitude towards cyber resources of the B.Ed. student the researcher used Dr.S.Rajshekhar (2010) scale. Output of the study were maximum students have natural attitude to use cyber resources. Male students were found to be better than the female B.Ed. students. There was no significance difference between the B.Ed. student residing in rural area and urban areas in respect of their attitude towards using cyber resources.

II. OBJECTIVES OF THE STUDY

1. To study the significant difference in Attitude towards using cyber resources, between the rural male and urban male pupil teachers in Raipur district of Chhattisgarh.

2. To study the significant difference in Attitude towards using cyber resources, between the rural female and urban female pupil teachers in Raipur district of Chhattisgarh

Hypothesis of the study

1. There will be no significant difference in Attitude towards using cyber resources, between the rural male and urban male pupil teachers in Raipur district of Chhattisgarh.

2. There will be no significant difference in Attitude towards using cyber resources, between the rural female

and urban female pupil teachers in Raipur district of Chhattisgarh

Method of the study

Descriptive survey method has been followed by the researcher

Sample of the study

Sample of the present study consisted of 600 pupil teachers of B.Ed. college of Raipur district, Selected by random sampling technique irrespective of their cast, creed, religion and family type. The selection of samples for male and female pupil teachers of B.Ed. College of urban and rural part of Raipur district were selected by using random sampling techniques. The study was conducted on 600 pupil teachers, out of them were 300 males and 300 females of B.Ed. college of Raipur district of Chhattisgarh

Tools of the study

To collect the data the researcher used "Attitude towards Using Cyber Resources Scale" By S.RajaShekhar.

Analysis of the data

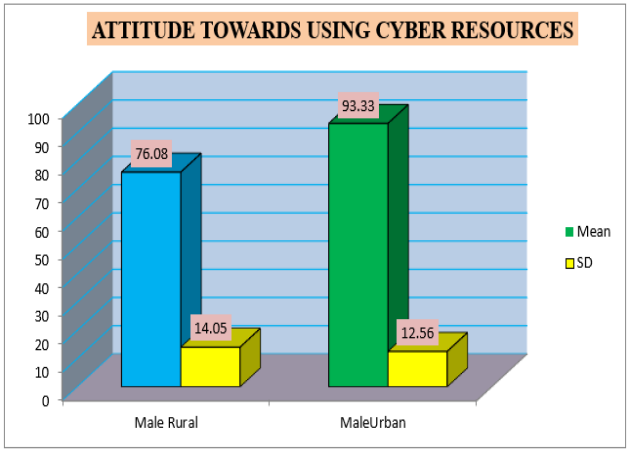
HO-There will be no significant difference in Attitude towards using cyber resources, between the rural male and urban male pupil teachers in Raipur district of Chhattisgarh

Table4.2.1 Local wise gender, M, SD, N, and 't'-test of Attitude towards using cyber resources among the urban male and rural male

Variables	Group	N	Mean Score	SD	Mean Difference	t-value	Significance
Locale wise Gender	Rural Male	150	76.08	14.05	1.49	1.50	Not Significant
Locale wise Gender	Urban Male	150	93.33	12.56			
Table value 1.96 with df 298 on 0.05 level of significance.							

The above data shows that rural male pupil teachers' mean score on Attitude towards using cyber resources is 76.08 and SD is 14.05.Where urban male pupil teachers' mean score on Attitude towards using cyber resources is 93.33 and SD is 12.56.The t-value between the urban male and rural male is observed as 1.50 at 298 degree of freedom. The level of significance is taken 0.05.Thus the calculated value of t is less than the table value 1.96. It proves that there is no significant difference found between the urban male and rural male pupil teachers' attitude towards using cyber resources. It hence is concluded that there is no significant difference between rural male and urban male pupil teachers and thus 1st hypothesis is accepted.

Bar graph shows the comparison of Attitude towards Using Cyber Resources among the urban male and rural male pupil teachers of Raipur district.

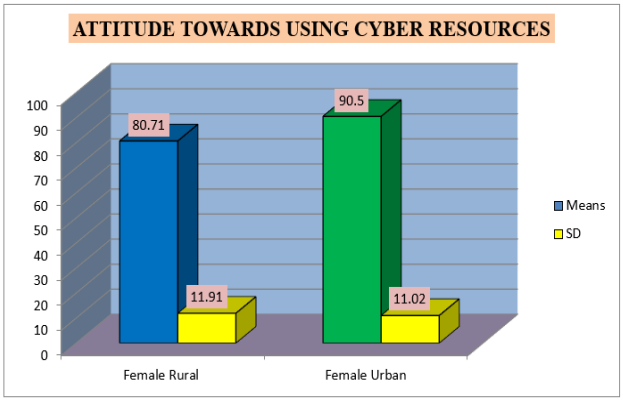


Local wise Gender, M, SD, N, and 't'-test of Attitude Towards Using Cyber Resources among the urban female and rural female

Variables	Group	N	Mean Score	SD	Mean Difference	t-value	Significance
Locale wise Gender	Rural Female	150	80.71	11.91	0.89	1.55	Not Significant
Locale wise Gender	Urban Female	150	90.5	11.02			
Table value 1.96 with df 298 on 0.05 level of significance.							

The data shows that rural female pupil teachers' mean score on Attitude towards using cyber resources is 80.71 and SD is 11.91.Where urban female pupil teachers' mean score on Attitude towards using cyber resources is 90.5 and SD is 11.02.The t-value between the urban female and rural female is observed as 1.55 at 298 degree of freedom. The level of significance is taken 0.05.Thus the calculated value of t is less than the table value 1.96. It indicates that it is not significant. It is concluded that there is no significant difference between rural female and urban female pupil teachers' attitude towards using cyber resources. Thus 2nd hypothesis is accepted

Bar graph shows the comparison of Attitude towards Using Cyber Resources among the urban female and rural female pupil teachers of Raipur district.



III. FINDINGS AND SUGGESTIONS

1. The finding of the study shows that there was no significant difference in attitude towards using cyber resources among the pupil teachers irrespective of locale and gender. Hence training colleges should arrange for seminars & workshops for the pupil teacher so that they should be aware about the updated aspects of educational technology.

2. Researcher suggests that the pupil teacher should develop their working skills and knowledge regarding cyber resources and should know how to handle and use cyber resources while teaching.

3. The training colleges of pupil teachers should make their trainees aware of the latest resources, their availability, scope, effectiveness and on the type of field for which the resources can be used, by arranging workshops on cyber resources.

4. Researcher suggests that the training college should provide updated and innovative teaching aids related to cyber resources to their trainees by which the trainee becomes well versed to those applications and develops positive attitude towards using cyber resources to achieve their teaching objectives.

5. Researcher suggests that awareness programs among the parents should be arranged by the central and state governments with the schools to increase the awareness about the importance of cyber resources.

6. Efforts should be made by the State Council of Education and Research and Training to train the teacher's of B.Ed. Colleges for making them more innovative while using cyber resources in their teaching learning process. This would enhance their teaching effectiveness while making it interesting.

University & College Finder & Recommender Web Application System

Habib Manihar, Sathyaprakash, Nitesh Pandey
Thakur College of Engineering and Technology Mumbai ,India
habibimanihar@gamil.com, satyaprakash000@gmail.com, pandeynitesh111@gmail.com

Abstract— **The University and College Finder & Recommender Web Application System is designed to help students make informed decisions about their higher education. The system offers personalized recommendations based on a student's academic background, financial situation, and personal preferences. With a comprehensive platform, students can easily compare and contrast different institutions, access detailed information about admission requirements, and obtain insights into campus life. The University and College Finder & Recommender Web Application System utilizes advanced algorithms to provide the most accurate recommendations to students. The system's recommendation engine takes into account multiple factors to make the best possible suggestions. The user interface is user friendly and intuitive, allowing students to navigate and find the information they need quickly and easily. In conclusion, the University and College Finder & Recommender Web Application System is a valuable tool for students searching for higher education institutions. It simplifies the complex process of choosing the right university or college, making it more accessible and convenient for students**.

Keywords—University and College Finder, Recommender Web Application System, higher education institutions, personalized recommendations, admission requirements, campus life, algorithms, user interface

I. INTRODUCTION

The University and College Finder & Recommender Web Application System is a platform designed to help students in their search for the best educational institutions and courses that meet their needs and goals. The application combines a comprehensive database of universities and colleges with advanced recommendation algorithms to provide students with personalized recommendations and a seamless user experience. The system offers a range of features, including a search engine that allows students to search for universities and colleges based on various criteria such as location, program offerings, and admission requirements. Additionally, the recommendation algorithm takes into account the student's personal preferences, academic background, and career goals to provide the most relevant and accurate recommendations. With the University and College Finder & Recommender Web Application System, students can easily find and compare the best educational options and make informed decisions about their future. The platform provides a one-stop solution for students, helping them to navigate the complex world of higher education and find the best path for their success.

II. LITERATURE REVIEW

In recent years, the higher education landscape has become increasingly complex, with a wide range of options available to students. To help students navigate this landscape and find the best educational options, a number of university and college finder and recommender web applications have been developed.

Studies have shown that students are often overwhelmed by the abundance of information available when searching for universities and colleges, and that they often struggle to make informed decisions about their education. In response, researchers have developed recommender systems to help students find the best educational options based on their personal preferences, academic background, and career goals.

Several studies have explored the use of recommender systems in the context of higher education. For example, one study found that a recommender system can significantly improve the accuracy of university and college recommendations for students. The study also found that students appreciate the convenience and personalized nature of the recommendations provided by the recommender system.

Another study explored the use of machine learning algorithms in the development of recommender systems for higher education. The study found that these algorithms can effectively predict student preferences and provide accurate recommendations. The study also found that students prefer recommendations that are based on their individual needs and preferences, rather than on generic criteria.

In conclusion, the literature suggests that university and college finder and recommender web applications can be an effective tool for students in their search for the best educational options. The use of recommender systems and machine learning algorithms can help to provide personalized and accurate recommendations, making the search process easier and more efficient.

III. METHODOLOGY

The methodology for the University and College Finder & Recommender Web Application System can be divided into several key steps, including:

Data Collection: The first step is to gather a comprehensive database of universities and colleges, along with information about their programs, admission requirements, and other relevant criteria. This information can be obtained from various sources, including academic databases, government websites, and educational organizations.

Data Cleaning: The next step is to clean and pre-process the data to ensure its quality and accuracy. This includes removing duplicates, dealing with missing or incomplete data, and standardizing the data into a consistent format.

Feature Engineering: The next step is to extract relevant features from the data and create a feature matrix. This matrix will be used as input to the recommender system.

Features may include information about the university or college, its programs, admission requirements, and other relevant criteria.

Model Development: The next step is to develop a recommender system based on the feature matrix. This can be done using a variety of algorithms, including collaborative filtering, content-based filtering, or matrix factorization. The goal is to develop a model that can accurately predict student preferences and provide relevant recommendations.

Model Evaluation: The next step is to evaluate the performance of the recommender system using a variety of metrics, such as accuracy, precision, recall, and F1 score. The model should be evaluated using a dataset of known student preferences and compared to other existing recommender systems.

Deployment: Finally, the recommender system should be deployed as a web application, accessible to students via the internet. The application should provide a user-friendly interface for students to search for universities and colleges, view recommendations, and make informed decisions about their education.

Existing System: -

Whenever we implement a new system it is developed to remove the shortcomings of an existing system. The computer has more Edge over the manual system. Getting an admission in a good College/University is a very tiring and complicated process. It may take weeks, even months to find relevant colleges which probably provide admission to students and even after wasting much time, students do not find colleges as per their requirement.

So firstly we will introduce the existing system, the existing system is based on a manual system i.e. users have to search each and every college individually for his/her admission process, which takes a lot of time to get relevant or deserving colleges list.

The Existing system earlier consisted of following operations-

• Manually Searching through search engines

• Getting data from respective college websites.

• Getting data from third party websites which hardly considered the necessary parameters for the college searching tool.

1. Absence of Recommendation System: -

The recommendation system is a very essential tool to provide list of colleges to the users which is evaluated automatically by the program based on the input data provided by the user after logging in the system

i. There are various sites which provide college finding facility but there are very few who provide recommendations to their registered users.

ii. This system is necessary to reduce the efforts of the user for getting an insight of which colleges he can apply for and have chance for getting an admit.

iii. This system analyzes and generates the list of colleges that a user can apply for based on his /her educational backgrounds or on the scores of the various entrance exams like GATE/SAT/CAT etc.

2. Data Redundancy

Take a few moments to inspect Figure 1. Notice that all of the fields now appear in a single table. Although this may seem simpler, it turns out to be a terrible idea. Look at the third and fourth rows in Figure 1. These two rows reflect the sales made to Kristin Reis. But look more closely and you‟ll notice that Kristin‟s information (First, Last, Street, City, State, Zip and Birth Date) is stored twice because she has been the customer in two different sales. If she had been the customer in 50 sales, this design would require that we store her name, address and birth-date 50 different times. Storing the same field values more than once (unnecessarily) is referred to as data redundancy. Three problems are caused by data redundancy. The first is that storing values multiple times wastes space. Under a proper design, Kristin's information is stored only once, in her record in the Customers table. The second problem is that when a field value changes, multiple occurrences need to be updated. For example, if Kristin moves, we'll need to change the values for her Street, City, State and Zip in multiple records. The third problem occurs if we forget to change the values in any of the records. The database would then have inconsistent data.

Figure 1: Data Redundancy Problem in table

i. Other Problems in Existing System

- Browser compatibility issues.
- Searching tedious.
- Do not cover all the modules that should be present for a college finding tool.

This methodology can be used to develop an effective and user-friendly university and college finder and recommender web application system. By combining a comprehensive database of educational institutions with advanced recommendation algorithms, the system can provide students with personalized and accurate recommendations, helping them to find the best educational options for their needs and goals.

IV. RESULTS AND DISCUSSION

- Proposed System

To overcome the drawback of existing system we have developed new system, which is a web based application in which the student/parent can simply search or explore the colleges anonymously. It also provides a special unit which specifies various career opportunities and course details for Masters/MBA applications. It is most reliable & time saving system for searching relevant and appropriate colleges from the comfort of your desktop.

1) A. Architecture of Proposed System

The components of the system are as explained below:

- **College Database:** The database is a repository for storing the college details as well as user details. The user related details can be updated through logging in their account.
- **College Finder Website:** The Website acts as an interface between user and database and helps to display information to the user.

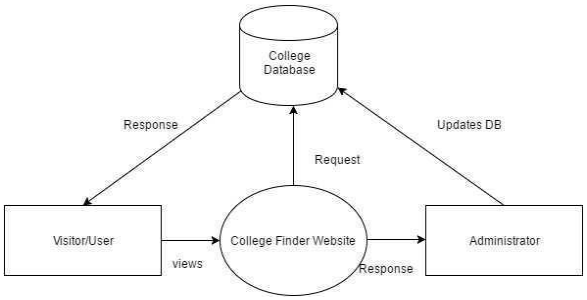

Figure 2: College Finder System Architecture

- User: The user retrieves information from the database about college data and manage their account.
- Administrator: The administrator updates the database as well as manage the users.

B. Operations of Proposed System

The proposed system has following operations as explained below:

1. Searching

Searching of colleges is used to find an appropriate college quickly. This feature is used to give accurate search results. The user enters a keyword related to the college and the colleges satisfying that keywords are retrieved.

2. Filtering

Filtering of colleges is used to find colleges based on various properties. This feature is used to give relevant college satisfying one or all the properties. The user enters options that they require (like Location, Degree offered).

3. Recommendation

It helps to recommend colleges to user based on the input data provided by the user after logging in their profile. The data of what user expects in the college is saved on the database and the colleges satisfying the data are retrieved.

4. Wish-List

It helps to add colleges to wish-list so that it is easier to review shortlisted colleges. The user has to login their profile in order to store the colleges to the wish-list.

VI. Conclusion

The University and College Finder & Recommender Web Application System is a powerful tool for students in their search for the best educational options. By combining a comprehensive database of universities and colleges with advanced recommendation algorithms, the system can provide students with personalized and accurate recommendations, helping them to make informed decisions about their education.

Studies have shown that students are often overwhelmed by the abundance of information available when searching for universities and colleges, and that they often struggle to make informed decisions. The use of recommender systems can help to simplify the process and provide students with recommendations that are tailored to their individual needs and preferences.

The methodology described in this paper provides a step-by-step guide to developing an effective and user-friendly university and college finder and recommender web application system. The system should be evaluated using a dataset of known student preferences and compared to other existing recommender systems to ensure its accuracy and effectiveness.

In conclusion, the University and College Finder & Recommender Web Application System is a valuable tool for students and educators, helping to make the process of finding and choosing the best educational options easier and more efficient. By providing personalized recommendations and a user-friendly interface, the system can help students to achieve their educational and career goals

VII ACKNOWLEDGMENT

The development of a University and College Finder & Recommender Web Application System would not be possible without the contributions of many individuals and organizations.

First and foremost, the authors would like to thank the students and educators who provided valuable input and feedback during the development process. Their insights and experiences helped to shape the final product and ensure its usefulness and effectiveness.

The authors would also like to acknowledge the contributions of academic researchers and experts in the field of recommendation systems. Their work provided the foundation for the development of the recommender algorithms used in the system.

Finally, the authors would like to express their gratitude to the educational institutions, government agencies, and other organizations that provided the data used to build the database of universities and colleges. Their contributions were essential to the success of the project.

This project was only possible through the combined efforts of these individuals and organizations, and the authors are grateful for their contribution

Music Therapy and Attention Deficit Hyperactivity Disorder (ADHD)

Adhish Kaushal, Sakshi Nagori, Yash Kamdar Abhinav, Bhandari
Thakur College of Engineering & Technology, Mumbai

Abstract: **One form of psychotherapy is music therapy. It is described as "a methodical intervention procedure where the therapist assists the client in promoting health, using musical experiences and the relationships that arise through them as dynamic forces of change." Children with autism spectrum disorders, elderly individuals with Alzheimer's disease, and those who have suffered serious brain trauma can benefit from music therapy. Music therapy for kids with attention deficit disorder (ADHD or ADD) improves focus and attention, lessens hyperactivity, and builds social skills. Structure is provided by music. It has rhythm, structure, and structure is comforting to an ADHD brain that struggles to control itself in order to maintain a linear route. According to research, listening to enjoyable music raises dopamine levels in the brain. This brain chemical, which is This neurotransmitter, whose levels are low in ADHD brains, controls motivation, working memory, and attention. Three separate characteristics can be used to categorize music therapy approaches: the degree of organization, the focus of therapeutic attention, and whether the active or receptive mode is used. The active mode includes activities like singing, playing musical instruments, and free improvisation of songs. Use of pre-written music for relaxation or listening to recorded music chosen by the client or the therapist are two examples of receptive approaches. The degree of structure describes the amount of guidance provided by the music therapist. A higher level of structuring can involve the therapist choosing the activities in advance, whilst a lower level might involve the client and the therapist negotiating the activities during the session. Between musical genres, structural levels differ. Depending on the needs of the client and the different music therapy approaches, structuring levels can vary. The processes taking place inside the musical engagement itself or the verbal reflection of the client's problems prompted by the musical processes may be the focus of attention. The goals of music therapy include (a) eliciting alertness, relaxation, satisfaction, self-confidence, and enthusiasm; (b) fostering an environment in which the client can open up about issues, feelings, and thoughts; and (c) assisting in the discovery of unconscious attitudes or suppressed memories and feelings. One outstanding feature of music therapy is its capacity to meet a broad range of needs in individuals of all ages, including physical, mental, social, emotional, and spiritual needs, frequently addressing several needs at once.**

Keywords: ADHD, Music therapy, Brain diseases, Therapist, Improved health conditions and better approach to life.

I. INTRODUCTION

Almost all kids occasionally exhibit uncontrollable conduct. They could move quickly, create noise constantly, refuse to wait their turn, and collide with everything in their path. Other times, they could become disoriented, as if daydreaming, and fail to pay attention or finish what they start. Most usually recognized and treated in primary school, Attention Deficit Hyperactivity Disorder (ADHD) affects children and is characterized by inattention, overactivity, and impulsivity. According to population research, 5% of youngsters globally exhibit hyperactivity and poor attention spans. Children in elementary school are diagnosed with ADHD about twice as often as teenagers, and boys are diagnosed with it about twice as often as girls. Depending on the source of identification (such as a parent or teacher), perception of the degree of functional impairment, diagnostic criteria, and the threshold selected for defining a "case," ADHD symptoms in the general population exist on a continuum and are considered a "disorder" to varying degrees. Early on, children exhibit the developmentally excessive levels of impulsivity, overactivity, and inattention that characterize ADHD. However, oppositional non-compliant behaviors, tantrums, and hostility that co-occur with early indicators of ADHD in preschoolers can obscure evidence of inattention and overactivity and cloud the diagnosis. Disruptive Behavior Disorder (DBD), which includes Oppositional Defiant Disorder (ODD), Conduct Disorder (CD), and ADHD, may be used to more broadly describe these behaviors. If not initially diagnosed at a young age, preschool-aged children with ODD often satisfy the criteria for ADHD by the end of the first grade. One of the concepts that has been bandied about a lot in recent years is "music therapy." Although there are several definitions for this topic, just a handful will be highlighted here. Professional music therapy is concealed in cultural processes, claims Stige (2012; 210). Studies have revealed the part music therapy plays in diagnostic and clinical evaluation, according to Wigram & Gold (2006).

Ansdell (2003;152-153) claims that music therapy may be viewed as the development of a continuous narrative about the use of music in the 20th century as a discipline, practice, and profession in certain circumstances and for specific purposes. A further challenge in defining music therapy, according to Bruscia (2016; 9), is that it has a

multidisciplinary nature. Music therapy is more than just a subject on its own; it is also a hybrid field that matches up with and covers the two fields (music and therapy) as well as other branches like art, health, medicine, education, psychology, human sciences, and others. Bruscia (2016; 11) asserts once more that music therapy is a discipline of art that is structured with science, focused on interpersonal and sociocultural processes, and as a science, gains life via art and is humanized by the therapist-counselor interaction. Wigram, Saperston, and West (1995) claim that music therapy is now regarded as both a science and an art. We can trace the history of music therapy to the founding of the National Music Therapy Association in the United States in 1950, according to Bruscia (2016;20) and Thompson (2009; 208). Wigram, Saperston, and West (1995) assert that the history of music therapy is both lengthy and recent. According to Merle-Fishman & Marcus (1982), Nord off & Robbins were the first researchers to examine a connection between musical behavior and disease.

According to Ak (2006; 235–243), there are essentially two approaches to employing music as a therapeutic tool: the active approach, which focuses on rhythm, sound harmony, dancing, singing, and the use of a musical instrument, and the passive approach, which focuses on listening. According to Thompson (2009; 210), the patients' engagement in music during active music therapy sessions involves both solo and group musical performances. Playing an instrument is also advantageous for the patients since it promotes the growth of attention, collaboration, and fine and gross motor control. According to James et al. (2015: 52), there are particular songs with lyrics that are associated to target abilities and musical improvisation in the research in the literature. Numerous studies and applications of music therapy have been done, and it has been shown that active treatments are employed more frequently than passive ones. (Rickson, 2006; Kim, Wigram, and Gold, 2009; Shore, 2003; Wigram, 1999; Gattino et al., 2011; MerleFishman, and Marcus, 1982; Wigram, 1999) Additionally, there is research that is conducted at music therapy facilities. 1992's Forinash In addition, there are other measures and methodologies in this field, such the Musical

Communicativeness Scale (Nordoff & Robbins: 1977, 2007) and the Music Therapy Communication and Social Interaction Scale (MTCSI; Guerrero et al., 2014). (Bell;2014:61) In 1959–1960, Nordoff and Robbins theorized their method. (Aigen: 2005) Music can facilitate verbal communication.

II. METHODOLOGY

Types of research Trials that use alternate allocation, a participant's birth date, or a case number to randomize participants are known as randomized controlled trials (RCTs) and quasi-randomized trials. Participant types There will be studies on teenagers and kids with ADHD who are under 18 years old. Adults (those above the age of 18) will not be permitted. Studies with participants aged 18 and younger and those with individuals aged 18 and older will be included if data for participants aged 18 and younger are separately supplied or can be obtained interventions' types. Any type of music therapy that complies with the criteria in Bruscia 1998 (see Background) will be evaluated in comparison to a no treatment control group or to standard care, including pharmaceutical or psychological interventions. Trials that combine music therapy with another kind of treatment will be included as long as both the experimental and control groups get the exact same intervention. Studies that don't specifically use music in a music therapy context or studies conducted by non-music therapists who use music will be disqualified. Result measurement types primary results:

1. The frequency or intensity of the primary symptoms
2. Inattention/Hyperactivity
3. Unfavorable result disruptive actions

The main findings will be derived from the child, parent, teacher, or other professional's comments on interviews or validated symptom rating instruments, such as the Conners

Teacher Rating Scale (CTRS) and Conners Parent Rating Scale (CPRS), both of which have been revised.

Secondary effects:

1. Academic and school performance
2. Results for families and society
3. The quality-of-life index
4. Disorders associated with ADHD:
   - Learning impairment
   - Disorder of oppositional Defiance
   - Behavior disorder
   - Emotional illness
   - Disorder tic
   - Affective disorders
   - Abusing drugs
   - Dysgenopathy
   - Somnipathy
5. Relationships with others
6. Any music therapy side effects that were mentioned in the trials

Official medical records, academic records, or validated symptom rating instruments like the Wechsler Individual Achievement Test (WIAT) or the Parenting Scale for Parents of Children with ADHD will be used to measure the secondary outcomes.

III. LITERATURE SURVEY

According to a review of the available data, music therapy is increasingly being used as a treatment option for Attention Deficit Hyperactivity Disorder (ADHD). Studies have looked into how well music therapy works to treat the impulsivity, hyperactivity, and inattentiveness that are hallmarks of ADHD. One study, for instance, discovered that after 10 weeks of therapy, children with ADHD showed significant improvements in their attention, hyperactivity, and impulsivity.

Another study looked at how music therapy affected people with ADHD's brain activity. According to this study, music therapy altered the activity of brain regions linked to attention, suggesting that it may aid people with ADHD who struggle with their attention and executive function.

Case studies and anecdotal data support the idea that music therapy may be advantageous for people with ADHD. Additionally, the sensory stimulation and emotional expression that music offers can also benefit those with ADHD. Music therapy can offer an organized, goal-oriented exercise that can help improve focus and attention in ADHD patients.

The literature also emphasizes the need for additional study to completely comprehend the mechanisms by which music therapy affects ADHD and to establish the best type and dosage of music therapy for people with ADHD.

The literature review concludes that music therapy has promise as a kind of treatment for people with ADHD. The evidence that is now available supports the use of music therapy as a complementary or alternative treatment for ADHD, even if additional research is required to completely understand its effects on the condition.

IV. LIMITATIONS

Music therapy for attention deficit hyperactivity disorder (ADHD) has its limits, much like any therapeutic strategy. These restrictions include, among others:

Lack of research: Although some studies have suggested that music therapy may be helpful for ADHD patients, further studies are required to completely understand the effectiveness of this treatment.

Limited accessibility: Music therapy is not available to all ADHD sufferers. This can be as a result of the expense, insurance coverage, or the scarcity of music therapists in the area.

Individual differences: Due to the wide range of reactions to therapy based on individual variations, including age, the severity of symptoms, and personal preferences, music therapy may not be beneficial for all people with ADHD. Limited duration of effects: Music therapy for ADHD may not have significant long-term effects. This could imply that in order for people with ADHD to continue to gain from music therapy, they would need to engage in it regularly. These restrictions emphasize the significance of taking into account a variety of therapeutic methods for ADHD, including medication, behavioral therapy, and other complementary therapies, to find the most effective course of action for each person. Working with a mental health expert is crucial because they can assess the unique requirements and difficulties of each person with ADHD and decide on the best course of action.

V. CURRENT TRENDS

The overarching goal of this study, which was motivated by a general dearth of research material, was to determine the degree to which the three core characteristics of ADHD behavior—inattention, hyperactivity, and impulsivity—appear both during musical engagement and after it has ended. Another focus was on the context and availability of active music production, which was motivated by evidence that suggests symptoms associated with ADHD may be minimized by an adequate teaching environment and good practice (e.g., Purves et al., 2011; Wiebe, 2007).

As a result, this study developed the following two research questions: (1) Can kids and teens with ADHD successfully participate in music education? (2) If yes, how does the presentation of ADHD vary when listening to music? The qualitative evaluations were strengthened by this quantitative data. The study's findings show that even though the affected people had symptoms associated with ADHD, they were still able to enjoy music and develop their musical abilities. ADHD was a disorder that varied depending on the pedagogical and artistic situation, not a static one. When participants were actively playing and performing music, their typical ADHD symptoms were either less noticeable or completely absent. A successful, context-sensitive, and inclusive pedagogy can incorporate students into successful individual and group music making, according to analyses.

VI. FUTURE SCOPE

For many years, patients with attention deficit hyperactivity disorder (ADHD) have benefited from the use of music therapy to better manage their symptoms and overall quality of life. It is anticipated that music therapy will gain more acceptance in the future as a supplemental treatment for ADHD and a variety of other mental health issues. Although research on the efficacy of music therapy for ADHD is still in its early stages, preliminary findings are encouraging. According to studies, music therapy can help people with ADHD focus better, feel less anxious, and have better moods. It's conceivable that music therapy will become increasingly more widely available and efficient as technology develops. For example, immersive, interactive music therapy experiences could be made using virtual

reality (VR) and augmented reality (AR) technologies. This might encourage improved therapy engagement and more therapeutic benefit in ADHD patients. Additionally, the introduction of wearable technologies, such as fitness trackers and smartwatches, may make it simpler for music therapists to monitor their patients' progress and modify their therapy sessions as necessary. Overall, music therapy for ADHD has a promising future, and it is probable that fresh discoveries and technological improvements will only serve to increase its advantages for those who suffer from this condition.

VII. CONCLUSION

To conclude, after reading this research paper, you should now have a better understanding of what music therapy is, how it functions, and how it might help you or a loved one who is dealing with a mental illness like ADHD. We hope that as soon as possible, these ailments are included to the list of those that have not yet been thoroughly investigated with music therapy so that even more individuals can benefit from its amazing effects.

VIII. ACKNOWLEDGMENT

Our HOD and project mentor, Ms. Sangeeta Vhatkar, provided great support that made it possible to complete this report and the research that went into it. This work was assisted by the Thakur College of Engineering and Technology. We are appreciative of the faculty at our university who provided information and insight that were very beneficial to the project. We also want to thank Ms. Sangeeta Vhatkar for sharing her thoughts and viewpoint with us throughout this endeavor.

Department Information System

Keyur Solanki, Rishabh Tiwari, Devyanshu Singh
Thakur College of Engineering and Technology Mumbai, India

Abstract -- **Department Information System is a computer-based system that is designed specifically to meet the needs of a particular department within an organization. The purpose of Department Information System is to provide a centralized platform for storing, processing, and managing data and information required for daily operations. The system will be used to store data for a department. It will store data such as staff member's information, events, and other data related to the department. The motivation behind the implementation of Department Information System is to bring significant improvements to the efficiency and effectiveness of the department, enabling it to better meet the needs of the organization.**

Keywords — Information, Information system, Information store, Data store, Database.

I. INTRODUCTION

1.1 Background

The departments in colleges need to store data related to various things. They need to store data about the teachers, the events that happen, fests, etc. The traditional way of storing this data is to manually do it using physical papers, files and folders. This becomes a problem in the modern world where more and more data is being stored. Due to this manually storing and recovering of data is time consuming in the modern business environment.

The modern business environment is characterized by an ever-increasing amount of data and information. Organizations must be able to manage this information effectively in order to remain competitive. The traditional methods of managing data, such as manual processes, are no longer sufficient in today's fast-paced and rapidly changing business environment. The traditional information management has the problems of low information recall, long query time, and poor information precision. This paper designs an information management system website on the department level.

1.2 Introduction

Department Information System is a management system for a department in a college or institute. It will be used to store information about students and faculties. It will manage all data in centralized manner and that can be accessed by anywhere and can be maintained by everyone in this project. The information system aims to fulfil the information requirements of staff and faculty of the Department, make the information source centralized and therefore easier to share, and also integrate with the other systems of the University.

Department Information Systems have become increasingly important in modern organizations, as they provide a centralized platform for storing, processing, and managing data and information required for daily operations. The purpose of Department Information System is to help departments work more efficiently and effectively by streamlining processes, improving communication and collaboration, enhancing data security, and providing real-time insights and analytics. The implementation of Department Information System has the potential to bring significant improvements to a department's performance, enabling it to better meet the needs of the organization.

The key elements of Department Information System include data management, workflow automation, communication and collaboration, reporting and analytics, data security, and integration with other systems. By improving data management, Department Information System helps to ensure that departments have access to the most up-to-date and accurate information, which is essential for making informed decisions.

1.3 Need of Department Information System

Department Information Systems are designed to meet the specific needs of a department, taking into account the unique processes and requirements of each department. The key elements of Department Information System include data management, workflow automation, communication and collaboration, reporting and analytics, data security, and integration with other systems.

(1) Data Management: Department Information System helps to ensure that departments have access to the most up-to-date and accurate information, which is essential for making informed decisions. By improving data management, Department Information System helps to reduce manual tasks and ensures that data is consistent and accurate. The system will also create backups so that the data doesn't get lost in the case if some problems occur.

(2) Workflow Automation: Department

Information System automates manual tasks, reducing the time and effort required to complete tasks and improving efficiency. This includes the automation of processes such as data entry, data validation, and data analysis. This will make it faster for the department and improve the efficiency of the work which would have been difficult in the traditional manual system.

(3) Communication and Collaboration: Department Information System provides a centralized platform for communication and collaboration, improving the speed and efficiency of information exchange. This includes features such as instant messaging, email, and document sharing.

(4) Reporting and Analytics: Department

Information System provides real-time insights into key performance indicators, enabling departments to make informed decisions based on accurate and up-to-date information. This includes features such as data visualization, dashboard creation, and data analysis.

(5) Data Security: Department Information System provides enhanced data security, helping to ensure that sensitive information is protected. This includes features such as data encryption, access controls, and data backup and recovery.

(6) Integration with Other Systems: Department Information System integrates with other systems, providing a seamless flow of information between systems. This helps to ensure that departments have access to the information they need, when they need it.

(7) Backup and recovery of data: The system will be able to backup the data. This will make it more reliable as even if data is lost in one place due to server failure or other technical errors, the department can still recover it using the other backups.

II. RELATED WORK

The literature survey on Department Information Systems shows that Department Information Systems has become an increasingly important tool for organizations to integrate and manage information from multiple sources. Many studies have been conducted to evaluate the benefits and challenges of Department Information Systems implementation, and researchers have proposed several improved models for Department

Information Systems design and implementation.

Studies have demonstrated the benefits of Department Information Systems implementation for organizations. Department Information Systems increase efficiency by automating and streamlining information management processes. Department Information Systems also improve communication and collaboration within and between departments, leading to more informed decision making.

However, the implementation of Department Information Systems also presents several challenges. The lack of standardization in Department Information Systems design and implementation results in inconsistencies and difficulties in integrating data from different sources. Department Information Systems implementation can also face resistance from employees who are reluctant to use new technology or lack the skills and knowledge to effectively use Department Information Systems. The need for specialized skills and robust technology infrastructure can also be a barrier to Department Information Systems implementation.

To address these challenges, we have proposed several improved models for Department

Information Systems design and implementation. A user-centered design approach involves users in the design process and ensures that Department Information Systems meets their needs and requirements. The adoption of best practices in Department Information Systems design and implementation, such as using industry standards, conducting thorough testing and quality assurance, and providing adequate training and support to users, can also improve Department Information Systems implementation.

The integration of artificial intelligence and machine learning algorithms can also improve Department Information Systems implementation by automating and streamlining information management processes, improving data accuracy and security, and providing insights and recommendations based on data analysis. Advanced data integration and management tools can also improve the efficiency and accuracy of Department Information Systems.

III. DESIGN

3.1 Database design

This project will be using MongoDB as its database to store the data. MongoDB is a document-oriented NoSQL database. MongoDB also allows the nesting of documents which will be useful for us to store related data such as events in fests, feedback of events. It is well-suited for modern web applications due to their scalability and flexibility in handling unstructured data. MongoDB provides features such as easy data storage, efficient querying, and indexing.

The database will store the following details:

• Login details: The data required for the users to log in the website. Every user will have a login id and a password that they need to login. The login will also store what type of user they are.

The user can be a teacher or admin.

• Users: The department information system will need to store the data about the users of this system or the staff members of the department. It will include the name, designation, username, etc.

• Fests: This will store the fests happened in the college. Each fest will have various events that have been in the particular fest. It will be stored in nested manner. The fests will also include feedback for each fest as a nested collection. The fests will store data like the events that happened, date, time and duration of the fest.

• Events: After logging in the users can view or add new events that have happened or will happen in college.

This will consist of seminars, workshops, and other events. The events collection will include feedback each event as a nested collection. The events will store data such as the date, name, purpose, participants, who took the event, etc.

• Feedback: This will store the feedback of the events and fests. The system needs to store the feedback too so that the department will be able to view the feedback and plan for future events and fests in a better way.

3.2 Pages

The system will include the following web pages:

(1) Login

This will be the first page that the user sees. They will need to login in order to use the website. Every user will have a login id and password that they need to login.

(2) Homepage

This page will appear after the user has legged in on the website. The user can go to other pages to add an event, view previously added events, view their profile data.

(3) Add event

The user will add events to the system on here. They will have to pick the type of event first. The user will have to fill various inputs about the event. The inputs will be data, time, name, taken by whom, etc.

(4) View events

The user can view the events that were previously added to the system. The events will store data such as the date, name, purpose, who took the event, etc. They can edit the events by clicking on edit button and then save the edits.

(5) Profile

The user will be able to see their information that is stored on the website. They can change the data if it is incorrect or ask the administrator to change it.

IV. METHODOLOGY

The methodology for the Department Information System project will utilize a database to store and manage information, and will be developed using MongoDB, Node.js, and a user interface.

MongoDB, a NoSQL database, will be used as the primary database for the project. NoSQL databases, such as MongoDB, are well-suited for modern web applications due to their scalability and flexibility in handling unstructured data. MongoDB provides features such as easy data storage, efficient querying, and indexing, making it a great choice for a web-based Department Information System.

Node.js will be used as the back-end technology for the Department Information System. Node.js is a popular platform for building fast, scalable, and efficient web applications. It provides a server-side environment for executing JavaScript code, which makes it well-suited for building web applications that interact with databases.

The user interface will be developed using HTML, CSS, and JavaScript. The UI will provide an intuitive and user-friendly interface for users to interact with the Department Information System. The UI will be designed with a modern and responsive layout, making it accessible on a variety of devices, such as desktop computers, laptops, and mobile devices.

The development of the Department Information System will follow an agile software development methodology, which emphasizes collaboration, iterative development, and continuous improvement. The Agile methodology will allow the development team to respond quickly to changes and provide regular updates to stakeholders throughout the development process.

At last the use of MongoDB, Node.js, and a user interface in the Department Information System project will provide a scalable, flexible, and efficient platform for information management. The project methodology, combined with the use of modern technologies, will ensure that the Department Information System is well-designed, user-friendly, and optimized for efficient information management.

1. Requirements Gathering: This stage will involve gathering requirements from Management and users to determine the specific needs and requirements for the Department Information System. This will help to define the scope of the project, and ensure that the Department Information System is developed to meet the needs of the users.

2. System Design: During this stage, the system design will be developed and refined based on the requirements gathered in the previous stage. The system design will outline the overall architecture of the Department Information System, including the components, modules, and relationships between them.

3. Implementation: In this stage, the actual development of the Department Information System will take place. This will involve the implementation of the system design and the development of the database, back-end, and user interface.

4. Testing: After the implementation is completed, the Department Information System will be thoroughly tested to ensure that it meets the requirements and is functional. This will involve both functional testing and performance testing to ensure that the Department Information System is optimized for performance and reliability.

5. Deployment: The final stage of the proposed work will involve deploying the Department Information System to the production environment. This will involve configuring the production environment, migrating the

data to the production database, and providing training and support to users.

The proposed work for the Department Information System project will involve the use of agile software development methodologies to ensure that the Department Information System is delivered on time, within budget, and to the required quality. The project will be continuously reviewed and improved throughout the development process, ensuring that the Department Information System is optimized for efficient information management.

V. RESULT AND DISCUSSION

The proposed Department Information System has the potential to be a valuable tool for organizations in the future. Its user-friendly interface, reliable performance, and scalability make it suitable for use in organizations of different sizes and types. The future integration of the Department Information System with other systems and the enhancement of its security will only make it more valuable to organizations.

The integration of the Department Information System with mobile devices, advanced analytics, and enhanced security will provide organizations with greater flexibility and efficiency in managing their information. The use of analytics will also provide organizations with valuable insights into their data, allowing them to make more informed decisions and improve their operations.

Overall, the Department Information System has the potential to significantly improve information management within organizations, providing a valuable tool for storing, accessing, and retrieving information. By continuously evaluating and improving the Department Information System, organizations can realize the full benefits of an effective information management system.

VI. CONCLUSION

The Department Information System is an important tool for managing information within organizations. A well-designed Department Information System can improve organizational efficiency, accuracy, and productivity. The proposed Department Information System project aims to address the challenges of information management by providing a user-friendly, reliable, and scalable information management solution.

VII. FUTURE WORK

In the future, the Department Information System will continue to evolve to better meet the needs of organizations. This includes enhancing its user interface and functionality, improving performance, increasing scalability, and ensuring security. Additionally, can will be integrated with mobile devices, enabling users to access the Department Information System from anywhere at any time. Integration with advanced analytics and machine learning will provide greater insights into information management, helping organizations make informed decisions. Finally, further research and development will be conducted to continuously improve the Department Information System and make it an essential tool for organizations.

charvi.rathod7391@gmail.com, premsharma04252@gmail.com, akash.singh123469@gmail.com

Abstract - **This paper reviews the enthralling category in the world of mobile software – Tourist Guidance System. When stuck at a tourist spot, one would assumingly be unfamiliar with the place and naturally, would need some sort of assist to know more about the surrounding. In a situation as such, an aid available at the tip of one's fingers would be of great benefit. The proposed mobile software is just the aid an individual might need. In this guidance system, the authors have implemented a framework of google that will allow the users to have a familiar and friendly experience with the User Interface of the application. Features and functionalities are invoked in the form of widgets. These widgets serve as the interactive UI in the application. Some additional features of the proposed software include vital information and list of things to be looked out for before visiting Uttarakhand, a state with extreme temperatures and intensely variable geography, so the tourists can be well prepared. Along with that is the information of all nearest services based on the location that the tourist can turn to in the hour of emergency. Furthermore, the authors state the advantages of using this software as compared to** the existing systems and how the gaps are bridged.

Keyword: Tourist guidance system, mobile software, google framework, user interface, widgets.

I. INTRODUCTION

Hands-free devices also known as mobile phones has made a critical excursion in the province of tourism. These devices have shown different intricate qualities that allows the tourist to look for assistance in an isolated environment. Since tourism seems to have a substantial influence in augmenting a nation's economy and societal employment, the creation of mobile guidance software is essential. Nowadays, the most fundamental issues appear to have been resolved, and the sophistication of smartphones and tablets assistants has risen, leading to the establishments of research and commercial brand names (e.g., Mobile Travel Buddy, Mobile Travel Guide). However, numerous limitations of mobile computing must be thoroughly examined by tourist-related service

providers: limited energy capacity, constrained computing power, quantity of memory and storage space; smaller screen layout, inadequate color and font number support, compact and stressful to even use keyboard; low network bandwidth and exorbitant cost of wireless connections. Most existing conventional applications and research methodologies throughout the discipline of mobile tourism fall into three broad categories, which may include:

- Tourist or exhibition help guide with pre-installed software packages, i.e., content that is rigidly defined and cannot be customized based on user preferences.
- Digital phones always like to connect mobile browsers and web portals to search for tourist information.
- Wireless handheld guides are devices that access context-aware services via wireless or mobile network or GPS connections.

In this study, we proposed a model for a mobile application on a travel guide in the Indian government for Uttarakhand. This model will assist the government in developing digital tourism policies. Mobile devices (smartphones) are used for model implementation because nearly 90% of society uses them to find tourism-related information. As a result, we focused on regulation and the challenges of developing mobile-based application currently centered on three platforms: Mobile web, Android, and IOS.

The method used in conducting this research is the method of creating a smartphone application. There are several development methods designed specifically for mobile development, including MASAM, SleSS, and Mobile-D. MASAM is a development method based on the agile framework, but the work steps and implementation are very similar to Mobile-D. This method was discovered in 2008 with the work process, namely preparation, embodiment, development, and commercialization, and it is suitable for development in small businesses. SLeSS is a SCRUM development method that has five work steps: definition, measurement, analysis, improvement, and control.

SLeSS was discovered in 2011, and its application was specifically for embedded software development, whereas Mobile D is a pioneering method in the field of mobile application development processes. The Mobile D method can be done in groups of up to ten individuals, and the time required for computation is relatively short, taking less than ten weeks. Mobile-D first appeared in 2004; it is a development method that prioritizes speed in both development and change processes, with five stages, namely: explore, initialize, production, stabilize, system test, and fix.

The following is how the paper is organized. Section 2 discusses previous surveys in the field of mobile tourist guides, while Section 3 introduces our evaluation framework, which includes a classification of mobile tourist services as well as a definition of certain services' design dimensions. Section 4 discusses the findings and implications for future research before concluding the paper with a summary in Section 5.

II. RELATED WORK

The focus study that was conducted on a variety of websites and applications created to provide information to tourists is presented in this section as its result. It might

be possible to find a range of flaws in these websites and applications through critical examination that would make consumers dissatisfied. A lack of user-friendliness, a failure to receive detailed information anonymously due to the fact that many applications require users to register with their personal email addresses or Facebook identities in order to receive more information, and a lack of security owing to the fact that personally identifiable information, such as tour plans, places visited with times and dates associated with those visits, etc., is stored on the servers of the service provider, are among the biggest shortcomings encountered. Lack of targeting was another significant problem noticed, as there was no segmentation of tourists and numerous websites included various points of interest, including shopping outlets, entertainment venues, and other tourist destinations, on a single page or listing.

According to the research done by Dr. Deepak Kaushal, Anuj, Dr. Kamal Pant and Dr. Mandakini Sharma [3], customers are significantly influenced by mobile applications when deciding on their travel location. Data was gathered from clients as well as tour operators in order to achieve this goal. The study's findings indicate that customers' choices about their trip destinations are significantly influenced by mobile applications. This comprises the crucial elements of perceived trust and utility, as well as the mediation of attitudes toward mobile applications, which help travel and tourism-related businesses improve their offerings for better outcomes. Any company that works in the tourism sector, if it manages its mobile application well, may benefit from a competitive edge over its rivals.

C. Grün, H. Werthner, B. Pröll, W. Retschitzegger and W. Schwinger [4] proposed an extensive framework based on a comprehensive evaluation framework that goes beyond previous ones by offering a classification of services as well as three design dimensions for how those services might be tailored for the end user. The emphasis has shifted away from technical concerns and mobile limits in mobile applications and toward the total value of the services. The evaluation methodology assists suppliers of mobile tourist guides in gaining a comprehensive perspective of their

services and developing methods for differentiating their services from others. It can be used as the foundation for consumer field research on how people react to various types of services in terms of service delivery, service commencement, and service modification.

Chawda, Yogendra Singh [8], present the creation of a tourist guide system based on Android. The system is built on a three-tiered design. The system allows users to search for information about tourist attractions such as hotels, restaurants, museums, and live entertainment. The system combines a smartphone and the Internet to facilitate the user's journey. A new Semantic Web framework for information sharing and reuse is presented. The Semantic Web enforces information expressed in web resources by applying agent technologies. This opens it up to collaboration between humans and computers, possibly in conjunction with intelligent network services such as search agents.

III. CHALLENGES

In this section, we identify the challenges that must be overcome in order to run the prototype for creating mobile applications related to travellers' users in Uttarakhand. These challenges can be demonstrated by a few applications available on the Android Play Store and the IOS Appstore that provide information about tourism in Uttarakhand. Most applications only provide tourism information and do not go into detail about the B2B (business to business) procedures.

A. Difference between Mobile Platforms

The first factor that makes mobile development a topic is the variation between mobile platforms. Numerous users and communities utilise several platforms, including mobile web, Android, and iOS.

B. Internet Access

Although Uttarakhand has recently gained access of internet connectivity in the major places, lack of broadband connection has been a problem that has so far taken on a life of its own. The existing disparity in internet connection between major regions of Uttarakhand continues to be concentrated mostly in areas with the potential to attract tourists.

C. Unorganised travel guide

There are numerous tourist attractions in Uttarakhand that visitors can visit, although this is restricted by limited infrastructure and availability to travel guides. Tourists find it challenging to visit Uttarakhand's tourist attractions because the majority of travel guides are written by people from outside the region. Making a guideline and a blueprint that the Government of India can adopt for Uttarakhand to enhance tourist attractions is therefore important.

IV. METHODOLOGY

A. Problem Statement

Tourists visiting Uttarakhand face challenges in finding comprehensive and reliable information about tourist destinations, activities, and services in the region. As a result, they often miss out on key experiences and miss

opportunities to fully enjoy their visit. There is a need for a comprehensive, easy-to-use mobile app that provides tourists with accurate and up-to-date information about the region, including recommendations for things to do and see, places to stay, and local services.

This problem definition sets the stage for the development of a tourism app that addresses the needs and challenges of tourists visiting Uttarakhand. The app should be designed to provide tourists with the information they need to make the most of their visit, including recommendations for tourist destinations, activities, and services in the region.

B. Mobile-D development

Due to the specific demands and technical constraints of the mobile environment, developing mobile applications is currently a very difficult task, such as

• Terminal devices' restricted efficiency and rapid evolution,

• Various standards, protocols and network technologies,

• Must be able to run on a variety of platforms,

• `Particular requirements of mobile terminal user and,

• Strict time to market requirements.

To overcome the challenges of mobile application development, we are adopting the Mobile-D agile development approach. The Mobile-D approach is designed for a team of less than ten developers working in a co-located office space to deliver a highly integrated mobile application in a short period of time (i.e., less than 10 weeks). Mobile-D was created in collaboration with three companies that create mobile software products and services. The approach has passed the CMMI level 2 certification assessment.

Figure 1 (Mobile-D flowchart)

The Mobile-D approach divides a development project into five iterations. Set-up, core, core2, stabilize, and wrap- up are the phases. Each phase consists of three distinct-

phases. There are three types of development days: planning days, working days, and release days. An Integration Day is also required if multiple teams are working on different components of the same product at the same time.

C. Research and analysis:

● By conducting surveys and interviews we can understand the profiles of a typical tourist visiting Uttarakhand, including their age, interests.

● We can also analyze existing tourism apps and websites that cater to tourists visiting Uttarakhand, and identify their strengths and weaknesses.

● Conducting research to understand the key tourist destinations, activities and services that are most in demand in Uttarakhand.

● Conducting user testing sessions to gather feedback on the app's design and features, and to validate the research finding.

This research and analysis will provide a comprehensive understanding of the market and target audience for a tourism app focused on Uttarakhand which is a beautiful yet difficult terrain. By taking these steps, the app can be designed to meet the needs of the target audience and to provide a positive experience for tourists visiting Uttarakhand.

D. Conceptual design

Uttarakhand is difficult terrain and it shouldn't be treated like normal tourist spots. After the heart-wrenching "cloudburst" of 2013 there is still fear among people regarding visiting Uttarakhand especially Kedarnath which is a very important pilgrimage among Hindus. Despite the government's continuous efforts to improve the infrastructure there is still some work that needs to be done in order to make things better. This app can promote tourism in Uttarakhand. The basic approach is simple.

Figure 2 (E-tourism Design)

Interviews, Library studies, and field observations will be used as data collection methods. The study of the library is useful to look for references from previous research. In addition, this research also uses KNN algorithm in its implementation. The KNN algorithm is used to classify objects based on the training data that are closest to the object. The data fed forms clusters of its own. The working principle of K-Nearest Neighbor (KNN) is to find the closest distance between the data to be evaluated with its closest neighbor in the training data.

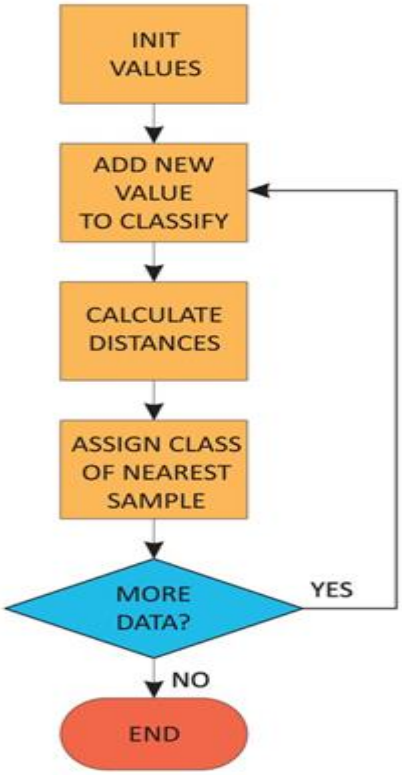

Figure 3 (KNN flowchart)

Flutter is a cross platform framework for creating a high-performance framework. Flutter was chosen as Google's application-level framework since it just relies on OEM widgets on the device instead of just consuming web views. Flutter applications run on Fuchsia in addition to Android and iOS. The hot reload feature in Flutter is known as stateful hot reload, and it is an important factor in shortening the development cycle. Dart is used to write every application in Flutter. Dart is a programming language created and maintained by Google.

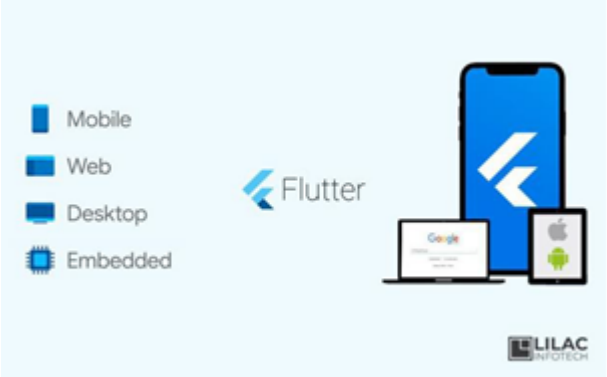

Figure 4 (Google-Flutter)

V. CONCLUSION

The state's enormous geographical, natural, and distinctive ecology, surrounded by gorgeous forests and rivers, provides significant opportunities for tourists to experience Uttarakhand. There are various roadblocks in the way of the state's tourist development that the government and locals must overcome.

The suggestion we make via a system based on mobile applications for tour operators in the Government of India for Uttarakhand. The government will use this approach to help with digital tourism policymaking. Utilizing the development method process, we leverage the steps of creating mobile applications in the proposed methodology (Mobile-D). We also create systems that minimize communication overhead and preserve battery life. A portion of the user's query can be handled locally using the data-caching technique, lowering the cost of wireless network traffic.

The google framework i.e., Google-Flutter, aids mobile tour guide service providers in gaining a comprehensive understanding of their offerings and in formulating plans to set them apart from competitors' offerings. Additionally, the google framework can serve as the foundation for field studies on customers' responses to various service delivery, commencement, and customization scenarios.

K- closest neighbor is a straightforward yet very accurate method that has worked well in a number of situations. The way the nearest neighbor algorithm categorizes newly discovered unlabeled data is by looking at the classes of its closest neighbors.

Abstract—**An abstract for a fitness guidance software would summarize the key features and benefits of the software. Here's an example:" Our fitness guidance software provides personalized workout plans and nutrition recommendations based on an individual's fitness goals, body type, and health information. The software includes interactive tutorials, progress tracking, and the ability to connect with certified personal trainers. The user-friendly interface makes it easy to stay on track and meet fitness goals. Whether you're a beginner or a seasoned athlete, this software offers expert guidance to help you achieve your best self." Here's another example of an abstract for a fitness guidance software:" Our cutting-edge fitness guidance software is designed to help people of all fitness levels reach their health and wellness goals. With its advanced algorithms, the software creates custom exercise programs and meal plans based on a user's physical attributes, health conditions, and personal preferences. The software also offers real-time tracking and progress analysis, as well as motivational support through built-in reminders and community features. Whether you're looking to lose weight, build muscle, or simply maintain a healthy lifestyle, our fitness guidance software provides the tools and support you need to achieve your goals." "Our innovative fitness guidance software provides a comprehensive and personalized approach to health and wellness. The software combines artificial intelligence and human expertise to create customized exercise plans and nutrition recommendations. With its user- friendly interface, users can track their progress, set goals, and receive real-time feedback and motivation. The software also offers a wide range of workouts and meal options to fit any lifestyle, from beginner to advanced fitness levels. With our fitness guidance software, you'll have everything you need to achieve your health and wellness goals, all in one convenient place**

I. INTRODUCTION –

"Fitness and wellness are crucial components of a healthy and balanced lifestyle, but finding the right guidance and support can be a challenge. That's why we've created our fitness guidance software, a comprehensive platform that comes in. This innovative platform provides personalized exercise plans, nutrition recommendations, and progress tracking, all based on each user's unique goals and needs. The software combines advanced algorithms with human expertise to create custom programs that are effective and easy to follow. With its user-friendly interface and built-in motivation tools, our fitness guidance software makes it easier than ever to achieve your fitness and wellness goals. In this project, we'll examine the key features and benefits of our software, and how it helps users achieve their best selves."

recommendations, and progress tracking. Our software combines artificial intelligence and human expertise to create custom programs that are tailored to each user's fitness goals, body type, and health conditions. Whether you're a beginner or an experienced fitness enthusiast, our software provides everything you need to achieve your best self. In this project, we'll explore the features, benefits, and impact of our fitness guidance software, and why it's the ideal solution for anyone looking to improve their health and wellness."

"Staying fit and healthy can be a struggle, especially with busy schedules and conflicting advice from different sources. That's where our fitness guidance software

II. EXISTING SYSTEM—

Based on a user's fitness goals, body type, and health information, the software creates custom exercise programs and provides step-by-step instructions and tutorials. The software offers guidance on meal planning and nutrition, based on a user's calorie needs and dietary preferences. Users can track their progress, set goals, and view their workout history, helping them stay motivated and on track. Some fitness guidance software allows users to connect with certified personal trainers for additional support and guidance. Many fitness guidance software systems are mobile-friendly, allowing users to access their programs and track progress from their smartphones or tablets.

III. LITERATURE REVIEW—

Conduct a review of existing research on fitness and wellness, as well as on the use of technology for health and wellness. This will help you understand the current state of the field and identify gaps in the existing literature. Provide an overview of the topic, including a background on the importance of fitness and wellness, and the challenges people face when trying to achieve their goals. Discuss the role of technology in the fitness industry, and the increasing

popularity of fitness guidance software. Discuss existing studies on the use of technology for health and wellness, including the impact of fitness apps and wearable devices on behavior change. Highlight the limitations of previous research and the need for further investigation. Discuss the potential benefits of using fitness guidance software, including increased motivation, improved physical activity, and better dietary habits. Also, consider the challenges that users may face, such as lack of adherence, technical issues, and privacy concerns. Review studies that have examined the impact of fitness guidance software on various health outcomes, such as body composition, fitness levels, and health markers. Consider the limitations of these studies and the need for further research. Discuss the user experience of fitness guidance software, including satisfaction, engagement, and user behavior. Review studies that have investigated the factors that influence user adoption and adherence to fitness guidance software. Identify areas for future research, including the development of more advanced

and personalized fitness guidance software, and the investigation of the impact of these systems on specific populations and health outcomes.

IV. RESEARCH METHODOLOGY —

Choose a research design that is appropriate for your study. For example, you could conduct a randomized controlled trial, a longitudinal study, or a qualitative study. Consider the strengths and limitations of each design and choose the one that is most appropriate for your research question. Define the inclusion and exclusion criteria for your study. Decide how you will recruit participants and how you will obtain their consent. Consider the representativeness of your sample and the generalizability of your findings. Decide on the methods you will use to collect data, such as surveys, interviews, or self-reported data from the fitness guidance software. Consider the reliability and validity of your measures and the feasibility of your methods. Decide on the methods you will use to analyze your data. For example, you could use descriptive statistics, regression analysis, or thematic analysis. Consider the suitability of your methods for your research question and the type of data you have collected. Consider the ethical implications of your study. For example, you may need to obtain ethical approval, protect the privacy and confidentiality of your participants, and ensure that your methods do not cause harm to your participants. If your study involves an intervention using the fitness guidance software, you will need to consider the design and delivery of the intervention. For example, you may need to decide on the frequency and duration of the intervention, the mode of delivery (e.g. online, app-based), and the level of support provided to participants. Choose appropriate outcome measures for your study that align with your research question and the goals of the intervention. For example, you could measure changes in physical activity levels, body composition, or health markers. Consider the reliability and validity of your measures and the feasibility of collecting the data. Conduct a power analysis to determine the sample size required for your study to have sufficient statistical power to detect meaningful differences. This will help ensure that your study is adequately powered to answer your research question. Consider strategies to ensure the quality of your data, such as using validated measures, training your data collectors, and checking your data for outliers and missing values. Consider the limitations of your study and the potential sources of bias in your data when interpreting your results. Consider alternative explanations for your findings and the implications of your results for practice and future research. Document your methods and procedures in detail to ensure that your study is replicable and transparent. Consider sharing your data and code to facilitate replication and further investigation. network analysis. Finally, the results should be evaluated and interpreted in order to gain a better understanding of the disease and identify potential strategies for its treatment.

V. RESULTS —

Report the basic demographic characteristics of your sample, such as age, gender, and baseline levels of physical activity. Report the results of the outcome measures you used, such as changes in physical activity levels, body composition, or health markers. Provide descriptive statistics such as means and standard deviations, and inferential statistics such as t-tests or ANOVA. Report the effects of the intervention, if applicable, including any differences between the intervention group and the control group in terms of changes in the outcome measures. Report any exploratory analyses that you conducted, such as subgroup analyses or regression models. Report on changes in quality of life, if this was one of the outcomes measures used. Report on the level of adherence to the intervention, if this was measured. Report on the user experience of the fitness guidance software, if this was assessed. Report on the level of user engagement with the fitness guidance software, such as the number of sessions completed, time spent using the software, and completion rate. Report on the acceptability of the fitness guidance software, such as satisfaction ratings, ratings of ease of use, and the proportion of users who would recommend the software to others. Report on the cost-effectiveness of the fitness guidance software, if this was measured. This could include the cost per user, the cost per session, or the cost per unit change in the outcome measure. Report on any factors that mediate or moderate the effects of the fitness guidance software, such as user motivation, social support, or perceived barriers to physical activity. Report on the sustainability of the effects of the fitness guidance software over time, including whether users continued to use the software after the intervention and whether changes in the outcome measures were maintained. Report on the health outcomes associated with using the fitness guidance software, such as changes in blood pressure, cholesterol levels, or glucose levels.

VI.CONCLUSION —

Summarize the key results of the study, including the effects of the intervention, the level of user engagement and satisfaction, and any adverse events. Discuss the implications of the results for the use of fitness guidance software in practice, including recommendations for future use and areas for improvement. Acknowledge the limitations of the study, including any potential sources of bias, confounding, or confounding variables. Discuss the implications of the limitations for the generalizability of the results. Identify avenues for future research on fitness guidance software, including areas where further investigation is needed and potential avenues for improvement. End with a concluding statement that summarizes the main points of the study and highlights the significance of the results.

VII. ACKNOWLEDGEMENT —

Acknowledge any funding sources that supported the study, such as grants, scholarships, or sponsors. Recognize the members of the research team, including co-investigators, research assistants, and data analysts. Thank the participants in the study, including any volunteers or study subjects, for their time and effort. Acknowledge any institutional support received during the study, such as access to facilities, equipment, or databases. Recognize any mentors, advisors, or

supervisors who provided guidance and support during the study. Thank any colleagues who provided feedback, support, or collaboration during the study

Abstract—**Life is becoming too busy to get medical appointments in person and to maintain a proper health care. The main idea of this work is to provide ease and comfort to patients while taking appointment from doctors and it also resolves the problems that the patients has to face while making an appointment. Online Doctor appointment is a smart web application, this provides a registration and login for both doctors and patients.**

Doctors can register by giving his necessary details like timings, fee, category, etc. After successful registration, the doctor can log in by giving username and password. The doctor can view the booking request by patients and if he accepts the patient requests the status will be shown as booking confirmed to the patient. He can also view the feedback given by the patient. The patients must be registered and log in to book a doctor basing the category and the type of problem patient is facing and the location.

The search results will show the list of doctors matching patients required criteria and he can select one and send a request the request will be forwarded to admin and admin forward to doctor and if he is available he will send the confirmation request back to admin the admin update the booking request and says confirmed to the patient. the patient can view the status in the status tab and also he will get the mail saying the booking is Confirmed.

Keywords: Appointment, online web application, hospital, scheduling, track, healthcare

I. INTRODUCTION

A doctor appointment booking system is a software or online platform that allows patients to schedule appointments with medical practitioners, such as doctors. The system typically allows users to search for available appointment times, select a preferred provider, and book the appointment online. This can streamline the scheduling process for both patients and healthcare providers, reducing the need for phone calls or in-person visits to book appointments. Some doctor appointment booking systems also provide features such as appointment reminders, online payment options, and medical history tracking.

The goal of a doctor appointment system is to improve patient experience: The system provides a convenient way for patients to book appointments, receive appointment reminders, and manage their schedules. This improves the overall patient experience and reduces the time spent waiting in line or on the phone to schedule appointments.

Increase efficiency: By automating the appointment booking process, the system helps healthcare providers manage their schedules more efficiently and reduces the risk of errors or missed appointments. Enhance communication: The system allows for easy communication between patients and healthcare providers, such as sending appointment reminders or sending test results. Streamline data management: The system provides a centralized database for storing patient information, appointment records, and other relevant data, making it easier for healthcare providers to access and manage patient information.

Save time and reduce costs: By reducing manual tasks and reducing the risk of errors, the system saves time and reduces costs for healthcare providers and their staff.

In short, a doctor appointment system aims to provide a better, more efficient, and more convenient experience for patients and healthcare providers.

II. LITERATURE SURVEY

A literature review on doctor appointment booking systems would encompass an examination of the existing academic and professional research related to the development, implementation, and impact of these systems. The review would likely cover topics such as:

1.Historical development of doctor appointment booking systems, including early paper-based systems and the transition to digital systems.

2.The benefits and challenges of doctor appointment booking systems for healthcare providers and patients, including issues related to accessibility, user experience, and privacy.

3.The impact of doctor appointment booking systems on healthcare outcomes, such as

reducing wait times and improving patient satisfaction.

4.An examination of different doctor appointment booking system models, including standalone systems, integrated systems, and those that use artificial intelligence or machine learning technologies.

5.A comparison of doctor appointment booking systems in different geographic regions, including the implementation of these systems in developing countries and the challenges they face.

6.The impact of doctor appointment booking systems on healthcare organizations, including

the role of these systems in reducing costs, improving efficiency, and increasing revenue.

7.An examination of future trends in doctor appointment booking systems, including the integration of telemedicine and the use of blockchain technology.

The literature review would aim to provide a comprehensive overview of the current state of doctor appointment booking systems, as well as an evaluation of their effectiveness and potential for future growth and improvement.

Application Referred:

1mg:

1mg is a healthcare technology company that provides an online platform for patients in India

to access information on medicines and health

products, book lab tests and diagnostic services, and consult with doctors through teleconsultation. The platform offers features such as medicine information, including generic alternatives and

pricing, appointment booking for diagnostic

services, and an online doctor consultation service. It aims to simplify healthcare and make it more accessible and affordable for patients. 1mg also provides a range of health-related products,

including over-the-counter medicines, wellness

products, and health devices.

Practo:

Practo is a healthcare technology company that provides a platform for patients to search, book, and consult with doctors and other healthcare professionals. The platform offers features such

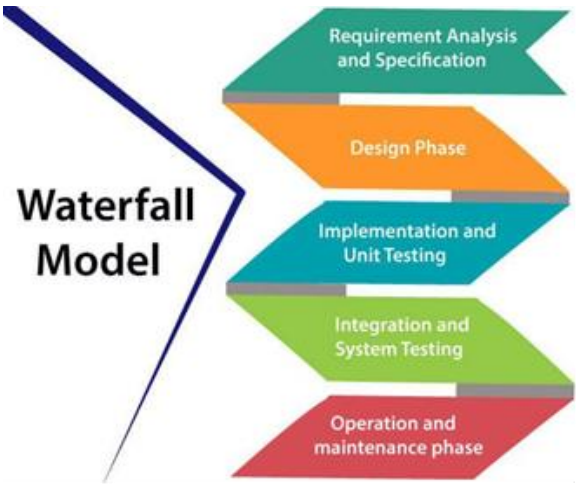
as doctor search, appointment booking, electronic

medical records, and teleconsultation services. It operates in several countries and aims to simplify healthcare and make it more accessible to patients

III. METHODOLOGY

The methodology implemented for problem solving is based on waterfall model. Scope of Further Development Online system is always a changeable system. It develops day by day, getting better and better to easier for peoples. This could be a revolutionary application that may help bonding between doctor and patient. We believe we can make this system more advanced in future. Advance features. and User interface will be updated in future. Our system is

already user friendly but we will try to make this system more user friendly in future. The methodology for developing a doctor appointment booking system would typically involve several steps, including:



1.Requirements gathering:

The first step would be to gather information about the requirements and needs of the stakeholders, including patients, healthcare providers, and administrative staff. This information can be gathered through surveys, focus groups, or one-on-one interviews.

2.System design:

Based on the requirements gathered, the next step would be to design the system, including its functional and non-functional requirements, such as user interface design, database design, and security requirements.

3.Prototyping:

A working prototype of the system can then be developed, allowing stakeholders to test and evaluate the system and provide feedback.

4.Development:

The next step would be to develop the final version of the system, incorporating any feedback received during the prototyping phase.

5.Testing:

The system should then be thoroughly tested to ensure that it meets the requirements and works as expected. This can include functional testing, performance testing, and security testing.

6.Deployment:

Once the system has been thoroughly tested, it can be deployed and made available for use by the stakeholders.

7.Maintenance:

The system should be monitored and maintained to ensure its continued performance and security, and to address any issues or bugs that arise.

The methodology for developing a doctor appointment booking system would typically involve collaboration between healthcare experts, software developers, and other stakeholders to ensure that the system meets the needs of all parties and is effective and user-friendly.

IV. CONCLUSION

With the help of IT , it is possible to transform health care and improve patient safety by better leveraging information technology to improve the efficiency, accuracy and effectiveness of healthcare system. Healthcare administrators and planners should take a long term view because the benefits will not be immediately tangible.

A doctor appointment system is an essential tool for modern healthcare providers. By providing patients with an easy and convenient way to book appointments and manage their schedules, and by streamlining appointment management for healthcare providers, the system helps improve the overall patient experience, increase efficiency, and reduce costs.

The proposed system outlined above is just one example of what a doctor appointment system could look like, and can be customized and tailored to meet the specific needs of healthcare providers. With the use of technology and

innovative design, doctor appointment systems are making it easier for patients to access healthcare services and are a valuable investment for healthcare providers.

A Systematic Study on Cybersecurity Technologies Issues and Its Challenges

Mrs. Rakhi Kalantri, Dr. Rajesh Bansode
Department of Information Technology Thakur college of Engineering and Technology Mumbai, India
rakhikalantri2007@gmail.com, rajesh.bansode@thakureducation.org

Abstract— ***With the development of technology, usage of the internet and digital/social media is rising quickly. Sites like Twitter, Facebook, WhatsApp, Instagram, and Messenger are examples of social networks, YouTube, and Snapchat have made it possible for people to interact effectively and regularly. Utilizing the internet has both benefits and drawbacks. Online gambling, harassment, pornography, and cyberbullying all have become more common as a result of Internet users' lack of self-defense knowledge and skills. Because of the present digital change, cybersecurity is a common subject in both our professional and personal life. Cyberbullying and cyberterrorism, in which terrorist organizations utilize social media platforms to recruit new members, other negative features of social media that have been linked to them. It is necessary to provide instructional and educational resources on cybersecurity to students who may end up being targets of exploitation. The primary contribution This article puts an emphasis mostly on difficulties that contemporary technology, ethical issues, and recent developments in cyber security pose.***

Keywords: Cyber Security, Cyber Attacks, social media, Cybersecurity Awareness, cyberbullying

I. INTRODUCTION

Internet usage has increased by a staggering 1,355% between 2000 and 2022. Currently, 5 billion people, or 63% of the world's population, use the internet. The Online world is among the most important innovations of the twenty-first century that has had a big influence on our lives. [1]. Internet has influenced how users connect, play video games, study, buy, meet new people, watch films, and make purchases for groceries. bill payment, etc. by removing all obstacles [2]. A new paradigm of communication and engagement has been established by the development of social media. In order to communicate among our neighbors, friends, coworkers, and others, it has evolved into a necessary component of the professional lives Additionally, it was mentioned how the widespread usage of social media sites like Facebook and Twitter had substantially changed how individuals utilized the internet for both personal and professional reasons. Despite the fact that social media platforms have privacy controls, unscrupulous users nevertheless manage to acquire sensitive personal data. Therefore, since social media security has a direct impact on our life. Our world is becoming more networked, with digital data supporting crucial services and infrastructures. Concern exists around threats to the privacy, accuracy, and availability of digital information nation states, businesses, and end users alike. Everyone recognize that in today's digital environment, our personal information is more vulnerable than ever. Our entire civilization is interconnected the location where information is stored on computers and other electronic devices, including government infrastructure and internet banking. Intellectual property, financial data, personal information, and other sorts of confidential material that might be compromised by unauthorized access or disclosure should be protected., may bepresent in one or more of those data components.Cybercrime will be one of the biggest challenges that humanities will face in the next twenty years [3]. To solve the problem awareness should be there basedon Cyber security which is shown in the following figure 1.

Figure 1: Cyber security awareness

II. BACKGROUND AND RELATED WORK

2.1Internet: In addition to its typical application, the internet can be classed into the following three "E" categories [4].

- Education: This refers to in-class work, homework, and assignments.
- Edutainment: Applications that encourage problem solving through games, riddles, and other forms of amusement.
- Entertainment: Video games, social networking, and other entertainment-related activities.

Figure 2 illustrates few more other internet-related applications.

Figure 2: Usage of Internet

2.2 Cyber Security:

Addressing the idea of cyber security is crucial. defined as safeguarding a user's assets from potential attacks online. The concept of cybercrime appeared to somehow be linked to digital platforms' lack of protection in the mid-nineties. Cybersecurity issues went beyond technical ones and contributed to a number of social issues [5]. In general, three aspects of information systems that require protection are referred to as "cyber security":

- **Confidentiality-** Privacy of communications and information is referred to as confidentiality. example, imply limiting access to classified material to those who are permitted in the government. It could refer to the preservation of confidential information in the business world.
- **Integrity** - The guarantee that data or computer systems have not been altered or destroyed. Loss of data integrity could manifest as instructions to the system that cause financial, material, or human losses in the case of vital infrastructures.
- **Availability-** A guarantee that data or services will be available when needed. Interfering with availability includes things like denial-of-service attacks, which overload system servers and crash websites.

2.3 Cyber Approaches [6]:

2.3.1 Authentication and authorization and password protection: One of the most important important ways to protect personal details is to utilize a user name and password. This may be the first step in a cyber safety plan.

2.3.2 Authentication of data: Before downloading, alldocuments must be validated, meaning they must havecome from a reputable and trusted source and haven't been changed. Antivirus software installed on the devices often authenticates these papers. Therefore, having strong antivirus software is equally crucial for shielding the gadgets from malware.

2.3.3 Virus scanners: The strategy usually examines each folder or document on the computer for hazardous bugs or other code. Malicious code is indeed a general phrase encompassing items like bugs, parasites, and Adware that fall under the category called malware.

2.3.4 Firewalls: Is indeed a piece of hardware or software that protects against internet dangers like intruders, infections, and spyware. This installed barrier is now in charge of monitoring any communications coming inside and going out of the system, stopping individuals who don't follow the established safeguards, also checking each communication because it arrives in quits the web. Due to this, barriers become essential towards finding vulnerabilities.

2.3.5

2.3.6 Antivirus software: A piece of software code known as an antivirus application seeks out and gets ridof harmful software programmes like viruses and worms. In order to check for reported cases as immediately as they are discovered, the most of security software packages offer a software update option which allows the system to obtain malware characteristics. Virus protection software is a crucialnecessity for any computer.

III. EVOLVING CYBER SECURITY TRENDS

The following list includes several factors can significantly affect cyber threats [6].

3.1 Web servers: Web apps are still susceptible to attacks that aim to collect data or spread malicious software. Utilizing genuine network services that are infiltrated, scammers distribute such spyware. The media regularly reports on attacks that steal data, but they also represent a major hazard. The protection of web servers and online applications must now take center stage. These fraudsters explicitlyuse web servers as their preferred platform for data theft. Use a safer browser at all times, especially whilemaking important purchases, to prevent being a victimof these frauds [7].

3.2 Cloud technology and its capabilities: Nowadays, most commercial enterprises, moderate, and huge progressively adopting cloud solutions. To put it another way, the earth is moving gradually more towards the clouds. The most recent development poses a serious threat to cyber security since transmissions may bypass standard port for screening. In order to safeguard against the loss of sensitive information, global framework for web programs and cloud hosting will be required to advance along with the diversity of internet apps. Safety concerns have been raised and although cloud services corporations are implementing own respective procedures. The cloudoffers a lot of alternatives, but it's vital to keep in mind that as it grows, security issues also materialize.

3.3APTs and focused cyberattacks: Advanced Persistent Threat is a new level of anti-cybercrime software (APT). Web filtering and intrusion prevention systems (IPS) have been crucial in detecting these targeted efforts for a long period of time (mostly after the initial compromise). Allow us guys recognize attacks as they happen and become more adventurous and shadier in their methods, attackers must link with other security services. So, in order to prevent the introduction of new

hazards, must strengthen our security mechanisms [8].

3.4 Mobile Networks: Individuals have access to international communication in the modern day. However, security is a significant worry for such wireless services. the application of firewalls and other protection mechanisms is less impenetrable in modern times as more people use gadgets like tablets, phones, PCs, and other comparable ones that also need extra security measures beyond those present in the programmes being used. The security concerns with It are necessary to continually keep these cellular services under view. Network operators are also very vulnerable to such cyberattacks, thus the need for extraordinary attention inside the occurrence of whatever safety difficulties.

3.5 Internet protocol version 6: A IPv6 protocol will replace the function of a IPv4 protocol, that was the main underlying infrastructure for modern networks. Moving IPv4 capabilities won't be enough to safeguard IPv6 on its own. Security policy still has to take into account a few very basic protocol changes evenwhen In regard to the number of IP addresses that are allocated, IPv6 entirely replaces IPv4. In in order to reduce the risks that are usually a good idea to convert

3.6 on IPv6 as early when it is feasible because of cyberattacks. [9].

3.7Encryption of the code: Data should always be encrypted via cryptography in to keep attackers or snoopers access getting things. During an encryption method, every message or information is encrypted and decrypted. Switching to IPv6 as early when it is feasible always seems to be recommended because of theft., resulting in an unintelligible cypher text. Typically, a key for encryption is used, which defines the best way to encrypt this information. Somewhere at least interesting, cryptography safeguards the authenticity and confidentiality of information. basic level. Butwhen encryption is used more often, cyber security risks increase. Data being transported across networks is protected using encryption [10].

IV. LITERATURE REVIEW

In 2016 S S Tirumala et al. presented “a poll on Online media use and student awareness of cyberattacks” This study offered information on existing cybersecurity knowledge and emphasized the need to raise students' understanding of cybersecurity using wireless intercoms and other means.

In 2021 Farzana Quayyum et al. proposed “Children's Digital Knowledge: A Comprehensive Literature Analysis”. This study focuses on cybersecurity risks, awareness, approaches and solutions among children.

In 2017 Jitendra Jain et al. Presented “A Recent Analysis of Cybersecurity Security's Fundamentals”. Numerous security concerns related to information security also are included in the study of cybercrime as well as its elements.

In 2016 APRA presented “Cyber Security Survey Results”. This paper presented and observed the frequency of important cyber security events, the variety of threats, and the prevalence of high-risk cyber security discoveries. They recommended that everyone who is regulated develop an ongoing planto deal with the many types of growing cyber risk.

In 2017 Farhad Alam et al. "Utilization data mining strategies towards preventing information security" is indeed a proposal. Researchers discussed about several approaches to data mining that really are significantly linked to internet protection. They demonstrated how incredibly useful data mining- based interruption location tools are for locating security holes.

V. CYBERSECURITY ISSUES FOR SOCIAL MEDIA

The quick expansion of social media has a lot of benefits, but it has generated serious security risks. Furthermore, attackers can utilize it as a glaring weakness. The following lists some related concerns [11].

- **Information Security:** Customers might breach consumers' confidentiality if individuals post personal stuff on social media. It may even cause the loss if confidential information or encourage terrorists to utilize it for bad intentions. As fact, when a customer decides to make personal data available by nature, anyone can access that.

- **Data Mining:** Everybody leaves a digital trail, mostly online. When someone creates a new account on social media and adds details like their name, date of birth, location, and personal habits, all of these traits are utilized and shared with third- parties for targeted advertisements without theuser's knowledge. Security concerns may arise since a third party might learn the user's location in real time [12].

- **Virus and Malware Attacks:** How Adverts that really are offensive frequently allow spyware and viruses can gain access to a computer. Whenever a criminal gained access to a network, they either steal sensitive information or completely damage the computer system. Personal, professional, financial, and other types of data are frequently lost as a result.

- **Issues involving the use of third-Party software:** With able to reach confidential info includes contacts, pictures, or location information, the majority of apps today ask customers' approval during setup. Several of these idle applications might unintentionally attack the customer's device or the other connected phone using infections.

- **Legal Concerns:** Potential consequences associated with online social media include using publishing negative information about either person, organization, or nation. Legal proceedings can often be undertaken when certain incendiary comments were

written and circulated either by individual or collective.

VI. RISKS ASSOCIATED WITH SOCIAL MEDIA

As more individuals engage with social media, the threats are also expanding.

- **Cyber Fraud:** Cyber Fraud: Since countless individuals divulge personal information when subscribe for one or even more social media platforms, such content is vulnerable to Because criminals have the ability to reset passwords, solicit loans, as well as other unscrupulous activities, cybercrime is indeed a concern.

- **Romance Scams:** Whenever a scam artist acts as connected to a victim, develops a relationship with someone, and afterwards utilizes it to attempt to obtain personal details and money through people, this is a clever strategy.

- **Whistle-blowers:** Individuals typically behave unpredictably or vent their frustration with superiors or colleagues via social networking sites. Somebody may intentionally disclose personal information, which would be extremely harmful again for brand's reputation.

- **Cyberstalking:** Such phrase refers to cyberbullying. Cyberbullies irritate its victims on media platforms by posting crude or disrespectful comments. They manipulate survivor photographs and publish them on media platforms while complaining that the person's life is becoming terrible due to gossip.

- **Cyberbullying:** This term describes bullying that occurs online. It may happen on chat, gaming, and social networking sites. It attempts to frighten, humiliate, or irritate the intended victim [13].

- **Cyber Terrorism:** The use of media platforms in favor of crime activities has recently increased. It can support, encourage, participate in, and disseminate terrorism propaganda such as calls to violence, recruiting, radicalizing training, and plotting terrorist acts [14].

VII. PREVENT FROM CYBER ATTACKS

To Prevent from Cyber Attacks following are the solution given in figure 3 and listed the same.

- Use capitalized and lower characters, numbers, and slightly different for produce interactive credentials. It shouldn't be documented somewhere; it is only to be retained in mind.
- When uploading or sharing content on social networking sites, people should use caution and avoid revealing private information such as personal identity number, birth date, personal details, and photos from the families.
- Make utilization of the confidentiality and safety features on social networking websites, including the two-factor authentication method and access controls. Use only the downloading features of auto-lock.

Figure 3: How to Prevent from Cyber Attacks

- Avoid using pirated software, turn on the firewall, and make sure the programme is patched up to date.
- Ensure that regular scans and antivirus updatesare carried out.
- Use caution when browsing the internet to avoid visiting dubious websites; never click on website referral links; instead, put the URL directly into the browser.
- Must accept only friend requests from individuals know, and anyone who posts objectionable content will be blocked orunfriended.
-

VIII. CASE STUDY: ATTACK BY THE ENEMY ON PUNE'S COSMO BANK[15]

Attack by the enemy on Pune's Cosmos Bank The following case study examines a malicious assault on the Cosmos Bank in Pune between August 11 and August 13, 2018, which is one of the better instances of a malware attack. The internal architecture of the bank and the ATMs were both affected in this instance. Multiple malicious central code assaults were used in the crime to switch between the central and core banking systems of the bank. In essence, the code responded to clients' transaction requests by generating false payment transfer requests. 450 fake non-EVM debit cards from several countries were used to authorize sizeable cash withdrawals from ATMs after sending phone standing-in requests, altering the account balances of the targeted customers, and engaging in other illicit acts. Attackers injected malicious software into The fund's Automated teller machine shifting mechanism, which forbids confirmation of any payments made by customers using POS/ATM devices. PJAEE, 17 (6) (2020) 4664 A transaction request (TRQ)
once a withdrawing transaction occurs, is sent to a consumer banking accounting information system to verify and authenticate your credentials. If indeed the identification is approved, a transmission actually slower is transmitted to the user to verify them. In this instance, malicious code was utilized to transmit phone transactions reply messages in response to each transaction request at the ATM/POS [13]. As a result, The shifting mechanism of the account was managed to manipulate by hackers, prohibiting any payment demands and money confirmation from becoming

delivered to the central banking system. As a result of this attack on Cosmos Bank, layers of banking system defense were breached and 84 crores of rupees were syphoned off in two waves of large transactions. The banking infrastructure and background monitoring system of the Cosmos bank had been extensively studied by hackers; it was discovered after additional investigation. For unexplained reasons, it's possible that the bank executives disregarded every signal the system generated. It was important to not overlook the auditing of reports generated by banks [14].

Table 1- Frauds involving Banking sectors: RBI Announcement, as reference 2019 [16].

Year	**2018-2019**		**2019-20**		**Apr-Jun 2020**	
Banks	**No. of Frauds**	**Amount Involved**	**No. of Frauds**	**Amount Involved**	**No. of Frauds**	**Amount Involved**
Public Sector Banks	3,568	63,283	4,413	1,48,400	745	19,958
Private sector Banks	2,286	6,742	3,066	34,211	664	8,009
Foreign Banks	762	955	1,026	972	127	328
Financial Institutions	28	553	15	2,048	3	546
Small Finance Banks	115	8	147	11	16	2
Payment Banks	39	2	38	2	3	0
Local area Banks	1	0.02	2	0.43	0	0
Total	**6,799**	**71,543**	**8,707**	**1,85,644**	**1,558**	**28,843**

IX. BASED ON CASE STUDY: OUTCOMES

- Phishing, identity theft, and malware are major criminal acts in the Indian banking industry.
- Small errors and a lack of knowledge about cyber security procedures might lead to even major crimes. Any suspicious activity should be treated cautiously, and before taking any action, the relevant authorities should be notified. PJAEE, 17 (6) (2020) 4665.
- System must undergo regular audits to check for security flaws.
- Public sector banks ought to devote greater attention to improving security through associated with early and devote more funds to data protection and security framework improvement.
- Along with tracking ATM/POS machines transactions, the changing system communication with the main banking system should be regularly observed. There should be a stable system packet sent and received between and as an acknowledgment notification.

X. CUSTOMER AWARENESS CAMPAIGN

The emphasized safety precautions are below part of a customer awareness campaign that all bank employees must adhere to [17].

- Use secure and distinctive passwords when logging onto network shares removing any unused shares.
- For any offshore outsourcing, use a Private Network (VPN) instead of revealing distant workstations (RDP).
- Working folders shouldn't include shared applications in exe format. When necessary, only download from a secure source with IT Security's consent.
- Tracking RDP access and turning it off when not in use.
- Maintaining constant browser updates and blocking add pop-ups.
- Promptly confirming the legitimacy of the visited surfing site and prompt notification of the bank's IT security in the event of any suspicion.
- Always save relevant websites in your bookmarks to prevent connecting to Phishing web pages,
- posting of private information on any unidentified websites is prohibited.
- Examining each message, the organization sends out. When receiving messages from unknown communicators, need not read them. Instead, notify them towards the fund's scamming section. Ensuring that OS patches and security applications are applied at regular intervals.
- When it's not in use, the webcam must be hidden.
- Regular data backups to a safe place.
- On every site that hasn't been vetted or safeguarded

by IT Safety, sensitive information should not be communicated.

XI. CONCLUSION

As the world becomes more interconnected and more crucial transactions are performed via networks, computer security is a large issue that is growing more crucial. With each New Year that goes by, cybercrime continues to take various turns, compromising information security. The newest and most innovative technology, as well as the freshest cyber tools are

dangers and emerge every day, new platforms and intelligence is needed to safeguard infrastructure, which poses a challenge to enterprises. To ensure Spite of the fact that there is no optimal solution, individuals must make each effort to minimize cyberattacks if they desire a secure and protected environment in cyberspace.

Security Enhancement for Data Transmission In 5G

Krishna Kaneriya, Sahil Mishra, Sudhanshu Mishra, Dr. Rajesh Bansode
Thakur college of Engineering and Technology Mumbai,India
krishnakaneriya2001@gmail.com, vickymishra2907@gmail.com, mishrasudhanshu2512@gmail.com, rajesh.bansode@thakureducation.org

Abstract- **Ensuring that 5G devices are secure from cyber-attacks and that sensitive data is protected is a major challenge for the industry. This requires the development of new security protocols and the implementation of robust encryption algorithms. The parameters of such existing algorithms are Key size – 128, Rounds – 32, Hardware Throughput – 22.9 kbps, and Software Throughput – 342 kbps. Because of the adaptability of the algorithm used in various applications and environments, data and key length can be chosen with various sizes. This adaptability is an outcome of the simplicity of the design and this straightforwardness of Simon is moreover beneficial, they are exceptionally simple to implement, and efficient implementation can be had for minimal work this is a contrast to the algorithms such as Advanced Encryption Standard (AES). This project is to optimize the SIMON algorithm to increase the throughput of the data**.

Keywords Light weight cryptography, 5G Technology, Simon Algorithm.

I. INTRODUCTION

Wireless communication has reshaped our society. The development of mobile communication as specified and provided by the second, third, and fourth generation of mobile communication systems (respectively referred to as 2G, 3G, and long-term evolution (LTE)) has transformed us. Most people today own a mobile phone, keeping it close by, and conducting not only phone calls, and Internet browsing, but also several other very convenient services, which may include money transfers, mobile tickets, paying for parking, video conferencing, and 3D television etc. [1]

Today, researchers and Network engineers are focusing on the next generation of mobile communication, the so-called 5G system. This next-generation mobile network is currently being specified by the third-generation partnership project (3GPP). Mobile carriers have started building 5G networks in some cities and there are already a few mobile phones offering 5G connectivity. The 5G system will be the enabling platform for achieving the original goals set up in IMT-2020 [1], which contains several use cases spanning from voice and fast connectivity to new use cases, such as smart city, smart home, industrial automation, self-driving vehicles, and mission-critical applications. The impending deployment of the fifth generation (5G) cellular network has created a lot of enthusiasm in both industry and the scholarly world especially because of its commitment to empowering new applications. 5G is not only envisioned as a replacement for home broadband Internet but also is supposed to influence the tactical combat zone and emergency management by improving situational awareness. All these potential novel and critical applications of 5G can be attributed to its following enhancements over 4G LTE:

1. Improvements in the physical-layer technologies enabling the support of large numbers of devices with substantially improved bandwidth.
2. Robust security posture due to the introduction of security measures in the upper-layer of the 5G protocol stack. The 5G standard, however, has opened the door to a wide array of new security challenges stemming from:

i. New security policies that are not formally verified against adversarial assumptions
ii. Retaining security mechanisms from 4G LTE and its predecessors. [2]

II. BACKGROUND

Lightweight cryptography has a trade-off between security and its lightness. Recently, several educational communities are doing a significant quantity of work regarding lightweight cryptography to implement conventional cryptography standards efficiently, to design and analyze new lightweight algorithms and protocols. The widespread utilization of small computing devices such as sensors nodes, radiofrequency identification (RFID) tags, industrial controllers and smart cards indicates there have been massive changes in people's lives.

A. Importance of the Project

This project is important as, 5G is in the near future and it will connect all the devices to the internet. The flaw in 5G network will lead to immense of cyber-attack at very ease. Because the company that are manufacturing internet-based devices like smart watches and automatic cars are not focusing much of its security. PC's and servers have enough power and speed to be able to appropriately use heavy algorithms such as AES and SHA-256, etc. On the other hand, devices such as RFID chips and devices with constraints need algorithms that they will be able to run properly with enough speed and security. It will be useful in deciding how lightweight algorithms can be used and modified for 8 resource constrained devices. It will also provide a detailed analysis of performance metrics such as speed and data size.

B. Objectives and Scope of the Project

The main objectives of this project are:

• To provide a secure end-to-end data transmission in 5G using lightweight algorithms.
• To enhance confidentiality using lightweight algorithms in 5G devices.

• To enhance confidentiality by strengthening/modifying encryption algorithm.
• Performance evaluation using a lightweight algorithm on resource constrained device.

III. 5G ARCHITECTURE

A mobile communication network consists of two parts: the radio access network (RAN) and the core network. A RAN connects individual devices through radio connections with their core networks, while the core networks provide services to the users. Compared to the Evolved Packet System (EPS) architecture in 4G LTE, the pivotal evolution of 5G architecture is the wide adoption of cloud and virtualization technologies to support diverse and flexible services. Mobile network architectures that existed before were designed mainly to meet the requirements for voice and broadband services, which have proven to be insufficiently flexible in 5G with diverse nodes, interfaces, and services. This becomes one driving force behind leading to the softwarized architecture of 5G. With SDN and NFV technologies being able to support and manage the underlying physical infrastructure, it becomes possible to virtualize the network functions and move them to the cloud and perform the central control, processing, and management there. Compared to legacy cellular networks where an enormous of proprietary nodes and dedicated hardware appliances are deployed, the software zed architecture can reduce the equipment and deployment cost and improve the flexibility and availability to the management and evolution. Furthermore, network slicing makes it possible to design isolated virtual networks dedicated to different services as needed, e.g., vehicular network service, over a single physical architecture, thus satisfying the different requirements of diversified services. Figure 1 shows the 5G architecture reference model from 3GPP specification [3], where the components in the architecture are called network functions (NFs), which used to be different physical elements.

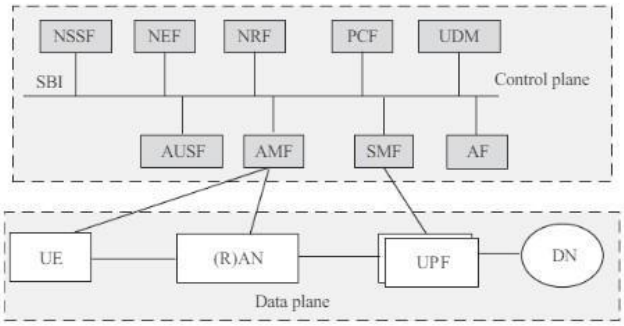

Figure 1. 5G Architecture

In 5G, these network functions are virtualized and software-based to be services, and thus can be well integrated to the cloud architecture. User equipment (UE) denotes a user and RAN is the radio access network. DN is the data network and the other components are the network functions residing in the core networks. Among them, user plane function (UPF) is a function working in the data plane, while others are in the control plane. Network functions are connected by reference points or service-based interfaces. Below we give some details to the access network and the core network.

Cloud/centralized radio access network (C-RAN) can be used in 5G for the radio access network, by utilizing the cloud and virtualization technologies to virtualize and centralize some functions of the base stations to the cloud, and thus reducing the cost on the deployment and management of the largely increased and densified base stations. The RAN then consists of distributed sites and a cloud centre. The RAN real-time functions, mainly at the physical layer and lower MAC layer, e.g., access network scheduling, interference coordination, modulation and coding, are still performed at the sites with dedicated hardware support; while some RAN non-real-time functions in the upper layers with low latency requirements, like inter cell handover, cell selection/reselection, user-plane encryption, could be moved to the cloud, where the resources can be shared and information exchanged [4].

IV. LITERATURE SURVEY

TABLE 1. LITERATURE SURVEY

4.1 Problem Statement

To experiment, modify and analyze lightweight cryptographic algorithms for data security and compare them based on total encryption/decryption time, memory consumption, size of input data, and power consumption using lightweight devices. The algorithm performance will be tested on a well-powered PC as well to see and optimize
it for resource limited devices.

V. ANALYSIS OF SIMON ALGORITHM

The SIMON block cipher with an n-bit word (and hence a 2n-bit block) is denoted by SIMON 2n, where n is required to be 16, 24, 32, 48, or 64. SIMON 2n with an m-word (mn-bit) key is referred as SIMON 2n/mn. For example, SIMON 64/128 refers to the version of SIMON acting on 64-bit plaintext blocks and using a 128-bit key. Each instance of SIMON uses the familiar Feistel rule of motion. The algorithm is engineered to be extremely small in hardware and easy to serialize at various levels, but care was taken so as not to sacrifice software performance.

ROUND FUNCTIONS

SIMON 2n encryption and decryption make use of the following operations on n-bit words: • bitwise XOR, ⊕, • bitwise AND, &, and • left circular shift, S j, by j bits. For k ∈ GF(2)n , the key-dependent SIMON 2n round function is the two-stage Feistel map Rk: GF(2)n × GF(2)n → GF(2)n × GF(2)n defined by Rk(x, y) = (y ⊕ f(x) ⊕ k, x), where f(x) = (Sx & S 8x) ⊕ S 2x and k is the round key. The inverse of the round function, used for decryption, is R −1 k (x, y) = (y, x ⊕ f(y) ⊕ k). The S key schedules take a key and from it generate a sequence of T key words k0, kT−1, where T is the number of rounds. The encryption map, then,

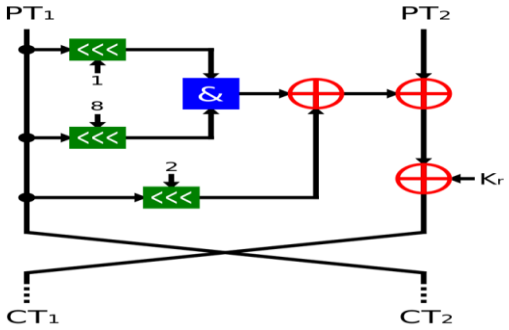

Figure 2. Feistel stepping of the Simon round function.

is the composition RkT−1 ◦ · · · ◦ Rk1 ◦ Rk0 , read from right to left. Figure 3.1 shows the effect of the round function Rki on the two words of sub cipher (xi+1, xi) at i step of this process. [5]

VI. PROPOSED SYSTEM

The proposed algorithm is a symmetric key block cipher. It constitutes 128-bit key. In any symmetric key algorithm, the encryption process is made up of several encryption rounds Sonic mathematical functions define each round to create confusion and diffusion. Increasing number of rounds will ensure better security but will increase the consumption of the device

A typical algorithm usually consists of on average 10 to 20 rounds so that the encryption process is strong enough, but the proposed algorithm restricted to only five rounds. The algorithm uses the Feistel network. It creates sufficient confusion and diffusion of data so that attacks can be confronted.

The algorithm consist of two parts:

A. Key scheduling

B. Encryption process

Key is the most fundamental component in the process of encryption and decryption. The entire security of the data is reliant on the key. the secrecy of the data will be test if an attacker happens to know the key. Therefore the

revelation of the key should be as difficult as possible. The Feistel network used here consists of five rounds each requiring five unique keys for the encryption/decryption purpose .On figure 4 the key scheduling block odd illustrated.
The proposed algorithm requires a64. Bit key. A64 bit of data can be encrypted or decrypted using the key. In order to guard against exhaustive search attack the length of the first key must be large enough to that it becomes difficult for the enemy to perform key searching attack .A cipher key takes input in 64-bit. The cipher key is input to the key expansion architecture. The block creates five unique key after going through much confusion and diffusion. The modification that is made from the existing algorithm is shown in dashed border. Inside the border there are four blocks called non-linear bit shuffling replacing conventional matrix operation. The non-linear bit shuffling of efficient in creating more confusion and diffusion then the other non-linear operation. The non-linear bit- shuffling is efficient in creating more confusion an

VII. RESULT AND DISCUSSOION

7.1 Performance analysis

After testing the data i.e. text files, audio files and video files of increasing key length we have obtain the below results in the form of graphs.

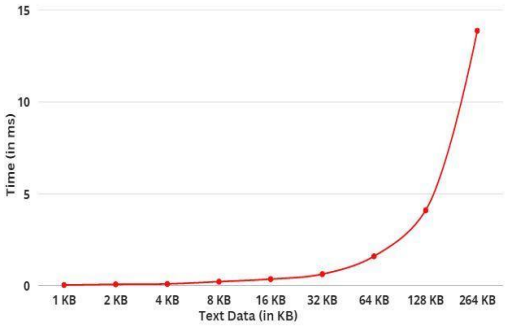

Figure 3.Encryption time vs. text data

The above Figure 3 is the graph of encryption time vs. text data and from Figure 3 it was observed that after 32kb of input data there is an exponential rise in time.

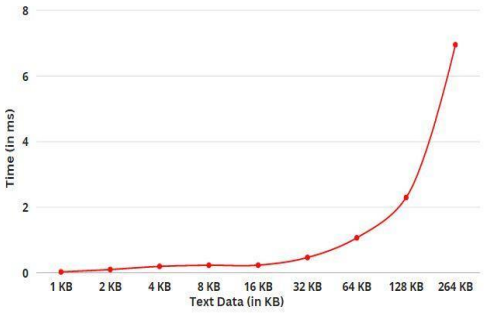

Figure 4.Decryption time vs. text data

The above Figure 4 is the graph of decryption time vs text data and from Figure 4 the pattern observed is similar to that of the graph of encryption time vs. text data (Figure 3).

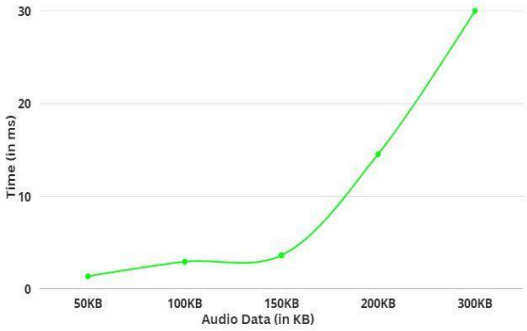

Figure 5 Encryption time vs audio data

The above Figure 5 is the graph of encryption time vs. audio data and from Figure 5 it was observed that after 150kb of input data there was a steep rise in encryption time.

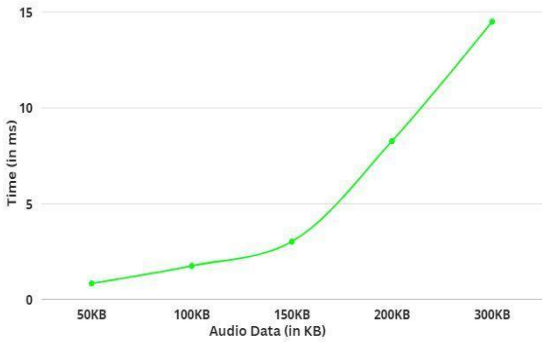

Figure 6 Decryption time vs. audio data

The above Figure 6 shows the graph of decryption time vs. audio data and from Figure 6 the pattern observed is similar to that of the Encryption time vs. audio data (Figure 5).

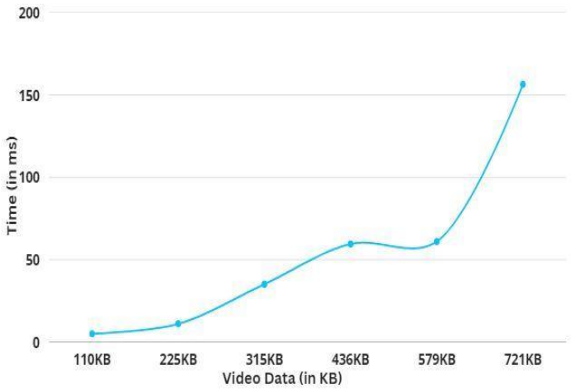

Figure 7 Encryption time vs. video data

The above Figure 7 represents the graph of encryption time vs. video data and from Figure 7 it was observed that after 579kb of input data there was a steep rise in the encryption time.

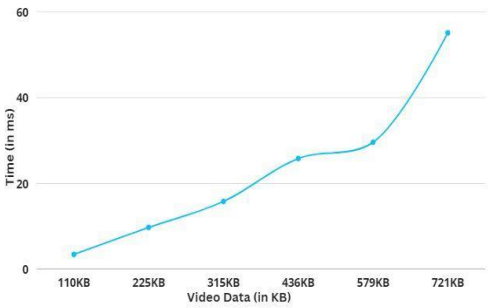

Figure 8 Decryption time vs. video data

The above Figure 8 represents the graph of decryption time vs. video data and from Figure 8 we observed similar pattern that of the encryption time vs. video data (Figure 7).

VIII. CONCLUSION

From the above observations it was discovered that as the size of the file increases encryption and decryption time increases exponentially. Also, it was found that there is a similar pattern between encryption and decryption of the same type of input data.

IX. FUTURE SCOPE

New and improved algorithms could be developed which are better in security levels and take less time for execution, have useless memory, and decrease power consumption. These would be beneficial for next-generation devices like the upcoming 5G devices. Similarly, the existing algorithm can be modified by changing the number of rounds and key size to make it more efficient.

A Study And Review On Quantum Cryptography

Ms. Prajakta Pote, Dr. Rajesh Bansode
Department of Information Technology, Thakur College of Engineering & Technology, Mumbai, India
praj.pote1@gmail.com, rajesh.bansode@thakureducation.org

Abstract— **Quantum cryptography is a new innovation that uses quantum physics to protect network communications between two individuals. The inviolability of quantum mechanics laws underpins the security of these transmissions. Quantum cryptography, by extension, simply employs quantum mechanics principles to encrypt and transmit data in an un-hackable manner. Quantum computers are a new and fascinating branch of computer science. Quantum computer technology depends on quantum physics laws and has high processing power due to the ability to be in multiple states at the same time and perform all possible permutations. When quantum computers are developed, it will be very easy to solve many problems, including the accurate solution of very complicated processes. This research paper will give a brief history of quantum computers, an emergence to quantum computers, a characterization of how they work , a summary of their attributes and functionality, and various potential scopes of quantum computers.**

Keywords— Quantum cryptography, Virtual Private Network, QKD Protocol, Shor's Algorithm

I. INTRODUCTION

A. *Histoty of Quantum Cryptography*

Steven Wiesner created quantum cryptography in the early 1970s with his studies [1] "Conjugate Coding", which took more than ten years to complete. Quantum cryptography is based on some fundamental principles of quantum mechanics: the Heisenberg Uncertainty principle and the photon polarization principle. Based on the Heisenberg Uncertainty Principle, measuring the quantum state of any system without distributing that system is impossible [2,3,4]. Due to the no-cloning theorem, which was first presented by Wootters and Zurek, an eavesdropper cannot copy unknown qubits, i.e. unknown quantum states, according to the principle of photon polarization. Because of the no-cloning theorem, which was first presented by Wootters and Zurek in 1982[5], an eavesdropper cannot copy unknown qubits, i.e. unknown quantum states. Quantum computer technology is based on quantum physics laws and has high processing power due to the ability to be in multiple states at the same time and perform all possible permutations. When quantum computers are developed, it will be very easy to solve many problems, including the accurate solution of very complex chemical processes.

B. *Moore's Law*

In the past few decades, we have experienced the spectacular and, at times, inconceivable advancement of PCs. Since the invention of Silicon transistors, PC control has grown at an astounding rate, while PC estimate has shrunk at a comparable rate. To be sure, this reality has manifested itself as a law, Moore's law, fig. 1, which states that the number of transistors on a chip pairs every eighteen months. The physical hypothesis of items separated from their surroundings. Because it is extremely difficult to isolate expansive items, quantum theory is essentially a hypothesis of the tiny universe of particles and their constituents.

As one of its primary standards are the double wave-like as well as molecule-like behavior of both matter and radiation, along with the expectation of probabilities in circumstances where conventional predicts certainty.

For numerous reasons, traditional material science gives a reasonable guess to quantum physical science, particularly in conditions with a large number of particles. Max Planck, a physicist, presented his quantum hypothesis to the German Physical Society in 1900.

He discovered the answer to his question by assuming that vitality existed in discrete units, similar to how matter does, rather than as a continuous electromagnetic wave, as was previously assumed, and was thus quantifiable.

The presence of these units became the primary premise of quantum theory.

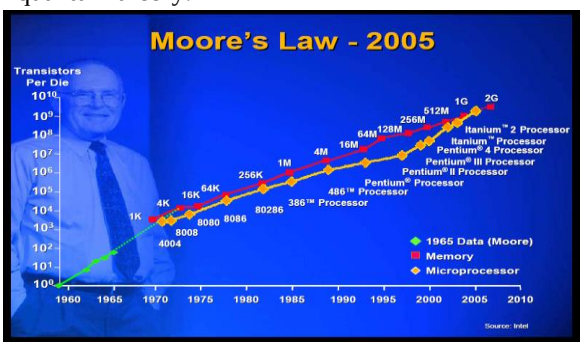

Fig. 1 Moore's Law[5]

Quantum Hypothesis Development

- Planck proposed in 1900 that vitality was composed of discrete units, or quanta.

- Albert Einstein predicted in 1905 that not only vitality, but also radiation, could be quantified in a similar way.
- In 1924, Louis de Broglie presented that there is no significant difference in the appearance and behaviour of vitality and matter; on the nuclear and subatomic levels, both can function as if they were made of particles or waves.

C. Quantum Computing

Quantum computing is a field of study that focuses on developing computer technology and describes the nature and behavior of energy and matter at the atomic and subatomic levels. It is based on the concept of quantum theory. The shortcomings of classical cryptography methods, which can be classified as "public-key systems," "private-key systems," and "one-time pad systems," inspired the development of quantum cryptography. In traditional cryptography, communicating parties must share a secret sequence of random numbers, known as the key, which is exchanged physically, putting security gaps open [6].

If the development of quantum computers is feasible, then from Abacus to modern-day Supercomputers, there will be a leap in computing capacity with a performance gain in the billion fold scopes and beyond. Alen Turning invented a programmable computer in 1936 to demonstrate that some mathematical problems could not be solved. Their argument was based on the idea that computers with sufficient resources are capable of realizing any appropriate algorithms. A quantum computer algorithm is a probabilistic transition for today's programmers that include imagining.

We can compare it to the first time we used a new technology, such as Object Oriented Programming or multithreading.

The computer that we use today fundamentally operates on two states: 0 or 1. A qubit (also known as a quantum bit) is a single unit of quantum information in quantum computing.

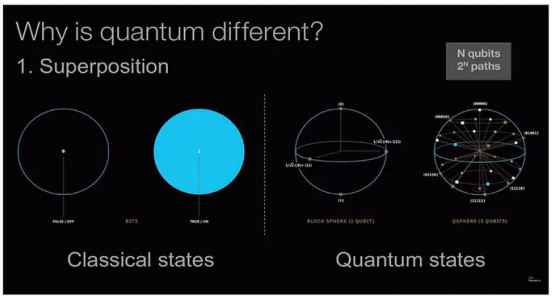

Fig.2. Superposition of Quantum [7]

Superposition is the property that states that a qubit can have both zeros and ones at the same time. According to the quantum system, a qubit does not have to be 0 or 1, but it can be in any ratio of 0 or 1. The quantum system allows you to be in several states at the same time.

D. Why quantum is different?

Entanglement is an extremely strong bonding between quantum particles. The correlation between quantum particles is extremely high, and even if they are separated by a great distance, their particles will be associated with one another. Quantum entanglement occurs when two particles or a group of particles behave in such a manner that their quantum superposition and properties cannot be characterized individually.

The distance between the two particles is irrelevant; they might be sitting perfectly next each other separated by billions of km. These particles appear to be linked in such a way that when one molecule is observed, it describes the state of the other.

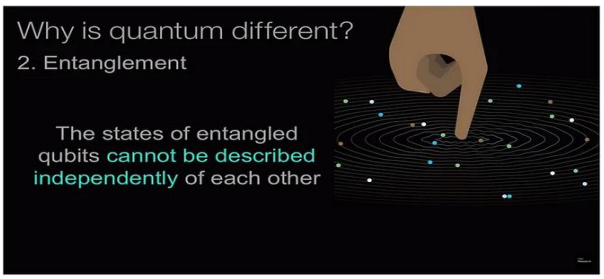

Fig. 3 Quantum Entanglement

E. Working of Quantum Computing

The quantum computer's operation is based on quantum physics, where the terms superposition, qubit, and entanglement are used to provide a better understanding of how it works.

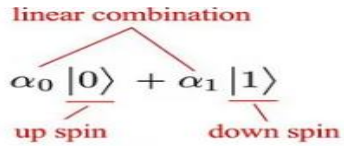
Now, consider the following hypothetical example to better understand how a quantum computer works to solve a problem: When working with a traditional computer, if one need to find a way out from one side of the tunnel to another opening end, they must choose one direction and begin following it until they reach the destination, which may be a dead end, at which point they must turn around and begin following another direction until they find the way out.

Now, for another approach, call two people and instruct one to stand at the tunnel entrance and the other at its exit. Now, in each direction, release a different colored gas; the individual standing at the exit point will determine the color of the gas particles that are initially noticed at the exit. As a result, the path determined by the individual standing at the exit point will be the best and shortest path through into the maze. A quantum computer functions similarly to the example above.

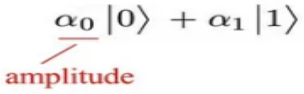
a. Qubits

A qubit is a physical quantum information carrier. It can encode an exponential amount of information with superposition, which can scale a solution better than classical computing. When measure a particle's spin, it is either in the "up" or "down" state. However, in the quantum world, the spin is in a state of

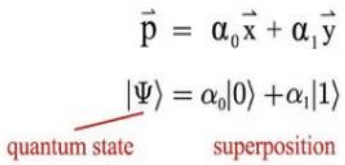
superposition. The mathematical description of a spin indicates whether it will be "up" or "down" when measured. Such uncertainty exists in reality until measure it. As a result, when one say a particle's spin is in a superposition of states, which merely mean it is in a linear combination of up spin and down spin.



The coefficient α is termed as the amplitude. It is associated with the likelihood of being "up" or "down" when measured.



The basis vectors are simply the up and down spin states (being 0 "up" or 1 "down"). The idea is similar to the x and y basis vectors in Newton's law of motion.



The superposition is shown in matrix form in The Dirac notation $|\psi\rangle$.

$$|\Psi\rangle = \alpha_0|0\rangle + \alpha_1|1\rangle = \begin{bmatrix} \alpha_0 \\ \alpha_1 \end{bmatrix}$$

superposition

The orthogonal basis vectors $|0\rangle$ and $|1\rangle$ are encoded as follows:

$$|0\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad |1\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

0: not spin up

1: spin down

It also has a dual form written as:

$$\langle 0| = \begin{bmatrix} 1 & 0 \end{bmatrix}, \quad \langle 1| = \begin{bmatrix} 0 & 1 \end{bmatrix}$$

F. Quantum computing And Algorithm

Quantum cryptography tries to provide information security by utilizing the fundamental features of quantum mechanics. Charles Bennett and Gills Brassard created the first key distribution mechanism in 1984.

It is designated as BB84. This is the first discovered quantum distribution scheme. The distribution of single particles or photons is the foundation of the quantum system, and the polarization of a photon encodes the value of a classical bit.

The Heisenberg uncertainty principle and the principle of photon polarization are two major foundations of twentieth-century quantum mechanics on which quantum cryptography is based.

According to the Heisenberg principle, certain physical qualities are linked in such a way that measuring one prevents the observer from knowing the value of the other at the same time. When measuring the polarization of a photon, for example, the direction of measurement impacts all subsequence measurements.

This means that a photon's or light particle's polarization can only be determined at the time of measurement. This idea is critical in preventing eavesdropping attempts in a quantum cryptography-based cryptosystem.

The photon polarization principle, on the other hand, describes how light photons can be polarized in a certain direction. Furthermore, an eavesdropper cannot duplicate unknown qubits, or unknown quantum states, because of the no-cloning theorem [7].

Quantum cryptography allows two communications parties to agree on a bit string without having to meet face to face, and those two parties can be confident that the agreed bit string is solely shared between them.

BB84 enables two parties, often "Alice" and "Bob," to create a secret common key sequence using polarized photons.

Each of these photons is in one of the four states depicted by the symbols —, |, /, \.

The first two photon states are emitted by a rectilinearly oriented polarizer, while the remaining two states are emitted by a diagonally oriented polarizer.

For example: +(0)= — , +(1)= | , x(0)=/, x(1)= \

If Alice sends random sequence of photons: ++xx++xxx++xx the binary number represented with these states is 1110010110010. Following figure shows a working of quantum cryptography.

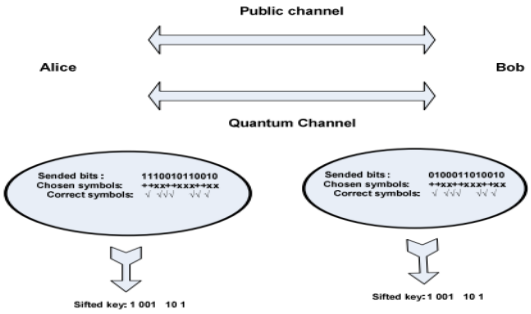


Fig. 4 Working of Quantum Cryptography [6]

II. DARPA QUANTUM CRYPTOGRAPHY NETWORK

The DARPA Quantum Network (2002-2007) was the first quantum key distribution (QKD) network in the world. The DARPA Quantum Network was entirely compatible with normal Internet technology and could be used to establish Virtual Private Networks (VPN), enable IPsec or other authentication, or for any other purpose. The cryptographic virtual private network is the DARPA security model.

Following figure shows that traditional Virtual Private Networks use public-key and symmetric cryptography to achieve confidentiality and authentication/integrity.

The public key mechanism facilitates key exchange or agreement as well as endpoint authentication.

Symmetric mechanisms (such as 3DES and AES) ensure traffic confidentiality and integrity.

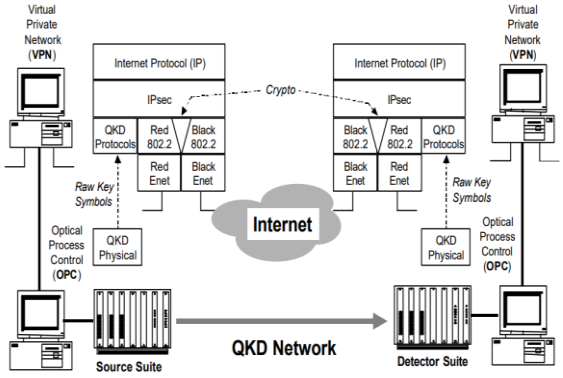

Fig. 5 A virtual Private Network (VPN) based on Quantum Key Distribution [8]

III. QKD Protocols

Basic steps required for to implement QKD Protocol Stack [9] is shown in below figure.

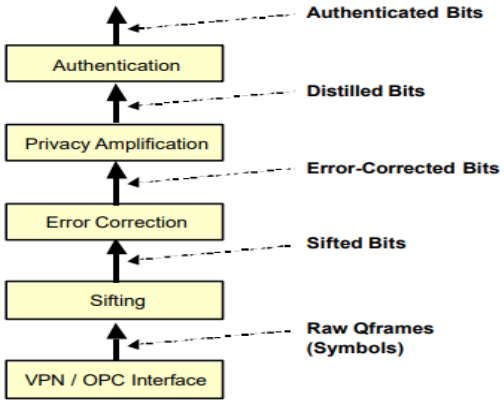

Fig 6 The QKD Protocol Stack [9]

Sifting is the process by which Alice and Bob filter out all of the prevalent "failed qubits" in a series of pulses. Sifting allows Alice and Bob to remove errors from their "raw" secret bit streams.

Error detection and correction allows Alice and Bob to identify all "error bits" within their shared, sifted bits and correct them. They have the similar sequence of error-corrected bits. The error detection procedure enables Alice and Bob to estimate the current Quantum Bit Error Rate (QBER) on their quantum channel, which can then be utilized as input for privacy amplification.

The method by which Alice and Bob lower Eve's knowledge of their shared bits to an acceptable degree is known as privacy augmentation.

Authentication protects Alice and Bob from "man in the middle attacks," which allow Alice to confirm that she is interacting with Bob (rather than Eve) and vice versa [10, 11].

IV. Shor's Algorithm

Shor's computation, discovered in 1994 by Peter Shor, is the standard scenario for a quantum calculation and one of the most crucial. The calculation used quantum figuring to solve the problem of determining the two prime variables of a whole number [12, 13]. This is a huge concern because most security systems rely on RSA encryption, which is based on a number being the result of two large prime integers. Shor's computation can factor a large number in polynomial time, but a standard PC has no known effective calculation for factoring large integers. If a person had a quantum computer with enough qubits, they could use Shor's calculation to hack into online banks, read other people's mails, and access vast amounts of other sensitive information.

V. Capabilities, Standards, and Resemblance with Current Systems

Quantum computers [14, 15] allow for quite vast concurrency: quantum parallelism is a property of quantum computers that allows them to solve a function f(x) for several possible values of x at the same time, whereas current techniques can only provide one solution at a time.

The computer provides a highly rapid environment for many computations: there are various difficulties such as mathematical equations, chemical formulas of chemistry, and physics concepts that the classical computer cannot evaluate, but the quantum computer solves them extremely quickly.

The quantum particles have such strong bonds that they remain connected even when separated by a vast distance, resulting in an excellent transmission.

Scientists and researchers are now expecting to use quantum simulation to create entirely new molecules for medicine. Researchers are also exploring for ways to use quantum mechanics to better understand how chemical changes function. Table 1 shows that Summary table for Quantum and classical cryptography. On a memory device, a traditional computer stores all information as either 1 or 0. (Binary system) [17]. Classic computers use this logic to solve specific problems with additional resources. Quantum Computers are the next level of computers that use quantum theory principles to solve problems. A qubit is a fundamental unit of the quantum computer.

A qubit can be 0 or 1 or a mixture or overlay in either st ate, whereas a binary bit can only be 0 or 1. Quantum algorithms are built on principles that are fundamentally distinct from standard algorithms. Quantum computers and bit developments have focused on quantum technology, such as quantum recreations, correspondence, calculation, climate, and sensors [17].

Table 1 a. Summary table for Quantum and classical cryptography [16]

Features	**Quantum Cryptography**	**Classical Cryptography**
Basis	Quantum mechanics	Mathematical computation
Development	Infantile & not tested fully	Deployed and tested
Existing Infrastructure	Sophisticated	Widely used
Digital Signature	Not present	Present

Bit rate	1 Mbits/avg. [10]	Depend on computing power
Cost	Crypto chip	Almost zero
Register storage(n bit) at any moment	One n-bit string	2^n n-bit string
Communication Range	10 miles	Millions

Scientists and researchers anticipate that quantum simulation will be used to build whole new molecules for medicine. Researchers are also looking into using quantum mechanics to better understand how chemical changes work.

Table 2 b. Classical computing vs Quantum computing [17]

Classical Computing	Quantum Computing
Calculates using transistors that can represent 0 or 1.	Calculates with qubits, which can represent both 0 and 1.
The number of transistors has a 1:1 relationship with power.	Power grows exponentially in direct proportion to the number of qubits.
Computers can operate with a low error rate at room temperature.	Computers have a high error rate and must be kept extremely cold.
The majority of everyday processing is best handled by traditional computers.	Ideal for tasks such as optimization, data analysis, and simulation.

Table 2b shows comparison between the classical and quantum computing areas in different parameters.

VI. Future Scope

Following a long period of laborious struggle with no promise of success, quantum processing is suddenly humming with warmer intensity and action.
Almost two years ago, IBM made a quantum PC available to the public: the 5-quantum-bit (qubit) asset known as the IBM Q encounter. That appeared to be more of a toy for experts than a means for doing any real math.

Transmon cryogenic 5-qubit gadgets, for example, have marked the end of the era of conventional Quantum PCs.
Experts worldwide are currently concentrating on establishing large-scale production of multi-qubit gadgets in order to enable the development of costly scale Quantum PCs with billions of qubits, which will be required to address real concerns.

Furthermore, quantum computers require additional effort to detect and correct errors because all qubit technologies available today are exceedingly fragile and prone to error.
Researchers in China and others have started to look into the feasibility of developing quantum systems using equivalent standards to quantum figuring.

Inside the long haul, the establishment of these systems would set the stage for a quantum web, a more secure correspondence framework in which data is stored and sent using cutting-edge cryptography. However, such a system won't be truly recognized until quantum PCs become multifunctional, which Science fiction supporters believe will happen before 2050. Researchers are eager to use Quantum PCs to analyze organisms in order to create new antibodies, which the Quantum computer could then use to improve to reduce undesired interactions.
Some scholars believe that Quantum PCs are critical for achieving achievement protection and medical standards for social insurance.

VII. Conclusion

In comparison to current conventional systems, quantum computing is a very advanced technology. Quantum computing processing is extremely fast, and it is also extremely powerful. As we can see, everything is connected to the computer, and every aspect of our work is dependent on computers, so quantum computing as an innovation in the field of computing will shape the future and learning thing for society, where various problems and difficulties will be easily solved in very little time.

However, the deployment of the quantum computer is challenging; for example, it is difficult to manage quantum particles, the quantum computer produces a lot of heat, therefore it requires a cool atmosphere, they are extremely costly.

The quantum computer is not designed for tasks such as word documents or email communication.

Abstract— **Along with its energy industry, the Indian economy is on the verge of a revolution in energy transmission. A more adaptable, intelligent transmission system dependent on cutting-edge technologies is already beginning to replace the conventional transmission system. The increase of electrical sources is beginning to put pressure on the Indian grid infrastructure. India will need a dependable EV charging infrastructure above all else. Blockchain technology has the potential to help India overcome its charging infrastructure development dilemma as well as the issue of the short electric range of these EVs. Blockchain even promises to give a viable answer for users' transaction privacy. With its distributed ledger technology, all transactions may be pooled together and allocated a specific unique code, preserving privacy. As the renewable sector expands at a rapid 17.33% CAGR. Transmission and distribution losses, as well as decreased power purchase agreement (PPA) prices for prosumers, drive blockchain technology forward. Indian enterprises should seize the chance with both hands and make the most of best practices combined with innovation. India has the potential to be a driving force in the digitally driven future of renewable energy distribution and transmission.**

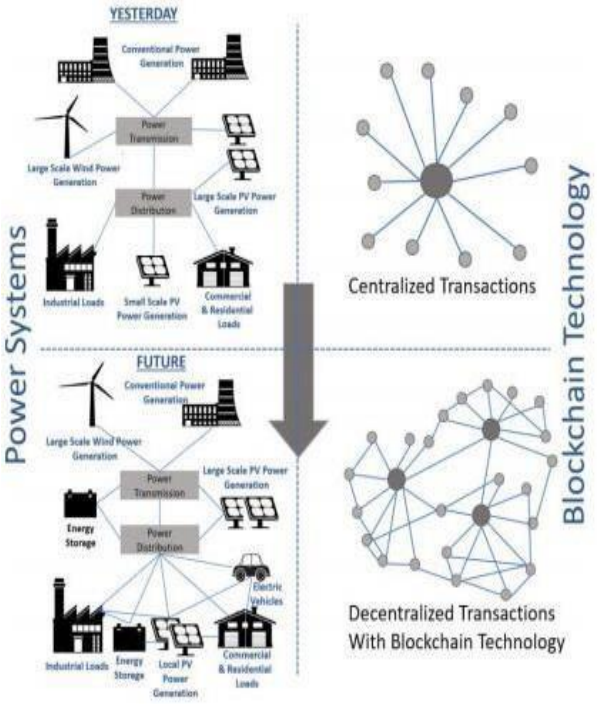
Keywords—Energy Blockchain, Peer-to-Peer Trading, Renewable energy trading, Energy Infrastructure

I. INTRODUCTION

Blockchain is a revolutionary technology that has emerged in this digital era and is based on cryptography. This technology enables transaction management in real time. Based on the term, Blockchain, construct a data block that is linked to the preceding block in the chain. Blockchain transactions cannot be changed since each block has a unique number and a hash function that is connected to the preceding block. This eliminates the need for a central administrator because the transaction is recorded on a distributed ledger and validated by network peers. In general, there is a conventional energy market in India, where users may purchase power from approved businesses. Peer-to-Peer trading is a new type of energy trading system.

The energy is subsequently stored in a digital electricity plant (VPP), which allows for asset management and tracking. Before each day of buying and selling begins, the gadget uses an average of predictions to estimate how much energy will be produced during the day. The energy consumers have a role in a smart grid since each energy

(4.) There is no incentive system in place to encourage the adoption of energy transfer using blockchain Both the consumer and the provider are involved. Excess renewable energy generation might be exchanged with the utility and other customers in need of power resources for mutual benefit.



II. LITERATURE REVIEW

Because of the increase in renewable energy sources, energy trade is transitioning from centralized to dispersed. The extra renewable energy generated can be transferred for mutual benefit to other users with power deficits via application. People have widely adopted Blockchain, a digital distributed public ledger technology. The government has also demonstrated their vision for smart grids, new models, and technologies that can produce solutions to efficiently manage energy and allow for an optimal flow of power. Individuals can only buy power in a traditional grid, however in smart grid technologies, individuals can be both power suppliers and consumers.

Challenges of Blockchain enabled Energy Trading:

(1.) In comparison to transaction costs, efficiency is low and it is impossible to achieve system requirements due to other technical shortcomings of the technology.

(2.) Because blockchain technology is complicated to understand, some people may decide not to use it at first. (3.) The pricing strategy for a deal is flexible.technology. How to safeguard the privacy of the data is the issue that needs to be resolved.

(5.) It is challenging to guarantee the lowest cost when there are so many variables that affect the system.

(6.) Strict, unclear rules or framework

(7.) Another difficulty now is the excessive powerusage & lack of interoperability.

III. METHODOLOGY

Based on the energy exchange mechanism now in place in Brooklyn, USA, a blockchain model was created. The construction of subtleties like infrastructure, procedure,

and phone apps model was made after a thorough analysis of the literature in the sectors of blockchain and energy transfer. A decentralized blockchain system feasibility assessment is then conducted. Numerous businesses, such Power Ledger, Ener Chain, Me SOL Share, etc., are now working to establish an energy blockchain. This paper is based on a careful analysis of numerous blockchain-based apps used by various businesses throughout the world. There are now some gaps inthe blockchain technology that limit its potential applications. Based on an analysis of these gaps under specific criteria using various research reports and expert publications, corrective methods are being offered to close these gaps.

IV. ANALYSIS

A. Applications of Blockchain

1) Wholesale distribution of electricity

Businesses looking to integrate blockchain technology into the wholesale power distribution sector are aware of the importance of tying end consumers to the grid. With the useof blockchain technology, consumers may purchase and sell energy instantly from the grid rather than from retailers. Grid+ is a blockchain energy firm that specializes in distributing wholesale power. The company has identifiedretailers as the primary driver of inefficiencies in the consumer energy sector. Very little or none of the grid infrastructure is owned by retailers. By adding a blockchain- based platform to existing retailers, it is possible to cut client costs by about 40%.

1) Peer-to-peer energy trading:

According to a Wood analysis, more than 50% of blockchain-based power projects engage in P2P trading. In this system, a person with excess power can trade with someone who needs power. No other agency is involved in this.

Enterprise versions of Ethereum are used by many businesses. For instance, the energy web foundation base builds up their platform using Ethereum, Truffle developer tools, and Gnosis multi-signature wallets. People who generate their own energy may be able to trade it with their friends and neighbors.

Power Ledger, a corporation with its headquarters in Australia, has linked groups together to form "micro grids." A micro grid is a collection of connected but dispersed energy sources. Additionally, in parts of the expanding world where electricity grids can.

However, blockchain can still enable more players to sell electricity even if it cannot completely replace the grid. For instance, Vattenfall, the largest utility in the Nordic region, is conducting trials in which it uses a private blockchain network to record energy transactions in which department stores or possibly individual homes can sell energy produced by distributed batteries or solar panels; in the past, such transactions may have been prohibitively expensive and time-consuming to process.

2) Electricity data management:

Customers may benefit from better performance and control over their energy assets thanks to blockchain. An immutable ledger also provides safe and up-to-date information on energy usage statistics. Market prices, marginal prices, compliance with power regulations, and fuel prices are only a few examples of the several sorts of energy records. Records are routinely purposefully manipulated, simultaneously altered, and omitted.

Businesses and governments may be hampered by the costs associated with intentional desecration and unintentional administrative errors. Like how open blockchains' simplicity reduces the likelihood of financial or record-related misuse.

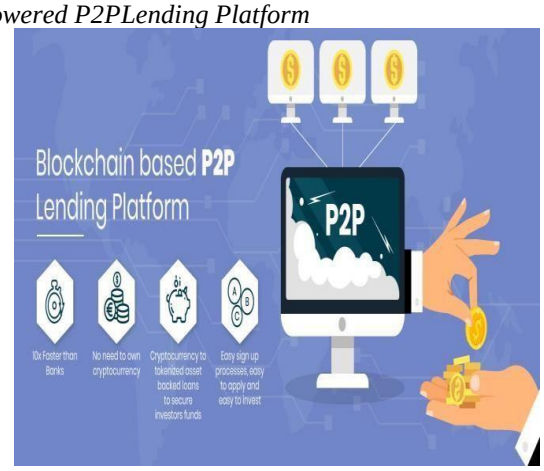
3) Trading in commodities:

Another area that might be disrupted by blockchain innovation is the exchange of gas and energy. Organizations have invested millions in the construction of customized trading platforms tailored to the unique needs of the energy business.

To maintain, modernize, and protect these frameworks, significant costs are necessary. Comparing current limiting frameworks to blockchain innovation for product exchange would be less expensive and more effective. The blockchain would allow for the modification of permanence, security, and instantaneity, eliminating the limited adaptability of extremely large-scale restricted frameworks.

International businesses involved in energy blockchain includes: GRID+, ONDIFLO, Radiant Earth [2].

B. Analyzing the Components of a Blockchain-powered P2PLending Platform



1) Peer-to-Peer Lending:

In this type of financial system, borrowers work directly with lenders to get unsecured loans. This system's weakness is that it depends on outside parties, which drives up transaction costs and transaction times.

2) Decentralized P2P Lending:

Decentralized P2P crediting either eliminates the need for outsiders or assumes cheap operational expenses for marginalized organizations. Additionally, the decentralized stance supports crediting schemes and implements themquickly. It makes it possible for a P2P advancing structure to function as a unified platform for people and organizations to successfully acquire and advance credits at competitive rates without the need for a middleman.

It offers accessibility from anywhere at any time in addition to quicker credit checks and KYC/AML (Know YourCustomer and Anti Money Laundering) standards. Additionally, any device with an active internet connection can access this new decentralized system

from anywhere.

3) Creating a public blockchain-based P2P lendingplatform:

Generally P2P lending platform is not a type of any financial construction and in most case all the banking regulation does not affect this system. In this system loans arenot secured and there is a risk on lender side in case the borrower default in repayment of the money.

4) Market Risks:

The system's primary flaw is that lenders earn if borrowers return their loans, while borrowers receive funds quickly.

A Public P2P Lending Platform Overview

For this platform, a model prototype was created. This prototype concept combines Ethereum, third-party connectors, and technology like smart contracts to speed up the entire process rather than centralized blockchain technology. In these platforms, it was possible to set up loan repayment using ERC20 currency.

5) A typical loan application process:

On the decentralized P2P platform, processing a loan application takes roughly 3–4 minutes (internet site). A blockchain-based entirely loan smart statement with a completely unique identification for the person who has requested the amount is created at some point during the process. The borrower must include their PII (personally identifiable information) to ensure compliance with neighborhood rules and KYC procedures. The resulting grade improves the KYC process by considering social media accounts, professional groupings, and verifiable website statistics. After the data has been successfully verified and scored, the platform offers or publishes the loan request for lenders. The lenders engaging in a reverse auction provide the loan to qualified debtors at competitively low interest rates.

6) Smart contracts-powered automated lending processes: When the borrower downloads the funds after accepting one ofthe offers, a smart contract based on blockchain technology islaunched. With this technique, funds were automaticallycollected, sent to the designated account, and a paymentreminder was sent. Platform automatically imposes penalties onthe borrower in the event of default. As soon as the paymentdue date approaches, it continues to alert the borrower. Higherinterest rates are incurred because of late payments, and theyare applied to subsequent installments.

7) Reducing the last market risk of lending:

The platform uses a Smart Compensation Fund Contract plan to reduce the last major P2P lending risk, which is default borrower. The Smart Compensation Fund is charged a nominal fee following each loan application process. Because there are more loan programs, the sum accumulates fractionally. It makes the Smart Compensation Fund act as asurety for lenders, lowering or maybe delaying the last significant threat to the system. This pricing structure is used to cover operational costs, raise revenue, and transform tokens into highly valuable digital currency.

There are numerous businesses that operate in the blockchain technology industry. One of them is oodles, a provider of P2P trading, syndicate loans, mutual funds, and other services. Users using their program can analyze business problems and make appropriate decisions [3].

8) Applying blockchain technology to electric power systems:

Our electric power systems are becoming increasingly sophisticated in modern times. Blockchain can be utilized to handle this complexity successfully. In 2017, a number of firms collectively received almost $300 million USD for the purpose of advancing blockchain technology in the energy sector. Blockchain can be used to monitor the creation of renewable energy. Blockchain technology is being developed for use in EV charging payments, among other things.

Due to coverage issues and the necessity for reliable returns, energy utilities are unable to swiftly react to the change, thus prosumers must put up their smart systems to help the grid match demand with risky renewable electricity supply. To ensure the electricity system runs well, utilities, customers, and outside businesses should work together to harness the massive amounts of real-time operational data.

The second most alluring business for investors is blockchain. Organizations like the Tokyo Electric PowerCompany in Japan and E. ON in Germany are launching theirown companies or collaborating with young startups.Businesses that own power plants and trade their electricity inthe wholesale market exist. They believe that blockchaintechnology can increase market efficiency. Big corporationsall around the world are collaborating with startups or startingtheir own projects because they think blockchain may help the transmission and distribution sector as well as the market. Companies collaborate with nonprofits in a different category. For instance, the largest oil firms in the world, likeShell and Statoil, collaborate with the charity organizationRocky Mountain to fund the Energy Web Foundation.

Building an energy application on a blockchain platform is a major objective.

It would be vital to keep an eye on the involvement of regulatory organizations in the commercial use of blockchain-based P2P power transmission because the power industry in India is extensively regulated with several rules and regulations.

9) Grid transactions:

Many energy trading systems that are less radical than a totally decentralized peer-to-peer network are considerably more likely to succeed commercially and receive support from established utilities and regulatory authorities. These"grid transactions" refer to the buying and selling of energy within the framework of an electric driven energy device, where the energy grid is still fundamental even though its design and features have undergone significant changes.

Enel is spearheading the Ener chain undertaking to use blockchain to enhance existing wholesale electricity markets.

Large energy plant owners in these markets sell significant volumes of power to utilities and retailers, who subsequently advertise the energy to end consumers. Now, those marketplaces necessitate a centralized company using proprietary software to mediate each energy transaction, which is both time-consuming and expensive. But transactions may be checked quickly and inexpensively if these markets indexed and cleared transactions on a blockchain

network. Similar to this, all market participants would have access to transparent transaction data, enabling more effective buying and selling. Because a blockchain community can handle a large number of smaller transactions that could overwhelm a centralized system, such wholesale marketplaces may eventually desire to expand their pool of players.

In response to charges that always duplicate the demands ofthe grid, businesses and even families could participate by reselling their excess distributed technology on the market.

Nevertheless, there is no such market that accounts for rapid variations in consumer demand among neighborhoods or limitations on neighborhood distribution capability on the more nearby scales handled by the distribution grid. Until far, utilities have spent heavily on expensive infrastructureupgrades, such as new electric substations, when the existing distribution grid cannot keep up with shifting community needs. Yet as the cost of allotted energy resources, such as solar panels, batteries, and fuel cells, declines, it would be more practical to use such resources, whether they were on a customer's property or at the distribution grid.

This might be something that brand-new "distribution markets" seek to enable. Many jurisdictions are experimenting with these markets, from south Australia to New York City. Customers could buy or sell power at time- varying prices based mostly on their location in such markets. Consumers can hire smart software vendors to operate on their behalf and optimize their energy production and consumption based on market signals. Customers should pool their resources if they joined up with third party aggregators, giving the grid the services of a so-called virtual energy plant, which would help the overall device maintain supply and demand in stability despite an influx of intermittent renewable energy at the grid.

Additionally, transactions should be automatically triggered by smart contracts built into the blockchain ledger when specific conditions are met. For instance, customers may offer to charge their batteries with extra grid power while the immediate payment for doing so exceeds a pre- programmed threshold, facilitating green trading. Yet, a blockchain infrastructure may still be improved upon in many ways to detect distribution marketplaces. A utility (or a few other firms entrusted with managing any such market) will need to install a variety of sensors on the distribution grid, establish the limits encountered at each point within the neighborhood, and conduct extensive computations to generate actual-time costs for the marketplace.

Indeed, the focus of Australia's experimental decentralized power alternative project is on solving those urgent technological challenges initially. Sponsors of the project are still unsure of whether the platform will eventually record transactions on a blockchain or not.

10) Energy financing:

Blockchain has increased the pool of investors, which makes it simpler to raise money for renewable energy projects. Even for traditional investors, if a tiny portion of the overall cost can be sourced through this mechanism, it may be appealing. As technology continues to progress, the cost of wind and solar projects has substantially decreased, making them more appealing to all types of investors.

Sustainability attribution:

The use of blockchain to store and exchange sustainability-related properties is one of the most prevalent on-the-spot applications to electric power. Examples of such characteristics are a unit of energy's renewable status and the amount of emissions produced during production. Today, systems for tracking these qualities are complicated, centralized, and vulnerable to fraud and error. Moreover, the compartmentalization of systems limits the smooth exchange of characteristics across geographical boundaries.

Accurate, transparent, and frictionless monitoring and trading of such traits should be possible in a decentralized blockchain community, which might encourage the use of sustainable energy sources and lower carbon emissions. For instance, the starting point software for the energy web uses a blockchain to track power generation down to the kilowatt- hour and to disclose details like the carbon emissions connected with energy production. This would make it possible for owners and consumers of low-carbon energy to calculate carbon offset credits more accurately and provide a mechanism to swap credits for carbon emissions decreased to balance out emissions made somewhere else.

Many utilities and businesses, including Microsoft, Singapore Energy, and Engie, are participating in experimental projects that employ starting place in recognition of this capability. Although current jurisdictions and regulations have failed to monitor and register emissions, via this, governments may become more suited to modify carbon emissions.

In the future, the government may employ designated ledgers for recording and trading carbon emissions from the production, transportation, and use of electricity. Russian Carbon Fund is a business unit of IBM that specializes in developing blockchain networks to track carbon footprints.

11) Electric vehicles:

Due to EVs' growing popularity, the distinction between the transportation and electrical power industries is becoming increasingly hazy. Although there are barriers to customer acceptance, such vehicles.

Particularly, a deficiency of public charging infrastructure may discourage prospective customers. The attraction andadoption of EVs should be increased through blockchain networks that enable private owners of charging infrastructure to easily sell charging services to EV owners.

Companies are having trouble lowering the cost of constructing and maintaining charging stations in the present environment. By using electricity that is not being used in homes or businesses, blockchain-based technology has the potential to lower transaction costs when used to charge electric vehicles. The main obstacle to the adoption of EVs can be removed if this becomes a reality. The blockchain network can also support unusual types of payment transactions.

EVs may also be utilized to be charged or discharged depending on demand, turning cars into moving batteries.

12) Other applications:

A company called Finland is striving to make it easier for power users to control a variety of internet-

connected gadgets. This firm wants to notify clients about their equipment' power use and record it, saving them money. For instance, the UK's electricity regulator Office of Gas and Electricity Markets (Ofgem) plans to register members' power meters as digital entities on a blockchain network to make switching energy suppliers more quickly (now it takes three weeks).

In the area of blockchain technology, several actions have been done to enhance the security of electrical power infrastructure. For instance, Siemens and U.S. government organizations, including the Departments of Energy and Defense, are collaborating on a pilot project to safeguard critical energy sector infrastructure and guard against unwantedintrusions using blockchain-based cryptographic algorithms. Because privacy is a fundamental human right that shouldn't be shared on such a platform, the European Union general data privacy law of 2018 demands for the deletion of some private information. The rate at which blockchain technology is commercialized might be accelerated by a set of standards assuring interoperability between various blockchain architectures. Currently, several nations are developing a brand-new pilot program called as a "sandbox," where entrepreneurs may test their ideas without harming the current electric grid, making it easier to collect money, scale up implementation, and support businesses [4].

C. Need for energy blockchain in India

1) Overview of Energy Sector in India:

India comes in sixth on the global energy consumption index. The primary cause of this is an increase in electricity consumption brought on by increased urbanization. The demand is thought to have grown by 3.6% annually over the past 30 years. As of December 2012, the installed capacity of power generating was 210951.72 MW, according to information posted on the power ministry's website. The entire demand in India is predicted to exceed 950,000 MW by 2030. On the other hand, there is still no electricity in two-thirds of the rural region. The main energy sources in India are thermal (coal, gas, and oil) — 67%, hydro — 13.5%, and nuclear
— 2.1%.

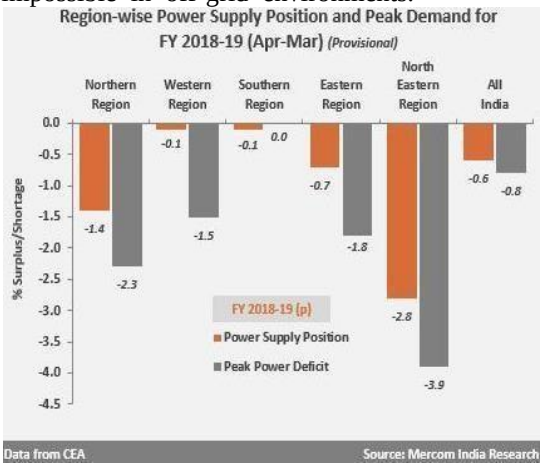
2) Thrust on Solar Power Generation:

India's carbon emissions are rising over the established ceiling norm. India is the third-largest emitter of greenhouse gases on a worldwide scale. A research claims that if India continues to use contemporary methods for producing power, the environment there might suffer greatly.

Given the circumstances in India, PM Modi has declared that by 2022, there should be 175 GW of installed renewable energy in India, of which more than 100 GW would come from solar energy. The Indian government, with the assistance of the state governments, provides subsidies for solar panel installation of up to 70%. The government is also promoting solar power parks around the nation.

From 2014 to 2017, the solar generating capacity expanded by a factor of four. It is 12.50 GW as of 2017. Moreover, the average price has dropped by about 15%, making it more affordable than thermal power.

3) Current Solar Power Distribution Landscape in India and Challenges: Solar energy must now be channeled towards centralized systems for distribution. There might not be an off-grid method to save on transmission costs, which results in waste. Additional infrastructure setups and administrative costs result from this. Solar farms must be able to resell electricity to the public grid in order to remain profitable, which is impossible in off-grid environments.



Also, this restricts the availability of electricity in remote areas without access to the power grid.

4) Blockchain can facilitate the distribution of off-grid, decentralized, sustainable solar energy Framework:

Solar power offers a lot of promise in a nation like India, where people in rural homes are still at a disadvantage when it comes to electricity. Solar energy is widely accessible and gives every family the chance to produce its own electricity. This opens the door for the creation of self-sustaining energy technology that depends far less on a centralized system [5].

Small businesses in a neighborhood may get together and buy/sell solar energy for a fee using a blockchain-enabled decentralized P2P micro energy grid structure without having to send electricity to a bigger grid. The conventional energy micro grid may link photovoltaic systems installed on different types of homes' rooftops. With the help of a main blockchain connected to the grid, the transactions may be controlled and recorded.

Owners of captive solar plants in a hamlet can band togetherto gain from the creation of a solar micro-grid based on blockchain.

I) Solar plant owners can create a cryptocurrency for the trade of energy after creating a consortium.

ii) Get funds in the form of equity and share distribution; utilize the proceeds to build infrastructure throughout rural India.

iii) Prices may be set using a method like the one used for setting gold prices, and they can be changed based on supply and demand in real time.

iv) Only investors who satisfy specific requirements are eligible to receive digital tokens in place of dividend payments[5].

ii) Business issues in energy supply:

The energy industry is currently operating in a highly competitive environment where both private and public entities are struggling to generate the projected revenue. As a result, it is very likely that businesses will try to raise the tariff rate, which will ultimately be paid by consumers, in an effort to cut their losses or boost their profits.

6) Increasing customer expectations for efficient energy provision:

India is a developing country, and customers there are currently more demanding of their needs and even

willing to pay for them, but they also require efficient energy provision, which is essential in all industries, including manufacturing, construction, and the automobile industry.

7) Providing electricity to remote areas where it is not feasible todo so using conventional methods:

Despite the government's efforts through programs like Sau Bhagya and the Pradhan Mantri Sahaj Bijlee Yojana, it is stillnot feasible to provide grid electricity to many villages and remote regions.

No gain for the consumer consuming less units:

Presently, if the customer is getting the benefit to install a captive solar plant on his roof and may use the electricity. If not, it wouldn't make economic to sell the electricity to the grid for

$3 per unit. If blockchain is supported, it may be possible to sell the power produced, which would shorten the solar plant's payback period.

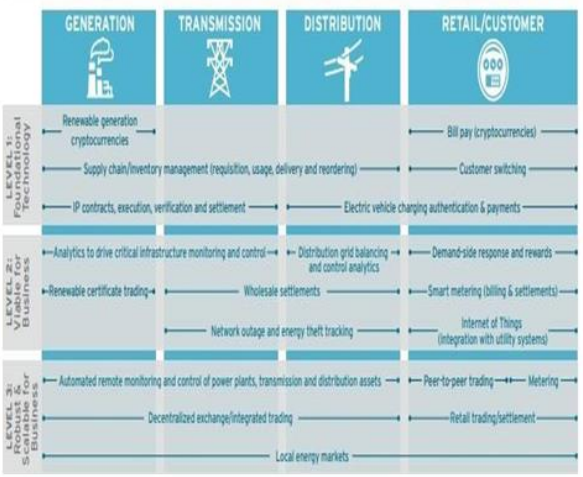
6) Current Transmission & Distribution Losses: To minimize DISCOM losses via transmission and distribution, the government developed the UDAY program, however that effort also fell short of expectations. The current T & D losses are 20%, which is double the global average.

D. Blockchain-based Solar Energy Sources' objectives.

1. Encourage the use of renewable energy sources: Now, energy cannot be transmitted to many villages in India. By establishing a captive blockchain-based micro grid in these places, it would be possible to simultaneously supply their energy demandsand lessen their reliance on conventional energy sources.

2. Disintermediation: All third parties, governmental agencies, DISCOMs, etc. would be eliminated. There is no requirement for an agency to keep track of meter readings, bill computations, or bill distribution to clients. For instance, the prosumer and consumer can create a unique contract that binds them both without the need for a middleman. The user would be able to view their actual energy usage and associated costs.

3. Low Cost: The elimination of middlemen and more equitable energy pricing as a result of increased marketopenness led to lower transaction costs.



4. Widening the scope of the energy market: Prosumers should be liberated from the central government and allowed to sell energy however they see fit. The ability to change suppliers and have adjustable rates would foster competition in the market and benefit users.

5. Exercises are permanently recorded: No extra efforts to record the interactions between various aspects are anticipated. Every hub movement on the blockchain is permanently and sequentially recorded for future use.

V. FINDINGS AND RECOMMENDATIONS

4. 1) Distributed ledger technology (DLT) offers solutions to some of the issues that P2P platforms face with regard to traceability and volume economics. The Digital Ledger Technology (DLT) is a system that allows for the simultaneous storage of the same data across different locations and the ability to update that data whenever a new entry is made by a stakeholder. There is no requirement for centralized data storage with this technique. Outside of the system, electricity is neither produced nor destroyed.

5. Thus, it is essential to retain a record of every transaction. The lifetime volume of power exchanged on the platform may be easily audited thanks to DLT.

Architecture Technology

6. For the architecture of P2P technology, Atlantic Power Exchange (APX) has used a remarkably original strategy. With this method, the technological stack is divided into domains to create a layering structure. They may quickly discover the groups that are pertinent to each domain using this method.

7. 2.1 Energy Area

8. Power is generated in this area and distributed to prosumers or consumers. The place where clever meters are used to monitor power use and improve system performance.

2.1 Control and communication domain

Digitized energy data transfer takes place inside the control and communication domain. This platform's layout acts as a domain export signal. With this feature, demand surges may be met with a coordinated mass reaction that can resolve many blackout incidents, especially those involving activities connected to frequency decreases. In this field, telecoms providers and communication devices both work.

2.2 Token domain

3. The token area is where the conversion of energy information into a token (tokenization), as well as the token exchange, takes place. Now, the transaction between suppositions and buyers (Nodes) is being managed and completed. This foundation handles the transfer of funds from the buyer to the consumer and interacts with the control and correspondence areas to complete the transfers [6].
4. Be specific and don't overcommit. Utilities should focuson evaluating and selecting a small number of blockchain-based solutions that answer their present business concerns andare cost-effective.
5. Start slowly and fail quickly. Utilities will gain an unrivalled perspective on new and upcoming improvements in the field by experimenting with blockchain through pilot projects.
6. Use caution with regards to administration. Given the very regulated utility environment, we anticipate that utilities will endure a brief to medium period of transitory administrative adjustments globally until a decent set of standards emerges that is both useful and acceptable to allutility organizations.
7. Establish relationships or alliances. Utilities must proactively work with specialized innovators, consulting organizations, and leading universities and businesses to continuously research blockchain solutions and make sure they stay on top of things.

8. Solutions that use models incorporating service providers It appears that a truly decentralized, distributed trading stage built on the Blockchain would be challenging to integrate into the existing legal system. To take use of the benefits of blockchain technology and to bundle the associated legal and administrative risks, an aid model can be used. Wuppertal Public Utilities, a German corporation, was the first in the world to put this concept into practice in 2017. They launched a blockchain-based service that allows customers to legally purchase electricity from local green power producers.

Blockchain frameworks require an expensive new foundation, specialized ICT equipment, programming, and many other things that raise investment costs and might outweigh the system's benefits. The cost of linking an existing smart meter with distributed ledgers to the infrastructure grid may also increase since smart meters are currently not technically compatible.

Facts may now be exchanged across blockchain systems at a reasonable cost, but data validation and verification need expensive hardware and energy. Verifying the stake or confirming the power estimates might also eventually make this situation better overall. Blockchain frameworks will need to deal with established procedures in the realm of network communications, such as telemetry, which isn't just often created but also fundamentally a lot less expensive innovation arrangement. Setting genuine data aside in "sidechains" and using the blockchain as a regulated layer rather than a capacity layer are promising solutions presented to handle this examination [7].

Blockchain developments can assist or speed up such locations, hence facilitating well with contemporary administrative needs. But, administrative processes may need to be updated to allow for more DLT reception. For instance, in many P2P power purchasing and selling endeavors, customer to consumer energy changing is not permitted due to the general lines float administrative frameworks. To represent agreements between prosumers and purchasers, new agreement types may be necessary, especially if counterparties use the open matrix. In particular, a different structure would call for additional, perhaps more flexible power taxes, which may be right now actively directed. The general guideline is that present administrative practices should be merged with neighboring or local energy markets.

The best view for regulators of blockchain application in the energy sector Use of blockchain in the energy sector:

- It is crucial that authorities comprehend the importance and applications of blockchain technology and devise strategies for managing the associated risks.
- The top priority, which might be expensive, is to employ personnel with the proper skills and qualifications.
- In order for regulators to push the market and bring about knowledge and innovations inside it, they must collaborate with established businesses and startups.
- Adequate framework and license requirements for energy producers
- Establish a situation where each consumer has many providers. Furthermore, provide suppliers the chance to participate in the peer-to-peer or peer-to-local energy trading market.
- Laws ought to be crafted to promote real-time pricing, which encourages more market participants. Help market players through sand-boxes: test, fail, repeat,succeed [8]
- Permissioned and privacy mechanisms:

Blockchains may be classified as either public or private. Every miner can contribute to public categories, however only those with accesscan utilize the site for private categories. As a result, permissioned chain usage should be done in application with established authorities or organizations responsible for management.

- Energy policy and regulatory layer: In every nation, decision- makers create a fundamental framework. Similar to this, the policy pertaining to the energy industry encompasses all aspectsof the sector, including technical, financial, and safety aspects. The task of creating all legal documents is delegated to policymakers with consideration for the needs of the nation or state. The implementation of the legislative texts follows a predetermined process after their creation or update.
- Business layer Investors: Trading firms, T&D system operators, investors, banks, etc. are some examples of market participants in a typical power market. Yet, in the most recent situation, a few new actors have entered this sector, such as prosumers and forward-thinking service provider organizations. There are also secondary stakeholders, such as service and product providers, who support the power network and supply goods and services to other stakeholders.
- Control and optimization layer: SCADA (Supervisory Control and Data Acquisition) systems have been employed in the power sector for at least the previous 20 years. The operation of intelligent energy systems is controlled and monitored using SCADA and other peer sophisticated technologies so that decision-making algorithms may be employed.

VI. CONCLUSIONS

The energy trading sector now needs more flexibility and improved efficiency, which Blockchain may provide. Energy trade on blockchains is progressively growing and has a high success rate. Blockchain technology is mostly used in the energy trading industry for the storing of transaction data, for privacy purposes, and as a quick and dependable method of moving energy from prosumer to consumer. To motivate users, a better incentive mechanism is introduced into the system. Also, the pressure on DISCOMs would be lessened by eliminating distributors on a smaller domestic scale, and pricing would be decided domestically between prosumer and customer.

Regulatory systems continue to be the key issue for all undertakings in this area. Despite being modest or pilot ventures, the current projects have achieved a lot of success. Evaluation of the investors' and customers' willingness to pay is also required. Moreover, the usage of edge computing will speed up transactions and deter harmful behavior, fostering a feeling of confidence among customers and other relevant stakeholders.

That would improve the performance of the RWE server, which manages several transactions simultaneously. To encourage sustainability in the energy industry and optimize the use of renewable energy sources, peer-to-peer energy trading is essential. More collaborations and connections with international blockchain-related businesses are required in order to build and maintain the blockchain infrastructure. Due to this, investors would see a modest but steady growth in the Indian market.

Abstract—**Electronic health record (EHR) is a system that collects patients' digital health information and shares it with other healthcare providers in the cloud. Since EHR contains a large amount of significant and sensitive information about patients, it is required that the system ensures response correctness and storage integrity. Meanwhile, with the rise of IoT, more low-performance terminals are deployed for receiving and uploading patient data to the server, which increases the computational and communication burden of the EHR systems. The verifiable database (VDB), where a user outsources his large database to a cloud server and makes queries once he needs certain data, is proposed as an efficient updatable cloud storage model for resource-constrained users. To improve efficiency, most existing VDB schemes utilize proof reuse and proof updating technique to prove correctness of the query results. However, it ignores the "real-time" of proof generation, which results in an overhead that the user has to perform extra process (e.g. auditing schemes) to check storage integrity. In this paper, we propose a publicly verifiable shared updatable EHR database scheme that supports privacy-preserving and batch integrity checking with minimum user communication cost. We modify the existing functional commitment (FC) scheme for the VDB design and construct a concrete FC under the computational *l* -BDHE assumption. In addition, the use of an efficient verifier-local revocation group signature scheme makes our scheme support dynamic group member operations, and gives nice features, such as traceability and non-frame ability.**

Index Terms—Verifiable database, cloud storage, functional commitment, privacy-preserving auditing, user revocation

I. INTRODUCTION

WITH the explosive increase of global information, the cloud service industry has been developing unprecedentedly. Many cloud service providers are rushing to launch cloud service platforms and products, such as Amazon, GOOGLE, Alibaba, Microsoft, and Huawei, etc. People start to outsource their large data storage tasks to cloud service providers (CSPs). It makes them no longer con-strained by limited local storage and computing resources. As a concrete and high-quality application example of cloud storage, the cloud-based electronic health record (EHR), which is a system that collects the patients' digital health information, is being vigorously promoted by many organizations, such as the Office of the National Coordinator for Health Information Technology (ONC) [6] in the United States and Canada Health Infoway [7]. The patient EHRs are written on the workstation or mobile device, and can be accessed and modified later. The patient EHRs up-loaded to the cloud can be shared among different medical institutions to help patients get better treatment, help scientific researchers to carry out disease analysis and re-search, and help public health departments predict, detect and potentially prevent the outbreak of epidemic diseases, etc. Since the cloud service provider (CSP) is an independent management entity, users actually give up the ultimate control over their EHRs. This brings security challenges for outsourcing tasks. For example, the cloud servers may re-turn incorrect results for various reasons, such as malfunctioning cloud equipments and a hacker's attack. The incorrect returned values can have serious consequences for every part of the medical system. Therefore, the primary problem faced by the EHR system is on how to verify that the server responses correctly each time. Benabbas *et al.* [9]. proposed the verifiable database (VDB) as a secure and efficient updatable cloud storage model for resource-limited users. In a VDB scheme, a client can outsource the storage of a collection of data items to an entrusted server. Later, the client can query the server for an item (a message) at position *i*, the server returns the stored message at this position along with a proof that it is the correct answer. However, the security of only verifying the server response correctness is far from enough for the EHR system, and it is not clear whether data that is not frequently accessed is still stored correctly. If these data are destroyed and not discovered in time, it can cause huge losses in the event of an emergency.

Many audit schemes [23] - [28] exist to check the data storage integrity. A simple idea to realize the server response correctness and the data storage integrity of EHR system is to use the VDB scheme and an audit scheme respectively. But there will be a lot of authentication tags generated and transmitted for verification. At present, with the development of the Internet of things, emerging wear-able devices are also deployed for receiving and uploading users' EHR information. For example, a smartwatch can upload information about a user's heartbeat and breathing, and an insertable cardiac monitor called Reveal LINQ [21] provides long-term heart monitoring. Similarly, mobile terminals with limited performance used in such applications. The main computation and communication of these low-performing terminals occurs when the user first up-loads the database and updates the data each time. In the traditional data integrity checking scheme, the user generates an authentication tag for each data block and uploades it to the cloud server together with the data in the above two stages. This 1-to-1 tag generation method results in the fact that low performance terminals have to reserve more storage space for temporary storage tags and spend more transport resources for transport tags.

Some audit schemes provide methods to reduce the number of tags. The scheme [23] proposed a method to re-duce the number of tags by expanding the size of each data block, but it still cannot realize the

aggregation of tags of each data block. Jiang et al. 's scheme [14] proposed to use vector commitment scheme to construct the audit scheme. Although the reduction of tags has been achieved, their scheme fails to achieve the expected security due to the neglect of the real-time performance of proof generation. There is still no good way to minimize the communication for low performance users.

The biggest feature of the EHR system is that patients' health information is shared in a group, including clinic, healthcare, hospital, medicine center, insurance and so on. Anyone in the group can upload, download, and modify the database. In most cases, the members in such group are not fixed. And a group manager (GM) is appointed to control members' join or quit. The scheme [28] provided an efficient audit scheme for group members to share cloud data, but only GM can upload the database. Jiang et al. [14] scheme involved the dynamic problem of group members, but their scheme can only realize the revocation and the case of users joining group is not considered. They used the group signature scheme with verifier-local revocation (VLR) [2] proposed by Boneh et al. to make group members revocable. However, their VLR group signature scheme does not have backward unlinkability (BU), which means that even if a member is revoked at a certain time, the signature before that time remains anonymous. It poses a threat to user identity privacy.

Also, security and privacy of medical data storage and access must be enforced by legal legislations [8]. Therefore, a powerful tool for EHR systems is needed to fulfill the le-gal requirements in protecting the security and privacy of the medical data.

1.1 Our Contribution

Our research focuses on the security and efficiency of large database storage, such as EHR. According to the characteristics of EHR system, two aspects of security deserve our attention, namely, the server response correctness and the data storage integrity. In order to deal with above problems, we use a new tool called functional commitment (FC) and design a publicly verifiable updatable database scheme based on functional commitment supporting privacy-preserving integrity auditing and dynamic group operation. Our contributions can be summarized as follows:

1. We modify the existing functional commitment [15] scheme in order to use the function binding of functional commitment to design an auditable VDB scheme. Two algorithms for updating are added based on the original scheme in [15]. And a modified concrete FC with updates under the computational assumption is constructed. Our construction has fewer parameters and is more efficient than the original scheme in [15]. -BDHE l
2. We point out security problems with scheme [14] and propose a publicly verifiable updatable VDB scheme based on the functional commitment and group signature without incurring too much computational overhead and storage cost. Moreover, our scheme is applicable for large-scale data storage with minimum user communication cost. Our pro-posed scheme not only preserves all the properties of the original VDB scheme, but also implements efficient privacy-preserving integrity auditing, non-frame ability and traceability. The scheme preserves data privacy from the auditor by using a random masking technique and the sparse vector is used for sampling auditing. Our scheme supports dynamic group member operations which include join and revocation. In addition, our VDB supports batch auditing and it supports multi-cloud server, multi-user and multi-storage vector scenarios.
3. Security analysis and experimental comparison with existing schemes are provided and it shows that our VDB is secure and efficient.

II. RELATED WORK

Electronic health record is a system that collects the patients' digital health information. It can reduce the medical errors, save EHR storage costs, and share medical information, etc. The transition from paper to electronic medical records has made the use of medical data more flexible and more usable. Research on data security of electronic health record system includes searchable encryption, privacy preserving, access control, and data storage integrity, etc. Many studies have been presented [16] – [19], and our work focuses on the security of the storage of large database, such as electronic health records.

As a secure and efficient dynamic cloud storage model for resource-limited users, Benabbas*et al*. [9] proposed the verifiable database (VDB). Every time a user accesses the database, the cloud server generates and returns a proof to convince the user of the response correctness. Besides, the process of query and the verification of query results should be irrelevant to the size of the database. They pre-sented the first practical VDB under a well-studied as-sumption. Their scheme only supports private verifiability, that is, results can only be checked by the database owner. Most existing publicly verifiable computation schemes do not consider the confidentiality of the final result while keeping public verifiability. Sun *et al.* [22] addressed this problem by proposing a confidentiality preserving publicly verifiable computation scheme. Their proposal achieves public verification for outsourcing Boolean function evaluation while keep final result secret to any third-party verifier. Catalano and Fiore [10] put forward the vector commitment (VC). In a vector commitment scheme, a vector can be committed to generate a commitment value. After that, the commitment value can be opened at the vector's particular positions. The updatability of the VC can be used to construct the VDB scheme. Chen *et al*. [11] found the vulnerability in [10] and put forward two types of at-tacks on the protocol which are forward automatic update (FAU) attack and backward substitution update (BSU) at-tack. To resist against both attacks, they presented a new VDB framework from the VC. Then, Chen *et al*. [12] formal-ized the concept of verifiable database with incremental updates (Inc-VDB). By using hierarchical commitment, Miao *et al*. [13] added more operations to the VDB scheme.

To check the integrity of cloud storage data, the concept of the cloud storage auditing [23] – [28] came into being. A public integrity auditing scheme is that data

integrity can be efficiently audited by any third-party auditor (TPA). Sachem and Waters [23] first put forward the notions of Compact Proofs of Irretrievability (CPR). They use the BLS signatures to build their first secure scheme in the random oracle model. And their second scheme uses the pseudorandom functions (PRFs). However, if a TPA conducts multiple queries on the same data during the auditing, it may expose the user's data to the TPA. In order to address this problem, the concept of the privacy-preserving audit-in has been proposed. Li *et al*. [24] provided a new certif-icateless public auditing scheme with integrated privacy protection for the Wireless Body Sensor Networks. In some scenarios, users may frequently update the database stored in the server, and the static auditing model cannot satisfy them. In order to make the auditing scheme dynamic, Soo-khak*et al*. [25] proposed Divide and Conquer Table to sup-port dynamic data. In order to reduce the computational burden of client, Shen *et al*. [26] constructed a light-weight cloud storage auditing scheme by introducing a Third-Party Medium (TPM). In this scheme, the TPM helps cli-ents to generate data signatures and verify the integrity of cloud data. Sometimes the cloud data that needs to be checked against its intergity may be shared in a group. Shen *et al*. [27] focused on enabling the cloud data sharing in a group member and in an anonymous manner. Using key agreement and the group signature, the scheme real-izes the traceability of group members.

The commitment scheme is a basic cryptographic primitive, which is an important component in many schemes. Many works focused on how to make the committer have flexible opening. That means one can reveal different par-tial information about the message during the opening stage. Catalano and Fiore [10] proposed the vector commitment. The VC scheme satisfies the property of position binding, which means the value of any position in a vector cannot be opened by an adversary to two different values. In addition, the values of commitment and opening in the VC should be irrelevant to the size of the vector (called concise). Kate, Zaverucha and Goldberg [5] proposed the polynomial commitment (PC) where committer commits to a polynomial and opens the commitment value to a calculation of this polynomial for a specific input. Libert, Ra-manna and Yung [15] were inspired by the VC [10] and the PC [5] to come up with the functional commitment. Like the VC scheme, the FC scheme allows a vector to be com-mitted to generating a commitment value. After that, the commitment value is opened as a specified linear function in a FC. They provided a concrete FC scheme for linear combinations under subgroup decision assumption. Their scheme satisfies two properties, called perfectly hiding and computational binding. However, in order to design the scheme under well-studied assumptions, their construction uses composite order bilinear groups, which has a number of parameters and is less efficient. And the scheme does not focus on the update algorithm.

Similar to ordinary digital signature, group signature means anyone can verify the correctness of a group signature. The difference is that after verifying the group signature, the verifier can only confirm that the message is signed and issued by a member in a group, but it does not know who signed and issued it, which protects the anonymity of the signer. When a dispute arises, there is a trusted group manager (GM) who can identify the member who actually signs the message. It is called traceability. One of the most important problem in using group signature scheme in practice is group member revocation. Boneh*et al*. [2] introduced the verifier-local revocation group signature scheme. In their scheme, the method of revocation is to send the information about the revoked members to the signature verifier. When the verifier checks the signature, he/she checks whether or not the signer of the signature has been revoked. However, their VLR group signature scheme does not have backward unlink ability. Another important property of group signatures is non-frame ability, which is to make sure no one, including group manager, can sign a message on behalf of other group members. Then, an efficient verifier-local signature scheme with these properties is constructed in [1]

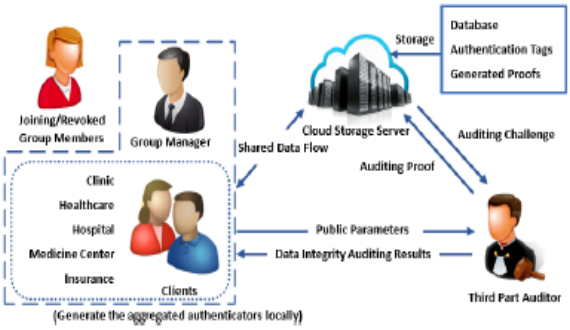

Fig. 1. The cloud storage model of our VDB scheme, which includes three entities, the cloud storage server, the clients and a Third Part Auditor (TPA).

III. PROBLEM FORMULATION

We first introduce our cloud storage model. Then, point out the security problems of the existing VDB schemes [10] –[14].

3.1 Cloud Storage Model

As shown in Fig. 1, there are three entities, which are the cloud storage server, clients and a Third-Party Auditor (TPA) in our cloud storage model. The cloud storage server provides remote data storage services for the client. TPA, which can be anyone in the system, checks the data storage integrity of client outsourced database. The clients, including patients, clinic, hospital, medicine center, insurance, etc., are able to outsource large databases to the server. Un-like most auditing schemes, the client generates the aggregated authentication tags locally and sends them to the cloud. Then, the user could query and update the database and check the data storage integrity. The TPA could check the data storage integrity of the frequently updated data-base using public key in an efficient way.

In our dynamic group member scenario, any group user can upload own database to the cloud and share them with other group members. And a trusted group manager is responsible for joining or revoking on a client.

3.2 Security Problems

Jiang *et al*. [14] who were inspired by the VDB scheme, constructed their integrity checking scheme. In the VDB

scheme, in order to generate a proof for each query, the server needs to involve all of the current stored data. The data contained in this proof will also be verified in the verification phase along with the data queried. However, their scheme uses the techniques of proof reuse and proof up-dating to improve the system efficiency. In the above techniques, the cloud does not have to re-calculate proof every time, and updating the proof requires only a small amount of computation. It greatly reduces the overhead and improves the efficiency and response rates of the system. However due to the fact that their model did not consider a notion of "real-time" proof, the use of these techniques makes their audit scheme and other VDB schemes incapable of checking storage integrity. In this case, only the queried data is involved in the verification process. This leads to verification only on the data being queried, while storage integrity of other cloud data is not checked. If the cloud data which is not queried is damaged, it will not be detected in time. When the damaged data is needed, there will be varying degrees of loss.

TABLE I
EFFICIENCY COMPARISON BETWEEN RE-COMPUTE PROOF AND UPDATE PROOF. t IS THE NUMBER OF PROOFS WHICH ARE STORED BY THE SERVER. M IS A MULTIPLICATION IN G_1 (OR G_2) AND E IS AN EXPONENTIATION IN G_1.

Technique	Re-compute proof	Update proof
Computa-tion	$(n-1)E+(n-2)M$	$1E+(t-1)M$

3.3 Design Ideas

To enable VDB schemes to gain the ability to checking data storage integrity, an additional auditing scheme is needed. However, the use of existing auditing schemes will lead to new computational overhead and communication costs; meanwhile the VDB scheme will lose its ad-vantages. This challenge inspired us to design a VDB scheme that achieves desired security goals without too much new calculation cost.

We add an audit stage for the VDB scheme. The goal is that the server must respond with the real-time stored data during the audit process. Our solution is that in each audit task, the auditor queries for many data blocks. Specifically, the auditor generates a random coefficient for each data block, and all the coefficients generated for multiple data blocks constitute a challenge vector. Whenever the cloud server receives a challenge vector from the auditor, the randomness of the challenge vector forces it must use the real-time stored data to perform a linear operation with it. Then, the server needs to produce an aggregated proof for the linear operation. Finally, the linear combination value is re-turned to the auditor for verification along with its proof However it is not easy to implement aggregate verification that maintains linear operations in the existing VDB.

A simple idea is to use the proof generated and stored for each data block in the VDB to generate the proof for aggregated verification during the audit stage. In this way, the auditable VDB scheme can take into account the low communication cost of users and no increase of server storage. However, since in the existing VDB, the trapdoor value of each data block i is the associated value . The different trapdoors result in the proofs of different data blocks cannot be aggregated to produce a proof that owns a unified trapdoor. Constrained by the construction techniques of the current VC scheme, these schemes cannot simply aggregate the proofs to achieve the integrity auditing of the data storage. We will use a modified FC scheme to solve this problem. For the design of VDB scheme, the original FC in [15] needs to be updatable. And the constructed scheme should be more efficient. i g

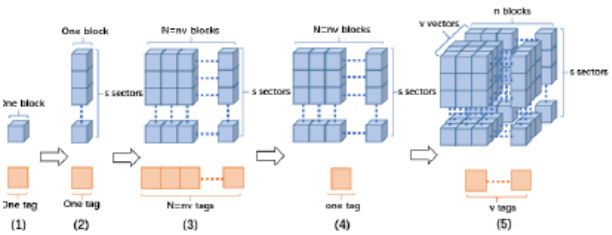

Fig. 3. The instruction for aggregating authentication tags for data blocks.

One of the original intentions is to provide low communication cost audit protocol for inefficient equipment. Fig. 3 shows how we aggregate the authentication tags. As shown in Fig.3 (1), in a general audit scheme, one data block has one authentication tag. As shown in Fig.3 (2), the protocol [23] proposed a method to expand the size of each data block. They enlarged each data block into *s* sectors, with each sector having the same size as one block in Fig.3 (1). This approach reduces the amount of data blocks to a certain extent, thereby reducing the number of tags. How-ever, as shown in Fig.3 (3), *N* data blocks in protocol [23] still have *N* tags. To be clear, data blocks are the basic unit of query for auditors. Simply using this approach to reduce the number of tags is not an ideal approach. For computational efficiency, with the expansion of a single data block, the computation amount of each response will increase greatly. For security, as the number of data blocks de-creases, the auditor can easily calculate the real data by solving the system of linear equations through multiple queries. As shown in Fig.3 (4), by using the FC scheme, the data is stored as an *N*-dimensional vector. Our VDB can further aggregate the tags of all *N* data blocks into one tag based on the scheme [23]'s method without reducing the number of blocks. When the amount of data is large, the length *n* of vector should be chosen with a tradeoff between computation and communication as shown in Fig. 3 (5). Data blocks can be stored as a *v n* matrix, still generating a tag for each vector. At the same time, the challenge data blocks will be selected from the entire matrix.

3.4 Design Goals

1. Security to guarantee that the adversary cannot convince a verifier to accept an invalid output for any database and PPT adversary in both storage stage and auditing stage.
2. Correctness to ensure that, for any database, the value and proof generated by the honest server can be always verified successfully by the verifier in both storage stage and auditing stage.
3. Privacy-preserving auditing: 1) Data privacy. It guarantees that the third-party auditor cannot derive the content of the real data from the cloud server's response in audit stage. 2) Identity privacy. In group members

share stored data scenario, it guarantees that the TPA cannot identify the specific group users who upload or update the data when auditing the integrity of group shared data, even if the group members change.

4. Traceability: to trace the last user who updates the shared data, when the updated data is generated by an honest execution of the relevant algorithm.

5. Non-frame ability: to make sure no one, including group manager, can update shared data on behalf of other group members.

6. Batch auditing to improve the efficiency of auditing, the auditing scheme supports performing auditing operations after the advanced combination of multiple auditing tasks. The batch auditing scheme supports multi-cloud server, multi-user and multi-storage vector scenarios.

IV. ANALYSIS OF THE PROPOSED VDB

4.1 Security

Our VDB scheme can securely and efficiently query and update database stored in the cloud and publicly audit data storage integrity. In the construction, some crypto-graphic tools are used as the basic module of the scheme. Assume that the following modules are secure, including the functional commitment scheme and the signature algorithm. Under the computational assumption, the following proves that our VDB scheme is secure. BDHE −l

Theorem 1. The proposed VDB scheme with updates based on computational assumption DL assumption DDH assumption and q-strong Diffie-Hellman assumption is correct and secure and supports privacy-preserving auditing batch auditing traceability andnonframeability. − l BDHE

The proof of the above theorem is given in Appendix F.

4.2 Efficiency

In order to illustrate the efficiency of our proposed basic auditable VDB scheme (AVDB) and revocable AVDB scheme (RAVDB), Table III shows the comparison of them with a composite scheme (CS), composed of Chen's scheme[11] and Shacham-Waters scheme [23], and Yuan- Yu scheme [28]. The composite scheme demonstrates that the VDB scheme uses an additional audit scheme to achieve VDB's security requirements for query result correctness and data storage integrity. Yuan-Yu Scheme [28] is a public auditing scheme for cloud data sharing that sup-ports user revocation.

Firstly, all four schemes are based on the amortized model, which requires a one-time costly computation in the algorithm. In particular, our schemes generate proof for different data blocks in the algorithm only once, which also has amortization efficiency. Second, our schemes achieve the desired security properties of public verifiability and privacy-preserving integrity auditing. Be-sides, our schemes are efficient. For the user, the amount of computation is independent of the database size. All the proofs used for verification can be generated by the server. This allows users to do very little computing. Users do not always have to be online. For the server, the amount of computation depends on the generation of the proof. Moreover, one of the biggest advantages of our scheme is that the proofs in audit stage can be almost all generated by the proofs in the storage stage. This allows storage and audit to be well integrated to reduce computation. In addition, different from the existing audit schemes where one data block has one authentication tag, our scheme has only Setup Query

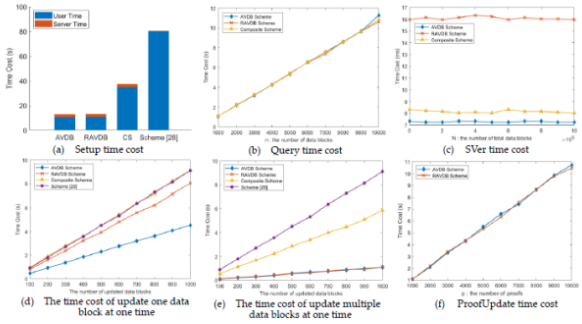

Fig 4.2. Setup and Storage Stage time cost

4.3 Performance Evaluation

We evaluate the performance of our proposed VDB scheme in experiments. We utilize the pairing-based cryptography library (PBC) and the GNU Multiple Precision Arithmetic library (GMP) on a LINUX machine with Intel Core i7- 8550U CPU 2.00 GHz processor and 16GB memory. We simulate all the entities including user, server and TPA on this LINUX machine to evaluate the overhead of our scheme. We set the base field size to be 512 bits and the size of an element in to be bits. q Z ||160 q =

In our experiment, the size of each data block in our schemes can be expanded by dividing each data block into sectors as in experiment [28] and [23]. However, in order to show the efficiency of our method only, we choose not to extend it, that is, take . Our simulations run on 100, 000 to 1, 000, 000 data blocks and the number of blocks per vector. s 1s =1000 n =

We simulate the computation overhead time cost of setup and storage stage for scheme [28], composite scheme and our AVDB scheme and RAVDB scheme in Fig. 7. Since the algorithm is amortized efficient, we only simulated the computation time when the total number of data blocks is . As shown in Fig. 7a, the server's time costs of our AVDB scheme and RAVDB scheme are similar, 10000 N =Setup

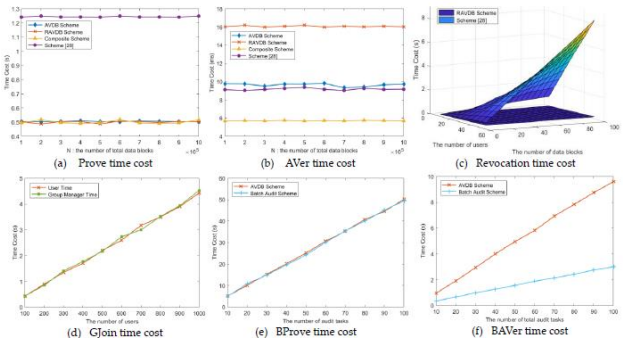

Fig 4.3. Audit stage, Revocation and Batch Audit time cost

which are 2.143s and 2.161s respectively. The server's time cost of composite scheme is 2.228s which is slightly higher than that of our schemes. This is due to the setup time of scheme [23]. Scheme [28] is the scheme that takes the least time for server and only needs 0.122s. In AVDB scheme and RAVDB scheme,

the user's times in this phase are 10.723s and 11.026s, while the time in the composite scheme is more than 3 times of ours, which is 35.030s. In scheme [28], since user needs to generate a tag for each data block, and the hash and exponentiation calculation in the Setup algorithm are more than the first three schemes, the computation time of 80.426s is about 8 times of ours. As shown in Fig. 4.3 b, the Query time cost of our schemes is linear with the number of data *n* and is the same as that of the composite scheme. It takes about 1.1s to query one time when=1000 and takes about 10.8s when*n*=□□000. However, the computational burden of the Query algorithm is on the server side, which has a powerful computational power. And thanks to the existence of the Proof Update algorithm, the cloud does not have to re-calculate proof every time. In addition, the size of *n* should be chosen with a tradeoff between computation and communication. As shown in the SVeralgorithm in Fig. 7c, the verification is performed by the user. Time cost of our RAVDB scheme is about 16.2ms, which is about twice that of 7.3ms of our AVDB scheme and 8.1ms of the composite scheme. This extra time is used to verify the group signature, which provides the RAVDB scheme with user revocation, while the other two protocols do not have this component. For Update and ProofUpdatealgorithms in the storage stage, the time costs of them are all linear with the computing count. User's efficiency of Update algorithm is shown in Fig. 4.3 d and Fig. 4.3 e, respectively, which is two cases of updating one data block and multiple data blocks at one time. In Fig. 7d, the composite scheme and scheme [28] are equivalent in time when updating one data block at a time, and 9.11s is required for 1000 updates. In the Update algorithm, users in our RAVDB scheme only need to update part of the group signatures, so the time cost of this scheme is slightly lower than the above two schemes, and it takes 7.97s to update 1000 data blocks. In the AVDB scheme, there is no complicated tag update process, so users can update 1000 data blocks in 4.53s. Fig. 7e shows the amortization efficiency of our scheme in the Update algorithm. In our two schemes, updating multiple data blocks at once requires only one signature update, which makes it only 1.11s to update 1000 data blocks. At the same time, the composite scheme update time of 1000 data blocks is reduced by 3.25s. The time cost in scheme [28] remains unchanged because there is no reduction in computation. In the Proof Update algorithm in Fig. 4.3 f, our two scheme take
about 10.6s to update p =10000 proofs. Proof Update algorithm is performed by the server, who is powerful enough to compute them. GJoinalgorithm is good for both users and GM. In Fig. 4.3 e, BProvealgorithm is just as efficient as the AVDB's Prove algorithm. However, as shown in Fig. 4.3 f, the batch audit method is 68.7% faster than the nomal audit method. For 100 audit tasks, the BProvealgorithm only needs 3s, while the Prove algorithm needs 9.6s. And as the number of audit tasks increases, the Prove algorithm grows much faster than the BProvealgorithm. The user's communication cost is mainly in the Setup and Update algorithm which are shown in Table IV. Since the size of data needed to be transferred for fixed data blocks is the same in the four schemes, we only compare the size of tags needed to be transferred for fixed data blocks. In the Setup algorithm of all four schemes, the size of tags to be transferred is proportional to the number of total data blocks N. When the user transfers 5 million data blocks, the AVDB scheme will transfer 0.03MB of tags, while the RAVDB scheme will transfer about 0.22MB. The scheme with large transmission size in this phase is the composite scheme. The transfer size of scheme [28] is
30.52MB, which is similar to the composite scheme. These two comparison schemes are about 1000 times of the transmission size as that of our two schemes. This is because in our experiment, we set n =1000 , and our schemes aggregate n data tags into one, which is greatly reducing the size of user transmission in the Setup algorithm. In the Update algorithm, the tag transfer sizes of AVDB scheme and RAVDB scheme do not increase with the number of data blocks updated each time. In the AVDB scheme, no matter how many data blocks are transferred each time, only about 0.06 KB of tags need to be transferred, while the RAVDB scheme is about 7 times more. The size of tag transfers in the composite scheme and scheme [28] is proportional
to the number of data blocks per update. The composite scheme needs to transfer 31.31 KB tags for$w$ = 500 data blocks, while scheme 28 needs to transfer 62.5 KB. It is equivalent to 1000 times of the AVDB scheme and 143 times of the RAVDB scheme. And as the number of updated blocks goes up, the difference gets bigger.

VI. CONCLUSION

The concept of verifiable database is a great tool for verifiable EHR storage. However, proof reuse and the technique of proof updating by the server to improve system efficiency fails to achieve data integrity checking. In this work, we propose a novel updatable VDB scheme based on the functional commitment that supports privacy-preserving integrity auditing and group member operations, including join and revocation. Two security requirements of EHR are implemented: the server response correctness and the data storage integrity. Our VDB scheme achieves the de-sired security goals without incurring too much

TABLE IV
USER TAG COMMUNICATION COMPARISON OF OUR PROPOSED AVDB SCHEME AND RAVDB SCHEME WITH COMPOSITE SCHEME AND SCHEME [28]. THE VARIABLE N IN THE **Setup** ALGORITHM IS THE NUMBER OF TOTAL DATA BLOCKS. THE VARIABLE w IN THE **Update** ALGORITHM IS THE NUMBER OF UPDATES.

		Scheme	AVDB	RAVDB	CS	Scheme [28]
Setup	N	1 million	0.0061 MB	0.0427 MB	6.1096 MB	6.1035 MB
		3 million	0.0183 MB	0.1281 MB	18.3288 MB	18.3105 MB
		5 million	0.0305 MB	0.2136 MB	30.5480 MB	30.5175 MB
Update	w	100	0.0625 KB	0.4375 KB	6.3125 KB	12.5 KB
		300	0.0625 KB	0.4375 KB	18.8125 KB	37.5 KB
		500	0.0625 KB	0.4375 KB	31.3125 KB	62.5 KB

computational increase. And our VDB scheme provides the minimum communication cost for the terminal with limited performance. To design a functional commitment scheme that applies to our program, two algorithms are added to make the FC scheme updatable. A practical im-proved concrete VDB scheme under computational assumption is presented. In addition, batch auditing for our VDB scheme supports multi-cloud server, multi-user and multi-storage vector scenarios. It makes the auditing process more efficient. Furthermore, we prove that our functional commitment scheme with updates and our VDB scheme can achieve the desired security proper-ties. The performance of our

scheme is more efficient com-pared with other different algorithms. BDHE –l.

VII. FUTURE ENHANCEMENT

Furthermore, we prove that our functional commitment scheme with updates and our VDB scheme can achieve the desired security properties. The performance of our scheme is more efficient compared with other different algorithms.

Abstract— **Graphical password authentication is a type of authentication method that uses images, patterns, and gestures to secure access to electronic systems. The method has gained popularity due to its ease of use, high memorability, and resistance to cracking attacks compared to traditional text-based passwords. This research paper explores the current state of graphical password authentication, including its strengths and weaknesses, and provides insights into future developments in this area. We present a thorough review of existing graphical password authentication techniques, such as pattern locks, cued click points, and drawing gestures, and evaluate their performance based on security, usability, and user acceptance. The paper also highlights the importance of user behavior analysis and cognitive psychology in improving the design and implementation of graphical password authentication systems. Our findings suggest that a multi-modal approach combining visual, behavioral, and physiological characteristics can significantly enhance the security and usability of graphical password authentication. The paper concludes with a discussion of open challenges and future research directions in this field.**

Keywords—security, graphical, password, authentication

I.INTRODUCTION

Password is a secret that is used for authentication. Passwords are the commonly used method for identifying users in computer and communication systems. It is supposed to be known only to the user. A graphical password is an authentication system that works by having the user select from images, in a specific order, presented in a graphical user interface (GUI). For this reason, the graphical-password approach is sometimes called graphical user authentication (GUA). Human factors are often considered the weakest point in a computer security system. Patrick, etc. [1] point out there are three major areas where human-computer interaction is important: security operations, developing secure systems, and authentication. Here we focus on the authentication problem. User authentication is one of the important and fundamental components in most computer security systems. Biometrics is one of the important authentication methods used to tackle the problems associated with traditional username-passwords. But here we will deal with another alternative: using an image as a password. According to a recent computer world news article, the security team at a large company ran a network password cracker and within 30 seconds, they identified about 80% of the passwords. On the other hand, passwords that are difficult to guess or break are often difficult to remember. Studies showed that since the user can only remember a limited number of passwords, they tend to write them down or will use the same passwords for different accounts. To address the problems with traditional username-password authentication, alternative authentication methods, such as biometrics [2,7] have been used. In this paper, however, we will focus on another alternative: using pictures as passwords. In addition, if the number of possible pictures is sufficiently large, the possible password space of a graphical password scheme may exceed that of text-based schemes and thus presumably offer better resistance to dictionary attacks. Because of these (presumed) advantages, there is a growing interest in graphical passwords.

Graphical password authentication is a type of authentication method that uses images or patterns instead of traditional text-based passwords. This method of authentication provides an alternative to the traditional password system and is based on the principle that humans are better at remembering visual information than text. In graphical password authentication, the user is presented with a series of images or patterns and is asked to select or connect specific points to create a password. The password is then verified by comparing the selected images or patterns with the stored password. This method has been widely researched and has been shown to provide improved security and improved user experience over traditional text-based passwords. This paper aims to explore the current state of graphical password authentication and its potential for enhancing the security of online systems.

The purpose of this research paper is to explore the efficacy and practicality of graphical password

authentication in comparison to traditional text-based passwords and to discuss the potential benefits and drawbacks of the system.

II. GRAPHICAL PASSWORD AUTHENTICATION METHODS

Existing authentication methods can be distributed into three main regions [2].

1. Token-based authentication method

2. Biometric-based authentication method

3. Knowledge-based authentication method

A. Token-based authentication

Token-based techniques, such as important cards, bank cards, and smart cards are extensively used. Lots of token-based authentication schemes also use knowledge-based techniques to improve security. For example, ATM cards are usually used and collected with a PIN number [3].

B. Biometric-based authentication

Biometric-based techniques, such as fingerprints, iris photographs, or facial appreciation, are not until now broadly accepted. The main problem of this scheme is that such schemes can be costly, and the identification method can be slow and often untrustworthy. However, this type of system offers the uppermost level of security [4].

C. Knowledge-based Authentication

Knowledge-based techniques are the most broadly used authentication methods and contain text-based and picture-based passwords. The picture-based methods can be further divided into two kinds: recognition-based and recall-based graphical techniques. Using recognition-based methods, a user is accessible with a set of images and permits authentication by recognizing and isolating the images he or she selected through the registration phase. Using recall-based techniques, a user is requested to replicate something that he or she produced or selected previously during the registration phase [5].

III. RELATED WORK

Graphical password schemes can be divided into three major categories based on the type of activity required to remember the password: recognition, recall, and cued recall. Recognition is the easiest for human memory whereas pure recall is the most difficult since the information must be accessed from memory with no triggers. Cued recall falls somewhere between these two as it offers a cue that should establish context and trigger the stored memory. Among existing graphical passwords, CCP most closely resembles aspects of Pass faces, Stories, and Pass Points.

Conceptually, CCP [6] is a mix of the three; in terms of implementation, it is most similar to Pass Points. It also avoids the complex user training requirements found in a number of graphical password proposals, such as that of Wein shall. Pass faces is a graphical password scheme based primarily on recognizing human faces. During password creation, users select a number of images from a larger set. To log in, users must identify one of their pre-selected images from amongst several decoys. Users must correctly respond to a number of these challenges for each login. Davis et al implemented their own version called Faces and conducted a long-term user study. Results showed that users could accurately remember their images but that user-chosen passwords were predictable to the point of being insecure. Davis et al. proposed an alternative scheme, Story that used everyday images instead of faces and required that users select their images in the correct order. Users were encouraged to create a story as a memory aid. Faces for memorability, but user choices were much less predictable. The idea of click-based graphical passwords originated with Blonder who proposed a scheme where a password consisted of a series of clicks on predefined regions of an image. Later, Wieden beck et al proposed to Pass Points, wherein passwords could be composed of several (e.g., 8) points anywhere on an image. They also proposed a “robust discretization” scheme, with three overlapping grids, allowing for login attempts that were approximately correct to be accepted and converting the entered password into a cryptographic verification key. Wieden beck et al. examined the usability of Pass Points.

There has been extensive research on the topic of graphical password authentication in the field of computer security. The main focus of these studies has been on the user's acceptance and memorability of graphical passwords, as well as the security of the authentication system. Some related works include:

1.A study by S. Dhamija and R. D. Wetzel (2006) which compared the memorability and security of graphical passwords to text-based passwords. The results showed that users found graphical passwords easier to remember and that the security of the system was equivalent to traditional passwords [7].

2.research by J. Gong, B. Prenell, and X. Wang (2007) which explored the use of dynamic images in graphical password authentication. The study found that using dynamic images increased the security of the system, but also made the authentication process more difficult for users [8].

3.A work by A. Adams, R. Biddle, and T. Moore (investigated the use of biometric authentication in conjunction with graphical passwords. The study found that combining biometric authentication with graphical

passwords provided a higher level of security compared to using graphical passwords [9].

4.Research by S. Lee, J. Lee, and H. Kim analyzed the security and usability of graphical passwords on mobile devices. The study found that graphical passwords were easier for users to remember and more secure than traditional text-based passwords on mobile devices [10].

5.In December 2009, H. Gao proposed a paper on a "graphical password scheme using color login." In this paper, Gao presented a graphical password authentication system that utilized color patterns as the password. The system required users to select a set of colors in a specific order to gain access to their accounts. The study found that the color-based graphical password scheme was both secure and user-friendly. The results showed that users found the color-based system easier to remember compared to traditional text-based passwords, and the security of the system was comparable to traditional password authentication methods. This study highlights the potential benefits of using color patterns in graphical password authentication and provides a new direction for further research in the field.

6.In May 2011, M. Sreelatha proposed a Hybrid Textual Authentication Scheme in a research paper. In this scheme, the user was required to select a set of characters and images in a specific order to gain access to their accounts. The combination of text and images was intended to provide a more secure and user-friendly authentication method compared to traditional text-based passwords. The results of the study showed that the Hybrid Textual Authentication Scheme provided a higher level of security compared to text-based passwords, and users found the system easier to remember and use. This study highlights the potential benefits of combining text and images in password authentication systems and provides a new direction for further research in the field.

7.Graphical Password-Based Authentication Based System for Mobile Systems" is a research paper written by Er. Aman Kumar and Er. Naveen Bilandi, is affiliated with the Department of Computer Science and Engineering at DAV University in Jalandhar, Punjab, India. The paper focuses on the development of a graphical password-based authentication system for mobile systems. The authors discuss the benefits and limitations of using graphical passwords for mobile devices and present a system that incorporates this method of authentication into a mobile environment. The results of their research provide insights into the potential effectiveness of graphical passwords for enhancing the security of mobile devices.

8.Password Authentication Using Text and Colors" is a research paper written by Miss. Swati Tidke, Miss Nagama Khan, and Miss. Swati Balpande, who is a student of Computer Engineering at RTM Nagpur University and M.I.E.T Bhandara. The paper presents a new method of password authentication that combines both text and colors. The authors describe the design and implementation of their system, as well as the results of their evaluation. The results show that the use of both text and colors can provide a secure and user-friendly method of authentication, and the authors suggest that this approach has the potential for wider use in various applications [11].

9.Graphical Password as an OTP" is a research paper written by Veena Rathanavel and Swati Mali, who are students of M. Tech in Computer Engineering at K J Somaiya College of Engineering in Mumbai. The paper focuses on the use of graphical passwords as one-time passwords (OTPs) for authentication. The authors discuss the security limitations of traditional OTPs, such as SMS-based OTPs, and present a new method of OTP-based authentication that utilizes graphical passwords. They describe the design and implementation of their system and evaluate its performance, security, and usability. The results show that the use of graphical passwords as OTPs provides a secure and user-friendly alternative to traditional OTPs, and the authors suggest that this approach has the potential for wider use in various applications [12].

10. Color Shuffling Password-Based Authentication" is a research paper written in 2017 by Aayush Dilipkumar Jain, Ramkrishna Khetan Krishnakant Dubey, and Prof. Harshali Rambade K. Elissa, who were affiliated with the Department of Information Technology at Vidyalankar Institute of Technology in Mumbai. The paper presents a new method of password authentication that uses color shuffling. The authors describe the design and implementation of their system, which utilizes a combination of color patterns and sequences to create unique passwords. They evaluate the performance, security, and usability of the system and provide insights into the potential benefits and limitations of color shuffling for password authentication. The results of their research suggest that color shuffling has the potential to provide a secure and user-friendly alternative to traditional text-based passwords [14].

These studies provide valuable insights into the potential benefits and drawbacks of graphical password authentication and demonstrate the ongoing interest in the topic.

IV. PROPOSED WORK

The first step in accessing the homepage is to create or log in to a user account. If the user is already registered, they are prompted to enter their credentials and log in. The system checks if the entered password matches the one on

record. If the password is incorrect, the user is allowed to try again a maximum of five times. After the fifth attempt, the user is automatically blocked to prevent unauthorized access. If the user manages to enter the correct password within five attempts, they are logged in successfully. On the other hand, if the user is not registered, they are required to provide all the necessary information to create an account. In this system, the password is not a traditional text-based password, but rather a sequence of images that the user is asked to remember. This image sequence technique is a unique approach to enhancing security, making it difficult for attackers to guess the password. However, it's important to consider the user experience and ensure that the user will be able to remember the sequence of images, as well as to implement secure methods for storing the password to prevent unauthorized access. Overall, a multi-layered approach to security and user experience is crucial when designing a login system [15].

The process in a step-by-step format:

a. The user accesses the homepage.
b. The system checks if the user is registered or not.
c. If the user is registered:
i. User is prompted to log in with credentials.
ii. System checks entered password
iii. If the password is incorrect, the user is allowed to try again up to 5 times
iv. If password the is correct, the user is logged in successfully
v. If 5 attempts are exceeded, the user is automatically blocked.
d. If the user is not registered:
i. User is prompted to enter details to create an account.
ii. User is given a sequence of images to remember as a password.
iii. The user is registered and the image sequence is stored securely.

A. Block Diagram

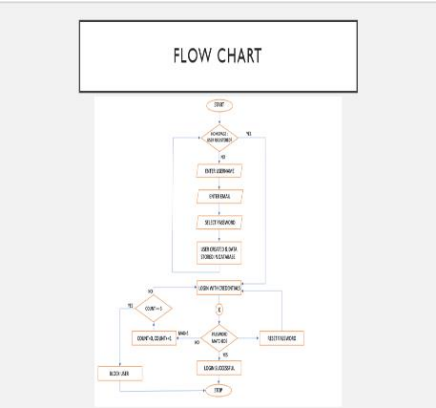

Fig. 1. Block Diagram of Graphical Password Authentication

V. RESULT AND DISCUSSION

Graphical password authentication is a relatively new method of authentication that uses images, patterns, and other graphical elements to provide a secure way for users to log in to a system. In this paper, we will discuss the results and implications of several studies on graphical password authentication.

Results

a. Usability and Memorability: One of the primary advantages of graphical passwords over traditional alphanumeric passwords is that they tend to be more usable and memorable. Users generally find it easier to remember images and patterns than complex strings of letters, numbers, and symbols. Furthermore, users can select images that are meaningful to them, which makes it easier to recall their passwords.

b. Security: Graphical passwords are considered to be more secure than traditional passwords in several ways. One of the main reasons for this is that graphical passwords are less vulnerable to dictionary attacks. These types of attacks involve automated software that attempts to guess passwords by trying a large number of possible combinations. Graphical passwords tend to be more complex and difficult to predict than alphanumeric passwords, which makes them harder to guess.

c. User Acceptance: Graphical passwords are generally well-accepted by users. Studies have shown that users tend to prefer graphical passwords over traditional passwords, particularly in situations where entering complex passwords can be difficult, such as on mobile devices.

d. Resistance to Shoulder-Surfing: Graphical passwords are also more resistant to shoulder-surfing attacks. These types of attacks involve an attacker watching the user enter their password. Because graphical passwords can be entered using a mouse or touch screen, it is more difficult for an attacker to observe the pattern or image used.

Discussion:

i. Potential for Increased Security: The results of these studies suggest that graphical passwords have the potential to provide greater security than traditional alphanumeric passwords. This is particularly true for mobile devices and other situations where entering complex passwords can be difficult. However, there are still concerns about the security of graphical passwords, such as the potential for smudge attacks. These types of attacks involve guessing the password based on the smudges left on the touch screen, which can be a security risk.

ii. Usability Concerns: While graphical passwords tend to be more usable and memorable than traditional passwords, there are still some usability concerns. For example, users may have difficulty creating complex and secure images or patterns. Additionally, there may be a learning curve associated with using graphical passwords, which could be a barrier to adoption.

iii. User Acceptance: The studies suggest that users generally prefer graphical passwords to traditional passwords, particularly on mobile devices. However, it is unclear how well graphical passwords would be received in other contexts, such as in a workplace or government setting. More research is needed to determine the extent to which graphical passwords are well-accepted in different contexts.

iv. Accessibility: Another potential issue with graphical passwords is accessibility. Users with visual impairments or other disabilities may have difficulty creating or remembering graphical passwords. This could be a barrier to adoption for some users.

v. Implementation: Finally, there are implementation concerns associated with graphical passwords. For example, the user interface for graphical passwords may be more complex and difficult to design than for traditional passwords. Additionally, there may be compatibility issues between different operating systems and devices.

The results of investigating the effectiveness of graphical password authentication techniques in user security can vary depending on the specific study and methodology used. However, in general, the findings suggest that graphical password authentication can provide an additional layer of security compared to traditional text-based passwords. The use of images, patterns, or shapes as part of the authentication process can make it more difficult for attackers to guess the password, especially if the sequence or pattern is unique and hard to remember.

On the other hand, some studies have also found that certain graphical password authentication techniques can be less

secure than traditional text-based passwords. For example, if users choose easily recognizable images or patterns, it may be easier for attackers to guess the password. Additionally, the complexity of the graphical password authentication process can also affect its effectiveness, as users may find it harder to remember a complex sequence of images compared to a simple text-based password.

In conclusion, the effectiveness of graphical password authentication in user security is dependent on multiple factors, including the specific technique used, the level of complexity, and user behaviour. It's important to consider these factors and implement multiple layers of security to provide comprehensive protection for users.

VI. CONCLUSION AND FUTURE WORK

Graphical password authentication techniques have been the subject of extensive research in recent years, with the aim of providing an alternative to traditional text-based passwords. The effectiveness of these techniques in enhancing user security has been a topic of debate, with studies providing varying results. However, it is generally agreed that the use of images, patterns, or shapes as part of the authentication process can provide an additional layer of security compared to traditional text-based passwords.

One of the key advantages of graphical password authentication is that it can make it more difficult for attackers to guess the password. This is because the password is based on a unique sequence or pattern of images, rather than a text-based password that is vulnerable to dictionary attacks or other forms of cracking. However, the complexity of the graphical password authentication process can also be a drawback, as users may find it harder to remember a complex sequence of images compared to a simple text-based password.

Another factor that affects the effectiveness of graphical password authentication is user behavior. For example, if users choose easily recognizable images or patterns, it may be easier for attackers to guess the password. Therefore, it is important to consider user behavior and psychology when designing graphical password authentication systems.

Graphical passwords have the potential to improve the overall security of authentication systems. This is because they are less vulnerable to common attacks such as dictionary attacks and shoulder-surfing.

Graphical passwords are generally more usable and memorable than traditional passwords, making them a better choice for mobile devices and other scenarios where entering complex passwords can be difficult.

Graphical passwords are widely accepted by users and can even be considered more engaging and fun than traditional passwords.

However, there are still some concerns about the security of graphical passwords. For example, there is a risk that users may choose predictable or weak images, which could make them vulnerable to attacks. Additionally, there are concerns about the potential for smudge attacks, where attackers can guess the password by analyzing the smudges left on the touch screen.

In conclusion, the effectiveness of graphical password authentication techniques in user security is dependent on

multiple factors, including the specific technique used, the level of complexity, and user behavior. It's important to find the right balance between security and usability to provide comprehensive protection for users.

The field of graphical password authentication is constantly evolving, and there is great potential for future work in this area. Some possible areas of focus include:

e. Developing new and more effective graphical password authentication techniques: This could include the use of machine learning algorithms to analyze patterns in user behavior or biometric identification methods to enhance security.

f. Improving the usability of graphical password authentication systems: Further research into user behavior and the psychology of password selection could help to improve the usability and security of graphical password authentication systems.

g. Integrating multiple authentication methods: Exploring the integration of multiple authentication methods, such as graphical passwords and biometrics, could provide even greater levels of security and user convenience.

h. Evaluating the security of graphical password authentication systems under real-world conditions: This could include conducting studies to evaluate the resistance of graphical password authentication systems to attacks by real-world attackers.

i. Improving the privacy of graphical password authentication systems: Future work could focus on developing privacy-enhancing technologies for graphical password authentication systems, such as using encrypted data storage or protecting user data from unauthorized access.

In conclusion, graphical password authentication is a promising alternative to traditional password authentication. It offers improved security, usability, and user acceptance. However, further research is needed to address the remaining security concerns and to improve the overall effectiveness of the method. the future of graphical password authentication is promising, and there is great potential for further research in this area. By exploring new and innovative methods of authentication, researchers can continue to enhance the security and convenience of authentication systems for users.

VII. ACKNOWLEDGMENT

We feel great pleasure in submitting the paper “Investigating the Effectiveness of Graphical Password Authentication Techniques in User Security”.We wish to express a true sense of gratefulness in the direction of our guide, Dr. Rajesh Bansode. We would also wish to thank our teachers in the department who at the very discrete step in the preparation of this paper contributes their valuable guidance and helped to solve every trouble that arose. Also, most likely we would like to express our sincere gratitude to our family for always being there when I needed them the most.

Transparent Blood Bank System (Using Blockchain)

Rishul Gupta, Niharika Harmalkar, Abhishek Mishra
Thakur College of Engineering and Technology Mumbai, India
rishulgupta16@gmail.com, niharikaharmalkar@gmail.com, vsabhishekmishra@gmail.com

Abstract: **- The Blood Bank System using Blockchain technology offers a secure and transparent way of managing the blood supply chain. It allows for a decentralized database of blood donors and recipients, making it easier to track the history of donated blood and ensure its safety. The use of smart contracts enables automated and tamper-proof processes for blood transfusions, further increasing the security and reliability of the system. By incorporating block chain technology, the Blood Bank System reduces the risk of fraud, and human error and improves the overall efficiency of the blood donation process. With this stem, there is an increased level of trust and accountability, helping to save lives and make the blood donation process more efficient. Certainly! The implementation of a Blood Bank System using Block chain technology can have many benefits. Firstly, the decentralized nature of the system ensures that all transactions are transparent, traceable, and tamper-proof. This helps to reduce the risk of fraud and counterfeiting and increases the confidence of both blood donors and recipients in the safety of the blood supply chain. This allows healthcare professionals to quickly and easily access critical information such as blood type, health history, and any previous transfusions, reducing the risk of adverse reactions and improving patient outcomes. The use of smart contracts also ensures that all processes related to blood transfusions are automated, reducing the possibility of human error and increasing efficiency.**

Keywords:-Blood-Bank, Decentralized Blood Bank, Blockchain, DAPP, SuPPy chain management, Transparent System for donor and receiver

I. INTRODUCTION

Blood is one of the essential parts of our body. Blood can be donated at blood banks, hospitals, and mobile blood drives, and the donated blood is then used to help patients with various medical conditions, including anemia, cancer, and injuries. There are various types of blood donations, including whole blood, which is the most common

type of donation, and various blood components such as red blood cells, plasma, and platelets. Donors are typically screened for eligibility and must meet certain criteria, such as age, weight, and health status, to ensure the safety of both the donor and the recipient. The benefits of blood donation include the saving of lives, reducing the risk of heart disease and stroke, and providing a sense of personal fulfillment.

Another benefit of the Blood Bank System using Blockchain is the automation of various processes through the use of smart contracts. These contracts can be programmed to automatically verify the eligibility of donors, track the movement of blood from donation to transfusion, and even handle payments. This helps to eliminate the risk of human error and fraud, ensuring that the blood supply chain remains reliable and secure.

In addition to these benefits, the Blood Bank System using Blockchain also offers increased efficiency. By streamlining various processes and reducing the need for manual intervention, the system speeds up the time it takes to get blood from donation to transfusion. This can be critical in emergency situations where time is of the essence.

Overall, the Blood Bank System using Blockchain technology offers a revolutionary solution for managing the blood supply chain. Its combination of security, transparency, and efficiency makes it a valuable tool for saving lives and improving the overall blood donation process.

It is important to note that blood supplies are always in demand and it is crucial to maintain a steady supply of blood to meet the needs of patients. By becoming a regular blood donor, individuals can help ensure that blood is always available when it is needed.

II. LITERATURE SURVEY

The main objective of the paper[1] is To automate blood donation management operations in a way that is entirely decentralized, traceable, transparent, auditable, private, secure, and reliable, they suggest using a private Ethereum blockchain-based system. To address the storage constraints, they combine the private Ethereum blockchain with the decentralized storage provided by the InterPlanetary File System (IPFS). The blockchain-based blood donation management system can be easily adjusted to the requirements of other industrial applications.

The proposed work of paper[2] is The suggested method, Online Blood Bank site, uses blockchain technology to fix the problems with the current system. The Blood Bank assists those in need of blood by providing them with general information about blood donors in their city who belong to the same blood group. Give these data security utilizing blockchain technology. The benefits of the suggested system are listed below. It is very adaptable and user-friendly, allowing those needing blood to look for

donors by blood type and city name. In the current method, a person's time and work are much reduced.

The paper proposes the BloodChain system, a blockchain-based blood supply chain. Blockchain technology can establish traceability in the blood provision process even with ambiguous data regarding blood origin and quality, challenging storage and transit conditions, and traceability issues. Patients can utilize this to access the system and view critical data while maintaining their privacy. Every stakeholder in the supply chain for blood donations has access to transparency and privacy thanks to blockchain technology. The development of the blood donation system will be greatly aided by blockchain technology, which promises to solve important problems in the healthcare sector that have never been studied previously.

III. METHODOLOGY

Blood donors can donate blood at campsites and blood banks, and the blood donation information will be recorded on the blockchain. A new data block is added to the blood bank containing information such as Aadhaar number, blood type, and blood ID. This blood has not been tested and cannot be classified as safe or unsafe. Blood is now taken to a blood testing center and declared "tested and safe" or "tested and unsafe" after a physical examination. A QR code is generated that consists of a hashed combination of the Aadhaar number, blood ID, and batch number. This QR code is automatically downloaded and placed on the physical blood pack. In both cases, donors are informed of the acceptance or disposal of their blood. Blood can be transferred by changing any of the following attributes:

Timestamp, Blood Owner, Owner Location, Verified. Blood marked "tested and safe" is now available to patients.

If blood is required now, the hospital should provide the required blood type. Algorithms find the best blood bank based on determinants. The coefficient of determination formula is calculated based on the idea that the distance between two entities is as small as possible. A large amount of blood must be available. Once you have found a suitable blood bank, transfer the blood from that blood bank to your current hospital. Hospitals can virtually see details of blood received You can also view blood bank locations on Google Maps. Finally, once the blood is physically received, upload the blood's QR code to confirm that the correct blood was received.

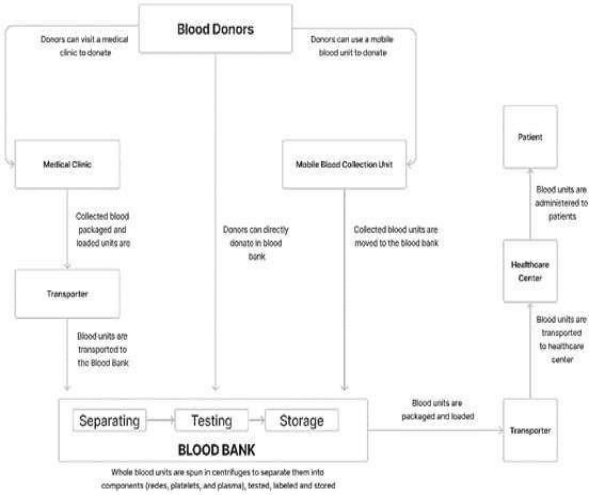

Figure 1 shows a typical blood donation process. First, there are three ways to donate blood. Option 1, is through a health center where blood units are sent to the nearest blood bank. Option 2, using a mobile blood collection unit. Option 3, is directly through a blood bank. Each donated blood is separated, tested, and stored in a blood bank. The separation process is based on centrifugation of whole blood units into red blood cells, platelets, and plasma components. Tests are then done to determine blood type and show possible infection. Once test results are obtained, transfusion-suitable units are labeled and stored in a refrigerated freezer or walk-in refrigerated freezer. According to Food and Drug Administration (FDA) and American Blood Bank Association (AABB) standards, red blood cells are stored refrigerated and have a shelf life of 42 days. Per FDA requirements, plasma is frozen in the freezer for up to 1 year and platelets are stored at room temperature for up to 5 days. Donated blood is packaged and loaded onto carriers for patient treatment as directed by doctors. Finally, after the health center receives the blood bags, they are handed over to the patient.

Solution:- Donors can donate blood, possibly at the campsite or at the blood bank itself. Information about the donated blood is recorded in the blockchain. A new block of data consisting of Information like Aadhaar numbers, blood group, blood ID, Fingerprint Etc. is appended to the Bloodstore. This blood is not yet verified; hence, it cannot be classified as safe or unsafe. Now the blood is taken to the blood inspection center, where after physically checking it, the Blood will be declared as "Tested and Safe" or "Tested and Unsafe". As this happens, a QR code will be

generated which is the combination of Aadhaar numbers, blood ID, and Batch number's hash. This QR code will be automatically downloaded and is to be stuck on physical blood packets. The Donor will be notified in both cases about acceptance or discarding of his blood. Blood can be transferred by changing one of the attributes from Timestamp, owner of the Blood, Location of Owner, and

verified. The blood, which is marked "Tested and Safe" can now be used for patients. Now, on the Hospital side, if blood is required, they have to specify the required blood group. Then our algorithm will search for the most optimal blood bank based on the Deciding factor. Deciding Factor Formula is calculated based on the thought that the distance between the two entities must be as minimum as possible. They must have a greater quantity of blood available. After finding the optimal blood bank, the Blood will be transferred from that blood bank to the current Hospital. Then the Hospital can see details of the Blood they have received virtually. They can also view the location of the blood bank on Google Maps, and finally, when the Blood is received physically, they can upload the QR code present on the Blood and verify the correct Blood is obtained.

IV. RESULT & DISCUSSION

A transparent Blood Bank System using Blockchain technology can have a positive impact on the efficiency and safety of the blood supply chain. Here are some potential results that could be achieved:

Increased Transparency: The decentralized database of the blockchain-based system ensures that information about donated blood, including its origin and testing results, is securely stored and cannot be tampered with. This makes it easier for medical professionals to access accurate and up-to-date information about the blood supply, improving the overall transparency of the system.

Improved Safety: The use of smart contracts in the Blood Bank System reduces the risk of human error and fraud, ensuring that the blood supply chain remains reliable and secure. This helps to improve the safety of blood transfusions, reducing the risk of adverse reactions and infections.

Increased Efficiency: By streamlining various processes and reducing the need for manual intervention, the Blood Bank System using Blockchain technology can speed up the time it takes to get blood from donation to transfusion. This can be critical in emergency situations where time is of the essence.

Improved Donor Management: The Blood Bank System can also help to improve the management of blood donors. For example, the system can automatically track the eligibility of donors and manage the scheduling of blood drives.

Better Supply Chain Management: The decentralized database of the Blood Bank System can help to better manage the blood supply chain. This can reduce the risk of blood shortages and improve the overall availability of blood.

Overall, a transparent Blood Bank System using Blockchain technology has the potential to revolutionize the way blood is managed and improve the safety, efficiency, and transparency of the blood supply chain.

Fake Product Identification System using Blockchain

Rishabh Rajavardhan Singh, Rishabh Ratnesh Singh,Aditya Singh
Information Technology TCET, Mumbai, India

Abstract — **In recent years, Counterfeit products play an important role in product manufacturing industries. This affects the companies name, sales, and profit of the companies. Blockchain technology is used to identification of real products and detects fake products. Blockchain technology is the distributed, decentralized, and digital ledger that stores transactional information in the form of blocks in many databases which relates to the chains. Blockchain technology is secure technology therefore any block cannot be changed or hacked. By using Blockchain technology, customers or users do not need to rely on third-party users for confirmation of product safety. In this project, with emerging trends in mobile and wireless technology, Quick Response (QR) codes provide a robust technique to fight the practice of counterfeiting the products. counterfeit products are detected using a QR code scanner, where a QR code of the product is linked to a Blockchain. So, this system may be used to store product details and generated unique code of that product as blocks in the database. It collects the unique code from the user and compares the code against entries in the Blockchain database. If the code matches, it will give a notification to the customer, otherwise it will give the notification to the customer that the product is fake. With the advent of globalization and the ever-growing rate of technology, the volume of production as well as ease of procuring counterfeit goods has become unprecedented. Be it food, drug or luxury items, all kinds of industrial manufacturers and distributors are now seeking greater transparency in supply chain operations with a view to deter counterfeiting. This paper introduces a decentralized Blockchain based application system (DApp) with a view to identifying counterfeit products in the supply chain system. With the rapid rise of Blockchain technology, it has become known that data recorded within Blockchain is immutable and secure. Hence, the proposed project here uses this concept to handle the transfer of ownership of products. A consumer can verify the product distribution and ownership information scanning a Quick Response (QR) code generated by the DApp for each product linked to the Blockchain.**

Keywords— Counterfeiting, Blockchain, Supply Chain

I. INTRODUCTION

The global development of a product or technology always comes with risk factor such as counterfeiting and duplication, which can affect the company name, company revenue, and customer health. The basic idea of the project is to verify that the product purchased by the customer is fake or real. In comparison with blockchain we have traditional supply chain. Traditional supply chain provides centralized network where the data is in the hand of the company which provides the service or the products in the market, and they own the data so they can manipulate as per their wish, so they are not secure. Counterfeiting of the product are produced to take advantage of the superior value of the imitated products. As mentioned, traditional supply chain provides centralized network whereas Blockchain provides decentralized data base, every transaction involving the data value for the product. Over the years, the identification of counterfeit goods in market has always posed a challenge for all supply chain stakeholders. As per the latest assessment of EU Intellectual Property Office (EUIPO) and the Organization for Economic Cooperation and Development (OECD), the global sales of counterfeit and pirated goods have increased alarmingly to 460 billion euros which is about 3.3% of the global trade [1]. The sales and profits of companies around the world have been affected by this phenomenon. The clothing and pharmaceutical sectors experienced sales losses of about 26.3 billion euros and 10.2 billion euros respectively [2]. Moreover, with the advent of recent technologies and E- commerce, the market of counterfeit goods has exploded on social media platforms. The anonymity, reach and segmenting tools of Ecommerce and social media have smoothed the pavement for counterfeiters. Hence, counterfeiting as in producing twins or fakes of real products pose great threat to innovation and economic growth This is done by creating a record whose authenticity can be verified by the entire community since blockchain runs by peer-to-peer network. In such a way manufacturer can use this system to provide genuine products to the customer. This will help to maintain the customer trust and to increase the brand value of the product in the market. In blockchain every block consists of data, hash, and previous block hash. Data contains the relevant information and hash consists of the unique code. It is impossible to change data of any block since person changing the data requires to own most of the network. If we try to change the data of any block the hash will get changed. So, this becomes the major advantage over the traditional centralized architecture where the data in blockchain is immutable so that the customer who buys the product gets the genuine information of the product. Our System provides the emerging technology of web use cases, Quick Response (QR) codes provide a robust technique to fight the practice of counterfeiting the products. Counterfeited products can be detected using a QR code scanner, where a QR code of the product is linked to Blockchain. So, this system may be used to store product details and generated unique code of that product as blocks in database. It collects the unique code from the user and compares the code against entries in the Blockchain database. If the code matches, it will give all the information of the product otherwise no information will be outputted to the customer which shows that the product is fake or counterfeited. In this paper, a decentralized application system (DApp) has been introduced that uses Ethereum blockchain technology in its architecture. The DApp simulates a real-world supply chain and ensures the ownership of product is transferred and recorded in the blockchain network. Besides, the system proposed here can also be implemented in

Ecommerce and retail sites that can considerably bring transparency in the virtual platforms for all consumers. Though Radio Frequency Identification (RFID) has been used for research in this sector previously, it has posed security and privacy risks which can be efficiently dealt with using blockchain.

A. MOTIVATION

In recent years, the spread of counterfeit goods has become global. There are many fake products in the current supply chain. According to the report, fake product incidents have risen in the last few years. It is necessary to have a system for customers or users to check all details of the product so that users can decide that the product is real or fake. In India currently, there is no such system to detect counterfeit products. So, the solution involves a simple QR code-based identification that can help the end-user or customers to scan and identify the genuineness of the

product by using a smartphone.

B. OBJECTIVE

The idea of this project came into existence because of the increase in the counterfeit products.

The objectives of this project are:

1.To Design Anti Counterfeit System using Blockchain.

2.To secure product details using a QR code.

3. Provide security to the clients by offering data to client.

II.. PROBLEM STATEMENT

The worldwide improvement of an item or innovation consistently accompanies hazard factors, for example, forging and duplication. Forging items can influence the organization's name and the client's wellbeing. Presently days discovery of phony item is the greatest test. Fake items are causing a significant impact on the organization and the client's wellbeing. Hence, item creators are confronting enormous misfortune. India and different nations are battling such fake and fake items. In the proposed framework, the framework produces QR codes utilizing Blockchain innovation. This innovation stores exchange records in blocks. These squares are secure and difficult to access and change the data from it. By utilizing a QR code we can recognize the fake items.

III. EXISTING WORK

In Existing system, 'A Comparison Survey Study on RFID Based Anti-Counterfeiting Systems' describes a frequency identification tag for the detection of fraud products that has been considered over the last few years. In this system we represent a review based on a test topic for duplicate items using Radio Frequency Identification tags in products. In this system, Radio frequency identification (RFID) and remote sensor networks are most used for remote development and It offers a number of possibilities for future while RFID tags like an actuator require a control signal and a power source. RFID detects areas and physical evidence of labeled objects – but unlike using laser light from verified tags, it uses low-frequency radio waves to collect and store data. In a cell or distribution center, this system is used to make the assortment of information automated. The transceiver scans the radio waves and sends them to the RFID tag. Separate data is then transferred from a small microchip tagged to the RFID reader.

IV. LITERATURE SURVEY

1] A Survey of Counterfeit Product Detection by Prabhu Shankar, R. Jayavadivel. Counterfeit products are growing exponentially with the enormous amount of online and black-market. So, there is a strong need to address the challenges of detecting counterfeit products and designing appropriate technology to improve detection accuracy. This is one of the active research areas to be explored in the current world. This paper discusses various techniques for identifying counterfeit products.

2] Smart Tags for Brand protection and anti-counterfeiting in the wine industry by steven, Marko. This paper describes a brand protection and anticounterfeiting solution for the wine industry based on smart tags and Cloud enabled technologies. The main idea behind smart tags is to utilize quick response codes and functional inks supported by the Cloud system and two-way communication between the winemaker and end-user.

3] A Blockchain-based Supply Chain Quality Management Framework by Si Chen, Rui Shi. In this paper, we propose a blockchain-based framework. This framework will provide a theoretical basis for intelligent quality management of the supply chain based on blockchain technology. Furthermore, it provides a foundation to develop theories about information resource management in distributed, virtual organizations.

V. METHODOLOGY

The Methodology used to develop this system includes a high- end development tool to run our own local blockchain for Ethereum called Ganache, to interact with Ethereum blockchain we make use of cryptocurrency wallet called Meta mask, Remix IDE tool to run the Smart Contract Program, XAMPP server provides interface for SQL (phpMyAdmin) which makes handling database easy, Blockchain proof-of-work implemented using PHP. First, we need to create a Meta mask account and run Ganache. •

In Ganache, open accounts tab and then copy the private key of any account present there. Paste the copied private key in the import section of the account. Here, we are setting up a node and use this private key to sign and approve the transactions. Now, we write the Smart contract code in the Remix IDE code section. We need to save this code and compile it. Then, we deploy it by choosing Injected Web3 as the environment. We need to copy the contract address and contract ABI to app.js file. Next, we need to go to the XAMP server and activate Apache and MySQL.

We need to make sure that our project folder is placed in the htdocs folder of the root directory. We then open PhpMyAdmin and write the SQL queries and execute it. The database is set up. Lastly, we need to open the

localhost URL to run this Decentralized Shopping platform that we have created.

The manufacturer's functions include adding the company to the blockchain by providing company name and setting the minimum registration fee to become a seller or retailer for the company. The manufacturer solely preserves the rights to enroll products in the network. The manufacturer can also control the distribution status of products and transfer ownership after a seller has bought the product stock. The manufacturer performs two major functions namely adding and distributing products in this system. For adding a product Algorithm 1 is used.

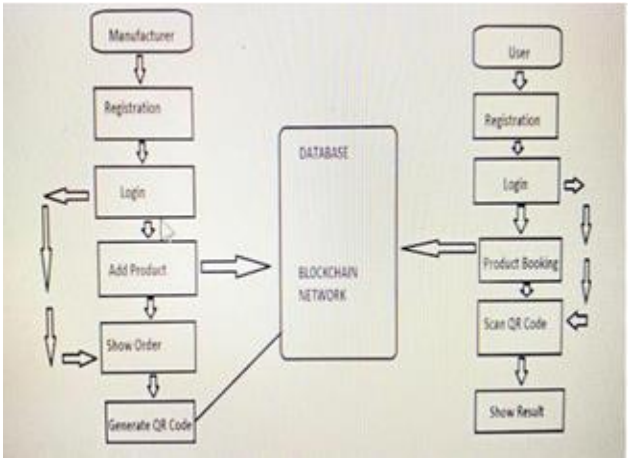
A seller can pay the minimum fee set by the manufacturer and register for the company. After registering once, the seller can buy any product as well as track its distribution. A product status is set from 'Ready To Go' to 'Shipped' after the manufacturer ships it out to the seller.

A consumer can scan the QR code provided with each product and verify the transfer of ownership of product from manufacturer to seller. The consumer can also verify the name of the current owner of the product and check its distribution status.

Blockchain technology provides promising opportunities in the supply chain management paradigm. Blockchain data is stored on nodes where each node has a complete copy of the blockchain database. Orders, payments, accounts, price of products etc. can be tracked, shared and secured using a blockchain network. Some important features of blockchain technology in supply chain management includes: 1) Security and Privacy: Blockchain uses public key encryption method of cryptography for data security. Users have public and private key pair which are used to validate transactions and these transactions are immutable and permanent. 2) Decentralization: As blockchain is a distributed ledger technology, it doesn't rely on third party or any centralized authority. 3) Transparency: Data stored in Blockchain is public and anyone can enquire on their transactions. The transactions can be governed by a set of rules known as the smart contract. The system proposed here uses Meta Mask cryptocurrency wallet for transactions and the smart contract here has been deployed in the Rinkeby Test Network of the Ethereum Blockchain. The DApp is based on three major stakeholders, The Manufacturer, the seller and the consumer.

F. Ethereum DApp Architecture Fig. 4 here depicts the base architecture of the system. The user interface (UI) here has been developed using ReactJS. If the user wants to interact with the smart contract, the DApp will use Web3.js which communicates with Meta Mask through its provider. Meta Mask creates a transaction and signs it with the user's private key. This transaction is then sent to Ethereum

network. The transaction is processed, verified and added to a block in the network. The private keys of the user are never recorded in the process so user can safely interact with the network.



VI. RELATED WORK

Various researchers have proposed different methods for establishing a blockchain-based supply chain management system. One of them presented a counterfeit product identification system using android application where a product can be searched in the Blockchain network. Another paper displayed a fake product detection system using blockchain where SHA-256 Algorithm was used to identify a product

There is no good solution before to differentiate fake products from original products. Blockchain technology can be helpful to tackle such problems. The project's main goal is to help people to identify the product is an original product or a fake product.

We proposed a fake product detection system using blockchain technology as an android application for the detection of counterfeit products. The proposed system ensures that the detection of fake products in day to-day life. The proposed system consists of three main parts, customer or user android application, Manufacturer's or company's android application, and Cloud/ Database.

The first application is the Manufacturers or company side application in which we have to first register ourselves. After registration login into the application, we have some options. One option is to add a product in which the manufacturer can add the product details. Another option is to show the order in which they can see customers' order details and after that, they can decide the accept or reject the order. The manufacturer also can see the product is delivered or not.

A second application is the Customer application in which we have to first register in-app after that we can log in to the application using id and password. In this application, there is an option to show products where customers can see the product details like name, total quantity, price of a product, details of the manufacturer. In that, we can product book the product by inserting the quantity of product. In this application, we can see orders using show my order where we can see the product details, name, quantity, date, time, price, and status of product which is produced is delivered or not. In this app we have a QR code scanner in which we scan the QR code of the product then it shows that the product is fake or real. There is another option which is a blockchain in which it displays the name of generated block product

quantity, generated Hash Value, and the product is corrupted or not.

In this project customer login, the in the application. After login, he fills in the details for ordering the product and book the product. The order of the product can be shown to the manufacturer. Manufacturer deciding whether the product request is acceptable or not. After the manufacturer accepting the order of the product it generates the unique QR code of a product. Once an order of product is stored on the network hash code is generated of that product and it is possible to maintain the transaction of the product. In the proposed system QR code is generated for a particular product. Customers scan the QR code on the product or package using the smartphone's QR code reader application or customer application have the option of QR code scanner. After scanning, we get the result of the product is real or fake. In the end, the Blockchain system holds these product details along with a history of transactions to enable the tracking of the product along the distribution chain. All the product details, block name, a hash value is stored in the firebase cloud database.

VII. CONCLUSION

Counterfeiting products are growing exponentially with the enormous amount online. So, there is a strong need to detecting counterfeit products and blockchain technology is used to detect fake products. Furthermore, the information is encoded into a QR code. Customers or users scan the QR code and then they can detect the fake product. Digital information of product can be stored in the form of blocks in blockchain technology. Thus, in this paper we discussed the system and the solution to fight against the malpractices of counterfeiting of the products and proposed the system which is useful for end user to detect whether the product is fake or not by checking the throughout history of the product in the supply chain. End user can scan QR code assigned to a product and can get all the information that has been put up throughout the supply chain in the blockchain on which end to end user can check whether the product is genuine or not.

Ownership tracking system is being reshaped through distributed ledgers of Blockchain technology. Due to rapid changes in the Ecommerce and business sectors, the current trends of supply chain are being affected. The DApp developed here ensures greater transparency in the supply chain management and can also be entrusted for use in Ecommerce. As such, administrative costs and complicated procedures are eliminated by this process. Besides, the cost for enrolling each product in the proposed model is only

0.000209 ether which is equivalent to 0.65 US dollars that can sufficiently reduce costs for large chain stores. The model also ensures enduser verification system through a QR code and transactions here can be verified on Etherscan too. As future work of the proposed model, the functions included can be improved further to bring reliability in the supply chain management.

Abstract—**Classification is a method of predicting similar information from the value of a categorical target or categorical variable. It is a useful technique for any kind of statistical data. These algorithms are used for different purposes like image classification, predictive modeling, data mining techniques, etc. The main goal of supervised learning is to build a simple and clear class labeling model of the predictive features. The classifiers are then used to classify the class labels of the test cases where the values of the predictive features are known with the value of the unknown class labels. In other words, the goal of machine learning is to build a concise model of the distribution of class labels in terms of predictor features. The resulting classifier is then used to assign class labels to check the cases where the predictive feature values are known. In this paper, we illustrate various classification techniques used in supervised machine learning that incorporate a number of parameters. We have compared four machine learning algorithms including Decision Tree, Random Forest, K-nearest Neighbor, Support Vector Machines using four different datasets regarding healthcare systems. In this review article, we summarize machine learning techniques that are widely used in the field of health systems due to their data processing and analysis capabilities.**

Keywords— **Healthcare, Classification, Machine Learning**

INTRODUCTION

Machine learning is a branch of artificial intelligence based on the idea that systems can learn from data, identify patterns, and make decisions with minimal human intervention. It has grown rapidly in recent years in the context of data analysis and computing, typically enabling applications to function in intelligent ways. Also commonly referred to as the most popular modern technology, providing systems with the ability to automatically learn and improve from experience without being specially programmed [11].

Through the use of statistical methods, algorithms are trained to perform classification or prediction, revealing key insights in data mining projects. This information then guides decision making across applications and businesses, ideally impacting key growth metrics. As Big Data continues to grow and evolve, the market demand for data scientists will increase, requiring them to help identify the most relevant business questions and, subsequently, data to answer them [13].

In order to create intelligent methods for identifying and treating disease, scientists are focusing on machine learning. Because ML can identify disease and virus infections more precisely, patients' illnesses can be identified earlier, the risky stages of diseases may be avoided, and there will be fewer patients overall. The work of anticipating COVID-19 infection can be automated, and ML can also assist in predicting COVID-19 infection rates in the future [4].We believe this technology will be a powerful tool for allocating medical resources and hospital capacity planning by making accurate real-time assessments of mortality risk, taking into account the highly specific characteristics of individual patients [12].

In healthcare, the most common application of traditional machine learning is in precision medicine - predicting which treatment protocols are likely to be successful on a patient based on various patient attributes. and treatment context. Most machine learning and precision medicine applications require a trained data set for which the outcome variable is known. This is called supervised learning [14]. Machine learning in healthcare is increasingly being used and helps patients and clinicians overcome industry challenges and create a more unified system to improve workflow. It requires advanced preparation before application implemented in healthcare to distinguish between types of data associations, similar types of data, learning from data gives the proper output. The larger the data sample provided to the "machine", the more accurate the machine's output becomes [5].

In high income nations like the UK, a team at the Cambridge Center for AI in Medicine created the
Cambridge Adjutorium system, which uses a state-of-the-art ML framework to precisely predict the rate of mortality, the need for ICU admission, and the requirement for ventilation in hospital patients with COVID-19. The system's accuracy rate ranged from 77% to 87 percent, which was a pretty high accuracy rate even though it was trained using extremely small datasets (CHESS data from Public Health England) [9]. The main advantages of ML/AI nowadays are diagnostic and predictive analysis, however efforts are being made to benefit

additional medical problem domains. Recently, considerable advancements have been achieved in the ability of machine learning algorithms, in particular deep learning algorithms, to autonomously diagnose illnesses while decreasing the cost and expanding accessibility of diagnostics [17].

I. Motivation

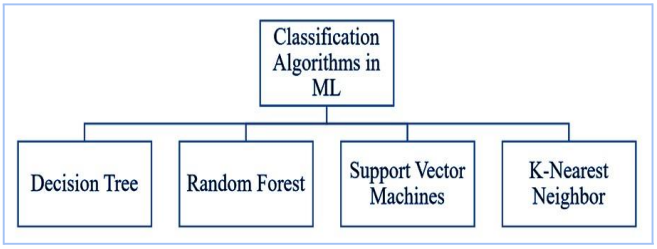
The research area of ML, or "machine learning," is constantly growing and offers many opportunities for investigation and application. Even if machine learning has had a minimal impact on healthcare, Mr. James Collin claimed at MIT that it is the technology that would define this decade. Several new companies in the ML sector are focusing seriously on the medical field. Even Google has entered the fray and created a machine learning programme for detecting cancerous tumours on mammograms. Stanford utilises a Deep Learning algorithm to detect skin cancer. The US healthcare system generates about one trillion gigabytes of data annually. Scientists and academic specialists have identified a number of risk factors for chronic illness as well as its distinct characteristics. Additional data stands for more learning for machine, but for higher precision, these many features need a huge quantity samples [8].

The use of machine learning is highly done in processes like feeding the data into ML models and guiding and correcting them to make the right judgments. The technology has a wide range of applications for enhancing research in clinical trials. By applying advanced predictive analytics to clinical trial applicants, medical professionals can evaluate a wider range of data and reduce the cost and time of medical testing. There are various ML applications that can further improve the efficiency of clinical trials and can help to determine the optimal sample size to increase effectiveness and reduce the likelihood of data errors. We believe machine learning technologies can help the medical and healthcare industries explore new fields and entirely rethink the delivery of healthcare [10].

II. Related Work

Mathematical models known as machine learning classification algorithms are utilized to approach classification problems. The method of organizing machine learning algorithms involves choosing the right algorithm to tackle a specific problem and achieve efficient results based on the available input datasets and the model preparation process. A classification algorithm's initial step in operating is to confirm that the variables, whether input or output, have been appropriately encoded. The next step is to separate the dataset into the training dataset and the testing dataset after it has been processed. The next stage is to choose the model that best fits our issue after partitioning the dataset into training and testing. [16].

These are the different machine learning classification algorithms that we have implemented to comprehend the datasets effectively.



The decision tree classifier is considered to be one of the most well-known methods to represent the classification of the classifier data. This approach is referred to as a decision tree since a tree can symbolize the collection of splitting rules used to divide the dataset [3]. It is used in text mining as a classification system to ascertain how customers feel about a product. The training data set is used to build a decision tree model, and the validation data set is used to determine the appropriate tree size needed to achieve the optimal final model. Businesses can use decision trees to determine which products will bring in more revenue when they are launched [7].

Random forest is one method of ensemble learning that falls into the category of homogeneous basic learners with respect to the type of constructive classifier. As the name suggests, all basic learners are decision trees, so they are simpler in structure than similar methods [2]. It also perform efficiently on large databases, can handle thousands of input variables without dropping variables, provide estimates of important variables, and are unbiased in generalization error as the forest grows. It produces internal estimates that are free of , has an efficient method of estimating missing data, and preserves accuracy [1].

Support Vector Machine or SVM is one of the most well-known Supervised Learning algorithms, which is based on statistical learning theory. It has played an important role in pattern recognition, a very popular and active research field among researchers. Research in some areas where SVM works well has spurred the development of other applications like SVM for large data sets, multiple classifications, and imbalanced data sets [15] . With as much as 90% of the compounds being correctly categorized, they have been used to classify proteins .

The K-nearest neighbor (KNN) algorithm is a supervised machine learning algorithm used primarily for classification purposes. KNN, a supervised algorithm, considers the features and labels of the training data to predict the classification of unlabeled data. In general, KNN algorithms can classify records using a training model similar to the test query by considering the k nearest training data points

(neighborhoods) that are closest to the query under test. By evaluating the most probable gene expressions, it can estimate the risk of prostate, cancer and heart attacks [22].

Logistic Regression is one other algorithm that is used for classification purposes. It focuses on how various independent variables affect a single result variable. Finding the association between independent factors and a dependent variable is done using regression analysis. It is a technique for predictive modelling that use an algorithm to forecast continuous outcomes. The logistic function's curve shows the possibility of several things, such as whether or not a mouse is obese depending on its weight or whether or not the cells are malignant, etc [25].

Naïve A family of classifiers known as "Bayes classifiers" is based on the Bayes theorem application and strong parameter independent requirements. They are probabilistic in nature. The Bayes theorem can be utilised as a classifier's decision rule for disease prediction. Using the Bayes method, the likelihood of the disease based on the number of symptoms can be predicted [26].

Gradient Descent is a general-purpose optimization process that may locate the best answers to a variety of issues. The general concept is to iteratively adjust parameters to minimise the cost function. The size of the steps, which is defined by the learning rate hyperparameters, is a crucial Gradient Descent (GD) parameter. The algorithm will need to go through many iterations in order to converge, which will take a lot of time. If the learning rate is too high, we risk jumping the ideal value.

There aren't many educational resources that concentrate on particular business difficulties, which is surprising given the variety of business problems that a data scientist must tackle. This essay seeks to cover the different components of one of the most prevalent business difficulties by particularly addressing the question, "What classification is in machine learning?". In general, the nature and qualities of the data, as well as the success of the learning algorithms, determine the effectiveness and efficiency of a machine learning solution. Techniques such as classification analysis, regression, data clustering, feature engineering and dimensionality reduction, association rule learning, or reinforcement learning are available in the field of machine learning algorithms to efficiently construct data-driven systems [6].

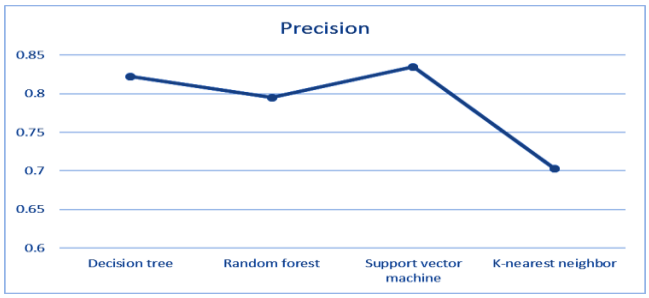
The performance of the classification models for a certain set of test data is evaluated using a matrix called the confusion matrix. Only after the true values of the test data are known can it be determined. A confusion matrix is a performance measurement technique for machine learning classification. It's a kind of spreadsheet that helps determine the performance of a classification model using a set of test data whose true values are known [23]. The need for confusion matrix and parameters is, it assesses how well classification models perform when they make predictions based on test data and indicates how effective our classification model is. Selecting fewer features may enhance categorization and provide a better understanding of the underlying process that produced the data, in addition to reducing the dimensionality of the data [24].

We have discussed and studied four classification algorithms which are Decision Tree, Random Forest, Support Vector Machine and K-Nearest Neighbour. We computed the various model parameters using the confusion matrix on the four different datasets and got the analysis accordingly.

Some of the confusion matrix and parameters that are progressively used are mentioned below:

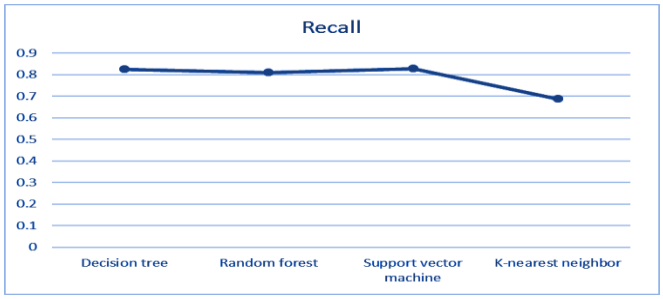
A. Precision B. Recall C. F1-score D. Support A. Precision

Precision is calculated by dividing the total number of true positives by the total number of true positives + false positives. False positives are instances where the model falsely classifies a case as positive when it is actually negative. A good classifier's precision should preferably be 1 (high). These metrics inform users about the percentage of positive predictions really positive [18].



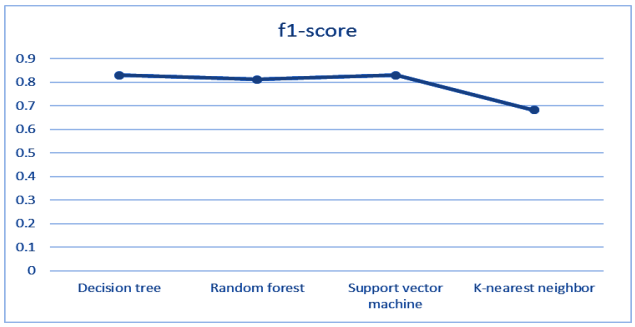
B. Recall

Recall is a metric that measures the proportion of accurate positive predictions among all possible positive predictions. Recall gives an indicator of missed positive predictions, unlike precision, which only comments on the accurate positive predictions out of all positive predictions. Recall measures the capacity to locate all relevant instances of a class in a data set. Measures the completeness of the classifier results. It is the ratio of the total number of positive flagged examples to the total number of truly positive examples [19].



C. F1-score

Also known as F-Score or F-Measure, this metric calculates the performance of an algorithm by considering both precision and recall. Although F1 is generally more beneficial than accuracy, especially if you have an uneven class distribution, it is not intuitively as simple to understand as accuracy. This metric balances recall and precision because it is difficult to compare two models when available, classifier it wasn't a balance. So it's a weighted average recall and precision values. [20].



D. Support

Support seems to indicate that it is the number of occurrences of each particular class in the true answers (the test set answers). It can be calculated by summing the rows of the confusion matrix. Disproportionate support in the training data may indicate structural weakness in the scores reported by the classifier, and may indicate the need for stratified sampling or recalibration.

Support is the number of true response samples that fall into that class is the actual number of occurrences of the class in the dataset. No difference between models just to diagnose the performance evaluation process [21].

ML for healthcare: Challenges

The identification and prediction of populations at high risk of experiencing particular unfavorable health outcomes, as well as the creation of public health interventions that are specifically aimed towards these populations, are significant applications of ML in public health. The medical curriculum has to incorporate a variety of ML-related topics so that medical personnel may successfully direct and analyze research in this field. Any ML model needs high-quality data that are typical of the population to which the model's outputs should be applied if it is to produce reliable results. 1) Safety Issues: Superior performance in a controlled lab setting—a frequent ML community practice—is not proof of safety. The ML/DL system's patient safety is assessed using its level of safety. The majority of a clinician's daily responsibilities are monotonous, and the patients they see have common medical issues. They have the responsibility of diagnosing uncommon, subtle, and concealed medical illnesses that affect one in a million people. Current systems must be made safe by enabling ML to perform effectively on hidden strata, outliers, edge, and nuanced instances.

2) Privacy Issues: Using user data by ML systems to make predictions raises privacy concerns, which is one of the main challenges in data-driven healthcare. Users (i.e., patients) anticipate that the providers of their healthcare services will take the appropriate precautions to protect their inalienable right to the privacy of their private information, such as their age, sex, date of birth, and health information. Two different forms of potential privacy dangers exist: disclosing private data and using data improperly (perhaps by unauthorized agents). Privacy is based on the traits and nature of the data being gathered, the setting it was developed in, and the patient population. As a result, it's crucial to use the right techniques to mitigate privacy breaches because they can have serious consequences.

3) Ethical and machine learning: Ensuring the ethical use of data is crucial in ML applications that focus on users, such as healthcare. Before gathering information to create ML models, explicit steps should be taken to comprehend the targeted user group and their social characteristics. Furthermore, it's crucial to recognise how data collecting can undermine a patient's wellbeing and dignity in this context. If ethical issues are not taken into consideration, applying ML in realistic settings will have unfavorable outcomes. Additionally, it is critical to have a comprehensive understanding of the system in uncertain and complex settings in order to ensure the fair and ethical operation of automated systems.

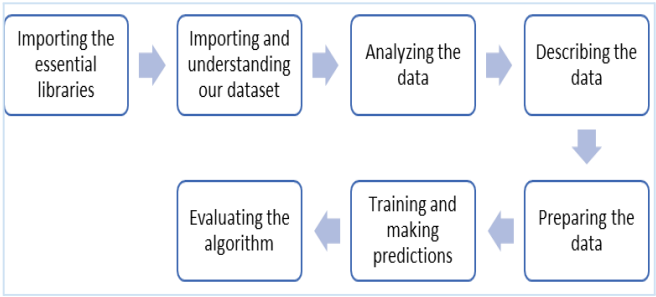
4) Access to High-Quality Data: One of the biggest problems in healthcare is the lack of representative, diversified, and high-quality data. For instance, compared to the many collections of large-scale, multi-modal patient data created on a daily basis by various small and large-size healthcare institutions, the quantity of data that is available to the research community is quite modest in size and restricted in scope. On the other hand, it can be extremely difficult and expensive to collect high-quality data that closely reflects actual clinical circumstances. The ability to forecast diseases and make treatment-related decisions is made possible by the availability of high-quality data. Subjectivity, duplication, and bias are just a few problems with the data that are gathered in practice.

III. Proposed Work

Without the use of any human intelligence, different data science models can quickly and accurately produce outcomes in the health care sector. In addition to generating precise and effective recommendations, machine learning models also free up healthcare professionals' time to focus on research and perform better in emergency situations by decreasing the manual work they must do.

For finding out which algorithm is best for a certain analysis of a health issue, this study was carried out. Classification algorithms in machine learning were implemented on four different datasets in the field of healthcare and a detailed evaluation was carried out. The first dataset is a heart disease prediction dataset where the "target" field pertains to the existence of the patient's heart problems. 0 means there is no disease, while 1 means there is a disease. The diabetes disease is the second dataset. The goal is to determine whether a patient has diabetes based on diagnostic parameters where the "outcome" field indicates if the person tested positive or negative for diabetes. The third is the chronic kidney disease prediction dataset. Based on specific diagnostic metrics present in the dataset, the dataset's goal is to diagnostically determine whether a patient has chronic kidney disease or not. "Class" serves as the dataset's target variable. The last dataset is about prediction of breast cancer in a patient. "Classification" variable acts as the indicator of the disease. Analysis was carried out by running the algorithms on these datasets.

The initial process was importing the datasets and checking the dimensions of the data. After that, the information is divided into attributes and labels and then into training and testing sets as part of the data preprocessing procedure. The training is done on the training data and then predictions are made. Lastly, the algorithm is evaluated and the confusion matrix for the same is derived for displaying the values of the important metrics used in the classification tasks. The steps followed during the classification:



A. Importing the essential libraries

Libraries are collections of commands and operations written in a particular language. A strong collection of libraries can help programmers complete complicated jobs faster and with fewer lines of code changes. As per our dataset we imported the basic libraries as numpy, pandas, matplotlib and seaborn.

B. Importing and understanding our dataset

Understanding data is being aware of its existence, the needs it will address, its location, and its content. After reading the csv file we will get to know what are the contains in the rows and columns by using word dataset. We imported datasets of health related to heart, diabetes, kidney and breast cancer. Further verifying it as a dataframe object in pandas.

C. Analyzing the data

The entire data analysis procedure is automated by machine learning to deliver richer, quicker, and more thorough insights. The shape of the dataset will show the number of rows and columns present in our dataset. And then printing out a few columns to stay organized with the contents present in our dataset.

D. Describing the data

With the project definition completed prior to data preparation and the evaluation of machine learning algorithms completed later, this approach offers a context in which we may think about the data preparation necessary for the project.

E. Preparing the data

The process of making raw data ready for further processing and analysis is known as data preparation. The gathering, preparation, and labeling of raw data into a format appropriate for machine learning (ML) algorithms, followed by data exploration and visualization, are crucial phases.

F. Training and making predictions

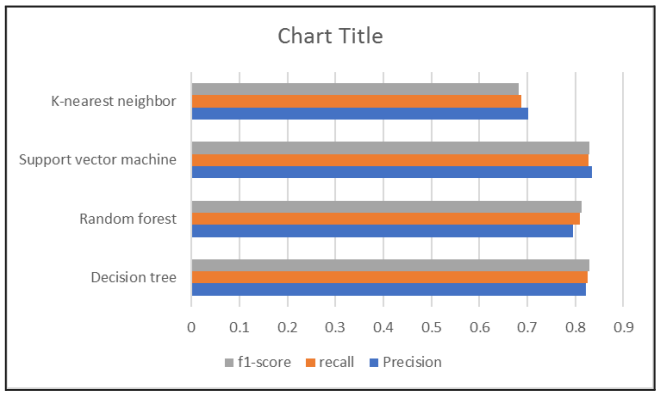
A very sizable dataset called training data is utilized to instruct a machine learning model. Prediction models that employ machine learning algorithms are taught how to extract attributes that are pertinent to particular business objectives using training data. The training data for supervised ML models is labeled.

G. Evaluating the algorithm

An algorithm will be tested against the test set after being trained on the training dataset. Any project must have a machine learning algorithm evaluation. Your model might produce satisfactory results when measured against one metric, such as accuracy score, but unsatisfactory results when measured against another, such as logarithmic loss. After carrying out the following steps, this chart was derived which showed the comparisons based on the parameters.

IV. Result and Discussion

The algorithms were evaluated and the best possible and suitable solution was tried to be achieved. It was observed that support vector machine and decision tree algorithms were proved to be the most effective for the four varied healthcare datasets.



There are three different colors of graphs used representing the f1-score, recall and precision for the classification algorithms. The f1-score and the recall values for support vector machines and decision tree seem to be almost similar through the chart above. But the precision value is what matters while comparing them as the support vector machine leads followed by the decision tree algorithm. The random forest is ranked the third regarding the precision value whereas the KNN is the least precise.

The precisions for SVM and decision tree algorithms are above 80% , declaring them as the most effective algorithms for our datasets. After that, the accuracy for the algorithms was also considered and it was found that SVM is the most accurate with a score of 83% and shortly followed by the decision tree with 82%. The lowest accuracy was for KNN with a value of 68%.

Parameters	Decision tree	Random Forest	Support Vector Machine	K-Nearest Neighbor
Training time complexity	O(n*log(n)*d)	O(n*log(n)*d*k)	O(n^2)	O(knd)
Run time complexity	O(maximum depth of the tree)	O(depth of tree* k)	O(k*d)	O(nd)
Accuracy	0.82	0.77	0.83	0.68
Advantages	i. Easy to Visualize. ii. Manages data which is both numerical and categorical.	i. Can deal with big datasets and missing values. ii. Will produce a variable's importance.	i. Optimal for highest dimensional spaces. ii. The algorithm is memory-efficient.	i. Fast computation time. ii. No data assumptions are made.
Disadvantages	i. Occasionally fails to generalise well. ii. Unstable when input data changes.	i. It is somewhat uncontrollable, like a black box. ii. Slow real-time prediction and complicated algorithms.	i. Won't offer probability predictions. ii. Can estimate probabilities but takes a lot of time.	i. Expensive in terms of computation and needs plenty of memory. ii. It is extremely sensitive to insignificant aspects.

Time complexity can be considered as a scale for how quickly or slowly an algorithm will operate given an input size. Time complexity is often expressed in terms of an input size like n. Runtime complexity defines how well an algorithm performs, or how much extra time or processing power is needed to run the algorithm. The time complexities are compared in the above table for these distinct algorithms based on some parameters like k which defines the number of neighbors and d which stands for the dimension of the data. The training time complexity demonstrates that random forest is used for a large amount of data with reasonable features. Also it can be observed that SVM should not be used if n is large and KNN loops through every training observation and computes the distance d. The pros and cons are as well discussed for estimating the algorithms based on various aspects.

V. Conclusion

All of the information obtained during a medical visit with a doctor is applied by machine learning approaches to extract specific patient traits. In our study, we tried to estimate which algorithm works the best on our datasets in the healthcare field by calculating their accuracy, precision and other factors too. Thus, we were able to conclude that the SVM worked way better than the decision tree, KNN and random forest after evaluating it on various parameters. If numerous fields are considered, there is a much higher need for specialists than there are qualified candidates. This causes a great deal of anxiety for doctors, and delayed diagnoses of patients who need life-saving treatment are common [16]. However, considerable advancements have been achieved in the ability of machine learning algorithms, in particular deep learning algorithms, to intelligently diagnose illnesses while decreasing the cost and expanding usability of diagnostics.

Acknowledgment

We are thankful to our college for providing us with the opportunity and direction to explore this sector. We also want to express our gratitude to everyone who assisted us in finishing this research. We express our gratitude to everyone who contributed to this study because without their

motivation and insightful comments, it might not have been possible to complete the research paper by the deadline.

Abstract: The proposed project analyses and forecasts the exchange rates on Indian rupee by using time series data concepts from the year 2020 to 2022, using the Box-Jenkins ARIMA technique. Based on the study presented, the ARIMA model's test results show that the proposed model is quite accurate and stable in showing results and hence works well for forecasting the USD exchange rates. Forecasting the exchange rates plays a vital role in minimizing the risks and maximizing the profits for the people working in the financial markets, trading as well as general public across the world. ARIMA uses the stationary time series dataset in order to provide accurate predictions. The time series data used in this paper has been obtained from Yahoo Finance, calculated and analyzed dollar exchange rate for the following day, subsequent 15 days, 30 days, 60 days respectively from the current date. In addition to that, we were able to achieve a small MAPE score/forecast accuracy i.e. 0.923 which indicates that the model gives better accuracy. The Daily exchange rates from 5th June 2020 to the current date were used for the prediction.

Keywords: Autoregressive Integrated Moving Average (ARIMA), forecasting, USD, INR, analysis

I. INTRODUCTION

As per the recent data provided by the Census Bureau's 2018 American Community Survey (ACS), there has been an increase of nearly 50 percent in the number of Indians in US from 2010 to 2018[1]. The IT workface from India is easily employed in countries like United States of America, United Kingdom etc. The sophisticated lifestyle and the exchange rate are the two main reasons for the migration.

The exchange rate which is also known as foreign exchange rate influences a variety of decisions made by participants in the foreign exchange market like investors, importers, governments, exporters, bankers, commercial banks, corporations, tourists and policy makers. It's one of the vital influencing factors for both developing and developed countries [1]. Exchange rate forecasting is essential for international finance enthusiasts and researchers, especially for floating exchange rates[2].

The significance of exchange rates forecasting from a practical perspective is that accurate forecasts can provide valuable information to people in various sectors such as firms, investors and central banks regarding asset allocation, risk hedging, and policy formulation. The real time importance of accurate exchange rate forecasting is that it has important implications for the development of efficient market hypotheses and theoretical models in international finance sector [14].

When it comes to buying and selling, forecasting/prediction is regarded as one of the most key things when choosing an investment market. Every prediction that gives an output needs to calculate accuracy. The accuracy and prediction is influenced by many errors and one such error is human calculation error. It wastes a lot of time and effort for the financial experts. We need a way to overcome this problem that is quite difficult to be solved manually.

Periodic data refers to the data observed over a period of time. The periodic data collected over a certain period of time is used for analyzing the patterns and forecasting of the outcome. ARIMA (Autoregressive Integrated Moving Average) models are models that completely ignore the independent variable when making predictions. This is a model used to measure statistics to measure events occurring over a period of time. Models are used to make sense of past data and predict future outcomes. An ARIMA model is a mixture of two models: an autoregressive (AR) model and a moving average (MA) model.

In this paper, the work has been divided into several sections. Section 1 describes about theneed of scientific and well-defined approach for this study. The similar, related research byvarious authors is discussed in section 2. In section 3, the methodology/procedure for the same is presented. Experimental evaluation and discussion of results are mentioned in section 4 and 5. Finally, conclusion and future related scope of the work is mentioned in the section 6.

II. RELATED WORK

The time series prediction models are developed based on the assumption that past data affects the forecasts of future statistical data points.[3-5] With the forecast item as exchange rate, ARIMA is demonstrated to be an excellent answer for prediction [16-18]. Nyoni (2018) has undertaken an intensive survey of empirical research in Nigeria and different international locations that use ARIMA-primarily based totally time collection tactics to forecast alternate rates [16]. El-Masry and Abdel-Salam (2007) analysed the impact of organization length and overseas operations at the alternate charge publicity of UK non- monetary companies. They discovered that that a better percent of UK corporations are uncovered to contemporaneous alternate charge modifications than

the ones stated in previous research. A majority of the researchers who have analysed this time series forecasting concluded that ARIMA is the best model for time series data[17].

Research that been achieved via way of means of Ahmad Amiruddin Anwary in 2011 has examined "Prediction Rupiah against US dollar", by using the approach of Fuzzy Time Series". with an accuracy degree of the expected outcomes measured via way of means of the Average Forecasting Error Rate (AFER) cost. This research used little amount of statistics, so the prediction will become barely much less than the optimal value [7]

In these days, many authors are interested about the forex rate problem in selecting the most accurate model for forecasting.[9-11].Among the ones, He and Jin [8] used the inverse ARIMA-GM model for forecasting the foreign exchange rate for (US Dollar/Japanese Yen). Their hypothesis stated that the merged model has better forecasting accuracy for exchange rate. Researchers V. Thuy and D. carried out the autoregressive disbursed lag (ARDL) bounds testing technique to analyse the relation between exchange rate volatility and exports carried out. The outcomes confirmed that the alternate charge volatility may have a opposite impact for the export magnitude over a long period of time [12].

The study proposed by RM Pattanayak and Panigrahi.S in 2020 explains that the performance of FTS forecasting model based on support vector machine is robust. It states that using FLRs (Fuzzy Logic Relationships), the statistical superiority of the model is high when compared to other models with a best mean rank value of 70.30[28].

The research paper by Nonita Shrama, Monika Mangla, SN Mohanty, entitled "Employing Stacked Ensemble Approach for Time Series Forecasting" demonstrates that the accuracy of forecasting can be improved significantly by using the stacked generalization ensemble model. The results of the study reveal that the model outperforms traditional methods such as Auto ARIMA, NNAR, ETS, and HW. [33] .

The study "The use of ARIMA Method to forecast Short Term Load Electricity Consumption" that has proposed by Febi Satya P. in 2015 shows the outcomes display that the Mean Absolute Percentage Error (MAPE) score is pretty high, which is 6.03%.[13].

Whereas the MAPE score we achieved for our study is around 92.3%. It is a fact that rise in the volatility of a variable and or the usage of vulnerable forecasting approach within the monetary marketplace is dangerous to monetary improvement because of their damaging effect on global exchange and overseas investments [31]. Hence, forecasting a variable in the monetary markets is an issue of vital importance, in particular within countries like United States of America[31-33].

Recent research study "Forecasting of Sunspot Time Series Using a Hybridization" proposed by S. Panigrahi and RM Pattanayak shows that their proposed PHM-MAX- ARIMA-ETS-SVM gives a better accuracy than the existing hybrid and individual models[6]. The research work titled "A novel probabilistic intuitionistic fuzzy set based model for high order fuzzy time series forecasting that was proposed by RM Pattanayak and H.S.Behara shows a novel probabilistic intuitionistic fuzzy time series forecasting (PIFTSF) model with the help of support vector machine (SVM) to solve the problem of both uncertainty and non-determinism that is related with the real time series data. Such methods work effectively when compared to other traditional methods [23-27].

In the recent study "A hybrid deep learning framework with CNN and Bi-directional LSTM for store item demand forecasting" done by Reuben Varghese Joseph, Anshuman Mohanty and Soumyae Tyagi the hybrid model proposed by the researcher CNN-BiLSTM with lazy Adam optimizer has given better accuracy when compared other traditional machine learning models for forcasting [34-37].

III. METHODOLOGY

In this section, we discuss the techniques used for collecting the data, developing the ARIMA model of the bellow-mentioned time-series data.

The study is divided into four stages: (1) The Dataset, (2) data preprocessing, (3) using the ARIMA approach, and (4) test accuracy.

IV. THE DATASET

The data utilized is the Dollar (USD) – Rupee (INR) exchange rate, which was obtained from Yahoo Finance. Seven attributes make up the dataset: open price, close price, high, low, adjusted price, volume, and date. The time series data has maximum of 657 records which starts from June5, 2020 to December 10, 2022. (Figure 1 shows a dataset collected from yahoo finance)

V. DATA PREPROCESSING

The data preparation/Preprocessing stage must be completed before the prediction process can begin. This stage involves the following steps (a) load data, (b) attribute reduction, (c) data cleaning, and (d) stationarity testing.

Load data refers to the process of loading data in .csv format. Following the successful completion of the data import procedure, the following results were shown in figure 3.

```
> INR = pdfetch_YAHOO("INR=X",from = as.Date('2020-06-5'), to= as.Date('2022-12-09'))

Figure 3. Load data

The procedure of deleting non-essential data attributes is called Attribute reductions. The researchers opted to eliminate the following attributes open price, closing price, high, low, and volume. As a result, the experiment only employs the two remaining attributes: adjusted price and date attribute. The adjusted price column was selected as it represents the steady price of the Dollar exchange on a given day. This column has been renamed Price. Figure 4 depicts dataset after reduction.

2021-06-15	73.1808
2021-06-16	73.3447

Figure 4. The dataset after reduction

In the data cleaning phase, the researchers have identified all the null values in the dataset and removed them.

The time series statistical property with remains constant with respect to time is called Stationarity. The model's performance depends on the Stationarity of the data in time series analysis[19-22]. Therefore, converting the non-stationary into stationary is curial part of the time series analysis. The researchers used the ADF test (Augmented Dickey–Fuller test) to assess whether or not the data is stationary (If the p value is less than 0.05, the data is termed as stationary; otherwise, the data is not.)

In this study the researchers use differencing to transform non-stationary data to stationary data. Data is turned into stationary data via differencing, that indicates the variation or change in value of observation. The process of subtracting unit root from the time series is knowns as differencing process[29-30].

The order of coefficient d on ARIMA will depend on how much differencing has been done. The data is referred to as non-stationer homogeny level d ARIMA if it has undergone a multiple differencing process to remain stationary (0, d, 0).

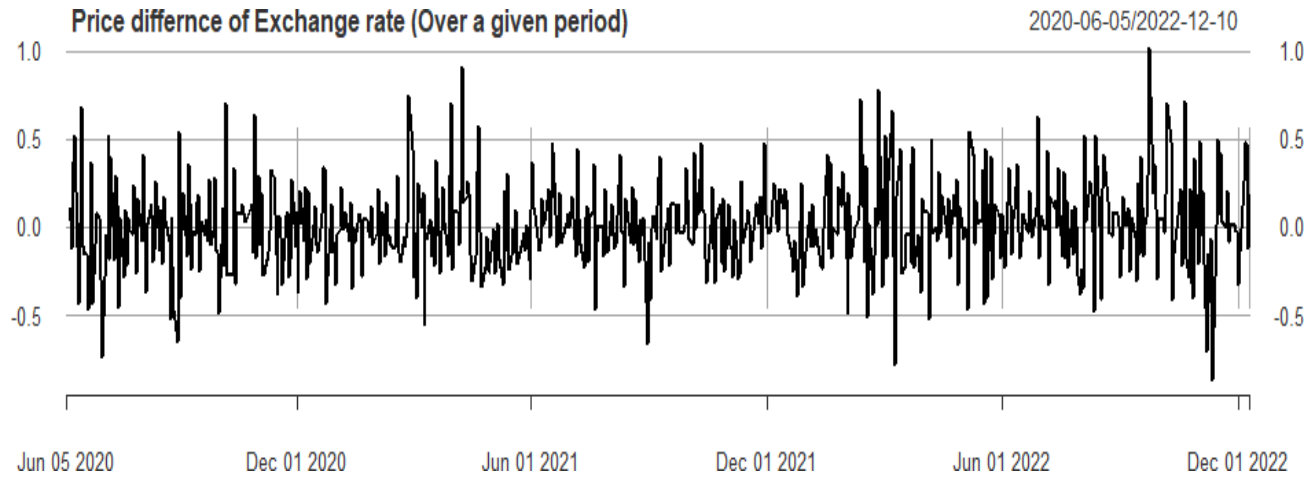

Figure 6. The data after converting it into stationary

VI. PREPARING THE MODEL

ARIMA (Autoregressive Integrated Moving Average) is an acronym that combines the moving average and regression models. We predict the variable of interest in an auto regression model by utilizing a linear combination of the variable's historical values. The moving average model predicts future values by leveraging prior forecast inaccuracy. The ARIMA equation, which combines the AR and MA equations, is abbreviated as given below.

$Xt = \mu + \emptyset 1 Xt{-}1 + \emptyset 2 Xt{-}2 + . . + \emptyset p Xt{-}p + et - \emptyset 1 et{-}1 - \emptyset 2 et{-}2 \ldots - \emptyset q et{-}q$

Where:

$\emptyset p$ = Autoregressive parameters to p

et = White Noise, error value at time t

μ = independent variable

$\emptyset q$ = Parameter of Moving Average

For the training and testing we have split the original dataset in 30:70 ratio. We fit the ARIMA on the training data with the appropriate P, q, and d values to obtain the best ARIMA model. By charting the PACF (Partial autocorrelation function) and ACF (Autocorrelation function) graphs, the order of AR(p) and MR(q) may be established (figure 7). After determining the optimal model, we forecast the future price of the USD v INR exchange rate.

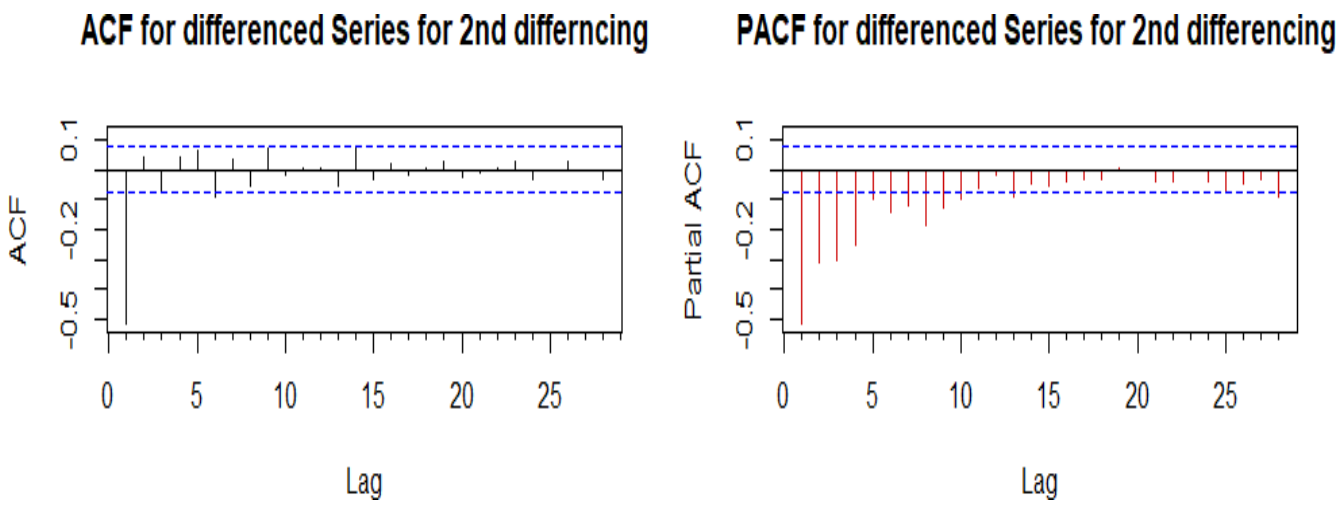

Figure 7 : PACF and ACF for the 2nd differencing

VII. RESULTS AND DISCUSSION

Experimental Evaluation

Performance Evaluation

The following measures are used to assess the model's accuracy:

Mean Absolute Error (MAE), Mean Percentage Error (MPE), Mean Absolute Percentage Mean Square Error (ME), Root Mean Square Error (RMSE) (MAPE).

The model with the lowest MAPE is chosen as the best fit model after we assess the model's performance on the test dataset.

Experimental Setup Used

The experiment was carried out on a conventional laptop which consists of Windows 11 operating system, i7 processor, 16GB of RAM. The result displayed in this study was the best result obtained when experiment was carried out.

The predictions were made by specifying the number of days that we are anticipating. We have forecasted Exchange rates for the following day, 15 days, 30 days, and 60 days. Figure 8 displays the prediction's outcome.

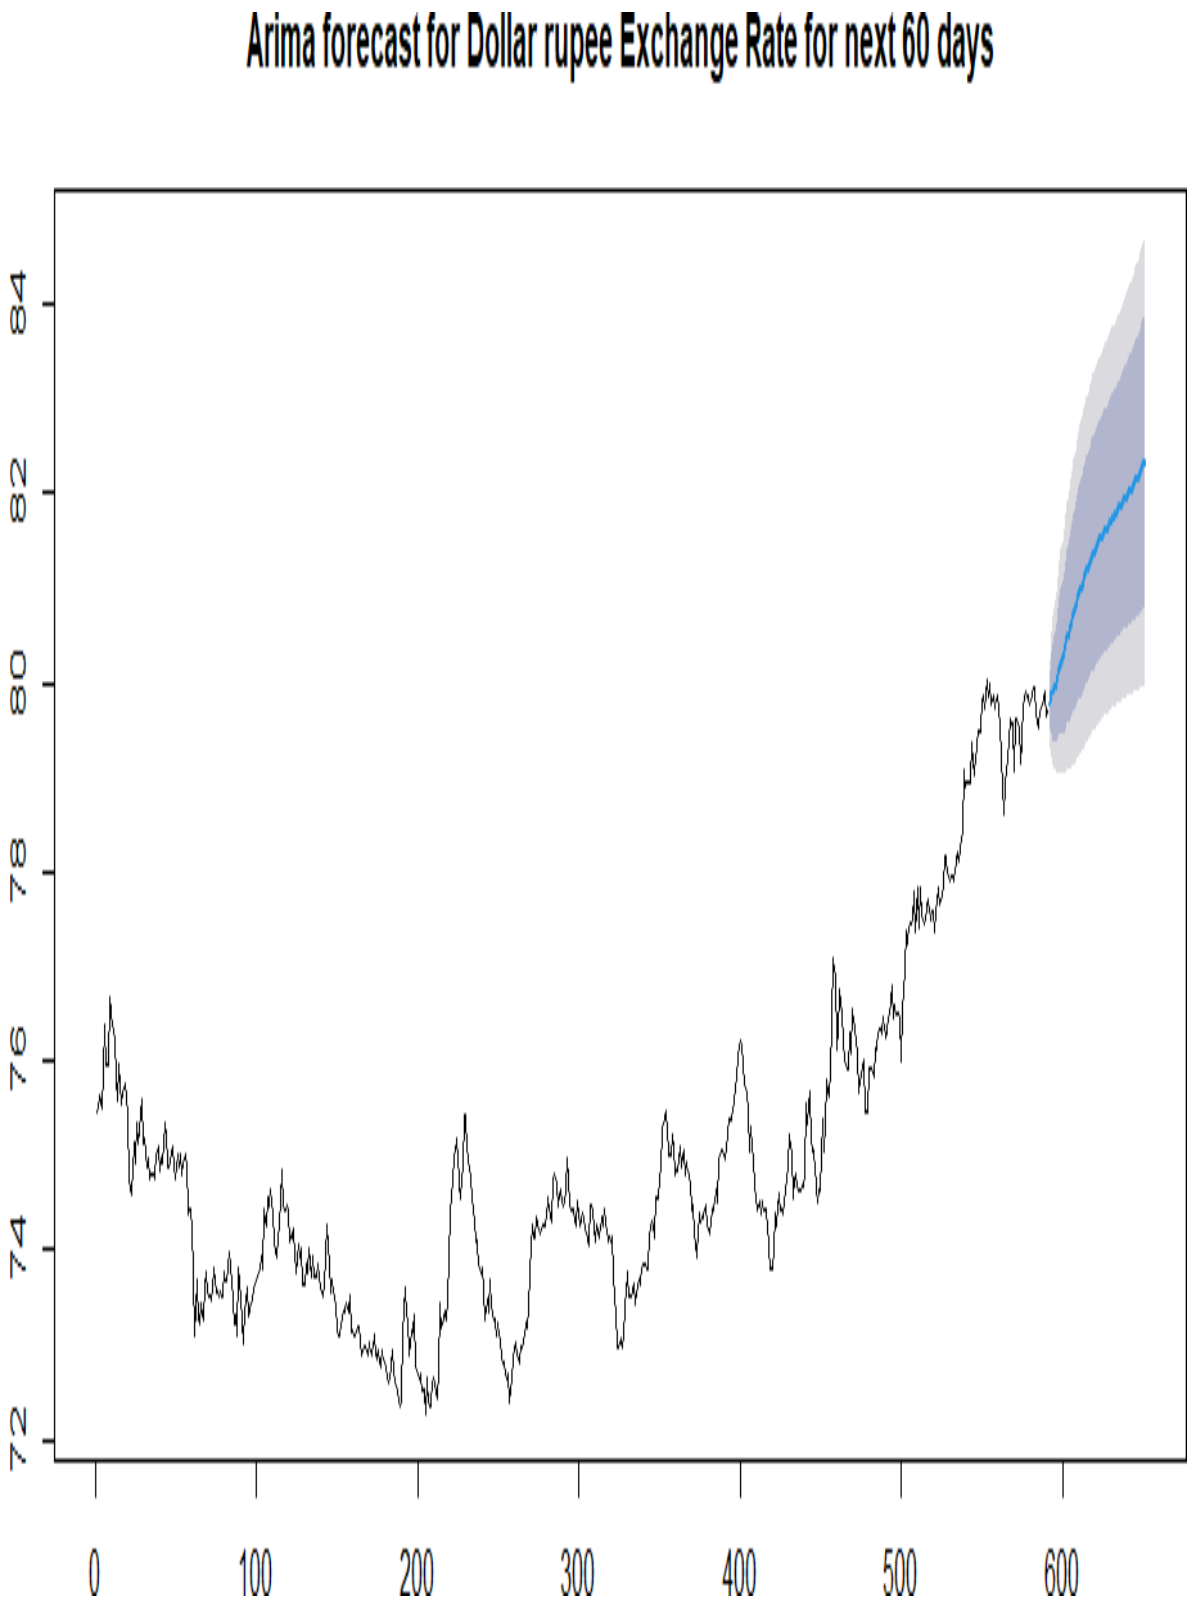

Figure 9 : The result of next day(a),15days(b),30 days(c)and 60 days(d)chart predictions.

From the below test result, we can observe that the performance of the model is with a MAPE score 0.9232047.

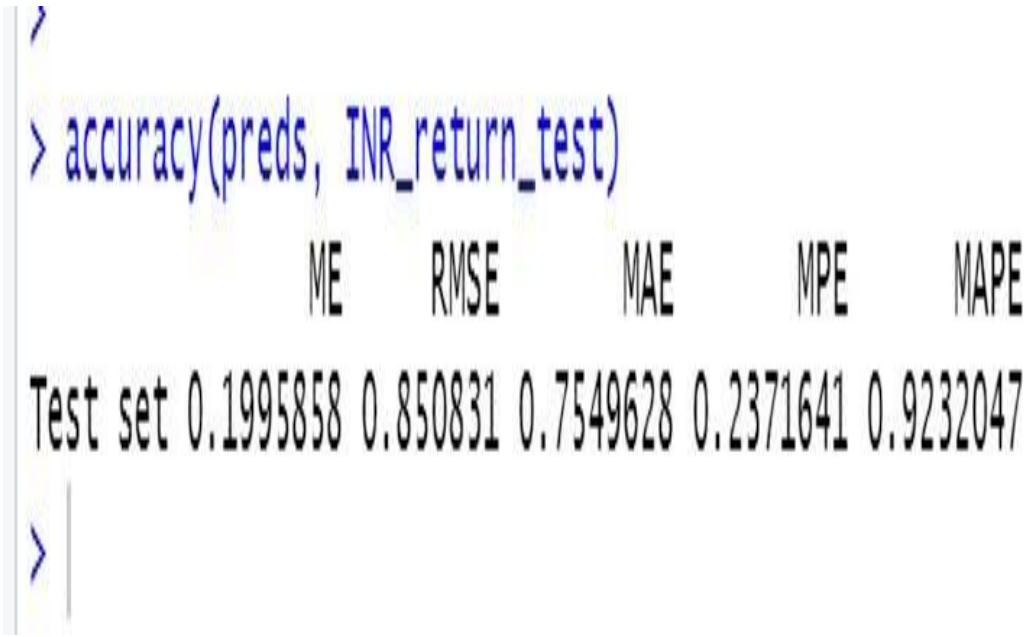

Figure 8: The test results

In this study, we have used ARIMA approach to forecast the future price of the dollar exchange with appropriate orders of auto regression and moving average which were observed form PACF and ACF graphs respectively in our the study we have observed the p(Order of Auto regression) value to be 20 and q(Order of Moving average) value to be 6

. As the data provided is not stationary we convert it into stationary data in our case we have 2nd difference to make the data stationary this gives the order of d.

From the accuracy of the model, we can say the model is performing very well with a low MAPE score of 0.923. According to the anticipated statistics, the dollar price will be slight rise during the following 60 days, beginning on December 11, 2022. Traders may rely on the model for preliminary dollar price predictions since it is both cost and time efficient.

VIII. CONCLUSION AND FUTURE SCOPE

Based on the findings, we came to the conclusion that the ARIMA (20,2,6) model is the most accurate model to forecast the value of rupee against the US dollar . The MAPE test results for the proposed ARIMA (20,2,6) model is 0.92322047, we can conclude that this model is workable to forecast the value of rupee against US dollar. The findings in the present study indicated that the exchange rate of rupee versus dollar increased slightly for the current day, 15 days, 30 days, and 60 days starting on December 10, 2022.

Since we have achieved a remarkable increase in accuracy of the model, this exchange rate time series can be extremely useful for the traders of FOREX market by making accurate predictions and reducing the risk factor in trading. The future scope of this research includes using various economic factors that influence exchange rate such as GDP (Gross Domestic Product), inflation and money supply. By using these factors various trends or patterns of movement are created that impact the exchange rate. Dua and Suri (2019) analysed the relationship between four exchange rates and found a significant bidirectional causality. Predicting these exchange rates in a Vector Autoregressive Integrated Moving Average (VARIMA) model can give better results, thereby improving the accuracy of the model. Such time series forecasts provides governments and policy makers a direction to design policies in the light of forecasts.

Abstract - **In this cutting-edge world, fast mechanical improvement makes ready for human local area to encounter the solace and headway throughout everyday life. In spite of the fact that the universe of science raises numerous advancements, people can always been unable to get their life from death, as life is questionable. All throughout the planet, a huge number of mishaps are going on consistently and for a large portion of them, tiredness of the driver is the significant reason. People can't handle the nature however can be savvy enough to deal with the nature. Lazy driving is a genuine danger for drivers. Sleepiness can be brought about by numerous reasons. Utilization of certain medications, drugs, liquor can likewise cause sluggishness. In this manner, languor is a genuine danger for drivers. There are numerous gadgets existing in the present-day market however a large portion of them costs exorbitant cost and furthermore they are not conveying precise outcomes. This model will fill in as the best minimal expense framework which gives exact outcomes. In contrast to other existing frameworks, this framework is fit for conveying yield in high exactness rate which is fundamental, as this a daily existence saving framework.**

Keywords – ***Drowsy, alert, Arduino.***

I.INTRODUCTION

As indicated by the National Sleep Foundation, about portion of the U.S. grown-up drivers concede to reliably getting in the driver's seat while feeling tired and about 20% confess to nodding off in the driver's seat previously year – with over 40% conceding this has occurred at any rate once in their driving professions [1] . These frightening figures show how pervasive sleepy driving is. What drivers may not understand is how much lazy driving puts themselves – and others – in danger [2]. Indeed, an expected 5,000 individuals passed on in 2015 in crashes including tired driving, as per a Governors Highway Safety Association report.

II. Drowsiness Effects While Driving

Driving while lazy is like driving under impact of liquor: Drivers' response times, consciousness of dangers and capacity to support consideration all deteriorate the drowsier the driver [2]. Driving in the wake of going over 20 hours without rest is what might be compared to driving with a blood-liquor convergence of 0.08% – the

U.S. legitimate cutoff. We are multiple times bound to be in a fender bender on the off chance that you are exhausted [3].

III. LITERATURE SURVEY

The creator examined various phases of rest is Observing framework for eye ball has been created for recognizing the sluggishness of the drivers [4]. A framework following the laziness of the driver was planned. The creator gone through a neurological report on rest and its stages [5]. Tech issues and extensions were studies to recognize exhaustion and for the weakness the executives [6]. Unwinding consequences for reaction time was dissected and considered [7]. A framework was produced for checking the condition of the driver for rest location [8]. Business transport security and life- guarding significance was dissected through this work [9]. A framework checking the sleepiness of the driver was created [10]. Electroencephalogram investigation for exhaustion driving location was carried out [11].

IV. EXISTING SYSTEM

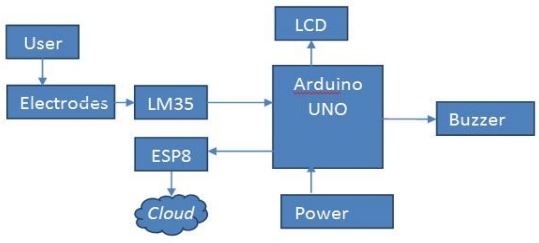
In the current framework, with the assistance of noninformative vision-based ideas, languor identification framework is created [12]. Numerous frameworks which are accessible require a camera which is introduced before the driver which point towards the driver's eye. In weighty vehicles this game plans aren't appropriate [13]. It identifies just 40% of the face. Essentially in guiding development observing framework, when the sensor gets broken or harmed the data it peruses and ships off the board will be mistaken and it is additionally be significant expense [14].

V. Proposed System

In the current frameworks, there are numerous inconveniences to list-down however the principle detriment in every one of the current frameworks is the expense and the exactness of the outcomes. Every one of the current frameworks are expensive that a low-end vehicle driver can never bear. Just the first class brands and top of the line models have the ability of conveying exact outcomes, such frameworks are by and large valued high on the lookout. In nations like India, where the greater part of the populace is working class, possessing low-end vehicles, they can't manage the cost of such exorbitant frameworks even though they save the existences of the drivers, which is beyond value.

In the proposed framework, the framework really works with the information that is brought from the mind through cathodes. Essentially, Brainwaves are observed and sleepiness is distinguished. So, the precision will be 100%.

The Proposed framework alarms in a flash when the driver feels sluggish which is exceptionally precise. This framework is convenient and simple to send. This framework is relevant to numerous gadgets. This framework is less expensive when contrasted with another existing enemy of languid ready framework.



The above figure shows the square graph of the proposed framework. Each square addresses a capacity associated with conveying the outcome. Cathode's block addresses the terminals which are utilized to get the essential contribution from the cerebrum. The procured signals are then shipped off LM358 ADC. In this square, the obtained simple sign is changed over into computerized signal and the sign is passed to the Arduino. Here, in the Arduino block, the sign is checked and just if the sleepiness condition is fulfilled, the sign is passed to the ringer and the bell gives the caution to the client quickly.

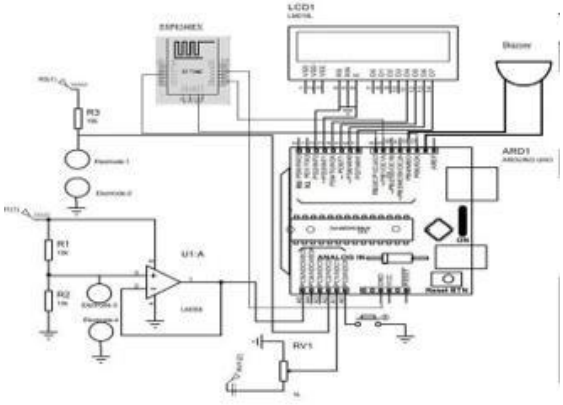


Figure 2. Circuit Diagram

The above figure shows the circuit graph of the AntiDrowsy Alert System. Terminals are utilized here to catch the electrical signs and the cathodes are getting associated with the Arduino UNO ATmega328P microcontroller. In this microcontroller according to the prerequisites and if the condition fulfills, the sign is given to the bell and the control is given to the LCD screen and the alarm message is shown on the LCD screen alongside ready sound. The terminals 1 and 2 are associated with the overhead headset and fixed at the scalp of the client and cathodes 3 and 4 are reference anodes where they are set at the fingers. At the point when the electrical signs of the client fluctuate as indicated by the developments of the body which then, at that point distinguishes the scope of the client accomplishes the languid state, the signal is then communicated to the microcontroller and the program gets executed and the ringer alerts. The LM358L Integrated Circuit utilized here changes the sign from simple over to advance by the prerequisites for the microcontroller. ESP8266EX is a Wi-fi module which sends the information to the

cloud for the investigation of the client and saved in the website page.

S.NO	Component	Specification
1	Electrode	Silver Chloride (AgCl)
2	Arduino UNO	Atmega 328, 14 digital pins, UART, Operating Voltage:5V
3	LM358L Dual OP-AMP	Supply range: 3V to 36V
4	Buzzer	Operating Voltage : 4V - 8V Minimum Sound Output-85dB
5	LCD display	16*2 display Operating Voltage : 4.7V -5.3V
6	ESP8266EX Wi-Fi module	32 bit microcontroller Maximum power supply : 3.3V I/O Voltage: 3.6 V(max) Source current:12Ma Frequency range :80-160mH
7	Overhead headset	-

Fig.3.Hardware Specification

Hardware set up of the proposed system The parts were associated and equipment arrangement was done effectively for the confirmation of the yield. Cathodes in the earphones notice the brainwaves from the mind and the got signal is passed to ADC convertor to change the acquired simple sign over to advance. Presently the changed over Digital sign is passed to the Arduino where the dynamic is done and if the Arduino discover the sign to be in the tired reach which is pre- modified, then, at that point the sign is passed to the ringer and through the bell, the alarm is given to the client immediately.

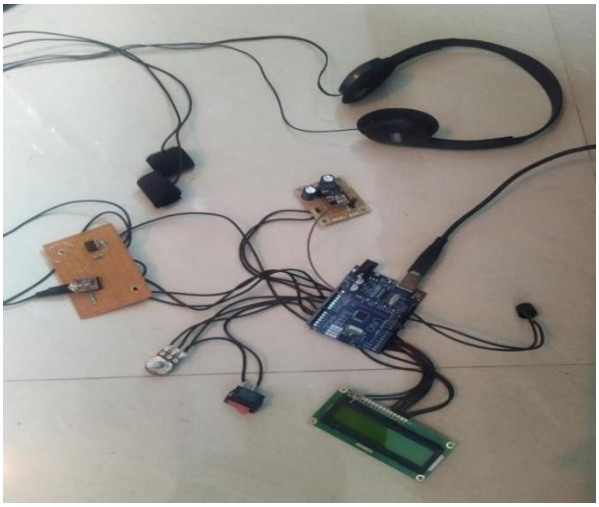

Figure3.Hardware set up of the proposed system

VI. RESULT & Conclusion

Lazy driving is a genuine danger to drivers and this framework successfully helps the driver not to rest by giving moment alert. This framework could be formed into an item in less term and everybody can bear the cost of this all things considered of minimal expense. Along these lines, this minimal expense against sleepy ready framework works effectively subsequently keeping the driver from mishaps because of laziness.

Abstract— **Attention deficit hyperactivity disorder and Specific or special learning disability are two diverse disorders that commonly co-exist in children. Children with attention deficit hyperactivity disorder are distinguished by problem behaviors, while one with specific learning disability is characterized by scholastic lags or difficulties. Both coexist in half of the cases, with each contributing to the consequences of the other. Currently, these disorders are screened and diagnosed traditionally by therapists, who conduct assessments that are largely in-person and paper-pen based. Instead of undergoing these expensive tests in accordance with medical guidelines, a digital and automated system that can help identify these specific learning disability, as well as attention deficit hyperactivity disorder, from the comfort of one's own home can be extremely helpful. This paper aims to develop this digital system via the use of pattern recognition, natural language processing, and computer vision to help identify individuals or students with these disorders.**

Keywords—***Special learning disabilities, natural language processing, computer vision, pattern recognition.***

I. INTRODUCTION

People with specific learning disabilities suffer from disorders that affect their ability to learn. The disability is commonly associated with dyslexia, dysgraphia, and dyscalculia. These disabilities are defined as shown below.

- Dyslexia is a brain based/neurological learning condition that primarily impacts reading, spelling and writing. However they do not have vision issues and are most likely to have a normal IQ and generally lack phonemic awareness.
- Dysgraphia is a a type of a neurological condition in which a human being has extreme difficulty in writing ability for their age level. They generally tend to use the wrong word for what they are trying to communicate.
- A dyscalculic individual is unable to comprehend or understand numbers, and they do not possess mathematical ability.

V U Umme Azra

It is a phonological processing problem that causes dyslexia. People with dyslexia must take a word such as "fantastic" and break it down into parts in order to read and understand it. Words like "stik" and "fone" are also regularly spelled phonetically for "stick" and "phone" respectively. This condition has something to do with how the brain of a dyslexic person works. The brain is sectioned into two areas:

- Left Hemisphere: It is concerned with the operation of the mind, speech, science, logic, and mathematics.
- Right Hemisphere: Activities such as creativity, instinct, art and music are taken care of here.

The right hemisphere and frontal lobe are more active in the brains of those with dyslexia than those without it. Thus, their mind needs to process information for a longer period of time, making it difficult for them to read.

Dysgraphic children are generally observed to have poor transcription skills. As a result, students struggle to complete written tasks such as copying notes from the blackboard and perform poorly in formal exams. Their writing is generally messy and challenging to read, irrespective of the type of written information.

Children with dyscalculia generally have a difficult time trying to decode mathematics. During counting sessions, they tend to skip numbers and have trouble determining patterns, such as the smallest and largest numbers. They struggle to identify numbers and can see "2" as "Z". They also have a hard time identifying quantities.

ADHD, on the other hand, is a behavioral condition that affects 2.4 million school-going children, which is almost equal to 9.66 percent of the world's population, according to a recent study conducted in July 2022. Both (SLDs and

ADHD) coexist in half of the cases, with each contributing to the consequences of the other.

These learning disorders, along with ADHD, only worsen with age. As a result, it is very important to identify such a condition at an early age, preferably among school-going children. There is a huge gap between identifying at-risk children, referring them for assessment, and then treating them. Each is a process on its own, and less than 1% of those identified will actually end up getting effective treatment. Treatment is a professional activity, best administered by trained professionals, but screening must be performed by someone who knows what the issue is. Technology, however, can aid us, and guide us at every stage of this right from identifying to treating such children.

To screen for such disorders and prevent them from affecting students, machine learning models have been developed that utilize data from students with diagnosable disorders, undiagnosed students, and students without diagnoses. After collecting the data, it is pre-processed. For the model, random forest, K nearest neighbors, decision Tree, and Support Vector Machine are used since these models have the best accuracy, ranging from ninety to ninety-six percent. This project aims to provide a digital means to detect disorders like Dyslexia, Dyscalculia, Dysgraphia, and ADHD when the symptoms are mild and easier to manage.

II. LITERATURE REVIEW

[1]"Radford, Jim, et al. Detecting Dyslexia from Audio Records: An AI Approach. HEALTHINF. 2021".

This paper includes the use of dyslexic and non-dyslexic students' audio files to detect dyslexia. Each audio file uses two parameters, namely Reading Reaction Time (the duration between the display and actual reading of the text) and Reading Time (the duration of reading the text displayed). Each of these parameters is used as input on various current AI/ML algorithms for the purpose of detecting any hidden patterns that can be used to identify or more likely separate dyslexic and non-dyslexic children. Once done, a neural network model is built that achieves higher accuracy than current algorithms in identifying dyslexia among students.

[2]" Raatikainen, Peter, et al. Detection of developmental dyslexia with machine learning using eye movement data. Array 12 (2021): 100087."

In this paper, Data was collected via a certain set of multiple choice questions that were supposed to be answered by them. Eye movement was tracked and collected using an EyeLink eye-tracker during the question display that contained the task and the distracter. Students were classified as having a learning disability if their reading frequency fell below the 10th worst percentile. Random forest was used to distinguish the movement of the human eye, which were then passed to the support vector machine classifier as inputs. In this paper, machine learning models are used to recognize students with poor reading performance using their eye movement, which was recorded when the student was tested for reading. The input for the support vector machine model was chosen using the most important eye movement patterns. This hybrid model achieved an accuracy of up to 89.7% with a recall of about 84.8%.

[3] "Jamhar, Mohammad Azli, et al. Prediction of Learning Disorder: A-Systematic Review. International Visual Informatics Conference. Springer, Cham, 2019."

This paper surveys various papers' models and trends of which machine learning model is being most frequently used. It analyzes the methods and the accuracy for models. The paper helps better understand how each model works for similar objectives or problems and helps give insight on how to use those models for similar problems accurately.

[4]"Dutt, Sarthika. Comparison of Classification Methods used in Machine Learning for Dysgraphia Identification. Turkish Journal of Computer and Mathematics Education (TURNCOAT) 12.11 (2021): 1886-1891."

For the detection of dysgraphia, this paper proposes two categories; Motor skills and cognitive skills. Survey for 240 students was conducted, out of which 142 students had learning disabilities. The proposed model uses Elastic Net, which is linear regression with penalties. Although the elastic net did not provide the most accurate results, it was identical to the other algorithms used to compare; namely K- Nearest neighbors, random forest and decision tree.

[5]"Ghasemi, Elham, Mansour Ebrahimi, and Esmaeil Ebrahimie. Machine learning models effectively distinguish attention-deficit/hyperactivity disorder using event-related potentials. *Cognitive Neurodynamics* (2022): 1-15."

The result of the study shows that the continuous usage of several right features has a vital role in increasing the efficiency of the classification. Accurate features in the processed classification had to be approved. This paper mainly included models such as Support Vector Machine (SVM), deep learning, generalized linear model, logistic regression, random forest, decision tree, naive bayes etc. This improves the accuracy of the model used.

[6] "Khale, Rohit Detection of ADHD using Machine Learning Algorithms ISSN: 2319-7064 Impact Factor (2018): 7.426. "

They can determine the functional and structural images of the brain for diagnosis of ADHD. For the given unlabeled dataset in the given paper they have provided gathering structure (k-means) to make clusters in view of MRI images of ADHD acknowledged students . Classification algorithm

K-Nearest Neighbor classifiers the input given in the paper [7]"Germanò, Eva, Antonella Gagliano, and Paolo Curatolo. Comorbidity of ADHD and dyslexia. *Developmental neuropsychology* 35.5 (2010): 475-493."

ADHD patients have issues such as problem solving, planning, managing orienting, alerting, cognitive flexibility, sustained attention and organizing , so developing the gray matter and size of the skull would develop with time.
In certain cases ADHD and RD co-exist such that patients might have comorbidity in identification and thus curing. A person with short attention span tends to lag in academics and sports and extracurricular activities such as dancing, singing and performing on stage.

[8] "ADHD and Dysgraphia: Underlying Mechanisms. Esther Adi-Japha1, Yael E. Landau2, Lior Frenkel1, Mina Teicher1, Varda Gross-Tsur2 and Ruth S. Shalev[2019]."

In this paper, Dysgraphia was identified using three primary factors, which include linguistic processing, motor programming and motor kinematics. Students with ADHD had more number of spelling mistakes and showed a pattern introducing letter interchanges, over writing and rewriting due to mistakes. This suggests that the spelling mistakes and writing mistakes in students with ADHD and reading are primarily from non-linguistic deficits, and linguistic factors do not play a primary role.

[9] "Giri, Nupur, et al. Detection of Dyscalculia Using Machine Learning. 2020 5th International Conference on Communication and Electronics Systems (ICCES). IEEE, 2020."

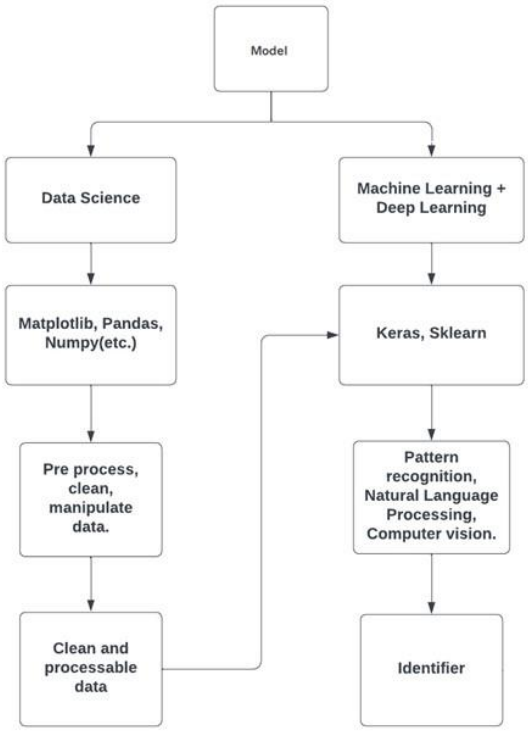
In this paper, machine learning models like random forest and decision tree was used. The initial questionnaire used to collect data was "Wide range achievement test". The data collected was used as input for a random forest, which was used for training of the model. Intelligence quotient questions were also considered to ask students and collect data. This model yielded 99.96 % accuracy.

[10]"Mobile Application for Dyscalculia Children in Malaysia. Ariffin, Mazeyanti & Abd Halim, Fiqa Azureen & Aziz, NorShakirah. (2017). "

It was developed with Android Studio. Number counting, object counting, addition operations, and subtraction operations are the four subsets of games that were created for the Calculic Kids. The target audience for this initiative is children with dyscalculia in Persatuan Dyslexia Malaysia. The results were seen how they responded and noted it for future reference. Additionally, for system improvements, teacher feedback was also gathered.

III. PROPOSED METHOD

3.1 Overview model



3.2 Inputs

For this model, four types of data is collect, they are as follows:

1)Corner's Rating Scale
2) Audio Recording
3) Maths Quiz
4)Handwriting

1) Conner's Rating Scale

From Conner's Rating scale extracting the questionnaire, wherein the approved questions which are asked to the ADHD children by teachers in a special centers or via parents.The following outputs from the questionnaire would determine the children stage of ADHD and thus it would be easy to identification of the child's ADHD
Identifying ADHD at an early stage can possibly be through their near ones where their child is under observation all while long and could possibly detect through their behavioral activities. With this the determination of the ADHD in a particular child at a certain age could lead to prevention and early access to the medical help required.

2) Audio Recording

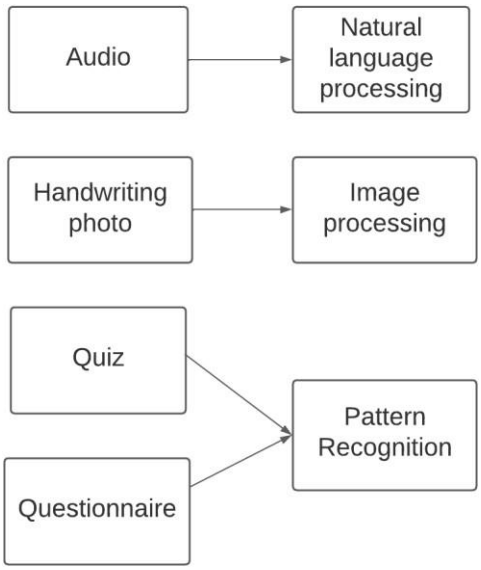
Collecting data from the audio of the student, and determining whether the child is dyslexic or not.
The Audio Recording process just records the audio and mostly determines all the SLD's that might as well help their kids with reading, writing and talking disabilities. Using the Natural language processing (NLP) pre-processes the audio. 3) Math Quiz

Child responding to dyscalculia, who is bad at math gives a quiz to determine their learning disabilities might give an assessment to conclude that he/she is not only bad at
academics but math in particular

4) Handwriting

Dysgraphia could be determined by the handwriting of the child, wherein the child doesn't know the recognition of alphabets or writes a mirror image of an alphabet. For example: b as d or p.
For the trained model, the input will be an image of the writing. This is then input to convolution neural networks.

3.2 Model



The proposed model has three parts.

1) Natural language processing 2) Image processing 3) Pattern recognition

1)Natural language processing

Dyslexia is the inability to read. While reading the student or child tends to mispronounce words or not pronounce the word at all. To identify this disorder, the input taken is an audio file. The type of audio file used is a WAV audio file.
WAV is basically the wave form and the audio data together. Inorder to use the WAV file, it should be pre-processed first. Noise and disturbances are removed from the WAV file in order to get useful and processable data. The cleaned WAV file is then divided into parts on the basis of sound, in other words phonemes. Phonemes are sounds like "ka", "sh" or "s". These are then put into an order which will create sentences. By analyzing the way words are being pronounced, dyslexia can be identified.

2) Image processing

Dysgraphia is the inability to write properly. To identify this disorder, the handwriting of the student should be analyzed. In order to do that, handwriting from students with no disorders and students with disorders are labeled accordingly. For the trained model, the input will be an image of the writing. This is then input to convolution neural networks. The model should be able to differentiate between the handwriting of students with dysgraphia and students without dysgraphia.

3) Pattern recognition

Dyscalculia is the inability to do basic math. It can be identified with a math quiz. The math quiz will contain questions like, differentiate between "x" and "+" and basic math problems. For ADHD, a behavioral questionnaire is used. Patterns are recognized using supervised learning, where we collect data from students diagnosed with dyscalculia and ADHD and students who do not have these disorders, this is the training set. The testing set will contain the combination of students with and without disorders, without labeling. According to how questions are answered and in which pattern, ADHD and dyscalculia is identified.

IV. RESULTS

This model aims to detect four disorders. In order to detect all the four disorders separately or if they coexist, five types of data are collected; For dyslexia the audio of dyslexic children, dysgraphia the handwriting of dysgraphic children, dyscalculia math quiz responses of dyscalculic children, for ADHD the questionnaire responses and responses of normal students for all the four disorders with respect.

V. CONCLUSION AND FUTURE WORK

This paper proposes a model to detect four disorders which can coexist. Students with learning disabilities experience problems in a traditional classroom learning environment leading to poorer mental health. Those difficulties can result in emotional struggles as well as social perceptions, resulting in a student's failure to succeed and being accepted by their peers. This model aims to detect these learning disabilities at an early stage by focusing on data collection from school going children early on. Future work for this model is to make a website for detection of these disorders.

Abstract — **In the course of working on this project, we conducted a regression analysis on the stock price of apple between the years 1980 and 2021. For this particular study, we relied on the technique of linear regression, from which we derived the accompanying graphics. These graphs are utilised to make projections on the value of Apple shares for the following year. The model will provide either numbers that are approximately accurate or values that are predictions. The dataset can be acquired from Kaggle, and the reference section will include a link to the site where it can be found. We will also be trying various regression approaches, and we will demonstrate that the regression obtained by linear regression is the most effective method for analysing this dataset.**

Keywords— **Apple, Stock, Prediction, Linear regression, Poisson regression.**

I. INTRODUCTION

In recent years, a great deal of exciting research has been conducted in the field of utilising Machine Learning Algorithms for analysing price trends and predicting the movement of stock prices and indexes. The majority of stock traders rely on Intelligent Trading Systems in today's market since these systems assist them in predicting prices based on a range of scenarios and circumstances, which enables them to make immediate decisions regarding investments. If a trader is intelligent, he or she will anticipate future stock prices and either purchase a stock before its price rises or sell it before its value falls. An accurate prediction prediction algorithm can immediately result in significant profits for investment firms, suggesting a direct correlation between the accuracy of the prediction algorithm and the profits generated by its use. Although it is extremely difficult to replace the expertise acquired by an experienced trader over the course of their career, it is extremely difficult to replace the expertise acquired by an experienced trader over the course of their career. The forecasting of stock market movements has been a popular topic for a very long time and is currently the subject of intensive study by academics from a range of disciplines. Machine learning is a well-established method that has numerous uses. It has been the focus of a substantial amount of research into its potential for predicting financial markets.

Investing in conventional financial institutions such as banks, which often offer a low return on investment [1, 2], is no longer seen to be a lucrative option by investors. These days, the stock market is often regarded as one of the most crucial aspects of the whole financial system [3]. The practise of purchasing shares of publicly traded companies is gaining ground in today's society. Almost all of us are drawn to the idea of being able to increase one's wealth in a very short amount of time while also realising returns that are often higher than average. In return, businesses that sell stocks earn capital that can be put toward expanding their operations. On the other hand, it is frequently a lengthy haul, and the money that is invested may not be recovered for several decades at a time. In other instances, the amount of money that is invested does not result in a profit at all but rather a loss. As a result, each step needs to have serious consideration put into it, and the acquisition of stocks needs to be done with the appropriate amount of consideration. Any potential investor in the stock market hopes to acquire the ability to accurately forecast the quantity and timing of stock purchases. However, the quantity of stocks an investor can purchase is also contingent on the total value of their assets. The subsequent analysis and evaluation of the historical development of stock prices and the company whose stocks we want to buy is the next important step for the subsequent valuation of the funds that were invested. This step is the next important step for the subsequent valuation of the funds that were invested. This comprises its overall economic status as well as its turnover as well as the introduction of new products to the market. There are a lot of different things that can

cause a gain or a drop in value in the long run. If we are able to accurately forecast how the stock price of a certain firm will evolve, we stand a good chance of realising a substantial financial gain [4]. This sensation, along with the capacity to make accurate predictions, is what differentiates successful investors from those who are not successful. The value of stocks is actually determined by the amount of interest in them. The supply and demand for stocks are the driving forces behind the development of stock prices. When there is a strong demand for a stock but a limited supply, the price of that stock will go up. This is true for every commodity that can be purchased on the market. As a result of fluctuations in supply and demand brought on by a variety of circumstances, the price of a stock naturally moves about over time. Stock prices are believed to be particularly dynamic and prone to swift fluctuations because of the underlying nature of the financial realm as well as in part because of the mix of known factors (Previous Day's Closing Price, P/E Ratio, etc.). This is due to the underlying nature of the financial sector, which is why this is the case. One is able to create predictions and judgements based on these criteria by utilising a range of methods to approach the data as well as the procedures. It is generally agreed that the so-called time series method is one of the most conclusive statistical methods for analysing the dynamics and development that have occurred over the course of time. It is vital to have a time series of changes in stock prices in order to discover the factors that caused changes in stock prices and defined their performance in the past, as well as for the purpose of estimating how stock prices will vary in the future.

Any person who is thinking about getting into the stock market eventually wants to be able to precisely predict the amount of stock they will buy and when they will buy it. However, the total worth of an investor's assets is also a factor in determining the number of shares of stock that they are permitted to purchase. The subsequent analysis and evaluation of the historical development of stock prices and the company whose stocks we want to buy is the next important step for the subsequent valuation of the funds that were invested. This step must be taken before the subsequent valuation of the funds that were invested can take place. The subsequent appraisal of the funds that were invested is dependent on this stage, which is the next critical step in the process. This includes the state of its economy as a whole, as well as its turnover and the introduction of new products to the market. Long-term changes in value can be brought about by a diverse range of factors, some of which generate appreciation, while others bring about depreciation. We have a decent probability of realising a significant monetary gain [4] if we are able to precisely estimate how the stock price of a particular company will develop in the future. This feeling, in conjunction with the ability to create correct forecasts, is what separates great investors from those who are not successful in their investment endeavours.

II. Literature Review

Apple Inc. is not only one of the richest firms in the world, but also one of the most well-known. As a direct result of the amazing success it has seen, Apple's liquid assets had a value of $121 billion as the company's fiscal year 2012 came to a conclusion. The corporation made the commitment in April 2013 to return up to$100 billion to shareholders through stock buybacks and cash dividends before the end of the 2015 calendar year [5]. Apple Inc. must have a well-established financial management and decision support system specifically due to the fact that the company is actively participating in the financial market. Knowledge-based decision support systems for financial management, according to Khan et al. [2], should be considered an essential component of investment strategies. [Citation needed] They came to the conclusion that investors stay away from traditional investment institutions like banks because of the low return on investment offered by these institutions. One of the most common places for people to put their money these days is in the stock market. The ability of day traders, investors, and data scientists to accurately forecast the price of stocks is getting increasingly challenging. These are complicated functions that are determined by a large variety of interacting elements that have an effect on the dynamic progression of price changes [6]. Politics, social prospects, sales of the company, and other socio-economic elements can all have an impact on the global perception of equities, which in turn is determined by the equilibrium between supply and demand [7]. This is also confirmed by Gupta and Chen [8,] who state that stock prices and financial markets are frequently based on sentiment. As a result, research efforts are being made to predict stock market trends using public sentiment expressed on social networks such as Facebook and Twitter. Gupta and Chen [8] also confirm this. [8] They say that stock prices and financial markets are often based on sentiment. It is possible to make more accurate forecasts by taking into account price swings and by gaining an insight of how people are feeling [9]. However, Chaudhari and Ghorpade [10] feel that predicting stock return is a significant difficulty in the financial sector due to the non-linear changes in the company's return on investment in stocks. This is one of the reasons why predicting stock return is difficult. Inaba [11] conducted an analysis of 37 developed and developing countries' participation in the global market for commodities and found that developed countries had larger profits on their international stock prices than underdeveloped countries did. On

the other hand, due to factors that change over time, the return on investment for stock investments increased more quickly in developing countries. These factors include not only the openness of international trade and finance, but also institutional factors representing the development of information and communication technologies, the protection of property rights, and the transparency of information disclosure. Moreover, these factors include not only the openness of international trade and finance, but also the openness of international trade and finance.

III OBJECTIVES

To design a model that would predict the stocks of Apple Inc using regression techniques.

B. Methodology

Linear

C. Regression

The method of linear regression analysis was the one that we utilised for this purpose. A quantitative outcome variable (y) can be predicted using linear regression, also known as the linear model. This prediction can be based on one or more predictor variables (x). To construct a mathematical formula that defines the variable y as a function of the variable x is the objective of this endeavour. After we have constructed a model that is statistically significant, we will be able to use it to make predictions about the future based on the new x values.

When you create a regression model, one of the steps that you must take is to evaluate how well the predictive model works. In other words, you need to evaluate how accurate the model is in predicting the result of a new test using data that was not used in the construction of the model. This data was not included in the initial data set.

When evaluating the accuracy of a predictive regression model, it is common practise to consider the following two key metrics:

Root Mean Squared Error

It determines how accurate the model's predictions are. It is the difference, on average, between the values of the outcome that have been observed and known and the value that has been predicted by the model. The formula for calculating RMSE is as follows: RMSE = mean ((observed - predicted)^2)%>% sqrt (). The RMSE should be kept as low as possible for the best models.***R-square***

IV PROPOSED SYSTEM

A. Dataset description

Individual data are gathered from Kaggle [12] for the purpose of conducting research on time series. This page details the evolution of Apple Inc.'s stock values over time, specifically providing daily data over the span of 1980 to 2021. Excel from Microsoft is used to perform processing on the data that was acquired. There are 10,469 rows total in the dataset. It contains 7 attributes namely date, open, high, low, close, adjclose and volume.

It is a representation of the squared correlation between the known values of the outcomes that have been observed and the values that have been predicted by the model. The better the model, the higher the R2 value should be.

Poisson distribution

One of the essential subjects is known as the Poisson distribution. It is put to use in the process of calculating the probabilities of an event using the rate of value on average. Poisson distribution is a discrete probability distribution.

The formula for the Poisson distribution function is given by:

$$f(x) = (e^{-\lambda} \lambda^{x})/x!$$

Where,

e is the base of the logarithm

x is a Poisson random variable

λ is an average rate of value

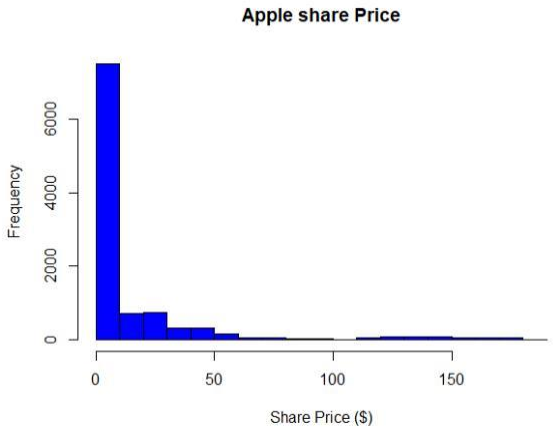

Fig1 depicts the Apple share price in a share price v/s frequency graph

Firstly, we have imported the dataset followed by that we have splitted the dataset into train and test datasets in the ratio of 0.8:0.2(80% train and 20%test dataset).Much of data pre-processing has not been done as the dataset seemed to be perfect without any null values nor any unnecessary attributes.
The obtained data are evaluated both qualitatively and quantitatively. The resulting values are also graphically illustrated.
Secondly, we have done predictions using both linear regression and Poisson distribution and the results have been graphically represented in the below section.

V. RESULTS

The linear regression model has given a residual standard error of 0.4376 and R-squared being 0.9997 for the given dataset.
Using Poisson distribution, the null deviance came out to be 424013 and the residual deviance was 115825, but Poisson distribution cannot be used as our data is clearly linear.

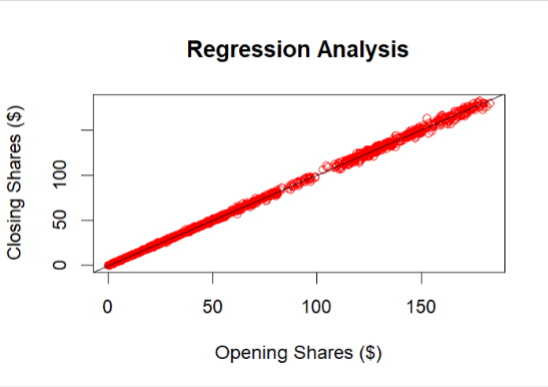

Fig 2: The linear regression analysis between opening and closing shares.

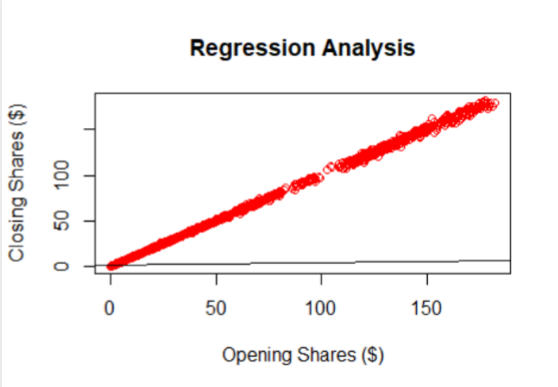

Fig 3: The Poisson distribution analysis between opening and closing shares.

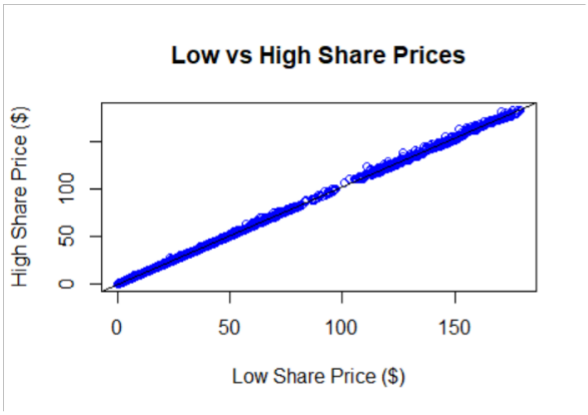

Fig 4: The linear regression analysis between low and high shares

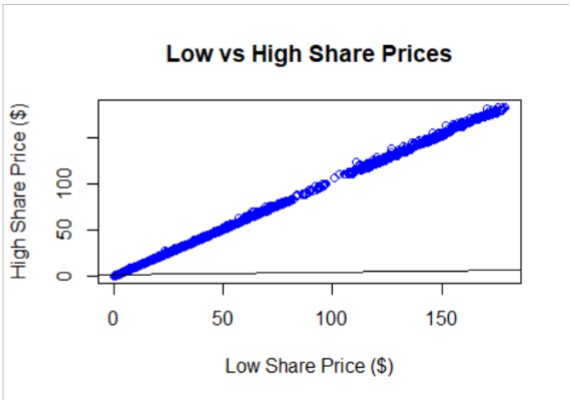

Fig 5: The Poisson distribution analysis between low and high shares

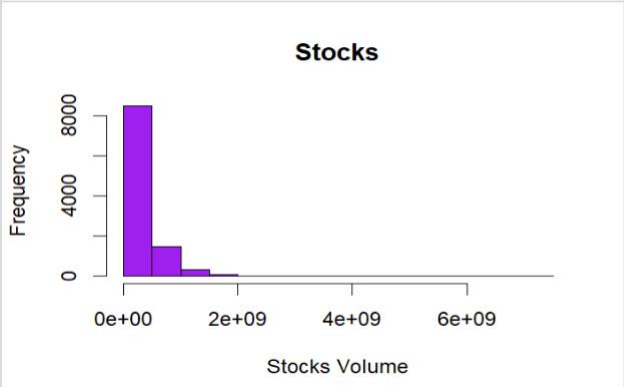

Fig 6: Depicts stocks volume v/s the frequency

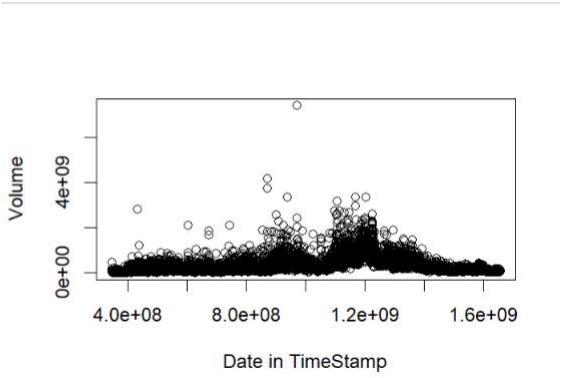

Fig 7 : Depicts date wise volume of stocks

V. FUTURE SCOPE AND LIMITATION

The extended scope of this project will require the addition of more criteria and aspects, such as the financial ratios and various instances, amongst other things. The greater the number of characteristics that are taken into account, the higher the level of accuracy. The algorithms can also be used to analyse the content of public comments and, as a result, identify trends and links between customers and the employees of businesses. The application of conventional algorithms and data mining methods is another method that can assist with performance structure forecasting for the entire organisation. In the not too distant future, one of our goals is to combine neural network analysis with additional methodologies like genetic algorithm or fuzzy logic. It is possible to employ a genetic algorithm to determine the most effective network architecture and training settings. The predictions made by neural networks are accompanied with an element of uncertainty, which can be taken into consideration with fuzzy logic's help. The application of their applications in conjunction with neural networks may result in an improvement to the prediction of the stock market. Because of the constraints of this research, our choice of statistical methods is limited to either linear regression or multiple linear regression. Due to the fact that the data is linear, it is not possible to utilise other regression methods such as Poisson regression or logistic regression

VI. CONCLUSION

Based on the findings presented above, we can draw the conclusion that the linear regression model is the most effective. It is not possible to use the Poisson distribution on these data because they can be linearly separated, and attempting to use the Poisson distribution with this dataset resulted in the model not functioning very well. In addition, linear regression was producing encouraging findings, with an error of 0.4 being the absolute minimum. As a result, we can reach the conclusion that linear regression is effective because it accurately predicts the results.

ACKNOWLEDGMENT

This paper on 'Apple Stock Price Prediction Using Regression Analysis' has been possible only because of kind co-operation lent by my teacher and project guide Dr. Sachi Nandan Mohanty without which this would not have been possible. We would also like to thank our parents, who have provided us with all possible resources to gain the best possible knowledge. At last, we would like to thank Mr. Durga Rao Jenjeti for his guidance and support.

Abstract—**The purpose of this study is to increase knowledge and understanding of how retailers implement customer relationship management in retail using business intelligence and data mining tools. Our projects focus on analyzing commercial sales and consumer demand for specific products/services, providing insight into how companies can maintain market leadership and gain an edge over their competitors.**

Analyze and draw conclusions based on three data sets. Based on commercially available products and customer demographics.On basis of customer purchase towards a product.Based on the data above, we analysis how a product is performing in the market to give the businesses a better information to enhance their product for better launch and execution of their product in the market.

Store's desires/objectives and techniques focused on marketing, customer service, information clients via statistics analysis and increasing acquisition and retention through client loyalty pack- ages. records mining gear recognized supported advertising and marketing and patron analysis efforts. Findings offer perception into the challenges outlets face as they implement a more client- centric business approach.

Keywords - **Retail Data , Analysis, Data mining, Finance study.**

I. INTRODUCTION

Retail Data Analytics does exactly what its name suggests. Analytics for everything in your business, from sales and inventory to customer data. This allows you to effectively track customer activity such as purchases and store attendance. Without the ability to track and analyze decision-making, purchasing and customer behavior, businesses risk falling behind. That's why retail data analysis is a powerful tool for your business.

According to Study, small businesses are not yet taking full advantage of technology in the marketplace. Our results show that 67 percent of single-store retailers still do not have a point-of-sale (POS) system, let alone one with analytics capabilities. In the world of retail, store owners face the challenge of how to leverage the vast amount of data at their fingertips. After all, operational data can give small businesses a competitive edge. Imagine You and your competitor operate in the same market, have approximately the same number of customers and the same product price. The same goes for how much you spend on advertising. So how do you get to the top? The answer lies in making better decisions using data-driven information. In the digital age, retailers need to keep track of a million things and there is not enough time in the day.

Retailers can use big data analytics to gain more insight into how customers are behaving or what the best prices are. Despite the potential benefits of using big data analytics, businesses have been slow to build big data platforms for decision making .

One among the most important motives to apply information analytics to guide decision-making is to make certain your selections are based totally on real reality (cold, tough numbers), not simply a person's notion of truth. Analytics can also assist

you understand what's taking place with your commercial enterprise in a lot more detail than you could in any other case. Practically speaking, a retailer can use information analytics to: recognize the price and range of merchandise offered in a mean order understand which products sell the maximum, the least, and everything in-between become aware of your most precious customers discover what your actual call for become as well as past misplaced sales decide top-quality counseled order quantities and recommend buy portions and allocations establish the surest rate point for a selected product at any precise area.

More than one studies strategy had been discovered beneficial to with a view to get analysis with at most accuracy. We've used each quantitative and qualitative studies techniques on this undertaking to analysis the records, to get insights the use of standards related with R programming, records mining additionally machine studying models. This segment intro- duces the historical past and composition of the retail quarter, which represented the premise of the retail chains examine, the information of the data acquisition approach utilized in capturing purchaser sentiment information, and, subsequently, a description of the categorization method used for textual con- tent mining client sentiment statistics in evaluation comments. We compiled a list of publicly traded stores from Kaggle which classifies 345 publicly traded firms as retail corporations . Dataset 1 summarizes the traits of the shops with appreciate to company size and class of the retail business. We categorized them as adopters or non-adopters of GROs based totally on content

analyses of their posted facts. those included company annual reviews, quarterly reviews, environmental reviews, and news release that are published. All of the retailers that have adopted green retailing practices constituted the populace of our survey observe. We set the sampling scope according to the goal "prescribed retailers" inside the which fulfills both object (1) or (2) as follows: (1) outlets that offer a) any meals or drink, b) any medicine or first-useful resource item, or c) the applications of Retail Data Analysis for Business Intelligence are extensive and include customer segmentation, predictive analytics, inventory management, data visualization and much more. Using these techniques, retailers can improve their operations, boost sales, and gain a competitive edge in the marketplace. Retail Data Analysis for Business Intelligence is a multidisciplinary field that draws on skills and knowledge from statistics, mathematics, computer science and business. Retailers who want to be successful using data analytics must have a good understanding of the technical aspects of data analytics and the business context in which the data is used. private hygiene or beauty product; and (2) shops with five or more certified outlets.

II. Literature Review

A. Structural components

1) Introduction: The need to seize, save and examine massive statistics is the purpose for the development of analytical methods and technology. .It affords a quick evaluate of numerous key massive statistics analytics technologies. These methods are drawn from the fields of mathematics and facts using data mining strategies here are used to extract patterns from records, such rule getting to know, cluster analysis, category and regression, which can be used to determining as an example the characteristics of a success employees or maybe decide customer purchase behavior.

2) Previous understanding: Below are some of the previous understandings on retail data analysis that have been surpassed by our model - 1.Optimization strategies are the numerical techniques the usage of to redesign a system or manner. Optimization strategies may be implemented to enhance over- all performance according to a sure measure. 2. Other way of understanding this is through Neural Networks. Neural networks refer to computational models primarily based on organic neural networks and used for detecting styles in information which can be used for sample reputation, image evaluation, optimization and adaptive manipulate . 3. Device gaining knowledge of machine learning is an artificial intelligence approach which permits computers to adapt behavior based totally on empirical information with a purpose to making sensible choices primarily based on information . 4. Predictive Modeling - Predictive modeling uses a fixed of fashions to expect the probability of an event happening. For example, it can be used to are expecting the likelihood that another product might be resold to a purchaser . 5. Cluster evaluation uses the method of breaking disparate corporations into smaller businesses with comparable traits and can be used to section consumers into groups for more powerful advertising . 6. ETL (Extract, remodel and load) ETL tool is a generation that may extract raw records from various assets.ETL transforms records right into a based layout that could help extract significant facts by means of transforming information according to its shape and loading it into a facts warehouse .

$$AxB = (x, y)|xA^{y}B \quad (1)$$

The cost of huge facts analytics is that they can be derived from big data analytics to help choice makers inside the retail industry.

3) Challenges and Opportunities in Retail Data Analysis: One of the key challenges in retail data analytics is the integration of data from different sources, such as customer data, sales data, and supply chain data. This requires a robust and flexible data architecture that can handle multiple data formats and resources. Another challenge in retail data analysis is the development of efficient analytical tools and techniques to handle the large and complex data sets commonly found in retail. This requires the use of advanced analytical methods such as machine learning and artificial intelligence, as well as a deep understanding of retail. Retail data is generated at high speed and often requires real-time analysis to support decision making and customer engagement. This requires the use of advanced data management and processing techniques such as in-memory databases and data stream processing to handle the large volume and velocity of retail data.

4) Key Applications of Retail Data Analysis for Business Intelligence:: Analyzing retail data can provide valuable insights into customer behavior, preferences and purchasing patterns that can be used to improve customer engagement and increase customer loyalty. Customer analytics can be used to segment customers, understand their needs and preferences, and customize their shopping experience. Analyzing retail data can provide valuable insights into market trends and consumer behavior that can be used to optimize pricing and promotional strategies. Pricing analytics can be used to analyze sales data, monitor competitor pricing, and make data-driven pricing decisions. Retail data analysis can provide insight into sales patterns and trends that can be used to optimize sales strategies and increase revenue. Sales analytics can be used to analyze sales data, monitor product performance, and identify sales opportunities. Retail data analysis can be used to optimize inventory management, reduce costs and increase efficiency. Inventory management analytics can be used to monitor inventory levels, analyze sales trends, and forecast demand to optimize inventory levels.

III. Methodology

The method we done the business retail analysis goes in four major segments. 1) The most important phase in retail information examination is to gather information from different sources like retail location (POS) frameworks, client relationship the executives (CRM) frameworks, and store network the board. Retailers can likewise gather information from outside sources, for example, web-based entertainment and statistical surveying organizations to get a more complete image of purchaser conduct and market patterns. 2) The following stage is to clean and set up the information for investigation. This might incorporate eliminating insignificant information, changing information into a usable configuration, and managing absent or deficient information. The objective of this step is to guarantee that the information is exact, predictable, and prepared for investigation. 3) When the information is prepared, the following stage is to examine it to acquire understanding into client conduct and market patterns. This might include utilizing spellbinding measurements, for example, mean and standard deviation to sum up information, or utilizing further developed scientific strategies, for example, relapse examination and bunch investigation to make expectations and reach determinations. Information representation is a significant piece of retail information investigation since it makes it more clear and convey information experiences. Retailers can utilize information representation devices, for example, diagrams and charts to envision information patterns and examples and convey bits of knowledge to partners. 4) The last move toward retail information investigation is deciphering information insights and going with information driven choices. Retailers can utilize bits of knowledge acquired from retail information examination to arrive at informed conclusions about client commitment, inventory network the executives, evaluating, showcasing and deals.

This observe is largely divided into three components:

1. Analytical strategies, 2. Modeling gear and 3. development frameworks and suggests how a lot of these three factors are conceptually connected. considering the primary element, this paper introduces the term ”analytical strategies” as rising research approaches which might be noticeably applicable to knowledge retail information evaluation on various multichain retail companies. Advert-hoc approach is an information eval- uation method used inside the preliminary research, especially to assist a particular venture. This sort of analytical technique is not often carried out without delay to live structures or manufacturing systems. The technique may be very dependent on abilities of the man or woman. *A. Weekly-sales unemployment*

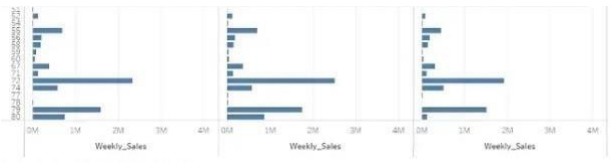

Fig. 1. Sum of weekly sales for each broken down by Date Year

IV. Result

This examine is basically divided into three parts: 1. Analytical techniques, 2. Modeling gear and 3. development frameworks and indicates how a lot of these 3 elements are conceptually linked. thinking about the first detail, this paper introduces the term ”analytical techniques” as rising studies processes which can be pretty applicable to understanding

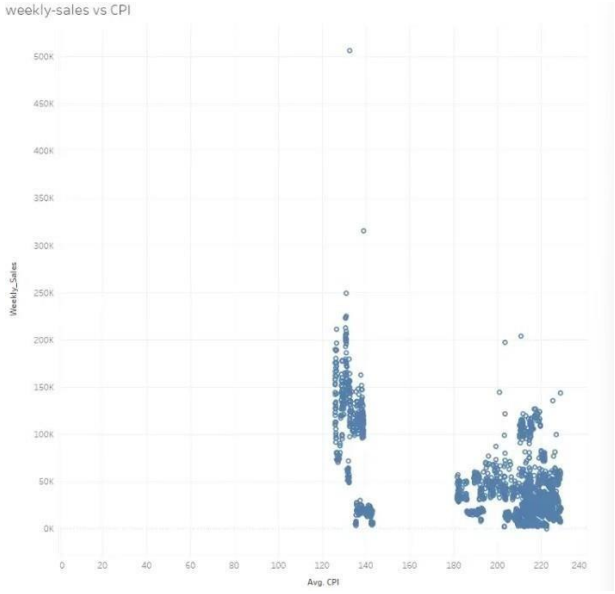

Fig. 2. Weekly Sales versus Average CPI

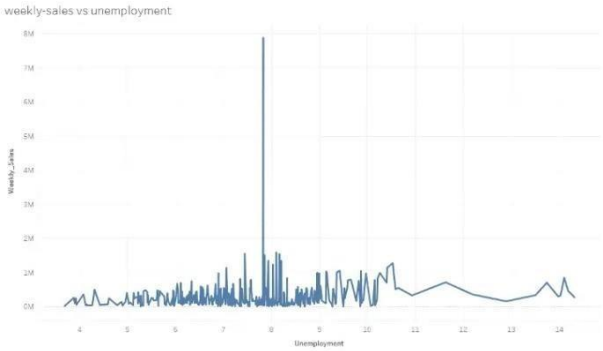

Fig. 3. Weekly Sales versus the Unemployment percentage

retail data evaluation on diverse multichain retail companies. From all the above graph plots and scatter plots it may be visible that the income of a store boom primarily based on the dimensions of the store but after attaining a size of 200000 units the correlation suggests an enormous down slope. Global factors such as Temperature in the area fuel prices have considerable impact on retail sales. After matching the outcomes with actual time statistics, it’s far observed that our records evaluation is accurate.

V. Discussion

Let's discuss the other approaches to get the retail analysis. One common approach to analyzing retail data is to use descriptive statistics to summarize key trends and patterns in the data. This can include calculating summary measures such as mean, median and standard deviation, as well as creating visualizations such as histograms and scatter plots.

Predictive analytics is another important technique in retail data analysis. This involves using statistical models to predict future events or trends based on past data. For example, retail-

Fig. 4. Percentage change of weekly-sales over the months

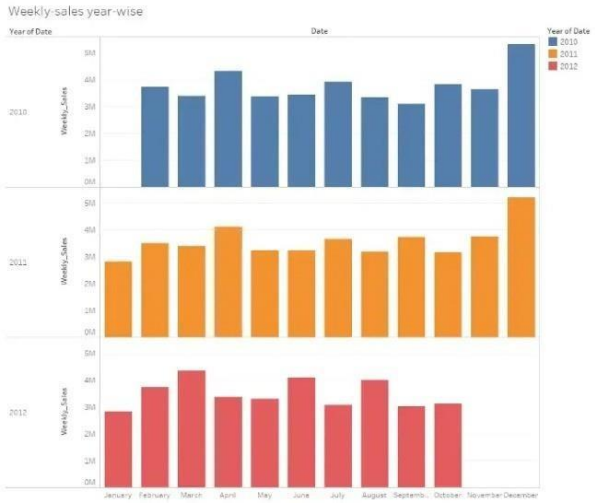

Fig. 5. Weekly sales versus Year wise sales

ers can use predictive analytics to predict demand for specific products, estimate customer lifetime value, and identify factors that influence consumer behavior.

Retail data analysis can also be used for customer segmentation, which is the process of dividing the market into smaller groups of consumers with similar needs or characteristics. Retailers can use this information to create targeted marketing campaigns and create personalized product recommendations.

Another important application of retail data analytics is inventory management. By analyzing sales data, retailers can optimize their inventory to ensure they have enough inventory to meet demand while avoiding overstocking and waste.

VI. Future Scope and Limitations

With a smaller wide variety of products/clients the evaluation isn't always beneficial. thinking about vacations and in unsure conditions occur in our society the facts may be misguided on occasion. Data cleansing should be done with the intention to avoid any misconception in making insights. As the world's populace is rapidly increasing the usage of retail statistics evaluation plays a chief function in commercial enterprise decisions in destiny. Retail corporations are very complicated, and there are too many correlations among elements (demand, fee, inventory, product collection,

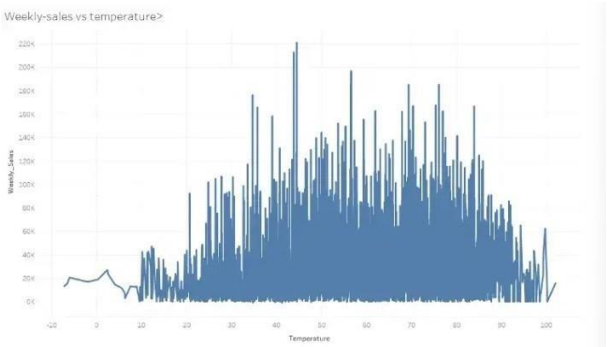

Fig. 6. Weekly Sales versus Temperature

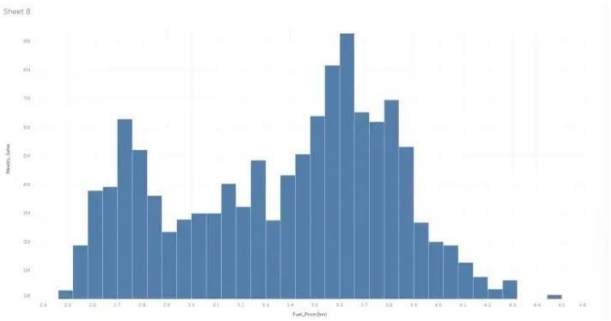

Fig. 7. Weekly Sales versus Fuel Prices

competitors, client behavior, and so on.) for any human to account for they all manually. That's why easy sales forecasts are a great deal much less correct than demand forecasts.

To appropriately forecast the destiny and account for the most critical correlations, retail predictive analytics need to use a combination of AI, superior arithmetic, and wise automation. Integration with the Internet of Things (IoT) is also expected to impact retail data analysis for business intelligence. IoT technologies such as smart sensors and wearables will provide new sources of data that can be used to gain insight into customer behavior and market trends. Predictive analytics is expected to play an increasingly important role in retail data analysis for business intelligence in the future. Predictive analytics can be used to predict future trends and patterns and support real-time decision making.

The quality and accuracy of retail data is a major limitation of retail data analysis for business intelligence. Retailers must ensure that the data they collect is accurate, consistent and

relevant, otherwise the insights gained from the analysis may be inaccurate or misleading. Technical expertise is another limitation of retail data analysis for business intelligence. Retailers must have access to experienced data analysts and IT professionals who have the technical knowledge and expertise to effectively analyze and interpret data.

VII. Conclusion

Retail records analytics are vital for agencies to thrive in nowadays' s dynamically converting markets, amid fastevolving client choices. It allows shops to live on pinnacle of

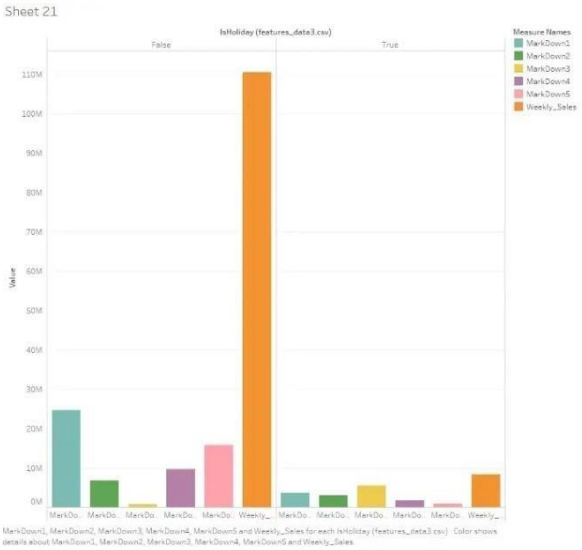

Fig. 8. Weekly Sales versus Fuel Prices

those modifications and improve the choice-making technique oriented at decreasing fees and growing revenues and make certain a high level of patron pleasure. Via accumulating and analyzing facts in massive and various volumes, retailers are capable of apprehend the deepest client needs and alter their supplying to fulfill customers' demands and offer customized, tough-to-withstand deals.

Retail records analytics guarantees providers have all the statistics they want to make the right commercial enterprise decisions below stress. The usage of historical facts, client insights and income information, they're much more likely to make smarter decisions and stay in advance of their competition.

Cardiovascular diseases (CVD) are a major cause of mortality worldwide causing about 17.9 million deaths per year. Cardiovascular illnesses are a group of con-ditions that affect the heart and blood arteries. These illnesses may have an effect on various parts of the heart and/or blood vessels. CVD encompasses coronary artery dis-orders (CAD), such as myocardial infarction and angina. To reduce the risk and deaths caused by cardiovascular diseases it is important to predict it at an early stage. It is crucial to be aware of these cardiac disease-related signs in order to forecast outcomes and offer a solid foundation for diagnosis for which data mining and feature selection prove to be useful. However, manual analysis and prediction are laborious and tiring due to the sheer volume of data. In this study, data science is used to predict cardiac problems. The potential method for heart disease prediction is one that analyses the relationships between variables and extracts hidden knowledge from the data. Through a variety of indications, our study attempts to anticipate cardiac disease correctly and promptly. We propose a cardiovascular disease prediction model which uses a dataset obtained from Kaggle on which we perform various data pre-processing techniques and feature selection is done using chi square and finally the refined data is given to differ-ent machine learning models for building predictive models of the decision-making system. We obtained the highest accuracy of 99.4% using Random Forest, demonstrat-ing the effectiveness and dependability of the heart disease prediction approach we pre-sented.

Keywords: Cardiovascular disease, Feature Selection, Random Forest, Machine learning

1 Introduction

A fist-sized organ that pumps blood throughout the body, the heart, is situated at the left of the sternum and is shielded by the ribcage. The main component of our circula-tory system is the heart. It primarily consists of four main chambers made of

that are propelled by electrical impulses that regulate the rhythm and speed of the heart-beat as well as maintain blood pressure. The heart valves, which act as gateway between the chambers of the heart which opens and closes to allow the flow of blood through the mitral and tricuspid valves, are controlled by the nervous system, which also con-trols the rhythm and speed of the heart rate.The neurological nervous system, which transmits impulses instructing our hearts to beat more slowly when we are at rest and more quickly when we are under stress, and the endocrine system, which releases hormones instructing our blood vessels to con-strict or relax, are the two main systems of the heart. From the aforementioned infor-mation, we can conclude that the heart plays one of the most important roles in a per-son's ability to survive. However, the truth is that heart conditions are among the most prevalent types of illnesses that people experience, and statistics indicate that 17.9 mil-lion people worldwide died from cardiovascular diseases in 2019, accounting for 32% of the deaths caused. 85% of these deaths are caused by heart attacks and strokes [4]. WHO estimates that 31% of worldwide human mortality is caused by cardiovascular diseases. About one person dies from heart disease every minute in the modern era [7]. As per WHO, ischemic and hypertensive heart attacks are one of the leading causes of death. This illness can be lethal if it is not carefully monitored [13].A blockage that obstructs the flow of blood to heart or brain is the main cause of heart attacks and strokes, which are typically sudden events. Unhealthy diet, physical inac-tivity, cigarette use, and problematic alcohol consumption are some of the risk factors for heart disease and stroke [8]. Heart attacks are primarily brought on by blood clotting in arteries, which can also cause chest pain or stroke. As a result, some individuals experience unstable angina [16]. When blood vessel function is impaired by heart dis-ease, coronary artery infections occur, which weaken the patient [6]. The underlying blood vessel illness frequently has no symptoms. However, the consequences of behav-ioral risk factors might manifest in people as high BP, high fasting blood sugar, high blood lipids, overweight, and obesity. An elevated threat of cardiovascular disease death and morbidity exists in those with type 2 diabetes [9]. Mostly low and middle-income countries globally contribute to nearly 75% of Cardiovascular deaths which is heartbreaking because most cardiovascular diseases are preventable and treatable when detected earlier. The inclusion of strategies for managing cardiovascular disease in uni-versal health insurance plans, such as making use of cutting-

edge tools like machine learning which are used to determine, track down, and forecast a variety of medical conditions, holds the key to reducing the prevalence of the cardiovascular disease. Our research's main goal is to provide clinicians with a tool for early cardiac issue detection. The advancement of machine learning applications shows that it is possible to detect cardiovascular disease in its early phases using electrocardiogram and patient data, which will help in overcoming the significant challenges in today's modern world that are contributing to huge number of deaths globally [10]. It will be simpler to provide patients with proper care using machine learning techniques' superiority in pattern recognition and categorization on comparison to the conventional statistical ap-proaches, medical professionals and researchers have resorted to them to create screen-ing tools, while avoiding serious effects on some of the most exciting applications of AI that lie in utilizing big data and machine learning to identify patients at high risk ofdeveloping chronic diseases. Researchers can forecast the chance that susceptible pa-tients may develop cardiac ailments by using data mining techniques [14]. Data science is needed in the healthcare sector to handle the enormous quantity of data that is gener-ated [7]. The objective interpretation of all outcomes for the same patient made possible by machine learning techniques may enhance the precision of each step's diagnostics [11].In order to reduce the input variable to our model by using only the pertinent data and eliminating noise, we have also employed the Feature Selection methods, which auto-matically selects relevant features of our dataset that are trained and tested on our ma-chine learning model based on the sort of problem we are trying to solve.In this study, we have implemented various types of techniques for the prediction of cardiac diseases which include preprocessing the data, feature selection using various data mining techniques and classification and prediction over various data mining mod-els. The rest of the paper is structured as follows: Section 2 addresses related work, Section 3 discusses methodology, Section 4 puts forth the results, and Section 5 con-cludes the paper.2RelatedWork Machine learning algorithms can be used to predict and diagnose heart diseasesResearchers make use of various data mining techniques and computational in-telligence models to predict heart diseases. Predicting heart diseases accurately and on time can save lots of lives and can be very useful for healthcare professionals for diag-nosis.There is a need to precisely predict and provide a reliable basis required for further treatment on time to reduce the risk, complications and death rate caused by heart dis-eases. Improving the ability to predict and identify heart diseases would benefit healthcare professionals and would decrease the risk of death and save lives. Several machine learning algorithms can be used to accomplish this along with feature selec-tion, data mining and various other techniques.esearch by Le, Hung Minh et al. provides a method by combining data mining and feature selection to study the presence of heart disease. The Infinite LatentFeature Se-lection (ILFS) approach is used to re-select heart disease characteristics based on the rank and weights supplied to them. Support Vector Machine is used to divide a subset of the chosen qualities into various heart disease classes. To produce greater quantities and types of data Synthetic Minority Over-sampling Technique is used. Experimental findings showed that the method distinguished between "no presence" and "presence" and obtained 97.87% accuracy and five separate categories of cardiac disease with a 93.92% accuracy [3].In a study by Bashir, Saba, et al. Multiple heart disease datasets are utilized in feature selection strategies and algorithms for experimentation analysis and to demonstrate ac-curacy improvement in predicting heart disease. Using the Rapid Miner tool; applyingfeature selection techniques like Logistic Regression, Logistic Regression SVM, Ran-dom Forest, Decision Tree, and Naive Bayes, and it is observed that the accuracy of the findings is improved [2].Zhang, Dengqing, et al. put forth a DNN and LinearSVC embedded feature selection method-based heart disease prediction system. Additionally, for the feature selection the LinearSVC method and L1 norm are used to choose the best feature subset. They examined the He normal, random normal, and Xavier weight and concluded that He initialization produces the best outcomes. The suggested approach has a 98.56% accuracy rate, demonstrating the viability and dependability of using deep neural net-works and feature selection to predict heart disease. [1].Features importance ranking of two gradient boosting techniques, XGBoost and Cat-Boost was calculated on SA heart, Statlog heart and Cleveland data sets, by Anuradha et al. and observed that CatBoost fared better than the other classifiers [4].The proposed work by Boukhatem et al. uses a variety of data mining approaches, in-cluding Logistic Regression, Random Forest, Naive Bayes, and Decision Trees to clas-sify patient risk factors and assess the chance of heart disease. The effectiveness of various machine learning algorithms has been compared; According to the trial find-ings, the Random Forest method has the best accuracy 90.16%. [7]. Mohan et al. pro-posed combining a linear model and a hybrid random forest to predict heart disease which showed improved results with 88.7% accuracy [5]. In a study by El-Hasnony et al. by iteratively selecting the most relevant data to query their labels, five multi-label active learning selection algorithms (AUDI, Random, Adaptive, MMC, and QUIRE) were used to lower the cost of labelling. [15].In a paper by Πεταρούδας et al. an impressive prediction system referred to Intelligent Heart Disease Prediction System (IHDPS) was proposed, which employs the three widely used data mining approaches of Decision Trees, Neural Network and Naive Bayes. The Decision Trees method is the most accurate, which obtained

an accuracy of 89%, Naive Bayes obtained an accuracy of 86.5%, and an accuracy of 85.53% by neural network [14]. Saikumar et al. Applied the DCAlexNet Convolutional Neural Networks technique to carry out the deep learning-based classification for heart disease detection. Performance metrics such as accuracy of 98.67%, the sensitivity of 97.45%, recall of 99.34%, and an F1 score of 99.34% are generated by the feature based fusion based confusion matrix of DCAlexNet-CNN. These numerical comparison results outperform application robustness and compete with present technology [12]

3 Methodology

Cardiac diseases can be predicted through various indicators so we considered a dataset from Kaggle which consists of 75 attributes or indicators and the target attribute field which alludes to the patient having heart illness or not, where having heart disease is indicated by 1 and no heart disease is indicated by 0. It consists of 1025 rows i.e. patient records of various ages, where 312 are female, and 713 are male. The considered da-taset is made up using four different databases named Cleveland, Hungary, Switzerland, and the VA Long Beach. To predict cardiovascular disease, we follow three major steps5that include Data Pre-Processing, Feature Selection using various data mining tech-niques and Classification using various models.

3.1 Data Pre-processing

Real-world data is inadequate, erratic, inaccurate, and sometimes in an undesirable for-mat and in order to make predictions, machine learning models cannot use the obtained data directly. Therefore, data preprocessing is performed and it aids in improving data quality and preparing the raw data for machine learning models by cleaning, formatting, and organizing it. It promotes the data to be mined for insightful information. Data preprocessing in machine learning is a data mining technique that transforms raw data into readable and understandable format. Data preprocessing includes various proce-dures like data cleaning, outlier removal, data reduction, data standardization, data nor-malization, data transformation, binning etc. which have been performed on the con-sidered dataset for the accurate prediction of cardiovascular diseases.Data cleaning eliminates large portions of irrelevant data, corrects inaccurate data in the train-validation-test dataset and minimizes duplicates.Outliers should be eliminated or rescaled as an important data preparation steps. Out-liers are data points that deviate significantly from the average. They may bias the find-ings and reduce the precision of the machine learning model. The most popular tech-nique for finding outliers is to utilize standard deviation, however there are other ap-proaches as well. Outliers are data points that deviate more than two standard deviations from the mean.

Data reduction is the process of taking a larger amount of original data and reducing it significantly while preserving its integrity. Data reduction techniques include Dimen-sionality Reduction, Numerosity Reduction, Data Cube Aggregation, Data Compres-sion, Discretization Operation.

Rescaling the parameters to have a mean of 0 and a variation of 1 is the process of data standardization. Standardization's objective is to reduce all characteristics to a comparable scale without distorting the variations in the value's ranges.

Data translation into a particular range usually [0 1] or simple data transformation onto the unit sphere are both instances of normalizing in machine learning. The process of connecting disparate, siloed, and normalized data into a single, dimensionally mod-elled, de-normalized, and analysis-ready state is known as data transformation. Without the right technical stack in place, data transformation may be expensive, time-consum-ing, and difficult. However, conversion will ensure the best data quality, which is nec-essary for accurate analysis and eventually allowing data-driven decisions.

Binning is used to reduce the impact of minor observational errors. It is sometimes referred to as data discrete binning or data bucketing. The original data values that lie inside a particular narrow interval are replaced with a value representative of that inter-val, usually mean or median. After successfully preprocessing the data, we move on to feature selection.

3.2 Feature SelectionA dataset consists of numerous features or attributes which help in prediction. But there can be huge number of features and many of which might not play an important role in prediction and as a result of the addition of extraneous information during model train-ing the model's overall accuracy is decreased, its complexity is increased, its capacity to be generalized is decreased, and it becomes biased. Filter methods, wrapper methods, and embedding methods are the three main groups of feature selection techniques. Fea-ture selection plays a crucial role in increasing the prediction accuracy by finding the ideal combination of characteristics or

features for a machine learning model. Better accuracy is obtained by using lesser data.Our data which is preprocessed is now undergoing feature selection, our data is now reduced to 7 features on feature selection, keeping the target attribute intact after pre-processing. The considered features play an important role in predicting heart disease and considering which we obtain higher accuracy and hence now machine learning al-gorithms are provided the data on feature selection for precise cardiovascular disease prediction.

3.3 Classification using various models

KNN:

K-Nearest Neighbour is a supervised learning technique. K-NN algorithm that stores

the data and based on similarity it sorts a new data point. It is used for problems like

classification and regression, although categorization problems are where it is most

commonly employed.

Decision Tree:

Decision Tree is a type of unsupervised machine learning in which the training data is segmented continually based on a particular parameter, on description of the input and the associated output. The two elements that may be utilized to describe the tree are decision nodes and leaves.

SVM:

Both classification and regression employ the Support Vector Machine (SVM), a su-pervised machine learning technique. The SVM method looks for the optimum line or decision boundary that may split the space into several categories as well as a hyper-plane in an N-dimensional space that unambiguously classifies the input points.

SGD:

Stochastic gradient descent is a simple yet very powerful technique for fitting linear classifiers and regressors under convex loss functions, such as (linear) Support Vector Machines and Logistic Regression (SGD). Gradient descent is a general-purpose opti-mization technique that may find the best solutions to a range of problems.

Random Forest:

In the Random Forest supervised machine learning method, a "forest" is created by growing a number of decision trees and combining them. It uses a variety of samples

7

to generate decision trees, using the majority of them for classification and the average of them for regression.

Naive Bayes:

A family of classification algorithms built on the Bayes' Theorem are known as naive Bayes classifiers. It is one of the most straightforward and effective Classification al-gorithms, assisting in the development of rapid machine learning models capable of making prompt predictions.

Logistic Regression:

Guided learning is demonstrated using logistic regression. Assigning data to a discrete set of classes using a classification method allows one to determine or anticipate the likelihood of a binary (yes/no) event occurring.

Gradient Boosting:

Classification and regression tasks are accomplished using a machine learning tech-nique called gradient boosting. It offers a prediction model in the form of several weak prediction models, such as decision trees. It is based on the supposition that the total prediction error is minimized when prior models are coupled with the best potential upcoming model. The main idea is to specify the expected outcomes for this subsequent model in order to minimize inaccuracy.

4 Results

The prediction of cardiovascular diseases was performed on a dataset obtained from Kaggle which was preprocessed using various data preprocessing techniques including procedures like data cleaning by imputing missing values and replacing them with av-erage or most frequent value, selecting relevant features using Chi2 Score with 80% proportion of features upon which the dataset now has 10 attributes or features and one target attribute. The features are now normalized and standardized to $\mu=0$, $\sigma 2 = 1$. We then removed the Sparse features i.e. removed features with too many missing values with a threshold percentage of 5. On removing the sparse features, we now have 8 fea-tures that are considered along with the target attribute. We now implement Principal Component analysis where data is normalized, build the covariance matrix, then find eigen values and eigen vectors, arrange the eigen vectors in highest to lowest order and select the number of principal components, in our data upon PCA we obtain 8 Principal Components. We then apply CUR Matrix Decomposition with rank 10 and relative error of 1.00 upon which we have 7 features in our dataset and one target attribute in which 0 means no heart disease and 1 means heart disease. The dataset is divided into a 30% test set and a 70% train set. Repeated Stratified K-Fold=5 validation of the mod-els KNN,

Decision Tree, SVM, SGD, Random Forest, Naïve Bayes, Logistic Regres-sion and Gradient Boosting on the train set containing the selected subset of features is

formed on 20 times repeat test/train. We obtain prediction accuracy of KNN 81.9%, Decision Tree 95.4%, SVM 86.3%, SGD 82.3%, Random Forest 99.4%, Naïve Bayes 79.8%, Logistic Regression 82.3%, and Gradient Boosting 97.0%

Table 1. Accuracy, Precision, Recall, F1-score of the considemodels

Model	Accuracy(%)	F1 Score(%)	Precision(%)	Recall(%)
KNN	81.9	81.8	81.9	81.9
Tree	95.4	95.4	95.4	95.4
SVM	86.3	86.3	86.5	86.3
SGD	82.3	82.3	82.7	82.3
Random Forest	99.4	99.4	99.4	99.4
Naïve Bayes	79.8	79.8	79.8	79.8
Logistic Regression	82.3	82.3	82.6	82.3
Gradient Boosting	97.0	97.0	97.0	97.0

Precision is a metric used to analyze a model's dependability and its accuracy in cate-gorizing a sample as positive. It is calculated using the ratio of True Positives to True Positives and False Positives.

= (1)

+

The Recall parameter is used to assess how well the model can identify positive test data. It is the ratio of Positive samples that are rightly labelled as positive to the total number of positive Instances samples. The greater the Recall value, the greater the number of positive samples detected.

10

= (2)

+

Models for classification include the F1 Score. The F1 Score is focused on precision and recall. The Harmonic mean of Precision and Recall is the F1 Score.

1=2∗ ∗ (3)

+

From Table 1. We can examine the accuracy of heart illness prognosis using different machine learning algorithms and we have obtained the highest accuracy of 99.4% for Random Forest. Thus, we can conclude that upon data preprocessing and feature selec-tion using data mining methodologies for prognostication of cardiac diseases is useful to predict heart diseases accurately which will help decline the death rate by predicting the risk of the disease and help in diagnosis.

5 Conclusions

Accurate cardiovascular disease prediction is crucial in lowering risk and death rate. In this research we proposed a cardiovascular disease prediction model which uses various data mining techniques, feature selection techniques which play a major role in increas-ing the accuracy by reducing the input variables by considering only relevant data and avoid noise. It reduces the data which in turn reduces the complexity of processing and prediction by the model and thereby increases the accuracy. We performed prepro-cessing and feature selection which included procedures like imputing missing values, selecting relevant features using Chi2 score with 80% proportion of features, it is now normalized and standardized to =0, =1, we then removed the sparse features with 5% threshold and then applied Principal Component Analysis and then applied CUR matrix decomposition with rank 10 and relative error of 1.00 upon which the dataset is now processed, refined, transformed, and 7 features have been selected successfully and one target attribute in which 0 indicates no heart disease and 1 indicates the presence of heart disease. The dataset produced is split into 70% train and 30%

test set. Further we performed 5-fold cross validation on various machine learning models namely KNN, Decision Tree, SVM, SGD, Random Forest, Naïve bayes, Logistic Regression and Gra-dient Boosting which produced accuracies of 81.9%, 95.4%, 86.3%, 82.3%, 99.4%, 79.8%, 82.3% and 97.0% respectively. We conclude that Random Forest has shown the highest accuracy of 99.4% with F1 score 99.4%. From the aforementioned results ob-tained we can conclude that machine learning models with feature selection, Data min-ing techniques can be useful for prognostication of cardiovascular diseases

ABSTRACT

People have been aware of the negative effects of mental stress on their health for decades. High-level stress must be detected early on to avoid these negative outcomes. Researchers have begun to notice excessive tension in people who use wearable technologies during their everyday routines, following the introduction of wearable technologies that have the potential to become a part of our daily lives.

We developed an automatic stress detection system based on smart wearable devices that people can use in their daily life. Our research was conducted using a previously published and well-established approach. This suggests that the proposed system has the potential to have a large impact on people's lives. It can be used to prevent stress in a variety of contexts, including job, school, and home. **Keyword**: GSM, GPS, Accelerometer, Arduino, Temperature Sensor, Pulse Sensor, WI-FI Module

I.INTRODUCTION:-

In today's culture, stress in everyday life is a huge problem. It's a growing issue that's become an unavoidable part of our daily lives. Acute and chronic psychological stress is the two types of stress. Acute stress is more common than chronic stress. According to the American Psychological Association, acute stress is induced by pressure from the recent past and the near future.

Athletic challenges, test taking, and anxiety while meeting new people can all produce acute stress. Chronic stress, on the other hand, might be brought on by long-term pressures and expectations as a result of socioeconomic

circumstances, interpersonal connection issues, or a bad job. Chronic stress, if not well handled, can lead to serious health issues.

Because the signs of acute stress are more obvious, it is examined more thoroughly than chronic stress. Stress is one of the world's most serious health problems. Stress has different effects on people's health depending on the sort of stress. Acute stress can result in mental distress, muscular tightness and tension, back pain, headaches, heartburn, digestive problems, and excessive arousal.Excessive arousal in people with heart problems can lead to heart attacks, arrhythmias, and even sudden death. Stress should be managed as soon as symptoms arise, according to researchers, in order to avoid long-term consequences. To put it another way, stress must be diagnosed early on in order to prevent further injury and chronicity.

Researchers have developed an autonomous stress monitoring system that employs smart wearable devices and powerful affective computing algorithms due to the negative impacts of stress on human health, social life, and the economy. This design is appropriate for

automobiles, aeroplanes, factories, and workplaces, as well as job interviews and everyday life.This technique can help determine social stress levels during meetings or reciprocal dialogue. The ideal plan would be practical in everyday life, with unobtrusive sensors and equipment that people might easily wear while going about their daily lives. We offer an autonomous stress level detection technique using a sensor network in this paper. The human body is monitored through sensors. In this study, we present and test a portable system based on the Arduino system for real-time stress detection. The hardware is made up of portable, wireless, and low-cost electronics components. . Our findings show that our approach has the potential to be a useful tool for stress monitoring, identification, and prevention in the field.

II.LITERATURE SURVEY:-

1. Personal monitoring systems, according to N.Attaran et al, can provide excellent solutions for human health and performance. Multiple streams of physiological signals must be sampled and processed in these systems. Feature extraction, data fusion, and classification stages are common, and they involve a significant number of digital signal processing and machine learning kernels.

However, in order to be functional, the processing architecture must be low-power and small in size. In this study, we offer such a flexible, multi-modal design for a tailored stress monitoring system. With both SVM and KNN

machine learning classifiers, several physiological and behavioural characteristics were investigated to maximise detection accuracy. Heart rate and accelerometer features

were determined to have the greatest classification accuracy for detecting stress in the given dataset, out of 17 different features from 5 sensors. While the KNN classifier outperforms the SVM classifier by 2% in accuracy, it consumes much more memory and computation. As a result, the SVM classifier was chosen for hardware implementation. The SVM processor occupies 0.2 mm2 and dissipates 20.2 mW at 125 MHz, according to post-layout implementation results in 130 nm CMOS technology. The suggested processor classifies each input in 800 nanoseconds and uses 16.2 nanojoules. This system's total categorization accuracy is 96 percent. [1]

2. J.A. Healey and colleagues The methods for collecting and evaluating physiological data during real-world driving tasks in order to estimate a driver's relative stress level are presented in this study. While drivers followed a predefined course via open highways in the greater Boston area, electrocardiogram, electromyogram, skin conductance, and breathing were continually monitored. For this study, data from 24 drives lasting at least 50 minutes were gathered. The information was examined in two ways. Analysis I distinguished three degrees of driver stress with an accuracy of over 97 percent across several drivers and driving days using characteristics from 5-min intervals of data collected under rest, highway, and city driving circumstances. Analysis II compared continuous characteristics determined at 1-s intervals throughout the journey to a metric of observable stressors derived from videotapes by independent coders.

Skin conductivity and heart rate measures are most closely connected with driver stress level for the majority of drivers evaluated, according to the findings. These findings suggest that in future autos with physiological monitoring, physiological signals could be used to offer a gauge of driver stress. A statistic like this might be used to manage non-critical in-vehicle information systems and offer a constant gauge of how varied road and traffic conditions effect drivers. [2]

3. Y.Shi and colleagues This is the age of the contemporary world. Careers in the age of email, text messaging, Facebook, and Twitter At any time, crisis news can be found from anywhere. We (humans) are bombarded with information disguised as facts, pseudo facts, jibber-jabber, and rumour. We text while strolling down the street and check our email while waiting in line.

When people think they're multitasking, what they're really doing is swiftly switching from one task to another. It has been discovered that it causes an increase in the production of stress hormones, which overstimulate the brain and induce mental fog or jumbled thinking. Stress management, on the other hand, should begin long before the stress begins to cause sickness.This research introduces a real-time

tailored stress detection system based on physiological inputs. It is dependent on the rate of pulse and the temperature of the body. This could be used to keep track of a person's stress levels. [3]

4. J.Zhai and colleagues It has been claimed that accurately identifying a computer user's stress level could assist the computer respond intelligently and help the user relax from negative emotional states during human-computer interaction.Our research focuses on using three physiological signals to automatically monitor the stress condition of computer users: blood volume pulse (BVP), galvanic skin reaction (GSR), and pupil diameter (PD). The creation of hardware and software instrumentation, as well as the signal processing approach utilised to identify changes, are discussed in this work.within the context of a specific experimental task, in the stress level of a person engaging with a computer For this study, a computer game was created based on the 'Stroop Test,' a clinical mental stress test that was customised to make the individual feel two levels of stress His/her BVP, GSR, and PD signals were constantly recorded while he/she was awake. To extract useful features of the subjects"stress' status, several data processing techniques were used. According to the current findings, there is a substantial link between changes in those three signals and changes in emotional states when stress stimuli are introduced into the interaction context. [4].

5 .F.-T.Sun et alContinuous stress monitoring has the potential to aid in the understanding of various mental stress patterns and how clinical intervention can be most effectively applied. Because the electrical conductivity of skin fluctuates with physiological arousal, measuring galvanic skin response (GSR) is a cost-effective technique to identify stress.

We investigated the impact of various activities (sit, stand, and walk) on GSR measurements in this study. A GSR sensor system and an activity recognition system were implemented. We found that utilising two accelerometers (one on each thigh and ankle) improved activity detection accuracy by +27.3 percent when compared to using a single sensor node system. We also showed that using activity data could improve the sensitivity of stress detection in both sitting and standing situations. [5]

6. Krutika Patil and her colleagues This system records all parameters in real time and sends them to the base station using a GPS module and a wireless body area sensor network. The humidity sensor, temperature sensor, and pulse sensor are among the various types of sensors employed in this system, all of which aid in determining the health status of that particular army officer. The most crucial aspect of this concept is the wearable technology. [7]

7. Akshita V. Armarkar and colleagues GPS is utilised to track soldiers, and GSM is employed

to facilitate wireless communication. We use biomedical sensors such as temperature sensors and heart rate sensors to check the health characteristics of soldiers. An oxygen level sensor is used to measure ambient oxygen levels so that soldiers can be properly outfitted in the event of climatic changes. [8]

8. Jasvinder Singh Chhabra and colleagues Soldiers can communicate anywhere utilising RF, DS-SS, and FH-SS, allowing them to communicate with their squad members whenever they need to. Circuit complexity and power consumption are reduced. The use of an ARM processor and low-power peripherals reduces the overall power consumption of the system.

The modules used are compact and lightweight, making them easy to transport. Soldier security and safety: GPS tracks a soldier's whereabouts anywhere on the globe, and a health system monitors the troop's essential health indicators, ensuring soldier security and safety. [9]

III. PROBLEM STATEMENT AND OBJECTIVES:-

PROBLEM STATEMENT:-

Stress is an unavoidable component of today's fast-paced lifestyle. Furthermore, a growing amount of scientific evidence suggests that the elevated, semi-permanent stress levels many of us experience are linked to a number of health issues. Stress is regarded as an epidemic by some.

OBJECTIVES-

- It can be used in medical intelligence.
- It is useful enough to improve people's quality of life.
- It is a useful tool for stress monitoring, detection, and prevention.
- It is beneficial to recognise stress.

IV. PROPOSED SYSTEM BLOCK DIAGRAM:-

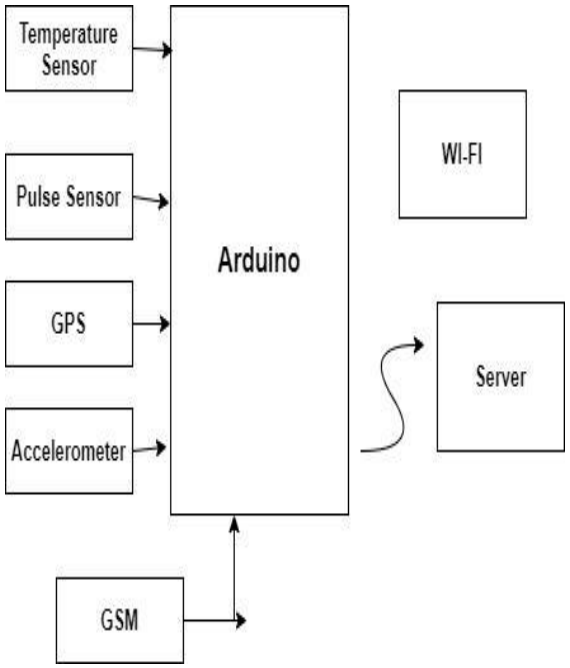

Fig 1 : Proposed Block Diagram

Hardware Requirements

- Accelerometer
- GSM and GPS
- Wifi

• Arduino

• Pulse sensor

• Temperature sensor

System Design

Researchers focused on the activity of alpha-amylase in saliva (salivary amylase) in order to establish a simple quantitative assessment technique for monitoring human stress in the existing system. Which is extremely important to comprehend and use. The proposed system will use a multi-sensor network to monitor a person's stress level.The proposed technology will detect stress levels and alert the control room.

V.**METHODOLOGY:-**

In terms of sensor integration, the applicable methodology differs slightly. In order to prototype the smart wearable jacket design, we use a few specialised components, which are listed below:

Temperature Sensor #1

2. Pulse Detector

3. Accelerometer

4. GPS, GSM, and ESP8266 Wi-Fi Shield

5. Arduino

1. TEMPERATURESENSOR

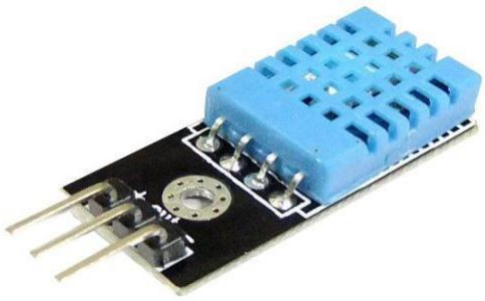

Fig 2

A temperature sensor is an electronic device that records, monitors, or signals temperature changes by measuring the temperature of its surroundings and converting the input data into electronic data. Temperature sensors come in a variety of shapes and sizes.

Some temperature sensors (contact temperature sensors) require direct touch with the actual object being monitored, whereas others measure the temperature of an object indirectly (non-contact temperature sensors).

2. PULSE SENSOR

Fig 3

When a finger is placed on the heart beat sensor, it produces a digital output of heat beat. The beat LED flashes in unison with each heart beat while the heart beat detector is operational. This digital output can be directly connected to the microcontroller to measure the BPM rate. At each pulse, it works on the idea of light modulation by blood flow via the finger.

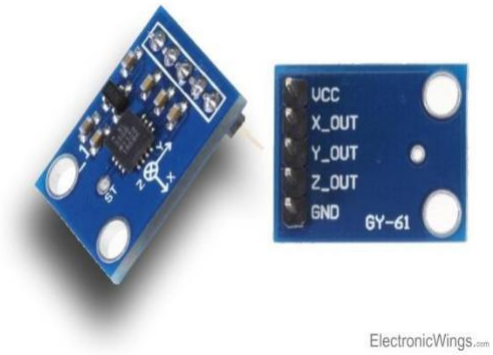

Fig 4

Please see the datasheet for more information.

Features

- SMD design based on a microcontroller
- The heat beat is indicated by an LED.
- Instant digital signal output for direct microcontroller connection
- a small size
- +5V DC Working Voltage

Applications

- Monitor your heart rate with a digital heart rate monitor.
- System for Patient Monitoring
- Robotics and applications with bio-feedback control

3. ACCELEROMETER

An accelerometer is a mechanical instrument that measures the force of acceleration. It only shows acceleration due to gravity, i.e. the g force. The acceleration is measured in g units. On Earth, 1g corresponds to a 9.8 m/s2 acceleration. It is 1/6th of the size of the earth on the moon, and 1/3rd of the size of the earth on Mars.

Tilt-sensing applications as well as dynamic acceleration caused by motion, shock, or vibration can all be done with an accelerometer.

4. GPS

Fig 5

The NEO-6MV2 is a navigation module that uses theThe network is structured into several discrete sections:

GPS (Global Positioning System). The module simply determines its position on the globe and outputs the longitude and latitude of its position.

It's part of a line of standalone GPS receivers that use the u-blox 6 positioning engine for great performance.

These versatile and cost-effective receivers come in a small (16 x 12.2 x 2.4 mm) design with a variety of connecting choices. NEO-6 modules are suited for battery-operated mobile devices with severe cost and space requirements because to their tiny architecture, power, and memory options. Even in the most difficult conditions, the NEO-6MV2's innovative design provides superb navigation performance.

- Base station subsystem – the base stations and the controllers that control them
- Network and Switching Subsystem – the part of the network that most closely resembles a fixed network, sometimes known as the "core network"
- GPRS Core Network the optional part that supports packet-based Internet connections
- Operations support system (OSS) – upkeep of the network

5.GSM STRUCTURE

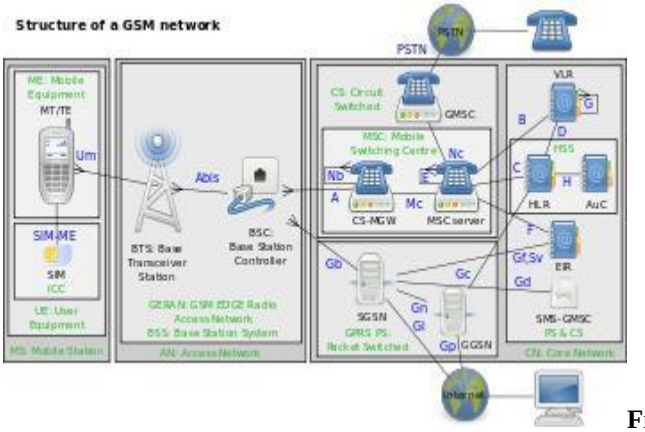

Fig 6

6.Arduino

Fig 7

Arduino Uno is an 8-bit ATmega328P microcontroller-based microcontroller board. It includes extra components to assist the ATmega328P microcontroller, such as a crystal oscillator, serial communication, voltage regulator, and so on. There are 14 digital input/output pins on the Arduino Uno (out of which 6 can be used as PWM outputs),A USB connection, a Power barrel jack, an ICSP header, and a reset button are all included..

How to use Arduino Board

Using the pinMode(), digitalRead(), and digitalWrite() functions in Arduino programming, the 14 digital input/output pins can be used as input or output pins. Each pin operates at 5 volts and may deliver or receive a maximum of 40 milliamperes. It also contains a 20-50 kOhm internal pull-up resistor that is unplugged by default.

VI.OTHER SPECIFICATION

a. ADVANTAGES:

• High levels of dependability

• Power consumption is low Latency is low.

b. LIMITATIONS

• Increased computational difficulty**c. APPLICATIONS:-**

- It may be used in medical intelligence;
- It is powerful enough to improve people's quality of life; and
- It is a useful tool for stress monitoring, detection, and prevention..

VII.RESULT

The circuit design in the proteus software with expected output is shown below.

Circuit design:

Expected output:

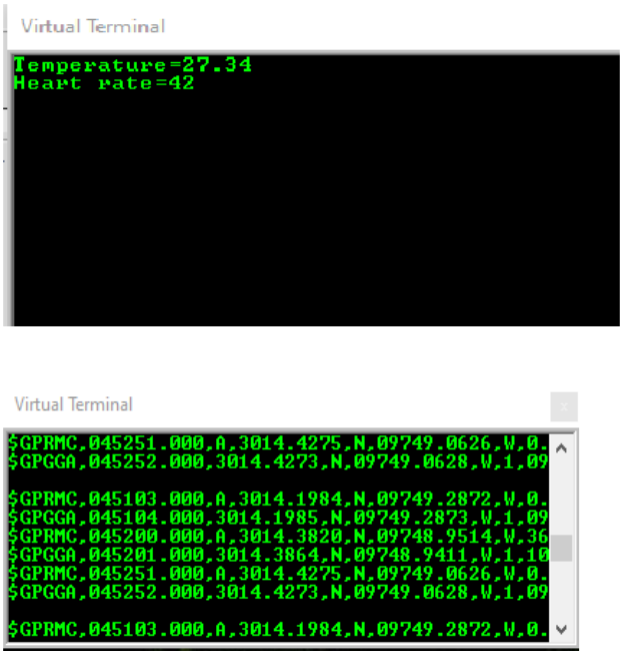

Fig 9

VIII. CONCLUSIONS AND FUTURE WORK

Preprocessing, feature extraction, and machine learning kernels are all required in health monitoring applications, as well as sampling from numerous physiological signals at varied rates. We used several physiological signals to develop an accurate stress monitoring system in this work. . Using heart rate and accelerometer measurements to determine the amount of stress produced the highest accurate classification with both KNN and SVM classifiers, according to our findings.

Resume classification-based on personality using Machine Learning Algorithm

Mrs. Praniti Ram Patil

Post Graduate student, Department of Computer Engineering, Thakur College of Engineering and Technology, Kandivali (E), Maharashtra, India, 400101

Abstract- **This paper describes personality classification experiment by applying k-means clustering machine learning algorithms. Several previous studies have been attempted to predict personality types of human beings automatically by using various machine learning algorithms. However, only few of them have obtained good accuracy results. To classify a person into personality types. With the onset of the epidemic, everything has gone online, and individuals have been compelled to work from home. There is a need to automate the hiring process in order to enhance efficiency and decrease manual labour that may be done electronically. If resume categorization were done online, it would significantly save paperwork a k and human error. The recruiting process has several steps, but the first is resume categorization and verification. Automating the first stage would greatly assist the interview process in terms of speedy applicant selection. Classification of resumes will be performed using Machine Learning Algorithms Random Forest**.

Key Words: **Personality types, machine learning, Jungian, kmeans clustering on personality test resume classification Job seekers, Resume recommendation, Job search, Resume matching, Machine learning,.**

I. INTRODUCTION

Interviews are becoming time-consuming affairs. Employees are required to travel to locations and conduct interviews, and it is difficult to manually remember each and every aspect of a candidate or the interview process. In many instances, the artificial intelligence system assists us in simplifying things. Using the conventional method of recruitment, an organization's HR department invites individuals based on their resumes to an interview for a specific position. This HR department manually evaluates a candidate's skills based on their résumé to determine if he or she is qualified for the position or not. HR's conduct interviews, and the panel plays a significant role in determining who is the best applicant for the post. They examine not just the candidate's talents, but also his or her personality Personality is a combination of a person's characteristics and attitudes in dealing with different social situations as in kindergarten, school, university, family, working team, etc. Humans are addicted to biases and prejudices that might affect their judgmental accuracy

Personality can be taken as assessment in various fields such as selection of staff, choice of profession, relationship and health counseling. There is a great effect of personality on learning capabilities of humans. For instance, in learning performance we may see significant performance we may see significant differences between extroverts and the ones belonging to introverts. Maintaining resumes and profiles of all candidates becomes a very tedious job when it comes to big mass recruitment companies because they provide employment in bulk, and thus maintaining or storing data physically is not possible. Machine Learning enables the path through which a computer can be trained to follow specific instructions again and again to make human life easy. The most common usage of machine learning is for the classification of objects. In machine learning, iteration is important because models are exposed to new data and adapt accordingly. Machine learning models learn from previous results and computation to produce correct and reliable decisions. In statistics, classification is a supervised learning concept in which segregation of data.

1. OBJECTIVE

Today the major problem being faced across the industry and candidate is how to acquire the right talent, using minimal resources over the internet and in minimal time. there are three major challenges that are required to be overcome, to bring efficiencies to the complete process

find the personality candidate.

find the job title for candidate.

The solution would help to find the right CV from the large dumps of CVs; would be agnostic to the format in which CV has been created and would give with the list of CVs which are the best match to the job description provided by the recruiter The proposed solution involves supervised learning to classify the resumes into various categories corresponding

to the various domains of expertise of the candidates. A multi-pronged approach to classification is proposed

2. PROPOSED SYSTEM

Nowadays searching for jobs is a difficult and tedious process for both the employees and the employers. The traditional method for classifying resumes is very time consuming and the concerned authorities need to go through every resume sent by the large number of candidates. This process becomes very complicated because there are millions of engineering graduates passing out every year runs for getting a job. For making the process easier there needs to be match between qualification, experience and many more criteria of candidate and company expectation. In our system, candidates will be sending resume and Classification will be done using Machine Learning such as k-means and random forest

• This project is based on three modules:

1. This Module is used to find the Personality of a person. 2. This module is used to find the Job title of individual.
3. This module is used to classify the resume

3. DATASET AND MODEL DESCRIPTION

This data was collected (2020-2021) through an interactive on-line personality test. The personality test was constructed with the "Big-Five Factor Markers" from the Participants were informed that their responses would be recorded and used for research at the beginning of the test, and asked to confirm their consent at the end of the test. The following items were presented on one page and each was rated on a five-point scale using radio buttons. The order on page was was EXT1, AGR1, CSN1, EST1, OPN1, EXT2, etc. The scale was labelled 1=Disagree, 3=Neutral, 5=Agree

Personality test also known as OCEAN Model analyses personality types of individuals based on five dimensions – Openness(O), Conscientiousness (C), Extraversion (E), Agreeableness (A), Neuroticism(N). With each of the dimensions signifying a different personality type. It uses keywords to identify traits and analysed in which personality a person fit.

Openness: As the word suggests, This quality features characteristics such as openness and imagination and curiosity.

Conscientiousness: Conscientiousness talks about a high amount of thoughtfulness, a goal- oriented attitude and good decision-makers.

Extraversion: Extraversion also means extroversion is identified by excitement, talkativeness and assertiveness.

Agreeableness: Agreeableness refers to features such as trust, affection and social behaviour of an individual.

Neuroticism: Neuroticism includes attributes like sadness, moodiness and sudden burst of emotions.

Fig1 personality question

4. SYSTEM ARCHITECTURE

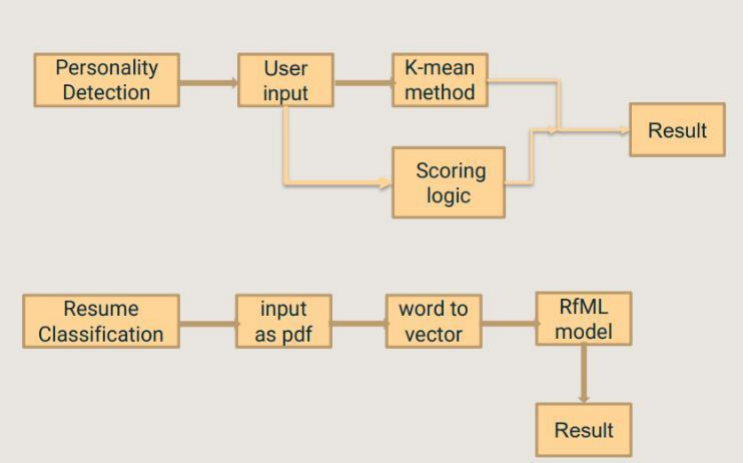

Fig2 SYSTEM ARCHITECTURE

First the dataset needs to be scraped which can be done using various websites. Once the dataset has been scrapped, pre-processing of data is to be done by doing proper stemming and lemmatization, removing stop words and filler words store the relevant words in a separate column for further process. After the pre-processing of data is done, making sure that the relevant data have the words which have occurred the highest amount of times need to be put in a term-frequency document using TFIDF Vectorization. Once the previous steps are done, the cleaned data is now ready to test and form classification models using machine learning algorithms. Analysing the model by their accuracy and the forming confusion matrix for the same is required for better understanding of the results.

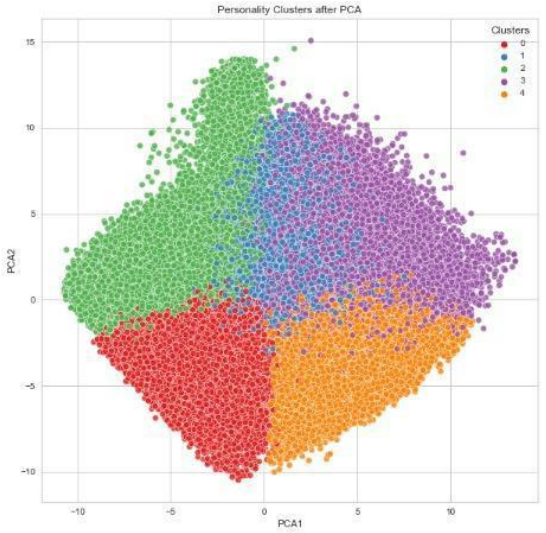
5. ALGORITHM

5.1 k-means Clustering Algorithm

The k-means method is the most popular clustering method. It refers to unsupervised learning part in machine learning field. The most well-known algorithm utilizes an iterative refinement technique. By cause of pervasiveness, it is regularly called the k-means algorithm. The algorithm continues by switching back and forth between two stages Assignment step: Assign every observation to the cluster with mean (average of a set of values), which has the slightest

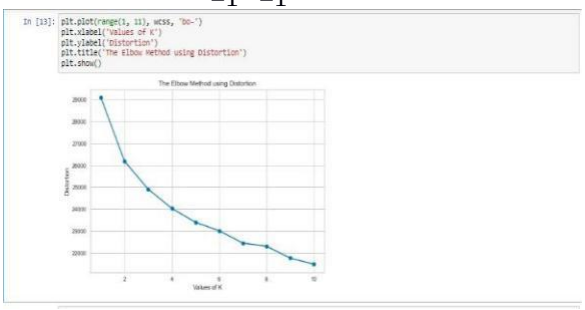
squared Euclidean distance which shows how close or far away two observations from each other [36]. We calculated the distance as follows: where x and y are samples in n-dimensional feature space. Update step: Calculation of values of new means is made of clusters that will become the centroids of observations in the new clusters. If the assignments do not change, the algorithm converges. Generally, we define randomly k clusters in the plane, then we calculate distances of each data point to these k clusters and assign the observation to the closest centroid, after that we move centroids to the mean of assigned values to them. We repeat this process until convergence, when the values of centroids do not change after iteration. Using this algorithm, we cannot be sure that the most optimal result will be found. We can stop the algorithm from converging using other distance functions as Manhattan distance functions for instance. There are other k-means transformations, especially the spherical k-means and k-medoids.

$$\cos(\ ) = \frac{\cdot}{\|\ \|\ \|\ \|} = \frac{\sum_{=1}}{\sqrt{\sum_{=1}^{2}}\ .\ \sqrt{\sum_{=1}^{2}}}$$



the error of each data point

$$= \sum\sum\| \quad - \quad \|^2$$
$$=1 \quad =1$$



5.2 Random Forest Algorithm

Random Forest is a classification algorithm that works on the principle of decision trees. It takes in input of many decision trees and gives the best majority output from all the inputted decision trees. On the RF Classifier the training data is fitted. Then, in the validation dataset labels are being predicted.

Step 1 − First, start with the selection of random samples from a given dataset.

Step 2 − Next, this algorithm will construct a decision tree for every sample. Then it will get the prediction result from every decision tree.
Decision tree

$$= \frac{\Sigma\ :}{\Sigma\in}$$

fi sub(i)= the importance of feature
i ni sub(j)= the importance of node j

Step 3 − In this step, voting will be performed for every predicted result.

Normalized to a value between 0 and 1

$$= \frac{}{\Sigma\in}$$

Step 4 − At last, select the most voted prediction result as the final prediction result.

$$= \frac{\Sigma\in}{}$$

RFfi sub(i)= the importance of feature i calculated from all trees in the Random Forest model
normfi sub(ij)= the normalized feature importance for i in tree j
T = total number of trees

6. EVALUATING THE MODEL& RESULTS

The results obtained from our model are summarized in the following table:

Model Evaluation

Algorithm name	Accuracy
RandomForest	
DecisionTree

Resume classification

7. CONCLUSIONS

Two models have been built on the cleansed data: i) Classification - Based on the resume and category the model has been designed to categories the resume in the right category and ii) describes personality classification by applying k-means clustering. We provided explanations of advantages and disadvantages of k-means clustering

Abstract

For protecting environment and human health water quality monitoring is very essential. In recent years Artificial Intelligence has paved the way to bring a great improvement in the classification and prediction of water quality. Here, for developing a reliable approach to forecast water quality and to to distinguish between Potable and Non-Potable water, we have used various machine learning models in this study. The studied machine learning classifiers and their stacking ensemble models included Logistic Regression, Gaussian Naive Bayes, Bernoulli Naive Bayes, Support Vector Machine(SVM), Kth Nearest Neighbours(KNN), X Gradient Boosting, and Random Forest. In this study, our used dataset has 3277 samples and it's a historical dataset which was collected for over 9 years from various places of Andhra Pradesh, India. It has been taken from Andhra Pradesh Pollution Control Board (APPCB). We have used precision-recall curves to evaluate the performance of the various classifiers. Among our used models, Random Forest provided the highest accuracy with a percentage of 78.96, where SVM provided us the least amount of accuracy with a percentage of 68.29.

Keywords **Water quality, Machine learning, Logistic Regression, Gaussian Naive Bayes, Bernoulli Naive Bayes, Support Vector Machine(SVM), Kth Nearest Neighbours(KNN), X Gradient Boosting, Random Forest**.

1 Introduction

For drinking and domestic use, food production or recreational purposes safe and readily available water is essentially important. Despite having a massive amount of water, the amount of drinkable water is still inadequate [1]. In India, around 70% of surface water is not fit for consumption [2]. In case of poverty reduction better management of water resources, improved water supply and sanitation can favour a country's economic growth.Transmission of contagious disease, such as cholera, diarrhoea, dysentery, hepatitis A, typhoid, and polio etc are directly linked the contaminated water and poor sanitation. Generally, after collecting water samples from various sources, manual water sampling and lab analysis of water quality can not be efficient. At the same time, it can be time consuming and prodigal. Therefore, the use of intelligent systems are increasing exponentially to monitor water quality especially when we need real time data.[3][4]Machine learning is a subset of artificial intelligent which teaches a system to automatically learn and improve from the experience without the manual interference[5] . The procedures that are used in machine learning are trained to capture trends and pursuant to they update themselves [6],

In water studies, Machine learning paves the way to assess, classify and predict water quality indicators. For instance, we can successfully simulate hydro-logical processes subject to the accessibility of bountiful sets data. However, using this water potability dataset of Vijayawada, Andhra Pradesh [8] and applying machine learning to it, we are going to distinguish between

Potable and Non-Potable water using some parameters such as pH value, chloramines, sulfate, conductivity, organic carbon, hardness, solids, conductivity, Trihalomethanes, turbidity, potability.

2 Literary Survey

For classifying the water quality of Chao Phraya river, RivSillberg et al. have developed a ML-based technique integrating attribute-realization (AR) and support vector machine (SVM)[9] . Attribute realization has identified the most significant elements of improving the quality of river, using the linear function. The most availing characteristics were TCB, NH3-N, FCB, DO, BOD, Sal and DO in the assortment, with contributed values in the range of 0.80–0.98. Using SVM linear approach, they got the best classification results, which had an F1-score average of 0.84 ,accuracy of 0.94, a recall average of 0.84 and a precision average of 0.84. With 0.86–0.95 accuracy AR-SVM was a strong and effective method for identifying the quality of the river water. They could find it when they applied to -6 parameters. To simulate the quality index of Akaki river water Yilma et al used ANN [10]. They calculated the index using 12 WQ indicators from 27 different wet & dry season sample locations.Almost all projected findings figured low WQ. The exception was one upstream location. The ANN model was corroborated and trained using the number of hidden layer neurons (5, 10, 15, 20, and 25), hidden layers (2–20), learning functions and transfer training. It was performed through 12 inputs. In their research, ANN with fifteen hidden neurons and eight hidden layers predicted the water quality index with an accuracy of 0.93.

In Malaysia, to calculate the water quality of Kinta River, Gazzaz et al. [11] designed a feed-forward, three layer, fully connected neural ANN model and the IoT . In Iran, to predict water quality index in 47 springs and wells, Sakizadeh [12] used 3 different artificial neural network algorithms, such as, an ensemble of artificial neural network, ANN with early stopping and artificial neural network with Bayesian regularization.

3 Proposed Methodology

We have taken prior actions to prepare the data as input before employing ML models (Logistic Regression, Gaussian Naivd Bayes, Bernoulli Naive Bayes, Support Vector Machine, Kth Nearest Neighbors, X Gradient Boosting, Random Forest). We have divided the data into two sets, training and testing sets to train our 7 machine learning models and assess the performance. In addition, we have cleaned the dataset by removing inexact values and replacing empty cells with the median of the dataset's input variables. The following figure (Fig.1) has demonstrated the framework of the proposed system.

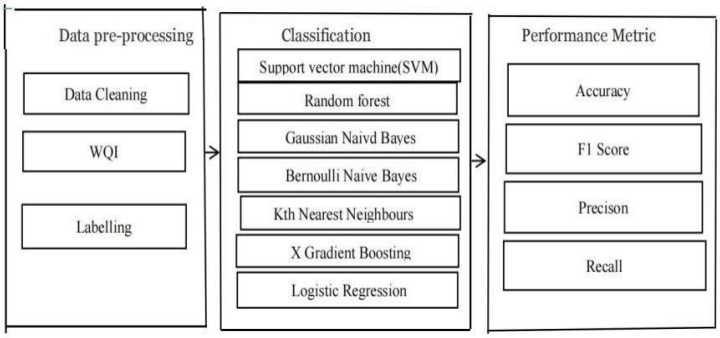

Fig.1 Methodology of the proposed system.

3.1 Data Description

Our dataset contains water quality metrics for 3277 different water bodies and 10 features, such as pH value, chloramines, sulfate, conductivity, organic carbon, hardness, solids, conductivity, Trihalomethanes, turbidity, potability. At first we have imported all the necessary libraries which have been used to train the machine learning models or visualize the data. Then using a Pandas's function read_csv(), we have loaded the data set. Then we have performed Exploratory Data Analysis. In Exploratory Data Analysis, firstly have checked the shape of the data set. Then after handling the null values we have checked the value counts of our target feature Potability. After that, we were able to visualize the potability using a countplot function of seaborn

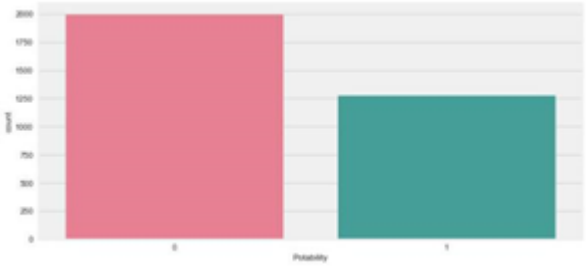

Fig.2 Visualization of the potability

(Fig.2). Then, we have displayed the entire dataset using the hist method (Fig.3). One can explore the dataset through it. We can say, there is no correlation between any feature. Because ,in the visualization of the correlation of all the features using a heat map function of seaborn, we found no relation(Fig.4). So, we can conclude that, the dimension cannot be reduced.

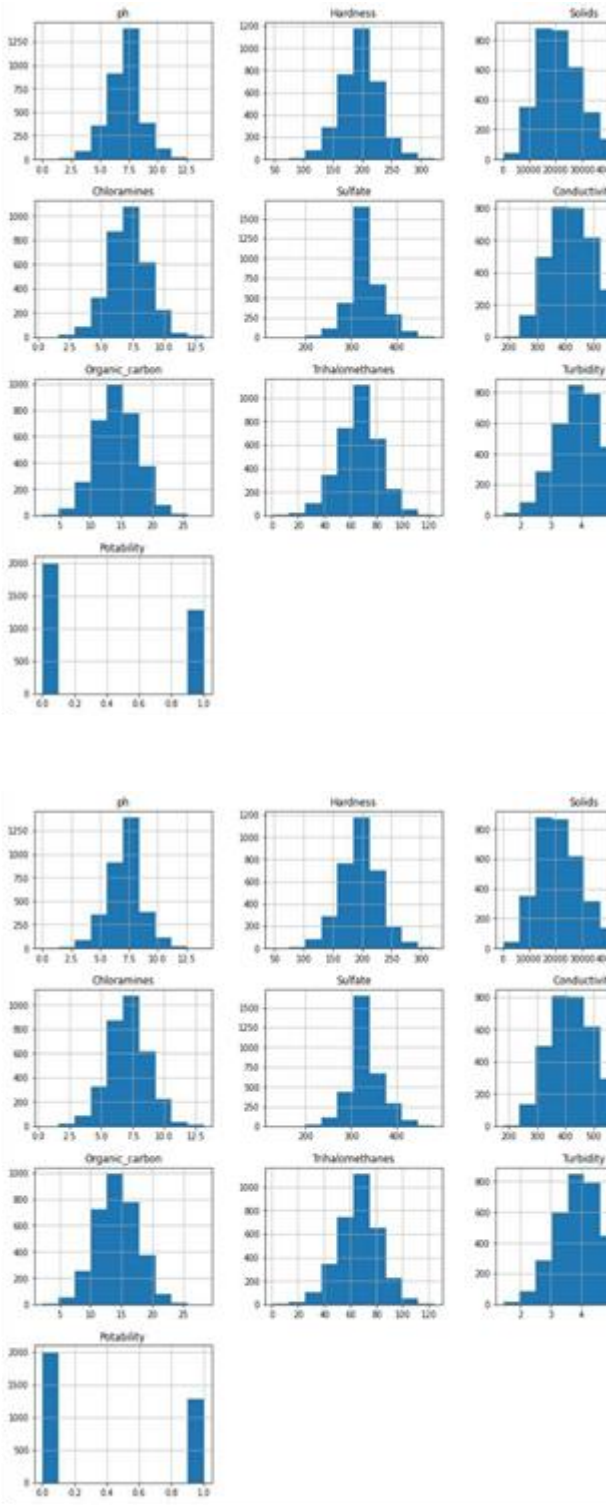

Fig.3 Visualization of the entire dataset using hist method

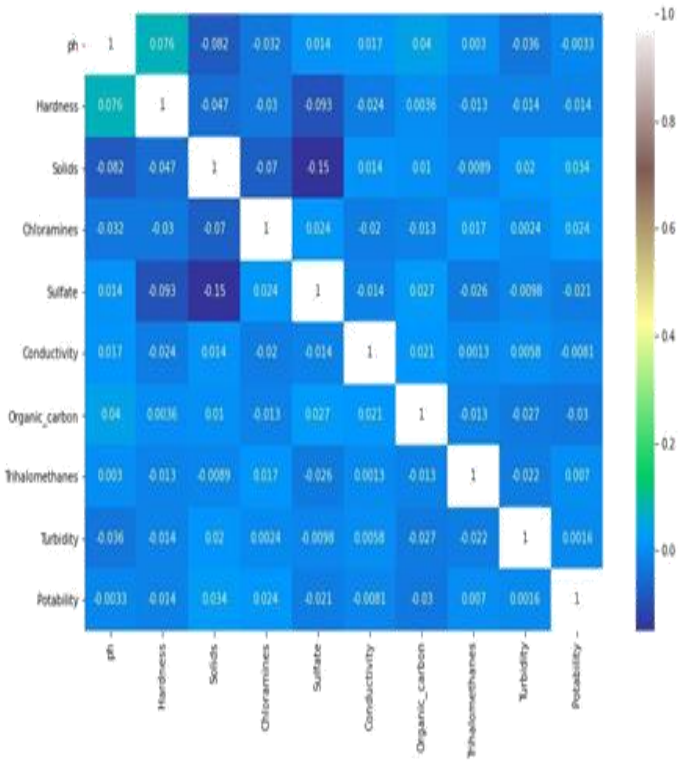

Fig.4 Correlation heatmap

3.2 Data Preparation

In data preparation, we have divided the data into two categories, dependent and independent features. Except potability, all our features are independent. Then using train_test_split function we have split the dataset into testing and training. After that, using the data set (X_train, Y_train), we trained the model and defined the decision tree classifier model. Using the test data set (X_test), we tested the model. Finally using the accuracy score, we have evaluated the model , confusion matrix and classification report. The techniques of evaluation take two parameters; the first one is the predicted data and the second one is actual data. Here we are demonstrating a graph of models vs accuracy (Fig.5)

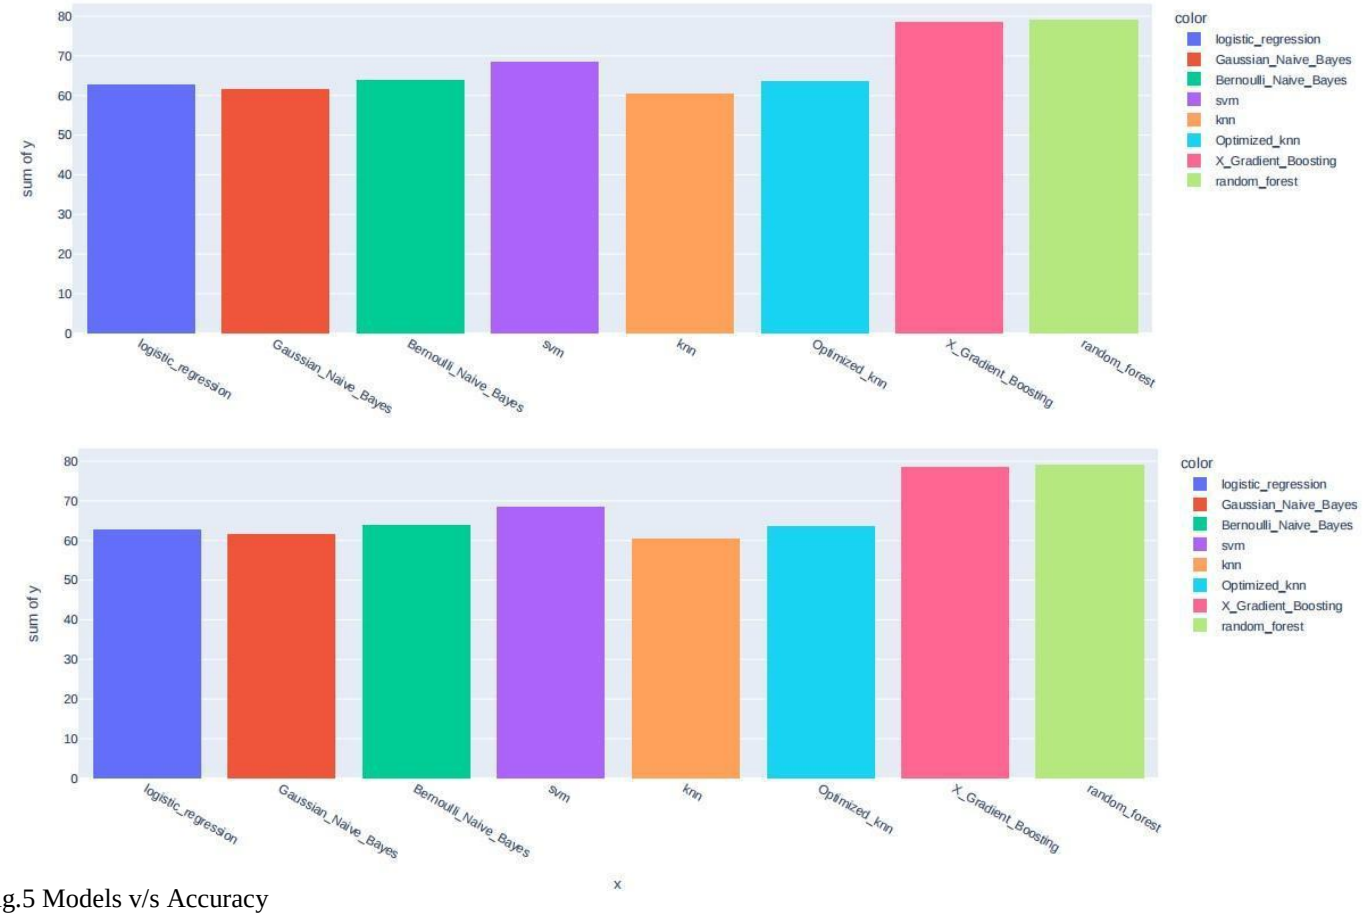

Fig.5 Models v/s Accuracy

4 Experimental Analysis

Using the boxplot function, we can find outliers where these are contained by the solid feature (Fig.9). But these outliers cannot be removed. Point to be noted, the water will be safe to drink if the

Now we are going to see the performances of our used machine learning models (Logistic Regression, Gaussian Naive Bayes, Bernoulli Naive Bayes, Support Vector Machine, Kth Nearest Neighbours, X Gradient Boosting, Random Forest.) through performance metrics, Precision, recall, f1 score and accuracy (Table.1 to Table.8)

outliers are removed from the solid feature. Basically these outliers in solid features make the water impure. Presence of high amount of solid particles make the water unsafe to drink. But we cannot remove this outlier to train the model.

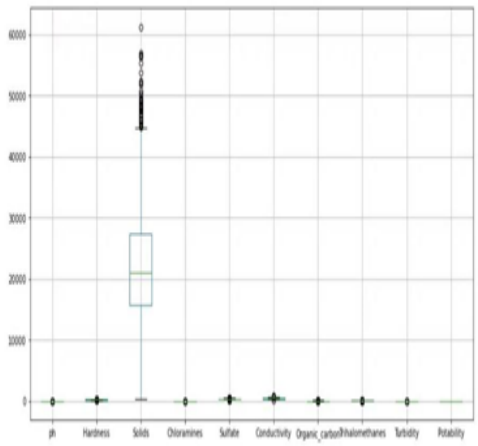

Fig.9 Outliers in the solid feature.

Model Name	Accuracy	Precision	Recall	F1_score
Logistic Regression	0.63	0.63	1	0.77
Gaussian_Naive_Bayes	0.61	0.65	0.85	0.74
Bernoulli Naive Bayes	0.64	0.68	0.8	0.73
Support Vector Machine	0.68	0.68	0.93	0.89
K Nearest Neighbours	0.63	0.68	0.69	0.73
X Gradient Boosting	0.78	0.81	0.86	0.83
Random Forest	0.79	0.8	0.88	0.84

Table.1 performances of our used machine learning models

4.1 Logistic Regression

Logistic regression is one of the regression algorithms of supervised learning. We use it to predict or calculate the probability of a binary (yes/no) event occurring. Its function is a simple S-shaped curve that is generally used to convert data in binary expression (0 or 1).

$$h\Theta(x) = 1/1 + e - (\beta o + \beta 1X)$$

Here, in our study, 0 represents “non-potability”and 1 represents “potability”. We are going to demonstrate its performance metrics.

Precision	Recall	F1 Score	Support	
0	0.63	1.00	0.77	412
1	0.00	0.00	0.00	244
Accuracy			0.63	656
Macro avg	0.31	0.50	0.39	656
Weighted avg	0.39	0.63	0.48	656

Table.2 Performance Metrics of Logistic Regression

4.2 Gaussian Naive Bayes

Naïve Bayes algorithm is one of the supervised learning algorithms based on Bayes theorem. Generally we use it for solving classification problems. Basically it’s used in text classification which includes a high-dimensional training dataset. Gaussian Naive Bayes is an extension of naive Bayes. The following expression is its mathematical expression.

$$P(A \mid B) = \frac{P(B \mid A)\,P(A)}{P(B)}$$

Precision		Recall	F1 Score	Support	
0	0.65	0.85	0.74	412	
1	0.46	0.22	0.30	246	
Accuracy				0.62	656
Macro avg		0.56	0.53	0.52	656
Weighted avg		0.58	0.62	0.57	656

Table.3 Performance Metrics of Gaussian Naive Bayes

4.3 Bernoulli Naive Bayes

Naive Bayes is one of the supervised machine learning algorithms. Based on numerous attributes it can predict the probability of different classes. It indicates the likelihood of occurrence of an event. We also know it as conditional probability. Bernoulli Naive Bayes is an extension of naive Bayes

Precision	Recall	F1 Score	Support	
0	0.68	0.80	0.73	412
1	0.52	0.37	0.43	244
Accuracy			0.64	656
Macro avg	0.60	0.58	0.58	656
Weighted avg	0.62	0.64	0.62	656

Table.4 Performance Metrics of Bernoulli Naive Bayes

4.4 Support Vector Machine (SVM)

Creating the best line or decision boundary which can separate n-dimensional space into classes so that we can easily put the new data point in the correct category in the future. SVM can be used as both classifier and predictor.

Precision	Recall	F1 Score	Support	
0	0.68	0.93	0.79	412
1	0.69	0.27	0.38	244
Accuracy			0.68	656
Macro avg	0.69	0.60	0.59	656
Weighted avg	0.69	0.68	0.64	656

Table.5 Performance Metrics of Support Vector Machine

4.5 Kth Nearest Neighbours(KNN)

Among the simplest machine learning algorithms used for classification is K-Nearest Neighbors. Data points are classified based on their neighbors' classifications. New cases are classified based on similar characteristics based on the stored cases.

Precision	Recall	F1 Score	Support	
0	0.68	0.71	0.69	412
1	0.47	0.43	0.45	244
Accuracy			0.61	656
Macro avg	0.57	0.57	0.57	656
Weighted avg	0.60	0.61	0.60	656

Table 6 Performance Metrics of KNN

4.6 X Gradient Boosting

Gradient boost machines (GBM) are one of the most effective and mention-worthy algorithms of supervised machine learning. a, and X Gradient Boost is one of the implementations of GBM. In addition, it can also be used to solve regression and classification related problems.

Precision		Recall	F1 Score	Support	
0	0.81	0.86	0.83	412	
1	0.74	0.65	0.69	244	
Accuracy				0.79	656
Macro avg		0.77	0.76	0.76	656
Weighted avg		0.78	0.79	0.78	656

Table.7 Performance Metrics of X Gradient Boosting

4.7 Random Forest

Random Forest is one of the well performing algorithms of popular supervised machine learning . We can use it for both, regression problems and classification. Random Forest is based on the notion of ensemble learning.

Precision	Recall	F1 Score	Support	
0	0.80	0.88	0.84	412
1	0.76	0.64	0.69	244
Accuracy			0.79	656
Macro avg	0.78	0.76	0.77	656
Weighted avg	0.79	0.79	0.79	656

Table.8 Performance Metrics of Random Forest

Conclusion

The Bureau of Indian Standards (BIS) declared the upper limit of total dissolved solids (TDS) levels in water is 500 ppm. For having values of TDS on an average of 40 times as much as the upper limit o the safe drinking water, the solid level seem to contain some descripancy. Equal number of basic and acidic pH level water samples are contained in our data. Very less correlation coefficients has been noticed between the features. Among our used models, Random Forest provided the highest accuracy with a percentage of 78.96, where SVM provided us the least amount of accuracy with a percentage of 68.29.

But in case of training the model, XGBoost and Random forest performed the best. Both of the models gave us f1 score (Balanced with recall and precision) around 76%.

Abstract- **Rural India faces a lot of problems related to medicines and health checkups. One such issue is related to doctors with fake educational backgrounds, which has led to people not having trust in doctors in rural villages. Also, people from villages migrate to other places for working as laborers or other work. But during covid-period, when everything got locked and we got so dependent on doctors for our medical help, rural areas and some Tier-2 cities faced issues related to prescriptions generated by doctors. Doctors were not having previous health records of labor's who got migrated to other places and now are seeking medical help, which led to difficulties with prescribing them medicines as doctors don't know whether this medicine can give any side effects or not due to the non-availability of previous health data. Along with this, since they have migrated to other states for work, there are certain workers who face language barriers, they don't know the local language and are also not acquainted with the English language. So, when a doctor gives them a prescription in the local language, they can't understand the content written in the prescription. Our project Digivaidya focuses on solving such a problem by having a doctor with verified degrees use our platform and giving doctors such a platform where we remove language barriers and prescribe their patients prescription in languages used by people in their state locally. With your Aadhaar card being considered a valid legal identity for you to be recognized as an Indian citizen, we are using an Aadhaar-based login system since Aadhaar is available to almost everyone. Such a login system provides a secure way through which doctors can access patient records only when the patient willingly shares the OTP received on a registered phone number. All data stored on a central database system will help doctors all around India, to easily prescribe medicines by looking at their past medical records digitally and this will help in creating a safer medical environment around India and making everyone safer and healthier.**

I. INTRODUCTION

The rapid growth in the field of Machine Learning (ML) & Deep Learning (DL) in urban healthcare sector has been tremendous in the past decade, but this potential growth mostly goes untapped in rural India healthcare digitization. The ground-breaking research and advancements in healthcare has not reached the rural borders. Migration of current digitized healthcare infrastructure is difficult to setup due to appropriate health infrastructure and lack of manpower to facilitate and maintain the usage of such technologies. Due to ignorance of healthcare on such scale the mortality rate in such regions is on a dramatical rise. The rural areas of India have had a tough time receiving basic healthcare needs from the govt. These areas have had to struggle to even receive the basic care from healthcare professionals. The individuals must travel far to getting a chance to get proper medical care and for consulting to a doctor.

The situation of such rural areas has been witnessed in these recent pandemic times where the actual might of India's healthcare sector was tested. And with no hard speculation the healthcare system in such rural areas was seen to be compromised. The lack of timely response to appeals from the rural areas. These issues can be fixed with the help of modern standards of teleconsultations with doctors as well as electronic health records that help counter such discrepancies in current rural healthcare infrastructure available. NLP being one of them that can help address issues in healthcare like parsing medicinal information, semantic identification of medical conversations, tagging of required information, and extraction of condign terms.

NEED OF NATURAL LANGUAGE PROCESSING

Natural language processing (NLP) can be used to improve patient health records, according to a recent study published in the Journal of Medical Internet Research. NLP can be employed judiciously, with considerations for suboptimal term linking and algorithmic pitfalls, to support electronic health record usage. NLP is an emerging field for supporting patient health management systems. EHR's, gives patients glimpses into their medical records and clinical notes, aim to better engage patients with more information about their own health. Though there really are no limits to how NLP can support the healthcare industry, here are three primary use cases:

Improving Clinical Documentation: Rather than waste valuable time manually reviewing complex EHR, NLP uses speech-to-text dictation and formulated data entry to extract critical data from EHR at the point of care. This not only enables physicians to focus on providing patients with the essential care they need, but it also ensures that clinical documentation is accurate and kept up to date.

Accelerating Clinical Trial Matching: Using NLP, healthcare providers can automatically review massive quantities of unstructured clinical and patient data and identify eligible candidates for clinical trials. Not only does this enable patients to access experimental care that could dramatically improve their condition — and their lives — it also supports innovation in the medical field.

Supporting Clinical Decisions: NLP makes it fast, easy, and efficient for physicians to access health-related information exactly when they need it, enabling them to make more informed decisions at the point of care.

Usage of NER in analysis of clinical notes, patient-doctor conversations, past medical records while extracting keywords and assigning them to specific entities such as Symptoms, Medicine, Duration, Basic info are the standard practices that are adopted using NER. NER plays the most crucial role by giving out the first meaningful chunks of a clinical note, and then feeding them as an input to the subsequent downstream tasks such as clinical assertion status, clinical entity resolvers, and de-identification of the sensitive data. However, segmentation of clinical and drug entities is a difficult task in biomedical NER systems because of complex orthographic structures of named entities.

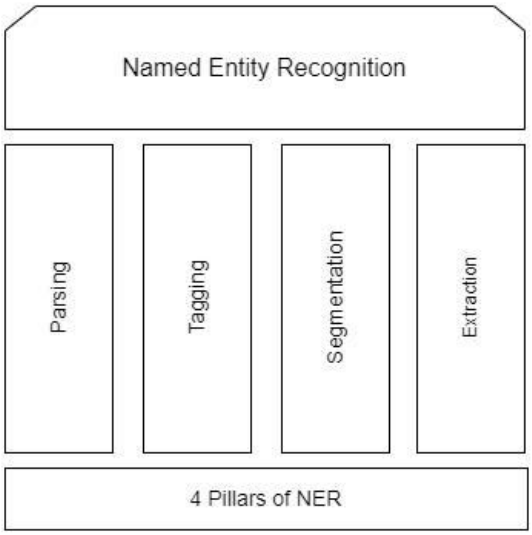

Fig 1: Four pillars of NER

II. LITERATURE SURVEY

Around 64.61% of India's population of 1.39 billion people live in rural areas. To address the health problems of this population, the government has set up various healthcare centres at rural locations, including Sub Centres, Primary Health Centres (PHC), and Community Health Centres, under a program called the National Rural Health Mission (NHRM), which is a sub-mission of the National Health Mission. NRHM seeks to provide equitable, affordable, and quality health care to the rural population, especially the vulnerable groups. In rural India, regional languages are used majorly. It is difficult to enter text in Indian languages on computers, so it is better to ask questions using voice mode. Usually, 60 seconds is enough time to describe the problem completely.[1]

Achieving health equity and enhancing healthcare quality for vulnerable communities is a

critical societal responsibility, particularly in developing nations. Some government agencies, groups, and academic institutions have been monitoring the situation and seeking answers. Rural populations in underdeveloped nations have lower life expectancies and health difficulties than urban residents. Poverty is a significant socioeconomic predictor of healthcare. The direct cause of ill health is a lack of access to quality healthcare. The doctor-to-population ratio in India was 1.71 physicians per 1000 people in urban areas and 0.45 doctors per 1000 people in rural regions. Medical AI technology has the potential to both improve the availability of healthcare access and healthcare quality within rural areas of developing countries. The application of AI technology in primary health settings, many AI-driven systems have been developed for special diseases in rural areas. For example, a low-cost swallowable endoscopic capsule with AI analysis technology can be used to screen for upper gastrointestinal cancers, thus replacing expensive or difficult traditional screening equipment.[02]

The healthcare system in rural India is managing patient data in a traditional paper-based system. Most of the rural hospitals in India are lacking in resources to maintain and manage the patient health data. As India moves towards digitization, one of the main challenges in developing countries like India is in making the healthcare data accessible from rural to urban in digital form. Advancement in IT technology in healthcare sector has made it possible to maintain and manage the patient data in digital form in all levels of healthcare system.[03]

The EHR system allows healthcare professionals to capture and maintain patient's past medical history and present symptoms. This allows for a better diagnosis of the current illness as details of past illnesses such as hypertension, diabetes, kidney disease, heart disease, asthma, tuberculosis, and other needs are recorded. The various lab tests and multimedia images need to be presented to the doctor along with the EHR contents. The drug history mainly captures the list of drugs that the patient was taking prior to admission to the hospital. In addition to this, the EHR system has provisions to provide details of drug allergies, dosage, duration, and recently stopped medicine. Addiction history such as smoking, tobacco, and alcohol details need to be recorded. The health history of the patient and the patient's family helps to address acute health problems and minimize the chronic condition of the patient. [04-05]

The increasing use of network technology in the medical field has led to the accumulation of a large amount of personal information in Electronic Health Records (EHRs). Therefore, research on how to effectively share EHR data is of great significance for countries, EHR institutions, and individuals. At the national level, EHR data can be used as a good indicator of the overall health of the population; at the institutional level, EHR data sharing can help doctors effectively assess patients' conditions and make correct diagnoses; and at the individual level, having complete EHR data can improve the quality of EHR service.[06]

There are two main reasons why speech processing is so important. The first is that it can be used to convert speech into text using speech-to-text technology, which can then be analysed using Natural Language Processing to glean a lot of relevant information, such as sentiment analysis, quality of speech, vocabulary, and other important clues that can be valuable for rehabilitation or diagnostic purposes. The second, more analytical reason, is that speech can be processed and analysed iteratively to identify speech patterns such as slurred speech, or to identify the symptoms that are mentioned in a patient-doctor conversation, to name just a few possibilities.[07]

Information sharing is a key factor that influences the way connections are created and data is interpreted in making decisions. However, the process is very complex due to the variety of actors involved and the diversity of medical data. This can lead to ineffective medical treatment and decreased quality of life. Resolving the issue of interoperability between systems containing medical information would lead to an estimated $77.8 trillion in US alone.[08]

Aadhaar cards serve as digital identities. The Unique Identification Authority of India (UIDAI) issues an Aadhaar card to every resident of India which contains a 12-digit unique identification number. This number can be used as an identity proof for availing all services of government and non-government organizations. Each person is only allotted one Aadhaar number, which is linked to their voter card. Having one identity proof for every resident of India would be the best authentication method to be used for verifying, identifying, and storing the personal medical record. With the advent of high-speed network in India, this system becomes feasible and would save time in comparison to maintaining data in physical paper formats. [09-10]

The most important aspects of a human being, such as health records, must be added to the smart

card to maintain and conduct research on demographic areas and countries. The user details are stored in the form of a QR code along with a 12-digit Aadhar card number. Scanning the QR code will retrieve and display all coded information. [12-13]

As AI has been shown to be useful in healthcare, researchers are now suggesting that it may also be helpful in fighting COVID-19. Recent research on COVID-19 using AI suggests that it can be helpful in detecting COVID-19 infection and infected populations, predicting the next outbreak, finding the attack pattern, and even finding a cure. Some recent research has shown the implications of AI like biological data mining and machine learning (ML) algorithms in the detection, diagnosis, classification of COVID-19, and vaccine development. Researchers assessed these techniques in machine learning-induced healthcare selected studies focusing on reliability and acceptability. In this, the authors evaluated and benchmarked the AI techniques used in the image data and presented a set of future guidelines for the evaluation metrics. In contrast, our research explores the works on a broader spectrum including but not limited to the application of AI in detection, diagnosis, epidemic forecasting, and performance evaluation.[14]

The goal of electronic medical record (EMR) systems is to improve patient care management and support clinical and transitional research. In the past decade, the amount of patient health-related data stored in EMR systems has increased massively. Patients' clinical data are stored in EMR systems in either a structured format (which is easy to query and mine) or an unstructured, free-text format report (which requires tools to extract terms of interest). Natural language processing (NLP) methods are used to transform the text into computable data. Some of these methods are used in the clinical field to extract concepts from free-text clinical reports. Some open-source clinical NLP tools are Clamp, cTakes, and MedLEE. Most NLP software tools rely on medical dictionaries such as the Unified Medical Language System (UMLS) or the Systematized Nomenclature of Human and Veterinary Medicine (SNOMED) to match concepts to text vocabularies and follow either a rule-based approach or a machine learning approach. The rule-based approach consists of manually created rules to map words and phrases within free-text to categories. The machine learning approach uses a training set of large, pre-annotated reports to extract named entities. The NLP process is complex and challenging to NLP solution designers as they must consider clinical abbreviations, temporal events, and the context to design and implement an efficient and well-performing NLP product.[19]

III. ARCHITECTURE

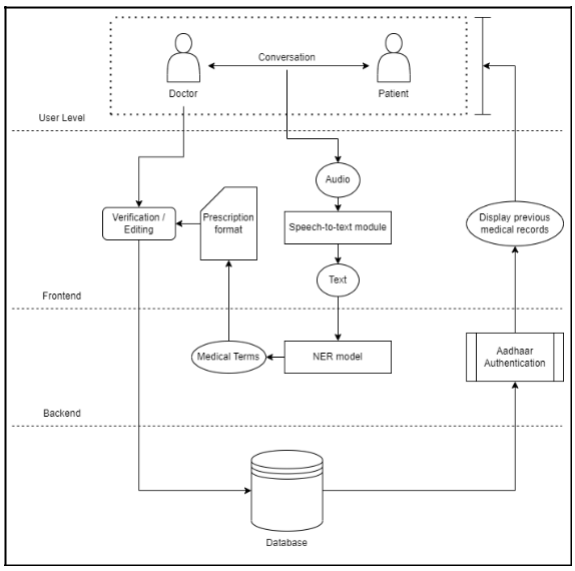

Fig 2: Architecture

The system tackles the problem experienced during consultations, as well as how the use of smart technology may not only change, but potentially revolutionize, how we experience medical meetings. The system is designed to record audio between a doctor and a patient and process it to give the intended output i.e., prescriptions in our case. The architecture of the system can be well explained by breaking it into 3 parts namely:

1. USER LEVEL:

This is the topmost layer in the architecture of our system, which is responsible for recording of conversation depending on which whole system is intended to work and provide output. The doctor is given access to a portal where he/she can migrate to the record page and then record the conversation that is going to take place between them.

2. SYSTEM LEVEL:

This layer is the second layer of architecture and is further divided into 2 parts that are frontend and backend. Both have their own architecture on which they are doing all required tasks.

A. Frontend:

The audio that was recorded is passed to speech to text module, from which text is extracted and passed on to Named Entity Recognition (NER) model which is at the Backend. NER model extracts all clinical terms that it gets from the text that was passed to it, and then the generated output of NER is

moved to prescription format where it is displayed to the user at the front-end side. Later, at the final stage there is an option provided for doctors to verify and make any changes if they want before saving it to the database and sending it to the patient. Frontend is also responsible for displaying the previous medical record to the doctor after getting verification approval from backend.

B. Backend:

It consists of a NER model which extracts medical terms. Along with that, it consists of Aadhaar authentication, which we use to display previous medical record of a patient to doctor only if correct One Time Password (OTP) is provided by that patient to doctor as One Time Password is only sent to the patient registered mobile number as per Aadhaar records.

3. DATABASE LEVEL:

This is the bottom most layer, yet the most important one, as it handles all the records of doctors and prescriptions. When a new prescription is generated, it is stored in the database as a new document having a unique identity. Also, when a new doctor joins the portal, the data related to the doctor is also stored under a new document having a unique identity. Both User level and System level takes help of the database level in some of their functioning to achieve the target.

IV. USER FLOW DIAGRAM

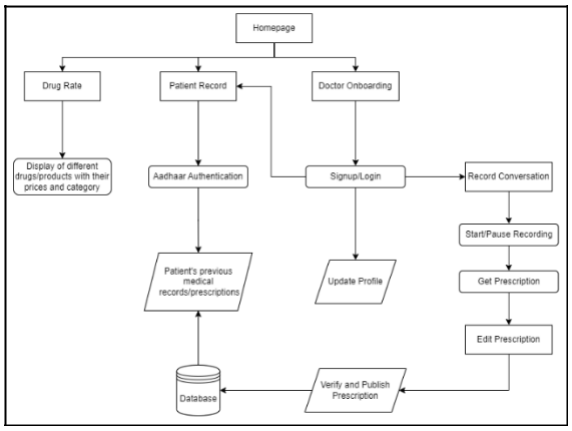

Fig 3: User Flow Diagram

The system is comprising of a webapp for user interaction. The user intended to work on the webapp is a doctor. The doctor lands on the homepage where several options are given for access.

The drug rates portal can be used for checking the verified drug rates of about 8000 drugs/products. These rates can be used to compare the different complementary drugs to get the best option among them. These drug rates are authorized by the govt. The drugs are displayed along with their composition for a detailed comparison.

The patient record section is used to access previous medical records of patients. The records can be accessed via proper authentication using Aadhaar OAuth. After which, the records are fetched from the centralized database.

The doctor onboarding section is where the doctor can signup/login to access his/her profile and to work with the recording section of the portal.

The record conversation section provides functionality for recording the conversation of the patient and the doctor. The doctor can start or pause the recording at any point in time. The record text can then be used to generate the prescription.

The edit prescription section provides functionality to make changes to the medical record/prescription. After verification the records can be published onto the central database.

V. FLOWCHART

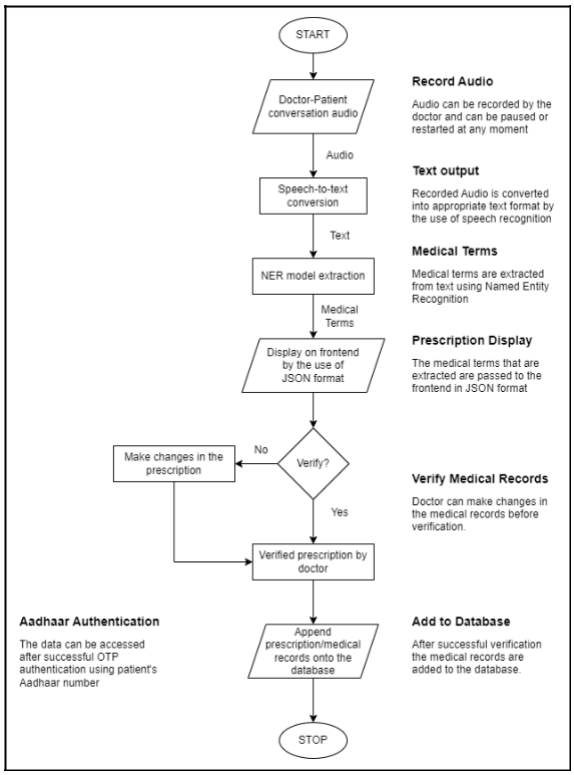

Fig 4: Flowchart

The idea of creating the system is to digitize the consultation process i.e., the process of interaction between a doctor and his/her patient. To automate this process the conversation between the doctor and

patient is used to provide a digital copy of a prescription to the users i.e., doctor and patient.

The system passes through a series of phases before the appropriate prescription can be modelled and be displayed to the end user.

The system provides a web app for interaction and is mainly focused on providing an interface for the doctors. The doctors are the main users and hence have to login to work with the system.

The doctors initiate the process by using the record privilege that is provided. The doctors can pause, start, or restart the recording anytime. The conversation is converted into text in real time using speech recognition models and can be seen virtually on the portal provided.

After successful capture of audio and conversion of text, the text that is acquired is passed to the backend where the extraction takes place. Named Entity Recognition is used for processing the text and for obtaining all important medical terms. The text is passed through the SciSpaCy model which is used to extract medical terms like drug name, dosage, strength, frequency as well as the symptoms spoken of in the conversation.

After successful extraction of all the terms spoken of in the conversation, the terms are saved in a JSON format and passed further for formulating an appropriate representation for displaying it to the end user i.e., the doctor. The doctor then has the option to check all the terms and verify any discrepancies in the medical record that is displayed. If there are any issues identified, then the doctor can make changes and correct the issues there itself with the edit option that is provided.

So, after proper verification from the doctor's side, the document/prescription can be published onto the database. This step makes it a permanent entry on the database along with all the diseases identified and the medicines prescribed, symptoms diagnosed and so on. This creates a proper medical record for that visit with the doctor.

For accessing these medical records there is an option to see the patient's medical records where the system asks for the patient's Aadhaar number. After entering the Aadhaar number, an OTP is sent on the patient's registered email ID, this OTP is then used for authentication. This allows the user to see all previous medical records linked to that patient's history. Hence, allowing for a quick access to the health records.

VI. WORKING METHODOLOGY

Digi-वैद्यis developed using modern technology stack used in web development i.e. MERN stack which consist of technologies like MongoDB which acts as a database and responsible for storing of data, ExpressJS which enables routing functionality between front-end and back-end of the application and also responsible for data flow between frontend and backend, ReactJS is the frontend module that is used to creating the design and working of front-end part of the project, and lastly we have NodeJS which is back-end JavaScript runtime environment which is responsible for executing of JavaScript code outside a web browser. Along with these technologies, we also used Flask where our Machine Learning code lies that helps in extraction and generation of prescriptions. Talking about the flow of the project i.e., how it is working let's look at it step by step.

1. Doctor onboarding:

As the name suggests, it is where doctors will be creating their account and filling up all basic details related to their education, previous work experiences, expertise, and similar other details. After getting all the details, the system will save doctor's credentials and basic details into the database for future usage.

2. Getting patient's previous medical record:

After the doctor is logged in into the system, the first thing that he/she needs to do is to check the previous medical history of the patient. Since we are trying to make everything paperless, here we are expecting that the patient has not come with previous health related data and previous prescriptions, so the doctor will be viewing it directly through the central library that is being created along the way to store patient records. The doctor will ask the patient for their Aadhaar card number and then the system checks whether the Aadhaar card is avoided or not and after validation it sends the One Time Password (OTP) to the registered mobile number that patient needs to give to the doctor so that doctor can view his/her data. The concept of OTP was introduced to protect patient privacy and it will require OTP to access any patient's medical record without which the doctor won't be able to see any record. After successful One Time Password verification, the doctor can now see what all illness has been registered for the patient and prescribe the medicines accordingly.

3. Generation of prescription:

The system takes voice as an input, the voice comes in the form of communication that takes place between doctor and patients. The system keeps recording the whole conversation and after that it generates the prescriptions according to whatever insight the Machine Learning model has received in the form of speech. We are using the Named Entity Recognition [NER] technique to detect clinical terms from the speech which is first converted to text and later passed to the model for detection of named entities. After detection, it is segregated into categories such as drug name, duration, frequency basically all the categories that a prescription needs to have. Along with these it also gives out all the symptoms that were detected from the conversation. Since the project works with Machine Learning, it is not always hundred percent accurate in getting details, there might be some error in detections, so to prevent these we have a double-check mechanism that let doctors have a final edit advantage to make sure everything is correct and later print the prescription and give it to patient. One additional feature that the project offers is that prescriptions can be generated in almost all possible languages that each state in India speaks locally which helps the patient in understanding such prescriptions in a more detailed manner.

4. Medicine price rates:

The Government of India (GoI) releases the price rate of medicines with chemical names on their website, but very few people read them. We also aim at increasing awareness regarding the real prices of the medicines that GoI has attached, and it can be directly viewed on our website without the need of having an account, and the patient can buy the medicines based on chemical name which will helps in getting generic medicines from certain medical shops at lower price, which will indirectly help in improving the health infrastructure of the country.

This was all about the working of various components that are involved in Digi-वैद्य.Since each and everything involved here is connected to back-end database that keeps track of everything happening in the portal provided to the doctor, we can easily keep track of which medicines are prescribed by which doctor, whether the educational background provided by doctor is correct or not, or the location of doctor's clinic where this prescription was generated. These all will help in making a safer medical environment for people of India.

VII. RESULT & DISCUSSION

Digitalization in rural India, elimination of language barriers, faster backtracking in case of any error or frauds, central medical health library is some of the advantages that we can create with the help of this mechanism. We can achieve this by use of existing technologies available, understanding them, and integrating them to solve a larger problem i.e. In our case, it is betterment of the medical health industry in rural parts of India. The model that we are using for detection and extraction of clinical entities from the conversation is implemented using SciSpaCy, a model that is trained over a big corpus of data of clinical texts. When a doctor starts the portal, the system first asks for their preferred language in which they want to use and based on their language selection the whole system works and displays content.

Although as of now the prototype of our system accepts the voice in the English language only to work efficiently. But it can display and generate prescriptions i.e., the final output in the language preferred by the doctor at start or based on patient required language can be updated and the prescription will be modified accordingly. Everything related to data is stored in the database in English language only as we are also focussing on collection of data that will help medical researchers improve their research and testing medicines on certain people and later identity what would be the side effects on others based on the data that our system will collect over the period. So, to have consistency and increase usability the data is stored in the English text.

As the system will scale up in future, we will be prioritizing availability over consistency. The reason behind that is during a medical emergency, if our certain part of the system stops working, we should have some sort of data related to the patient available in the database for usage by doctors. But if we would have focussed on keeping consistency as our priority, it would have some serious consequences such as non-availability of data during medical emergencies. If such an issue arises then our system fails to solve the root cause of the problem that it was made to solve. Hence, we focussed on availability by compromising consistency.

The prescription that is generated by our system is in tabular format having each row with columns as drug name, strength, frequency, duration. There is another table attached immediately after the prescription table which tells about all the symptoms that were mentioned by the patient. The purpose

behind having symptoms is also displayed so that when the patient visits the clinic next time, the doctor would be able to determine easily why so and so medicines were prescribed to the patient. As the system works on Natural Language Processing (NLP) which is a part of Machine Learning (ML), there are chances of error during detection of clinical terms from the conversation that takes place between doctor and patient. Wrong prescription will have serious consequences for both i.e., patient and doctor. In order to solve this particular and major issue, we added a double-check mechanism which only comes up after the prescription is generated based on the initial conversation that occurred between them, so in case any mistakes system has made during detection can be rectified by doctor, also if any new additional information patient has given that got missed out during the recording can be updated by doctor while making corrections (if any). Any additional feedback that the doctor wants to mention can also be mentioned which will be stored in the database for future reference.

VIII. FUTURE SCOPE

Every Institution, business and economies around the world are moving towards use of data science extensively. Data helps in generating greater valuable information regarding a problem and helps in getting faster solutions. Talking about Covid times, there were certain companies who wanted to sell their covid vaccines in India, but they were not able to guarantee the safety of people due to less availability of data regarding people of India. Our project ultimately will be generating good chunks of data that will be stored centrally, and when covid like situation arises or if any medical researcher wants to test certain medicines, it can be done by testing on few people and then matching its trait with help of data and getting insights on how this will affect the health of other individuals. The future usage of Deep Learning (DL) and Natural Language Understanding (NLU) in the healthcare industry seems to be very promising.

1. The system will be having a vast range of improvements from design perspective to performance perspective. Some of them includes:
2. Storing voice (with consent of doctor and patient) that is being recorded during the conversation which will help in improving the architecture of speech-to-text models in the medical as well as other fields.
3. Time to Time re-training of data, based on new data that is being collected to keep the model trained with new entities and terms used or introduced in recent times.
4. Creating a progressive web application (PWA) for doctor's so that they can quickly access it from their laptop or computer screens instead of searching it on the web.
5. Making our system take voice input in other local languages as well.

IX. ACKNOWLEDGEMENT

We would express our gratitude towards the Department of Electronics Engineering (THAKUR COLLEGE OF ENGINEERING AND TECHNOLOGY).

X. CONCLUSION

The healthcare sector has ever been an important sector for the well being of the society. The situation of healthcare professionals has been well witnessed in the recent pandemic times where the whole world crumbled upon the issues faced by the healthcare system. The healthcare system failed as a vast majority of patients could not be addressed at the time of need.

The rural areas moreover were at the worst possible position as they had to travel far to just get to see a doctor for once. The rural areas have been suffering for a long time when it comes to the basic healthcare needs, whether it be fast and convenient consultations, proper doctors, or access to drugs and medical products.

The proposed system considers the need of digitalization of this process of consultation between the doctor and the patient to provide an option for a convenient and easily accessible medical record.

The automation mentioned in the proposed system takes the conversation between a doctor and a patient and provides a digital prescription / health record which is generated using the audio recorded while conversing. This recorded audio is converted into a text and worked upon to capture all important medical terms like drug name, strength, frequency, dosage, etc.

These medical terms are used to prepare a medical prescription/record which can be stored into a centralized database for future access.

This makes it possible for a frequent and convenient facility for accessing the previous medical records at any place anytime. Also, the process of automating the consultation process makes it fast and improves the condition of no human errors in handwriting or recording as such.

Abstract- Advance Driver Assistant Systems (ADAS) are a group of electronic technologies that assist drivers in driving and parking systems, bringing safer, easier transportation. ADAS systems use advanced technologies to assist the driver by using a combination of sensor technologies, Artificial Intelligence (AI), radars, and cameras to perceive the world around the vehicle. Computer vision is the core of AI to decode and understand the visual data acquired from cameras. The decoded data from the camera helps in activating driver assistant systems such as Adaptive Cruise Control (ACC), Collision Warning Systems (CWS), Intelligent Speed Adaption (ISA), and automatic windshield wiper activation. These driver assistant systems are activated based on the weather condition predicted by computer vision models. In adverse weather conditions, the camera output becomes noisy and becomes challenging for computer vision algorithms to decode the visual data.

Multiple computer vision algorithms are proposed by many research institutes and leading automakers for a faster and more accurate classification of images. Decision-making for activating the driver assistant systems using various image classification algorithms are dependent mainly on Frames processed Per Second (FPS) and the accuracy of image classification models on streaming data. A comparative study of these algorithms on the benchmark DAWN dataset was conducted in this research.

Keywords: Autonomous cars, Safety systems, ADAS, Image classification, DAWN dataset

1 Introduction

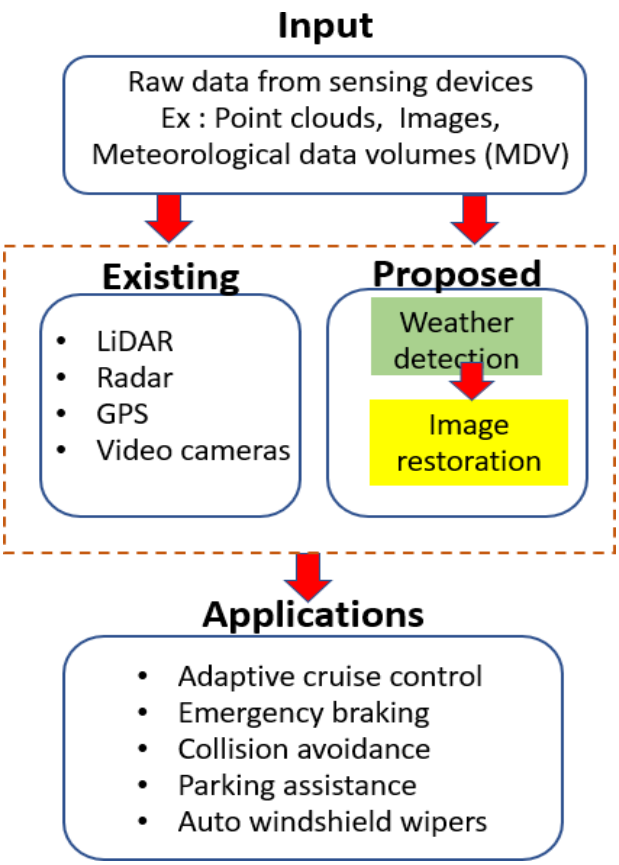
ADAS is a group of electronic technologies that assist drivers during driving and parking functions. ADAS are developed to automate, adapt and enhance vehicle technology for safer and better driving comfort. ADAS functions can be taken as two main groups mainly, custom functions and safety functions. Custom functions mainly include giving a warning trigger to the driver such as a flashing light, or vibration alert. Safety functions take care of the vehicle control in case the driver is not responding to the potential warning alerts. Some of the custom and safety functions are Forward Collision Warning (FCW), Lane Departure Warning (LDW), Automatic high beam assist, pedestrian detection, Automatic Emergency Braking (AEB).

Computer vision algorithms play a crucial role in the development of ADAS. These algorithms are responsible to deliver accurate and clear image data by processing the raw data from edge devices so that ADAS systems can better understand the environment around the car. The raw data from the camera may not be clear always due to blur, dust on the camera, and also due to harsh weather conditions. Some of the applications of computer vision in ADAS are:

- Emergency brake systems
- Automatic windshield wiper activation
- Pedestrian detection
- Rear camera parking assistance

2 Literature Review

Computer vision-based driver assistant systems are blooming with a wide range of application and being a promising technology for solving real-world problems such as driver monitoring [1,2], speed adaptation [3,4], parking [5,6], lane departure warning [7], intelligent headlamp control [8]. For driver monitoring, the AdaBoost algorithm is used to extract the potential features from a large set of available features in [1]. For detection and recognition of road signs, and alerting the driver an integrated approach is designed using neural networks in [2]. For 360-degree parking assistant systems, a unique brightness balance algorithm is proposed in [6] that can adjust the brightness between input data streaming from 4 fisheye cameras around the vehicle. Various approaches for utilizing visual sensors in ADAS are discussed in [7] explaining the overall architecture for computer vision applications.



These assistant systems need to operate on any occurring environmental conditions such as heavy rain, bad lighting conditions, tunnels, highway, intercity, etc. Some of the studies are conducted for analyzing the effect of adverse weather conditions on primary sensors such as LiDAR, cameras, and radar by using simulation. In various studies, it is demonstrated that in adverse weather conditions the ADAS sensors fail regardless of vehicle speed [9]. In some of these studies, it is proved that LiDAR visibility and intensity is severely affected by bad weather condition [13- 15]. For example, in Lane Detection Warning System (LDWS) image detection, it is analyzed that environmental factors affect the performance of sensors [10,12] and it is proved there is a need for complex sensors and regional factors considered for better performance. A systematic view of faults and corresponding measures to avoid them is discussed in detail in [16]. Faults related to adverse weather conditions are discussed majorly in this research and these faults are highlighted as the primary issues in extracting the features. In addition to this, in some of the studies, it is proved rain is the main source of radar signal abrasion [16]. Radars are also affected by snow or mist in the form of abrasion and backscatter [17].

In this aspect, there is a need to build an accurate and faster image classification technique for weather detection. FPS of 4.4 is achieved by ResNet15 on a normal CPU setup in [18]. On the weather data considered in this study, the number of layers is reduced from 50 to 15 for ResNet architecture. This resulted in faster FPS without reducing the model accuracy. The present study is focused on applying computer vision algorithms for weather detection and comparing the speed and accuracy of the results. VGG16 [20], ResNet50 [21], EfficientNet [22], and InceptionNet [23] architectures are proposed by various researchers for image classification problems.

3 Research methodology

As an alternate approach to the conventional way of using sensing technologies such as LiDAR and radar, a new workflow is designed by using cameras for some of the decision-making requirements in ADAS. This can benefit in cost, time, and computational power. With advancements in machine learning and deep learning techniques, this study helps in understanding the applicability of various image classification algorithms. This helps in predicting the weather for each frame in the streaming video data on a real-time basis.

Fig. 3.1. Traditional approach and proposed methodology

The present study is limited to some of the decision-making requirements such as emergency braking, traffic sign recognition, and obstruction detection. The proposed methodology as shown in Figure 3.1 is a novel approach for weather detection to most of the decision-making requirements, where the prediction result can be helpful in applying the appropriate denoising algorithms on the input data and also helps in faster decision-making for autonomous driving conditions.

The new approach can be stated as a pre-processing step before applying any denoising algorithm. This approach of using vision cameras is planned to eliminate high-cost sensing technologies in some of the applications where performance degrades in adverse weather conditions. This approach is also targeted for faster decision-making skills with minimal time for weather detection.

In the proposed methodology, computer vision models are trained on the benchmark dataset DAWN for detecting four types of weather conditions where the vision becomes noisy. The benchmark dataset is used in training various image classification algorithms such as VGG16, ResNet, InceptionNet, and EfficientNet. The trained models are fine-tuned for better accuracy and FPS using various hyperparameters such as learning rate, number of epochs, and dropout ratio.

4 Data Generation and Understanding

For deep learning applications to real-time in-stream video data, a higher system configuration is preferred for faster execution. In this study, Google Colaboratory (GC) is chosen for running different image classification models. GPU runtime with specifications mentioned in the table is used for faster runtime execution and FPS comparison. The runtime configurations used in this study are shown in Table 4.1.

Runtime source	**Specification**
GPU	Up to Tesla K80 with 12 GB of GDDR5 VRAM, Intel(R) Xeon(R) CPU with 2 cores @ 2.20 GHz, and 13 GB RAM

Table 4.1. Runtime configuration

Runtime source Specification

Table 4.2. : Classes in DAWN dataset

Class	Rain	Fog	Snow	Sandstorm
Samples	250	250	250	250

For image classification algorithm training DAWN dataset is used. This contains 4 different classes of weather such as rain, snow, fog, and sandstorm with 250 images for each class as shown in Table 4.2. This dataset also contains images captured during dawn, day, dusk, and night. Images in each class of this dataset are re-sized to 224* 224 pixels before passing to the image classification models. The DAWN dataset chosen for this study covers all the lighting conditions and weather conditions on a high level from the dashboard camera [19]. The dataset also contains object bounding boxes for autonomous driving and video surveillance scenarios.

5 Implementation

Tensorflow framework and Keras library are used in the present study. As discussed in the earlier section, original dataset contains 4 folders containing images captured in different weather conditions and bounding boxes for object detection. In the present study, bounding boxes are ignored as they are not relevant for the image classification tasks. Implementation steps for this study are shown in Figure 5.1.

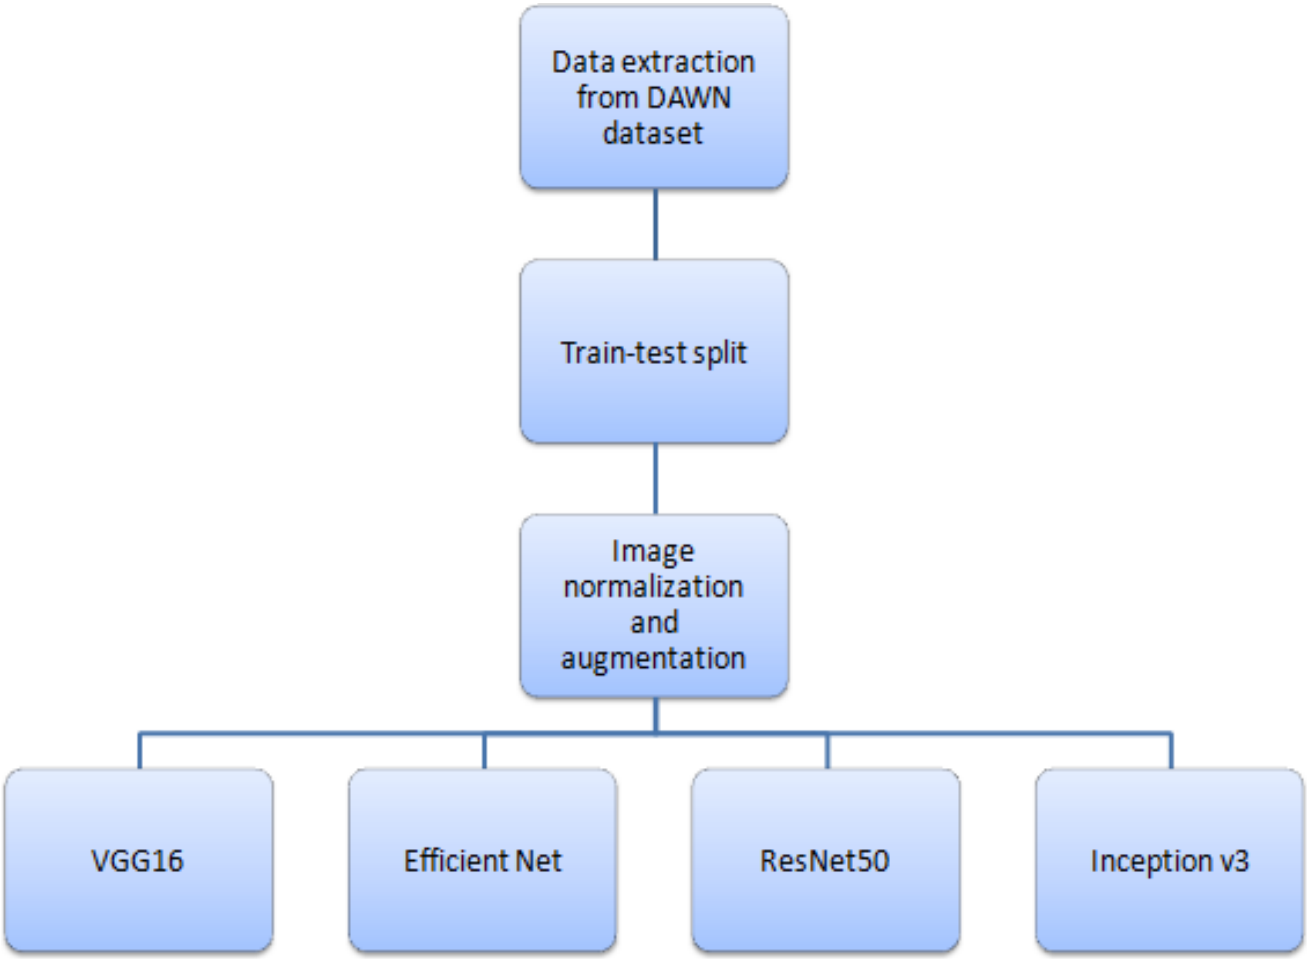


Figure 5.1: Implementation flowchart

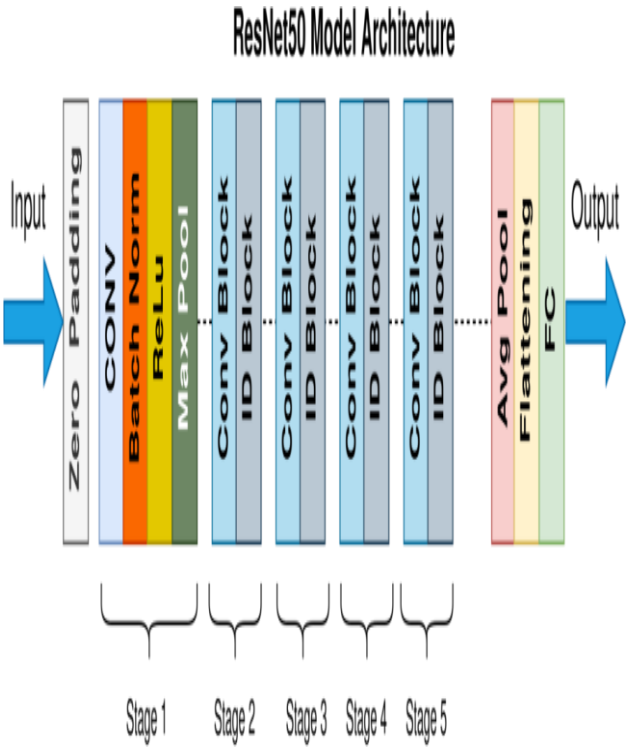
5.1 VGG16



This algorithm is one of the popular algorithms for object detection and image classification tasks. Transfer learning technique makes this algorithm adopted in an easy and faster way for computer vision tasks. This architecture contains 21 layers including pooling. The number 16 in the algorithm name represents the number of layers with weights. The architecture consists of 13 convolutional layers, 5 pooling layers, and 3 dense layers at the end. This algorithm takes input tensor size as 224*224 pixel with RGB data. The base network is trained on the 'ImageNet' dataset containing more than 14 million high-quality images with 1000 target classes. Using the transfer learning techniques, the weights for the hidden layers are adopted making the learning process faster and simpler. For the last dense layer, the target classes are set to 4 based on the DAWN dataset.

5.2 Inception-v3

Inception-v3 is a CNN architecture for image classification and it is a superior version of Inception-v1. Compared to the VGG-16, inception architectures like GoogleNet, and InceptionNet are computationally efficient both in terms of economical cost and the number of parameters generated. The major changes done to Inception-v3 compared to predecessors are the utility of auxiliary classifiers, factorization into smaller convolutions, spatial factorization into asymmetric convolutions, and efficient grid size reduction. The architecture contains a total of 42 layers with 24 M parameters. The default input image size is 299*299, and that can be changed to 224*224 for the present study. The ImageNet pre-trained weights are used for the transfer learning technique.

5.3 ResNet50

ResNet50 is convolutional neural network architecture with 50 layers and it is a variant of residual networks. In previous CNN models, deep networks are adopted for increasing the accuracy scores. This approach leads to training huge neural networks and vanishing gradients. In ResNet architecture, skip-connections are used to solve the vanishing gradient problem. This network can be easily scalable for a different number of layers such as ResNet18, and ResNet34. ResNet101, ResNet110, ResNet154. The network has an input image size of 224*224 pixels as shown in Figure 5.2.

Figure 5.2 : ResNet50 Architecture

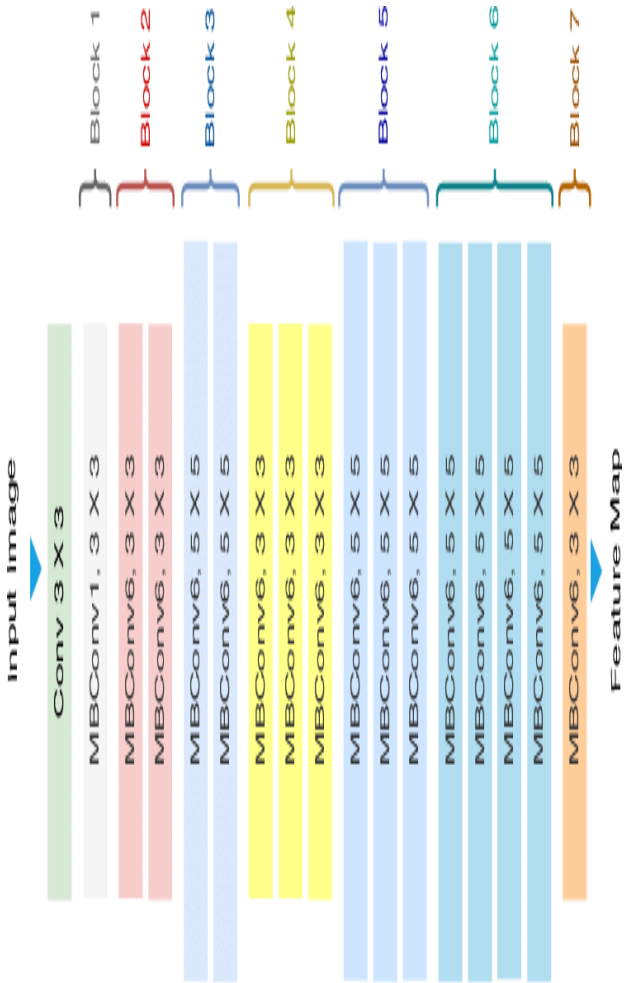


Figure 5.3 : EfficientNet Architecture

5.4 EfficientNet

Efficientnet is a CNN architecture and scaling method that uniformly scales all the dimensions of width, depth, and resolution using a compound coefficient. Before EfficientNet architecture is proposed, the most common way of improving the convolutional networks is scaling in one of the 3 dimensions i.e., the depth of the network, the width of the network, and the resolution of the image. But in EfficientNet, compound scaling is performed. This compound scaling takes care of balancing all the 3 dimensions of the network. Different scaling architectures are shown in Figure 5.3. There are several architectures ranging from EfficientNet-B0 to EfficientNet-B7.

Architecture	VGG16	ResNet50	InceptionV3	EfficientNet
Parameters (Millions)	14.7	23.5	21.8	64

Table 5.1: Number of parameters for each architecture

The number of parameters increases with each variant of the architecture. The base architecture EfficientNet-B0 contains 5.3 million parameters and EfficientNet-B7 contains 66M parameters. EfficientNet-B7 achieved state-of-the-art accuracy scores compared to other CNNs on ImageNet data as shown in fig. Compared to other CNN models, EfficientNet-B7 is lightweight and the accuracy score is high. In the present study, EfficientNet-B7 is used. Total number of parameters in each architecture is shown in the Table 5.1.

6 Testing and Validation

In this study for comparing the different architectures, "accuracy score" and FPS are considered performance metrics for evaluation. From the original data, 20% of the data is used for model testing. Test data is randomly selected from the original data ensuring the proper class distribution. Test data is augmented using the "ImageDataGenerator" utility from the Keras library. FPS is calculated using 10 unseen images. These unseen images are resized to 224*224 pixel size, preprocessed similar to the training dataset, and then fed to the trained CNN architecture. FPS for a single image is calculated by taking the average time taken for 10 unseen images.

.

In the first iteration (i1), a dropout ratio of 0.2 and a learning rate of 0.00005 with 20 epochs are chosen as parameters. The accuracy scores and FPS values are shown in Table 8.1. In the second iteration (i2), a dropout ratio of 0.2 and a learning rate of 0.0001 with 20 epochs are chosen as parameters. For this iteration, the accuracy scores and FPS are shown in Table 6.1

Architecture	Train (%)		Test (%)		Time (in sec for 10 Frames)		FPS (f/s)	
	i1	i2	i1	i2	i1	i2	i1	i2
VGG16	76	70	73	74	614	608	16	16
ResNet50	87	85	79	75	883	623	11	16
Inception	83	83	80	77	681	661	14	15
EfficientNetB7	86	88	74	66	1000	1004	10	9

Table 6.1: Accuracy and FPS for Iteration 1 and 2

Architecture	Train (%)		Test (%)		Time (in sec for 10 Frames)		FPS (f/s)	
	i3	i4	i3	i4	i3	i4	i3	i4
VGG16	74	68	75	70	70	618	16	16
ResNet50	86	85	78	78	78	655	15	15
Inception	81	82	78	78	78	691	14	14
EfficientNetB7	86	86	37	64	64	1009	9	9

Table 6.2: Accuracy and FPS for Iteration 3 and 4

In the third iteration (i3), a dropout ratio of 0.1 and a learning rate of 0.00005 with 20 epochs are chosen as parameters. The accuracy scores shown in Table 8.2.

In the fourth iteration (i4), a dropout ratio of 0.25 and a learning rate of 0.00005 with 20 epochs are chosen as parameters. The accuracy scores are shown in Table 6.2.

7 Analysis and Results

Various experiments were conducted by changing the hyperparameters such as learning rate, dropout ratio, and the number of epochs. Results from these experiments are noted and compared for all 4 architectures chosen.

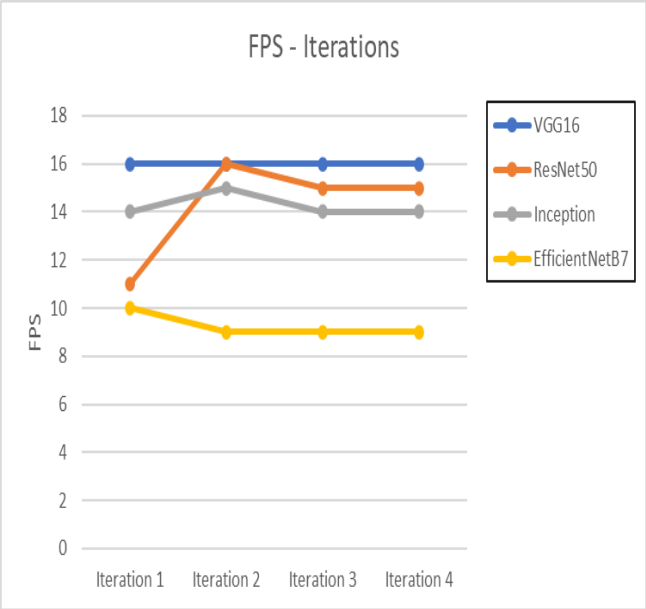
In first iteration, VGG16 network proved to give higher FPS due to less number of parameters, but the accuracy scores are less. Based on accuracy scores and FPS, Inception v3 architecture is giving better results in comparison to other architectures. With EfficientNet architecture, accuracy can be tuned and overfitting can be avoided, but the FPS value is lower than the industrial standards.

In second iteration, VGG16, ResNet50, and Inception v3 proved to deliver higher FPS scores. In terms of model accuracy, model overfitting and underfitting Inception v3 proved to deliver the best scores. EfficientNet model delivered a very low FPS

score and the model is overfitting for the DAWN dataset. Model training and testing accuracy score comparison is shown in Figure 6.1, 6.2. FPS comparison for all 4 iterations is shown in Figure 7.1.

Figure 7.1: Training set accuracy scores comparison

Figure 7.2: Test set accuracy scores comparison



In third iteration, VGG16, ResNet50, and Inception v3 proved to deliver higher and similar FPS scores. In terms of model accuracy, model overfitting and underfitting Inception v3 are proved to deliver the best scores.

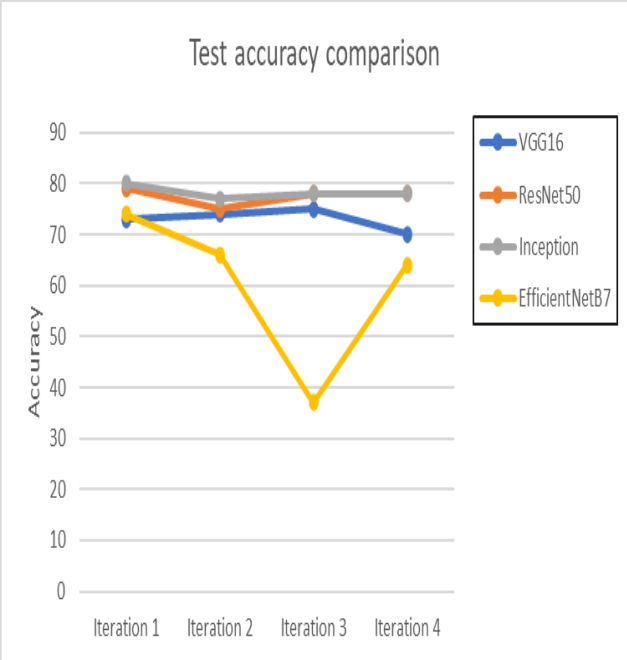
In fourth iteration, similar to the previous iterations, Inception v3 architecture delivered higher FPS and accuracy scores.

Figure 7.3: FPS comparison

8 Conclusion and Future scope

The above-discussed results are compared in terms of accuracy scores and also FPS values. In all 4 architectures, EfficientNet B7 with 64 million parameters is overfitting and delivered lower FPS for the DAWN dataset. VGG16 and ResNet50 architectures delivered higher FPS, but the model accuracy is low. Inception v3 architecture with

21.8 million parameters is proved to deliver higher accuracy scores and FPS. With the different experiments in this study, it can be concluded that inception v3 architecture with transfer learning technique is the best fit for deep learning architecture in comparison to VGG16, ResNet50, and EfficientNet B7.



The study can be extended by developing image restoration architectures under adverse weather conditions. As the DAWN dataset contains only 250 images per class, a new dataset with more images per class taken from the car dashboard cameras will help to achieve higher accuracy scores. Also, deep learning architectures in this study are limited to 4, and this study can be taken forward with more lightweight architectures for real-time edge devices.

Comprehensive Review of Lie Detection in Subject based Deceit Identification

Ms. Tanmayi Nagale, Dr. Anand Khandare
PhD Student, Thakur College of Engineering and Technology,
Associate professor,
Thakur college of Engineering and
tanmayinagale13@gmail.com, anand.khanadre@thakureducation.org2

Abstract— **Nowadays rate of crimes are increasing. Considering legal and security aspects, analysing deceit behaviour of human is an extremely vital issue. Various strategies have been developed in past to classify EEG data, deep belief nets are rarely used. Our work will propose the techniques to perform analysis on EFG data. First, apply a preprocessing technique to utilize only a small fragment of the EEG image instead of the whole image. The model describes a temporal feature map of the EEG signals measured during the lie detection test. The visual-temporal model of the proposed method shows that optimized balance between prediction accuracy and time efficiency. It will improve the performance by providing smaller size input data.**

Keywords— *deceit deception, subject based identification, Lie detection; EEG image; deep learning; machine learning.*

I. INTRODUCTION

Over the past few years, numerous deception detection tests have been created. One of them is the Concealed Information Test (CIT), which uses a series of questions to determine whether or not a subject is telling the truth. Both pertinent and irrelevant inquiries about crime are included in these queries. The inspected person's response is then noted. In earlier polygraph tests, the subject's bodily characteristics, such as heart rate, blood pressure, perspiration, etc., were recorded. The same is true because masculine motives can govern extrinsic behaviours. [1] New techniques have therefore been created to read brain signals and assess the conduct of guilty and innocent persons. The non-invasive method of electroencephalography (EEG) is used to collect brain signals for later analysis.

Event Related Potential (ERP) is created. When a subject respond to the stimuli, such as when lying, he or she must focus on the questions, which causes ERP. The P300 wave is the ERP that is produced when a subject is exposed to a meaningful or relevant stimulus. This wave is produced 300 milliseconds after the stimulus' start. The individual is exposed to three different types of stimuli: irrelevant, probe, and target. Target is the stimulus that is offered to both innocent and guilty subjects and is primarily concerned with keeping the subjects' attention. Test stimuli. [2]

The individual is exposed to three different types of stimuli: irrelevant, probe, and target. Target is the stimulus that is offered to both innocent and guilty subjects and is primarily concerned with keeping the subjects' attention. Only guilty subjects respond to the probe's crime-related stimuli, which causes a P300 response; the probe's irrelevant stimuli do not cause a P300 response. Significant research aimed at enhancing the interface between humans and robots has been published over the years. Bootstrapping is a statistical method for comparing how similarly different subjects' brains respond to the same stimuli.

[3].

The untruth seriously undermines the deceitful actions of numerous victims of fraud. The general populace frequently tells lies. Some limbs that automatically exhibit a distinct reaction when someone is lying can be used to uncover a lie.

II. RELATED WORK

Annushree Bablani, Damodar Reddy Edla, Diwakar Tripathi, Venkatanareshbabu K have proposed Empirical Mode Decomposition (EMD). Since polygraph tests for deception detection are regulated by humans, EEG-based lie detectors are gaining popularity these days. These devices examine any subject's covert behaviour using ERP EEG components. Empirical Mode Decomposition (EMD), which provides information about a signal's temporal and frequency domains, has been used in this paper to extract EEG features. The EEG data has also been subjected to a variety of classifiers to determine if the patient is guilty or innocent. On subject-specific EEG data, classifiers like SVM, QDA, KNN, and decision trees are utilised. With a variety of subjects, an innovative series of experiments is run to determine if the participants are telling the truth or lying. As part of an experiment, individuals are shown particular visuals as stimuli, and their reactions are recorded and subsequently examined. According to the results, SVM outperformed other methods on the recorded EEG dataset for the majority of the participants. [1]

Abootalebi, Moradi, and Khalilzadeh have designed approach for eeg feature extraction in p300-based lie

detection. It has been proposed to use the P300-based Guilty Knowledge Test (GKT) as an alternative to traditional polygraphy. The goal of this study was to improve a pattern recognition technique that has already been used for this application's ERP assessment. This enhancement was accomplished by both expanding the feature set further and using a mechanism for choosing the best features. Several volunteers completed the planned GKT paradigm, and their corresponding brain signals were captured as part of the method's evaluation. The P300 detection method was then put into practise using a few characteristics and a statistical classifier. From a primary feature set that included some morphological, frequency, and wavelet properties, the best feature set was chosen using a genetic algorithm and utilised to classify the data. 86% of guilty and innocent subjects were correctly identified, which was a higher rate than other previously employed techniques.

Arasteh, Moradi, and Janghorbani have proposed a novel method on empirical mode decomposition for P300-Based detection of deception. They are using alternatives for conventional polygraphy such P300based guilty knowledge test. EMD technique is used to extract features from EFG signal. Features are extracted from Pz channel for synergistic incorporation of channel information. Using genetic algorithm features are selected and this is challenging for input space dimension increase. Using this approach, accuracy of guilty and innocent subjects was 92.73 %.
[3]

Annushree Bablani, Damodar Reddy Edla, Venkatanareshbabu Kuppili have proposed deep learning technique using the restricted Boltzmann machine with wavelet to obtain the time and frequency domain information of signals. Stacking four RBMs results in the development of a deep belief network. At the output layer, softmax regression is used to categorise EEG data into guilty and innocent. By carrying out a "Concealed Information Test," an experiment has been carried out on EEG data that was captured. In the test, subjects are shown some important and irrelevant photographs as part of a simulated crime scene. After flashing these visuals, the
EEG signals produced are captured and examined. [4]

Junfeng Gao, Lingyun Gu, Xiangde Min, Pan Lin have proposed a method for analysing the underlying cognitive process and mechanism in deception. They are using the guilty knowledge test protocol for categorising guilty and innocent group of people. They have taken randomly 30 subjects for identifying the subjects based on functional connectivity patterns. Authors has proposed FTRPS technique to avoid false synchronization. The results show that four intuitive brain fingerprinting graphs (BFG) on delta, theta, alpha and beta bands were generated. Deception behaviour is identified with FTRPS technique in real application.
[5]

Andrew Chadwick and James Stanyer have proposed a method for enhancing the study of information, disinformation and misperceptions. Research that acknowledges the existence of erroneous and misleading information but stops short of describing their influence will benefit from an emphasis on deception. Additionally, by concentrating on how actors' deceptive tactics are crucial in their attempts to wield authority, it helps advance research on the cognitive and attitudinal biases that make people prone to error in perception. We outline the key concepts in the study of deception: media-systemic informational distortions; relational interactions that both create and activate cognitive biases; and the characteristics, tactics, and strategies of deceitful entities. The summary typology of the 10 primary factors and their
57 focal indicators serves as their conclusion [6]

Annushree Bablani, Damodar Reddy Edla, Venkatanareshbabu K, Shubham dedia have proposed novel Deceit Identification Test based on the Electroencephalogram signals to identify and analyze the human behaviour. This test is done with the help of P300 signals. It helps to get results in term of good classification accuracy using P300 signals. Using “symlet” Wavelet Packet Transform (WPT) technique, features can be extracted. EFG signals are recorded and analysed using BrainVision recorder and analyser. At the end they got 95% accuracy. [7]

Jennifer Tehan Stanley, Britney A, Webster have write review paper on deceit deception. They compared the efficacy of two training techniques to help older persons become more adept at spotting deception: valid face clues to deception and valid verbal cues to deception. 150 senior citizens were randomly assigned to a control condition, verbal training, or facial training. The participants finished their allocated training, a pre-test deceit detection task, and a post-test deceit detection task. Following training, both training groups greatly improved at identifying their respective trained cues. The control group showed increased deceit detection accuracy from pre-test to post-test while the facial cue training group showed decreased deceit detection accuracy post-test compared to pretest. These findings are in line with the body of deception research that indicates people still operate at about chance accuracy even after training. Training can enhance older persons' ability to recognise facial and verbal cues, but these enhancements did not lead to more accurate deception detection and even hindered performance in the facial condition. Perhaps because this condition encouraged implicit rather than explicit assessments of dishonesty, older persons demonstrated the greatest advantage from simple practise at detecting
deception (in the control condition). [8]

Abeer Abdulaziz AlArfaj and Hanan Ahmed Hosni Mahmoud have proposed a model that describes an analysis of the temporal features of the EEG data obtained during the lie detector test. During the learning phase, a deep learning attention model (VTAM) retrieves the temporal map vector. Through the use of this method, overfitting in Deep Learning architectures is lessened and computation time is decreased. We

provide a deep learning convolutional neural network-based model of cascading attention (CNN). Local and global features are extracted by the V-TAM model via distinct spatial and temporal routes. In addition, a novel Visual-Temporal Attention Model (V-TAM) is suggested to improve the EEG segmentation accuracy. [9]

D. Barsever and E. Neftci have proposed BERT's classification to develop examples of misleading and true writing that further illustrated the distinctions between the two, highlighting the fundamental similarities of deceptive text in terms of the part-ofspeech composition. Knowing how to spot lies or misleading statements in text is an important ability. This is partially due to the lack of knowledge surrounding the patterns underlying deceptive writing. The purpose of this research is to find patterns that describe misleading text. Training a classifier using the BERT (Bidirectional Encoder Representations from Transformers) network is an important step in this method. On the Ott Deceptive Opinion Spam corpus, BERT outperforms the state-of-the-art in terms of deception classification accuracy. [10]

Respatyadi Hari Nugroho; Muhammad Nasrun; Casi Setianingsih have proposed a method for lie detection. Every person is unique in their characteristics and habits. There are many persons in our world who frequently tell lies. The falsehood must create comprehension in other people, but the understanding it creates is incorrect. Pupils can be a good indicator of whether a person is lying or not since, in accordance with psychological science, dilated pupils are a sign of depression, which includes lying. The frequency of eye blinks might also be a clue as to whether or not someone is lying. By employing the circular hough transform method to observe changes in the dilated pupil and the frame difference approach to count the number of blinks, accuracy is reached. According to the study, a person who lies will have their pupils dilated by 4% to 8% of their initial diameter and will blink their eyes more frequently—up to 8 times—than they did before the question was posed. The lie detector system's accuracy in this study is 84%. [11]

Hannah Shaw & Minna Lyons have proposed a method for accuracy of deception detection has been the subject of conflicting results in the literature, and the majority of experiments have relied on small-scale lying. It's not yet apparent whether being aware of these indicators actually helps people detect lies, despite recent studies suggesting that high-stakes scenarios can provide reliable cues to dishonesty. Prior to seeing the film, participants were randomly assigned to either the cue condition (where they were shown previously recognised cues to deceit) or the no cue condition (where they were told to rely only on their gut feelings). Participants were asked if they were familiar with the case, whether they believed the appealer was telling the truth or lying, and how sure they were in their judgement. Participants recorded qualitative comments on the cues they employed during lie detection at the conclusion of the experiment. There was a positive correlation between accuracy and age, despite the fact that cue knowledge and confidence did not significantly predict accuracy scores. The ability to spot deception was dramatically improved among those who used emotion-based clues.
The findings are examined in light of the existence of trustworthy cues. [12]

Sinead v. Fernandes and Muhammad s. Ullah have proposed Levenberg-Marquardt classification method and the long short-term memory classification method. Based on the nine different training and testing combinations from the three separate sessions and their derived cestrum and spectral energy features, to assess the efficacy of deception detection. To lower the dimensionality of the retrieved features for further optimization, the principal component analysis is used. The four types of characteristics' projected main components exhibited increased precision in their ability to discern between honest and dishonest speech patterns. [13]

Z. Labibah, M. Nasrun, and C. Setianingsih have proposed lie detection method. The eyes are used to identify lies in this final task, specifically eye tracking and changes in pupil size using the Wavelet Transform to Gabor Image Processing technique, followed by classification to assess whether or not someone is lying using a Decision Tree. It is anticipated that having access to this lie detector will be beneficial for those who need to spot lying. The last test's outcomes are precise. The precision, recall, and accuracy values for this study are 97%, 94%, and 95% respectively. [14]

Y. Xie, R. Liang, H. Tao, Y. Zhu, and L. Zhao have designed convolutional bidirectional long short-term memory for deception detection. To maintain the temporal information in the original voice, the method extracts frame-level acoustic features whose dimension dynamically vary with the length of speech. To learn the context dependences in speech, bidirectional LSTM was performed to match temporal features with changing dimension. Additionally, in the conventional LSTM, which is used to extract time-frequency mixed data, the convolution operation takes the place of multiplication. The experiment's average accuracy on the Columbia-SRI-Colorado corpus is 70.3%, which is higher than it was in earlier works using noncontacting modalities. [15]

Jun-Teng Yang, Guei-Ming Liu, Scott C.-H. Huang have proposed several data preparation techniques for contaminated data and useless frames in the ground truth data. Visual and aural modality information can be extracted using a multimodal deception detection system. To analyse deception detection tasks, they present a novel emotional state-based feature called the EST feature. The change in emotional state in frames and audio segments is represented spatially and temporally by the EST feature. The video's deception detection accuracy and ROC-AUC are increased to

92.78% and 0.9265, respectively. [16]

Harun Bingol and Bilal Alatas have proposed methodology for detecting deceptive contents in social networks using text mining and machine learning algorithms is proposed, and the problem of deception detection in online social networks is modelled as a classification problem. This approach performs text mining operations and transforms unstructured data sets into structured data sets because the content is text-based. The structured data sets are then subjected to customised applications of supervised machine learning algorithms. The structured data sets are then subjected to customised applications of supervised machine learning algorithms. This study compares a variety of algorithms using real public data sets, including Support Vector Machine, k-Nearest Neighbor (k-NN), Naive Bayes (NB), Random Forest, Decision Trees, Gradient Boosted Trees (GBT), and Logistic Regression. The GBT algorithm produced the highest average accuracy value in Dataset 1, at 74.4%, while the NB algorithm produced the highest average accuracy value in Dataset 2, at 71.2%. [17].

Junfeng Gao, Xiangde Min, Qianruo Kang have proposed investigated the most significant information flows (MIIFs) that occur during deception among several brain cortices. First, the guilty knowledge test protocol was used, and electroencephalogram (EEG) signals from 30 subjects were recorded on 64 electrodes (15 guilty and 15 innocent). On the 24 regions of interest, cortical current density waveforms were then estimated (ROIs). After that, the cortical waveforms were subjected to a partial directed coherence (PDC) analysis and an effective connectivity (EC) analysis to determine the brain's EC networks for the four bands of delta (1-4 Hz), theta (4-8 Hz), alpha (8-13 Hz), and beta (13–30 Hz). The network parameters in the EC network with significant differences were extracted as features to distinguish the two groups using the graph theoretical analysis. The four bands' high classification accuracy showed that the suggested method was appropriate for lie detection. The "hub" regions of the brain were also identified based on the classification mode's best features, and the MIIFs between the guilty and innocent groups differed significantly. Furthermore, among all MIIFs at the four bands, the fronto-parietal network was discovered to be the most dominant. The roles of all MIIFs were further examined by combining the neurophysiology significance of the four frequency bands, which may aid in elucidating the underlying cognitive processes and mechanisms of deception. [18]

According to Merylin Monaro, Stephanie Maldera research, facial micro expressions can be used to reliably spot deception. Microexpressions are recognised using machine learning (ML) techniques, which have been trained to discern between truthful and dishonest claims. More encouraging outcomes recently emerged from the artificial intelligence (AI) discipline, where machine learning (ML) techniques are utilised to recognise microexpressions and are trained to differentiate between truthful and dishonest comments. It demonstrates that artificial intelligence outperforms humans at lie detection tasks, even when people have access to more data. The best performing approach was demonstrated by the results, which showed that support vector machines (SVMs) and OpenFace were responsible (AUC = 0.72 for videos without cognitive load; AUC = 0.78 for videos with cognitive burden). All of the evaluated classifiers performed better when the interviewee was subjected to an increased cognitive burden, demonstrating that this technique makes it easier to detect deceit. Human judges achieved an accuracy of 57% in the identical
task. [19]

Nidhi Srivastava, Sipi Dubey have propsed strategies for questioning. It is used in lie detection, also known as deception detection, to determine truth and untruth in responses. In this essay, truth and falsehood are determined using physical characteristics and voice traits. The linear detector model is modelled using the Mel Frequency Cepstrum Coefficient, Energy, Zero Crossing Rate, Fundamental Frequency, frame function of speech signal, and physiological parameters like heart rate, blood pressure, and respiration rate. Support vector machines and artificial neural networks are used to validate the outcomes. [20]

III. METHODOLOGY

Bablani A. has used the concept of Deep Belief Network using Restricted Boltzmann Machine.
Following test will be performed on EFG data.

1) Pre-processing is performed on raw EFG data.
2) Wavelet transformation is applied on Concealed Information Test (CIT)

At the end result with 4 RBM will be found. [1]

Different classifiers are used for feature extraction and accuracy is calculated.

Table 1: Different Classifiers used for features extraction

Classifiers	**Feature extraction**	**Data Set**	**Channel**	**Accuracy**
QDA	Various (Power, wavelet, Hjorth parameter, etc)	Emotion dataset	64	35.9
LDA	EMD	CIT Datasets	3 channels (Cz, Fz, Pz)	80.0
FDBN	Wavelet Transform	Motor Imagery	3 channels (C3, Cz, C4)	75.0
Deep Belief Network	Wavelet Transform	CIT Data	16	81.03

R. Nugroho; M. Nasrun has designed fuzzy logic algorithm for lie detection There are some sample questions to be asked to subjects. Based on answers given by subjects, lie detection test can be decided

whether the person is telling truth or not. According to survey they are asking the following question

1. You study at Telkom University, is that your choice or your parents
2. You enter Telkom University, is your choice or as a backup? Why?
3. Do you still have love for your ex-boyfriend or girlfriend?

Comprehensive review of lie detection in Subject based Deceit Identification

4. Are you currently confident when dealing with someone you like?
5. What do you with your current body size that is bigger than before?

Based on above question, response will be taken from set of respondent in terms of Eye movement, recognition of respondent. Eve movement can be right and left. Algorithm will capture eve movement and calculate enlargement of pupil and they will recognize whether the person is telling truth or not.

Taufiq Ari Wibowo, Muhammad Nasrun, C. Setianingsih [11] have done processing on training dataset. Eyes can detect someone is lying or not. They get following observation on datasets. They are checking for enlargement of pupils. If it is greater than 8 then person is honest otherwise telling lie. The following table shows results based on 2 respondents.

Table 2: Observations based on datasets

Sr. No	File Name	Early Pupils	Average Pupil	Pupil Enlargement	Total Blinks	Respondent
1	Respondent 1	2.65	3.25	0.6	28	Honest
2	Respondent 2	2.12	3.32	1.2	7	Lie

S. V. Fernandes, M. S. Ullah [13] have given comparison of different features classification method resulting with Recognition time. He invented their own classification methods such as Levenberg-Marquardt and LSTM. This algorithm extracts the features such as Time Difference Enery, Delta Energy, Time Difference Cepstrum, Delta Cepstrum. By using this algorithm during their experiments, and they repeatedly trained and evaluated it using LSTM and Levenberg-
Marquardt. The time-difference energy feature yielded the identical results (i.e. 100%) each time it was run. Overfitting might have happened as a result of the amount of the data used. The recognition rate, however, can alter from 100% if we increase the size of the corpus for additional study and verification of the test results of our suggested extracted feature using the same procedure and the classifier methods. Levenberg-Marquardt and LSTM methods are used for high accuracy and speed for feed-forward neural networks.

IV. PROPOSED WORK

The following are the key objectives should be considered during my work.

1) To design enhanced classification algorithm for the subjects such as target, irrelevant and probe using lie deception.

2) To design enhanced classification algorithm for EFG data recorded for lie detection based on innocent and guilty

3) To design enhanced classification algorithm to categorise the gender for predicting deception, predicting lie for females and truth for males. 4) To design enhanced classification algorithm for Lie Detector with Analysis Pupil Dilation and Eye Blinks Analysis.

5) To design a series of data collection mechanisms for extending the diversity of data for the deception detection tasks.

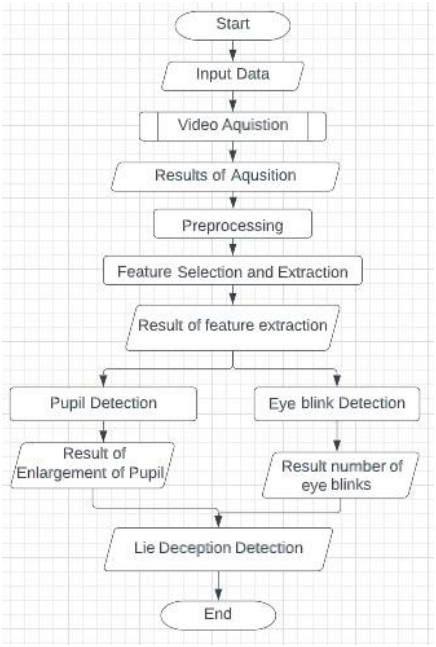

Fig: Process of Deception Detection

V. CONCLUSION

The lie is very detrimental to the fraudulent acts of many people who were cheated. The lies are common in the general population. To be able to reveal a lie we can detect through some limbs that unconsciously will show a different reaction when someone is lying. Among them, through organs of our eyes can detect someone is lying or not.

Abstract—**In order to achieve the necessary security guarantee, intrusion detection systems (IDSs) play a vital role in all networks and information systems worldwide. One of the best ways to prevent malicious assaults is to use an ID. In order to keep up with attacker's constant evolution of attack strategies and discovery of new attack vectors, IDS must likewise advance by implementing more advanced detection techniques. New research in the deep learning sector, including intrusion detection, has been made possible by the enormous rise in data as well as the considerable advancements in computer hardware technology. Machine learning (ML) techniques that are adapted on data learning representations include deep learning as a subfield. In this survey, we will examine 25 research papers about machine learning techniques and linked to detection models for intrusion detection, highlighting the numerous drawbacks of the current methodologies. This case shows different way to explore the journals, publication years, metrics, achievements of numerical evaluation techniques, and a number of variables support other factors. On the other hand, a technique analysis that considers the benefits and drawbacks of the methods is also presented. When upcoming projects and refine the sentiment analysis accuracy is estimate as more difficult for this paper. The relative assessment of the methodologies provides a thorough clarification of the research's motivation.**

Keywords— **Machine learning, Intrusion detection, journals, motivation, malicious attacks**

I. INTRODUCTION

Due to the information technology industry's rapid growth over the past decade, security is now one of the highest priorities for practically all organizations and businesses. Security systems must be able to handle a variety of threats since intruders are always trying to access network traffic [1][2]. The secured data transmits through an internet is not the easiest task. It has always been challenging to send secure data over a network [3]. The security of network traffic is becoming more crucial in particular situations, such as banking transactions, communications related to the military, and traffic on networks used by the government. In order to safeguard a network from malicious attacks, having a secure network monitoring and detection system that can quickly spot different types of attacks is crucial [4][5]. Fire-walls are designed to safeguard networks; however they cannot immediately identify intruders. Destructive cyber attacks
consequently present serious security challenges, making it necessary for adaptable and trustworthy IDS that can monitor malicious activity, policy violations, and illegal access. ML algorithms can be used to detect intrusions more effectively since they are capable of identifying patterns using statistical modeling based on past data [6].Intrusion detection is used to recognize all attack as positive and all fakers as negatively [7]. The requirements for the IDS policy are provided by the IDS goals. Potential objectives include [8] [5] gathering evidence [9][10], detecting attacks, preventing attacks, detecting policy violations, enforcing usage policies, enforcing connection policies, and detecting policy violations. There are five different classifications of IDS, including Network IDS, Host IDS, Protocol-adapted IDS, Application Protocol- adapted IDS, and Hybrid IDS. Network- adapted IDS can identify malicious network traffic. NIDS often need open access to the network to evaluate all data, including network traffic. Because they are passive, NIDS don't disrupt the traffic they are monitoring [11]. An intrusion detection system known as host-based IDS keeps track on the computer infrastructure on which it is placed, analyzing traffic and logging malicious behavior. PIDS, which is frequently installed on a web server, is used for the monitoring and analysis of the protocol utilized by the computing system [12]. An IDS that bases it's monitoring and analysis on a specific application or group of protocols utilized by the computer system is referred to as an application protocolbased IDS. A hybrid IDS is developed by combining more IDS methods. Hybrid IDS is combining the system data and network data in support of the view of network system [13]. In comparison to other IDS, hybrid IDS are more effective. There are two main classifications for intrusion detection systems such as behavior and signature-based IDS. The realtime behavior of the system is compared to known protection attacks via signature-based IDS [14][15]. Signature IDS are unable to identify unidentified attacks [6]. Given that CPS operates automatic for extended certain period of time and are thus challenging to interrupt for patching or updating in the field, this is critically crucial. In contrast, behavior-based systems are capable of spotting both known and unidentified attacks by monitoring a dynamic execution to detect suspicious performance [16]. Creating effective and adaptable IDS for unidentified future assaults has basically two issues. The

challenging task for anomaly detection is selecting correct features from the traffic dataset. Because of changing the evolving attack circumstances, the features chosen for one class of attack might not be suitable for another. Second, there is no labeled traffic dataset from actual networks available for IDS development [17] [18]. The development of anomaly detection-based IDS has made use of a variety of machine learning approaches [19]. To distinguish between regular traffic and anomalous traffic, IDSs are developed as classifiers. The difficulties of creating an effective IDS can be overcome with the aid of deep learning-based techniques [20]][21].

II. LITERATURE REVIEW

A. Intrusion detection based on deep neural network

A hybrid system for ID known as the sparse auto encoderdeep neural network was developed by K. Narayana Rao et al (SAE-DNN). The model developed a compressed method for extracting features based on sparsity regularization of the weights using three datasets, and it had the highest detection rate. Secure data transfer over networks has become a difficult undertaking as a result of the Internet's phenomenal growth in usage. In order to train deep neural networks for accurate network intrusion detection, Aqsa Saeed Qureshi et al. [5] used a DNN and an adaptive based transfer learning technique. Despite changing the network that has been taught to do tasks linked to regression, this strategy produced better results. Using a deep neural network (DNN) machine learning (ML) method, Sharuka Promodya Thirimanne et al. [6] described the technical aspects of a real time IDS. This technique recorded live network traffic and located malicious intrusions. The technique was hosted on a web server that made it possible for private and public sector networks to use it on their networks using an application programming interface for representational state transfer. The technique proved very useful for quickly identifying intrusions by examining inbound and outgoing network traffic. Je-Won Kang and Min-Joo Kang [22] created a powerful IDS adapted on a DNN for the security network. The parameter used to train of DNN involving some methods such as pre-training method of deep belief networks, the traditional stochastic gradient descent method which can pursue the in-vehicle network packets derivative through the probability-based feature vectors. The computational complexity was lowered by this technique.

B. Intrusion detection based on Recurrent Neural Networks

Modern malware, from planned botnets to more straight forward polymorphic worms, threatens the information transferred over the internet. RNNs were used in ID, which was developed by Soroush M. Sohi et al. [2] to uncover complicated model in attacks and create the similar ones. The usage of RNNs in this process helps to increase the intrusion detection rate by producing previously undiscovered attack variants and synthetic signatures from the most sophisticated malware. The key benefit of this strategy is that it is not dependent on a protocol or server data.

C. Intrusion detection based on Reinforcement learning

Due to the increasing number of numerous innovative attacks and varied network applications, developing effective IDS is a difficult challenge. In order to address these problems, Kamalakanta Sethi et al. [8] devised a revolutionary deep reinforcement learning-adapted IDS that made use of attention mechanisms and Deep Network logic in a number of scattered agents. The technique successfully identified and categorizes sophisticated network attacks. The distributed attack detection platform known as the multi-agent IDS was created with the goal of providing a security driven system, fault tolerant and scalable systems. This model produced greater accuracy while enhancing robustness. A approach that is strengthened by clustering and reinforcement learning was presented by Tripti Sharma et al. [23]. Clustering-based techniques have been widely utilized to create energyefficient protocols. Previously, it was believed that reinforcement learning was a set of algorithms drawn from animal behavior's operant conditioning. By using this technique, sensor node energy loss was decreased and power consumption efficiency was raised. The protocol ensures that the sensor network has a longer lifespan and reduces the energy consumption of sensor nodes.

D. Intrusion detection based on machine learning

System administrators can find network security problems in their businesses with the help of a Network IDS. However, there are numerous obstacles to overcome when creating a versatile and effective NIDS for unanticipated and unpredictable attacks. Quamar Niyaz et al. [21] created a deep learning-adapted method for creating such an efficient and adaptable NIDS to meet these problems. This method produced significantly lower false alarm rates and very high accuracy. K.G. Mukesh et al. [24] created IDS employing optimization and machine learning algorithms that successfully detected the invaders. In order to extract the traits that decreased the computational cost, a genetic algorithm (GA) was applied. In order to identify intruders in mobile ad hoc networks, Support Vector Machine (SVM) was used. Due to their high generalize ability and capacity to resolve dimensionality difficulties; SVM was the most widely used technique for anomaly intrusion detection. By simultaneously learning tiny training samples, traditional MLadapted ID approaches frequently produce prediction models. This approach is not always appropriate since industrial control systems must process regulated commands continuously while operating with limited computational resources. Guangxia Li et al. [25] designed an online learning technique that assisted in learning the prediction models from the data stream. The class-imbalance issue that plagues industrial intrusion detection systems was resolved by this approach. Initiating a self-recovery of a Virtual Machine under assault, Linda Joseph and Rajeswari Mukesh [26] used machine learning techniques to categories and recognize the attacks in various infection scenarios. Using the metasploit penetration tool, some files were mixed in among the malware-infected files as innocent, straightforward.exe files.

The API calls features were taken from the snapshot delta file samples and input for the SVM, naive bayes, and random forests algorithms. This technique speeds up performance and actually reduces on recovery time.

Fewer DL adapted ID preventing system suitable for IoT contexts are available. In recent years, many DL-based models for IDPS have been presented. A comparison between particular deep auto encoding models and traditional IDS and NIDS datasets was developed by Sirajuddin Qureshi et al. [27]. This technique had a high accuracy rate. The retrieval of linked devices has gradually

more important in current years due to the merging of standard networking equipment with a variety of IoT devices. Because there are so many different types of existing and developing connected devices, efficient and accurate categorization and type identification represent a very challenging task. Considering this issue, Fatima Zahra Fagroud et al. [28] evaluated the outcomes of feature selection in ML for effective connected devices for the precise categorization and identification of attacks. In terms of categorization, this approach delivered great performance and high accuracy. A ML-adapted model for identifying DDoS in IoT was created by Gafarou O. Coli et al. [9] while taking into account its unique characteristics. A DBM was used to create the initial deep learning-based model because of its capacity to handle data in real time, which is frequent in the IoT network, and its ability to learn high-level features from input using an unsupervised approach. This technique performed well in terms of recall and accuracy then they extracted high-level characteristics.

E. ID based on convolutional neural network

Shayan Taheri et al. [29] developed an ML-based botnet detection engine for usage in the IoT and wearable devices. Before being fed into the DenseNet deep CNN with or without taking transfer learning into account, the system converts the normal and botnet traffic data into images. This technique delivered better results. The self-management characteristics were described in the context of autonomous cloud computing by Sukhpal Singh Gill et al. [30]. The solution performs better in terms of security attack, resource contention, service agreement violations, execution time and cost.

F. Others

Sukhpal Singh Gill and Rajkumar Buyya [31] discussed the self-management of Cloud resources for the execution of clustering workloads, and it has the potential to operate automatically without human interaction. With no consideration for execution time, this strategy increased performance and decreased resource execution costs. A novel method of identifying attacks on Software Defined Networks (SDNs) was introduced by Ahmed AlErouda and Izzat Alsmadib [32]. It makes advantage of parallels with recent attacks that target networks, uses an inference technique to prevent negatives and false positives during the prediction process, and uses aggregation package to provide attack signatures that can be used to anticipate attacks on SDNs. When more non-Open Flow are utilized for guidance, the attack detection rate increases since this method detected different types of attacks on SDNs.

III. ANALYSIS BASED ON LITERATURE REVIEW

In this section, the detection model for machine learningbased intrusion detection is examined. The analysis based on the parameter measurements employed, dataset made available, software, publication year, and published journals are examined in the sections below.

A. Analysis based on metrics

The analysis is conducted through the parameter measurements that have been employed by numerous academics to demonstrate the model efficiency. Accuracy, precision, recall, f1 measure, Receiver operating characteristic (ROC), Area under curve (AUC), False positive rate (FPR), False negative rate (FNR), Positive predictive value (PPV), Negative predictive value (NPV), and other measures are noticed. According to the observations, researchers regularly use the metrics accuracy, precision, recall, and f1 measure, and they also frequently use the metrics sensitivity, as shown in table 1. The metrics used by the reviewers are interpreted in Figure 1.

Metrics	Papers
Sensitivity	[2][8][5][6][22][21][33][32][25][29][27][9]
Specificity	[2][18][5][25]
PPV	[2][18]

IV. RESEARCH GAP AND CHALLENGES

- Sub-network and gateway routers are impenetrable. Because routers have fewer potentially vulnerable services than hosts, it is frequently difficult to corrupt them [18].
- The Q-learning RL algorithm trains the agent the optimal action to take as it moves from one state to another. An estimated reward is measured iteratively in Q-learning and tabulated for each state and each feasible action inside that state. As the number of states and actions increases, the table will grow in size, making it difficult for us to keep and update the table [8].
- Deploying appropriate adversarial mitigation measures is crucial but difficult because it is frequently very difficult to detect and fix adversarial assaults [36].
- An occurrence in a labeled intrusion detection dataset may be classified as normal or intrusive. A trained model can automatically identify invasive instances by utilizing machine learning algorithms. Zero-day attacks, however, are challenging for signature-based IDS to identify [5].
- In order to reduce security attacks in Mobile Ad Hoc Networks (MANET), IDS techniques have been proposed. These techniques help to attain accurate results of attack detection. Although, it doesn't have the high speed of detection. MANET faced some difficulties obtained as a result of security threats like packet delivery and ratio energy consumption.
- Several issues were increase in the design of IDPS in MANET, including the inability to detect routing attacks with a high alarm rate, the impossibility to scale and implement in real-time, the inadequacy of the collection of current evidence, the inability to be message loss tolerant, the high message and computation overheads, and the lack of automatic and real-time routing recovery [34].
- Each client would be installed at a different company in a real-world scenario, creating the network connection between them more difficult [35].

V. CONCLUSION

All networks and information systems throughout the world depend on intrusion detection systems (IDSs) to provide the necessary security guarantee. One method used to lessen harmful attacks is an ID. As attackers constantly adapt their attack strategies and discover new attack vectors, IDS must also advance by implementing more complex detection mechanisms. New studies in the deep learning sector, including intrusion detection, are now available as a result of the enormous rise in data and the major improvements in computer hardware technology. To have a deeper understanding of the intrusion detection techniques available, the articles are carefully examined. The thorough analysis of the methodologies opens the path for future improvements in intrusion detection, and in the future, more publications relevant to intrusion detection may be studied in organize to develop new, more effective detection methods.

Study of NLP applications in software engineering

Veena Kulkarni,Dr.Anand Khandare
Computer Engineering
TCET,Mumbai, India
veena.kulkarni@thakureducation.org, anand.khamdare@thakureducation.org

Abstract—**NLP (Natural language processing has wide range of application and is used to identify semantics from natural languages. Software engineering is the field in which the process of software development is considered. There are various challenges in Software engineering which can be solved by using NLP and machine learning. This paper follows the various processes in software engineering product building and identifies the various documents, case studies generated during each phase. Then a study is done to identify how Natural language processing and software engineering can be combined and can be applied to the documents generated for partial or fully automation of the process. There are various tools which are capable of generating code from class diagram, generating UML diagrams from requirement specification and tools which can be used for bug severity and prediction. There has been use of machine learning algorithms e.g. supervised along with NLP.**

Keywords— ***NLP, SE, NLP assisted software testing, bug triage, requirement engineering,***

I. NATURAL LANGUAGE PROCESSING

Natural language processing is a field of Artificial intelligence that makes machine understand human language. It focuses on the interaction between human language and computers. NLP involves the use of algorithms and statistical models to analyze, understand, and generate human language.NLP has a wide range of applications, including machine translation, sentiment analysis, text classification, information retrieval, and speech recognition. The common examples of NLP in everyday life include virtual assistants like Siri and Alexa, translators e.g Google translator, search engines e.g auto suggestion, to correct the grammar using Gramerly spam filters in email services, and language translation tools. NLP is a rapidly developing field with many exciting opportunities for research and application. NLP can be used in various fields like fake news detection, video label identification, machine or language translation, Model to model transformation in software engineering, speech recognition etc.

II APPLICATIONS OF NLP IN SOFTWARE ENGINEERING

Software engineering is field that encompasses the process of software requirement identification and development. NLP can be applied in the phases of software engineering. There are various documents generated during the phases of software engineering,

1. Requirement specifications
2. DFD, UML diagrams
3. Code
4. Test cases, test scripts, documents related to bugs generated
5. Documentation

The various phases of software engineering are as given below

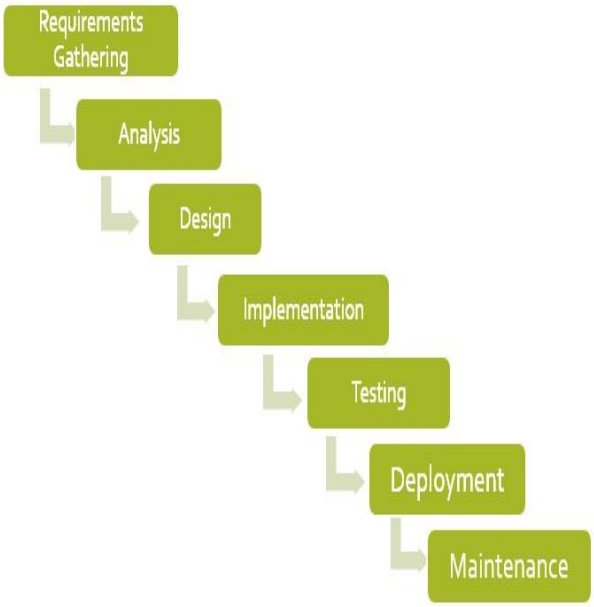

Figure 1: Phases of Software engineering

During each phase, Natural language processing can be applied

1. Requirements Engineering:this is the first phase of SDLC, where the customer gives their requirements, which are documented into business specifications. Natural language processing can be used to extract information from natural language requirements or business specification documents, such as user stories, use cases, and requirements specifications [1]. NLP algorithms can identify the key concepts and requirements from the text, and map them to specific system features and functions. This involves using techniques such as named entity recognition, part-of-speech tagging, and semantic parsing to identify key concepts, entities, and relationships.

It can be used to analyze stakeholder feedback and customer support requests to identify common issues and user requirements. By analyzing the language used in customer

feedback and support requests, NLP algorithms can help to identify patterns and trends that can be used to improve the system's functionality and user experience.
NLP can be used to identify inconsistencies, ambiguities, and contradictions in the requirements documentation. By analyzing the language used in the requirements documents, NLP algorithms can help to identify conflicts and inconsistencies that can be addressed before the system is developed.
NLP can be used to generate test cases from natural language requirements documents. By analyzing the language used in the requirements, NLP algorithms can help to generate test cases that cover all the requirements and ensure that the system meets the user's needs.

Sentiment Analysis: NLP can be used to analyze the sentiment of stakeholders towards different features and requirements of the system. This can help to identify areas where there are conflicts or differences in opinion.

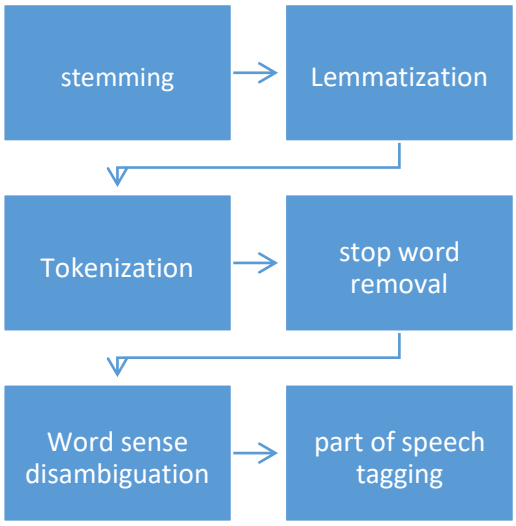

Figure 2: Steps of NLP

Summarization: NLP can be used to summarize large requirements documents, making it easier for stakeholders to understand the key features and functionality of the system.
Summarization is of two types abstractive and extractive [2]

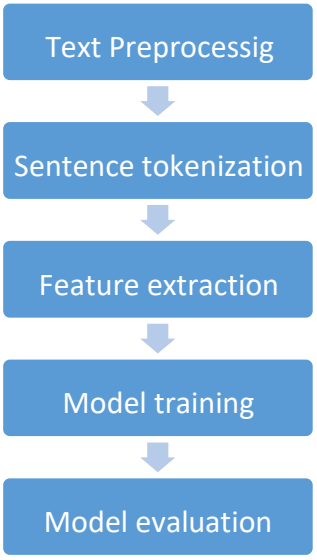

Figure 3: Steps of Summarization

Requirements Generation: NLP can be used to automatically generate requirements based on natural language inputs from stakeholders. This involves using techniques such as sentiment analysis, chatbots, entity recognition etc.

Requirements Prioritization: some requirements can be of high priority based on the time to market and their importance to the stakeholders NLP can be used to prioritize requirements This involves using techniques such as classifying the data as customer feedback, user stories, topic modeling and clustering to identify related requirements, and then using machine learning algorithms to assign priorities based on stakeholder feedback. e.g. EMR data, bug
/requirements prioritization. [4]

2. NLP in design process
NLP can be used in design to improve the efficiency and accuracy of the design process, and to ensure that the final product meets the user's needs and expectations. The requirements can be often complex, ambiguous, uncertain, incomplete, inconsistent, and incoherent. [3] It can be used to generate natural language descriptions of the product's features and functions. NLP can be used to generate the UML designs from the requirement documents, user stories etc. tools have been generated that are used to capture software requirements, and then the analysts analyze and generate the UML diagrams such as class, use case diagrams etc. it can be used to analyze the software designs and identify potential issues, such as usability problems, security vulnerabilities, or compatibility issues with other software.

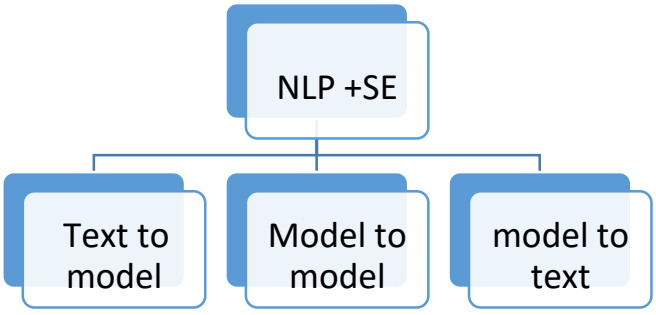

Figure 4: NLP in software design

In [5], it discusses the generation of requirements from UML's class diagram. The paper describes techniques to get NL specification from class diagrams. The paper uses WordNet to clarify the structure of UML string names and generating the semantically sound sentences. In [6], class diagrams are generated from controlled requirements specification.

In [7] paper, the issue of relation extraction from graphical models focused on the detection of semantic relationships within the given text is addressed based on using machine learning techniques.

The other applications of NLP in SE are,

Template Generation: NLP can be used to generate document templates based on the requirements of a given document. This involves using techniques such as NLG and machine learning to generate templates that are appropriate for the type of document being generated.

Machine Translation: NLP can be used to do machine translation that automatically translate documents between different languages. This involves using techniques such as machine translation and language models to generate accurate translations of the original document. Following are the approaches to machine translation Direct, Rule based, Corpus based and knowledge based[8].

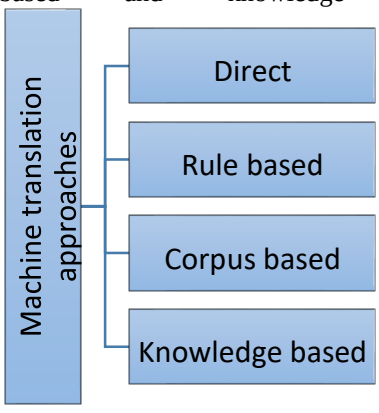

Figure 5: Machine translation approaches

Personalization: In order to increase and retain customers, nowadays personalized shopping experience is used. NLP can be also in marketing by analyzing the user sentiments on social media and providing them with targeted advertisements. People use text, photos, music, emoticons and video to express their emotions or their points of view which is accounting large unstructured data. It can be used to personalize the content of a document based on the preferences and interests of the intended audience. This involves using techniques such as user modeling and recommendation systems to tailor the content.

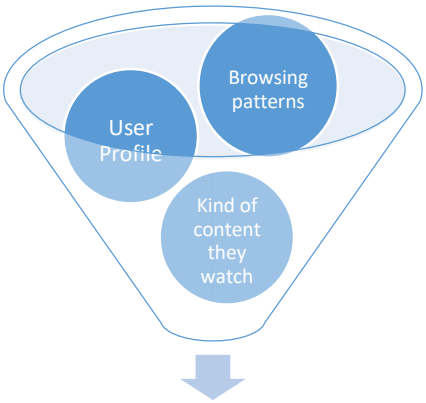

Figure 6: Personalization The next step is the implementation, where code has to be generated.

2.Code Generation: During code generation, NLP can be used to automatically generate code based on natural language text. This can help in automating the process of creating new software systems or modifying existing ones. It can be used to generate code from natural language commands and queries. The developer can give a sentence e.g." get two inputs and generate sum of two numbers". Using NLP model to parse the sentence and generate code for the same. The process is known as natural language programming, which helps the non-technical stakeholders to communicate requirements to developers.

This involves using techniques such as program synthesis and code templates to generate code that fulfills the intent of the natural language input.

Also NLP can be used to analyze code and generate comments for the code automatically. this will help reduce the developer time to write comments.

The other applications are

Code Summarization: NLP can be used to generate natural language summaries of code, making it easier for developers to understand and review the code. This involves using techniques such as summarization and paraphrasing to generate a human-readable summary of the code.

Code Completion: NLP can be used to predict and generate the next lines of code based on natural language input. This involves using techniques such as language models and machine learning algorithms to predict the most likely code completion given the natural language input.

Refactoring: Refactoring is a technique where the code is restructured without changing the logic e.g. a big method can be broken into smaller methods [11]. NLP can be used to suggest improvements and refactoring's to existing code.e.g the names of the classes ,methods, and atrributes which are inconsistent and can pass was it does not affect the output. This involves using techniques such as code similarity and pattern matching to identify areas of the code that can be refactored for better maintainability and readability

The method used in the paper [11] is

1. Tokenization of all names
2. Then classification of words into syntactic and semantic synonyms
3. Apply proposed rules to detect inconsistent names

Code Translation: It consist of translating code in different programming language. NLP can be used to automatically translate code between programming languages. This can help to improve software maintenance by allowing developers to work with code written in different programming languages. e.g. Transcode is a tool which can translate code between in programming languages Java, C++ and Python3[12]. It is useful when the legacy codebases need to be translated into modern languages.

NLP can be used in testing phase as follows, Testing is an important part in software Nowadays research is going on for NLP assisted software testing. the various field in software testing where NLP can be applied are as follows

Bug Detection: There are many bug reports generated which needs to be triaged. NLP can be used to detect bugs in software systems by analyzing natural language descriptions of the system. This helps to identify duplicate bugs and thus they don't get assigned to developers [14] This can help in improving the accuracy and speed of bug detection, as well identification of similar bugs, leading to more robust and reliable software systems.

ID	Name
3091	Mouse Hover not showing data on images
3082	unable to get text over image

Figure 6: Example of duplicate bugs

Bug Classification: there are lots of bug reports generated and they need to be resolved on time in order to improve performance. The time for fixing the bugs can be reduced by quick bug classification and assignment. Manually assigning the bugs can be a time consuming task . This paper [15] classifies the bugs using various classification algorithms e.g. Naïve Bayes, Random forest, decision trees and regression. NLP can be used to classify bugs into different categories based on the natural language descriptions of the bugs from the bug reports. This involves using techniques such as text classification and clustering to group similar bugs together and assign them to the appropriate category.

Bug Severity Prediction: the bug which has high impact and cause performance issues can be of high priority and hence need to be resolved before next release. While the bugs with low priority can be resolved in next versions. NLP can be used to predict the likelihood of bugs based on natural language inputs. Various techniques such as machine learning and deep learning is used to analyze the natural language descriptions of the software system and predict where bugs are likely to occur as well as the severity of the bugs.

Bug Triage: Bug triaging means to select a suitable developer to resolve the bug. Incorrect assignment of bug reports to developers can be very expensive in large software projects as the bugs can be tossed between the resolvers. A bug report is something that stores all the information needed to document, report and fix issues(bugs) in software. The summary of the bug report is used for both bug triage assistance and severity prediction [16]. NLP can be used to triage bugs and prioritize them based on their severity and impact. There are various techniques such as topic modeling and clustering to group similar bugs together and assign them to the appropriate team for resolution.in paper [17] a Triage assisting technique known as MLtriage has been suggested which is a supervised ML algorithm. In paper [18] they have focused on prediction of severity of bugs by using reports from Bugzilla as their input. They have done pre-processing by tokenization and stemming and have trained the datasets with various classification algorithms.

Bug Localization: NLP can be used to identify the location of bugs in the software system. This involves using techniques such as natural language processing and program analysis to identify the code segments that are most likely to contain the bug. In paper [18] they used a decision tree for predicting the location of bugs using eclipse jdk bug reports

In paper [20], a method DeepLoc is proposed which uses an enhanced convolutional neural network (CNN) that considers bug-fixing recency and frequency, together with wordembedding and feature-detecting techniques.

6.Documentation Generation: NLP can be used to automatically generate documentation for software systems based on natural language descriptions of the system. This can help in reducing the time and effort required for creating and maintaining software documentation.

Text Generation: NLP can be used to automatically generate text for documents such as reports, summaries, and emails.

ACKNOWLEDGMENTS

"Acknowledgment(s)" is spelled without an "e" after the "g" in American English.

As you can see, the formatting ensures that the text ends in two equal-sized columns rather than only displaying one column on the last page.

Abstract—**There is a digital divide of language due to which people are missing out on taking advantage of immense content being produced in today's world. In addition to that even the content producers have tough time to make their content in every language and gain wider reach. We also validated the same by conducting survey. Hence to solve this problem we have proposed a solution which leverages advanced technologies like Generative Adversarial Networks, Natural Language Processing and Computer Vision. The developed solution has the capability to generate close to real synthesized videos.**

Keywords—Generative Adversarial Networks, Natural Language Processing, Computer Vision.

I. INTRODUCTION

The rise in consumption of digital content i.e., MOOCs, videos. Content creators want their content to be available for everyone. Digital divide of language, people are missing out to take benefit of the rise in digital content being produced. The divide varies from entertainment to education sector. There are about 14.18 % people in India that understand and speak English language [1]. While we understand majority of the content is provided in English. The language barrier is not only in terms of India it affects majority of the population around the world. Out of the world's approximately 7.8 billion inhabitants, 1.35 billion speak English [2]. Of the top 250 YouTube channels, 66% of the content is in English [3]. We do understand through these statics that people who don't understand English are at a disadvantage when it comes to content availability, also the native creators are failing to get traction from this huge English-speaking market since most people can't understand the produced content. Our solution wants to make the content available to every person irrespective of their language by leveraging technologies like deep learning. The aim of the solution is to provide the video content that was originally in foreign language to the people in their native languages while taking care of the quality of the video. Our solution translates the audio, synthesizes the translated audio like the speaker's voice and synthesizes the speaker's lip so that it looks like he is speaking the translated words.

II. LITERATURE SURVEY

This [4] article tries to implement dubs using Artificial Intelligence. The implementation attempts to translate the speech of one language to another. The translated speech has a robotic voice and doesn't include lip sync.

Impressive results in picture production [5, 6], image editing [7], and representation learning [6, 8, 9] have been attained using Generative Adversarial Networks (GANs) [10, 11, 12]. For conditional image creation applications, such as text2image [13], image inpainting [14], and future prediction [15], as well as for other domains including movies [16] and 3D data [17], recent algorithms have used the same concept. The concept of an adversarial loss, which causes the generated images to be, in theory, indistinguishable from real photos, is essential to the success of GANs. Given that this is precisely the goal that much of computer graphics attempts to accomplish, this loss is particularly potent for jobs involving the creation of images

In this [18] paper they have used cyclic GANS to translate the audio/speech of X to a target domain Y thereby synthesizing the audio of the person X speech to person Y's voice. The implementation requires a person to recite a script and doesn't also provide translation.

In this [19] paper they try to lip sync a video to match the target speech segment of the audio provided. This implementation doesn't have features that we are trying to provide such as no synthetic audio generation and no language translation.

This [20] article gives that speech to text is a software that lets the user control computer functions and dictates text by voice. The system consists of two components, first component is for processing acoustic signal which is captured by a microphone and second component is to interpret the processed signal, then mapping of the signal to words. Is not able to detect accents and cannot comprehend multiple people talking.

III. SURVEY ANALYSIS

Survey Questions:

Q1. Do you think people miss out on digital media produced in different languages? Suppose you want to watch a video in different language (say Korean) but you cannot watch it since you don't understand that language?

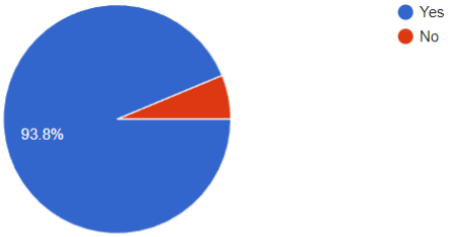

Figure 1. Question 1

Q2. If provided a service, where you can convert any video to desired language while preserving vocal features of the original speaker with proper lip sync. Would it enhance your viewing experience or wider your reach to larger audience?

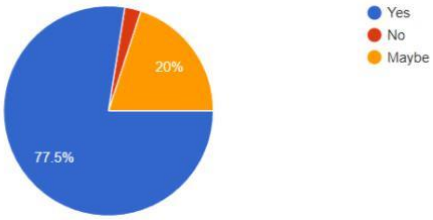

Figure 2. Question 2

Q3. There is a surge of MOOCs and Video Tutorials being produced (primarily in English). Do you think the people living in rural parts are missing to take advantage of it?

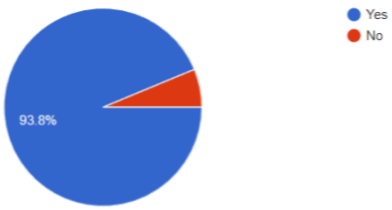

Figure 3. Question 3

Based on these survey results some of the conclusions are: Question 1 appeals that there is a problem due to digital divide people miss out on digital media because of the language barrier. Question 3 was asked to reinforce the fact the people in rural areas couldn't capitalize on the education content out there as we saw majority of the content present, is in English. Question 2 being more relevant to our solution this question asks the relevancy of our project whether there is a market where its required. Question 2 survey results gave our project a positive affirmation that our solution had a market or need.

IV. PROPOSED SOLUTION

From the above analysis and research, we are aiming to build a solution which will solve the aforementioned problem. Our proposed solution consists of many components which contribute to form a service. Following figure demonstrates the flow chart and different components that will be required to build such a solution.

When a user uploads a video to be synthesized, the video goes through the components mentioned in Fig 4.

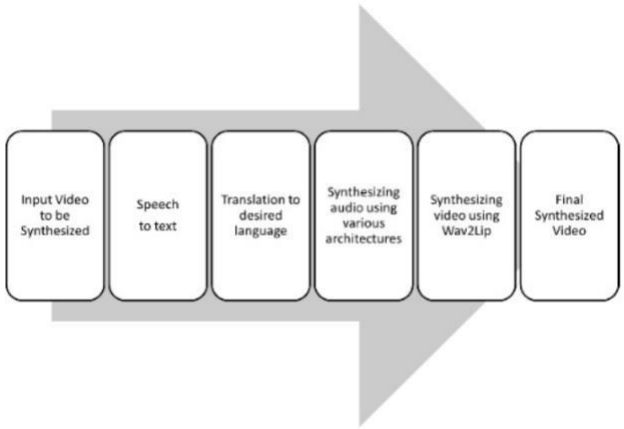

Figure 4. Solution Components

The first component is speech to text, where the transcripts of the video will be obtained which will be given to the next component that is translation to desired language, where the obtained transcripts will be translated to user specified language. Afterwards, this translated transcripts are passed to speech synthesis component where the algorithm clones the users voice in translated speech. This synthesized audio will be passed to video synthesis component where it syncs the lip movement to make it realistic.

For speech to text and text translation components, we will be using advanced encoder decoder algorithms. And for speech synthesis and video synthesis, we will be leveraging Generative Adversarial Networks.

Wav2Lip is a more advanced lip sync model that the authors have developed since the "Towards Automatic Face-to-Face Translation" study [19]. The discriminator is the key distinction between the two.

A visual quality discriminator and a pre-trained lip-sync expert are both used by Wav2Lip.

A updated, deeper SyncNet with residual connections trained on colour images serves as the expert lip-sync

discriminator. It calculates the dot product of the voice and video embeddings with ReLU activation. The likelihood that the input audio-video pair will be synchronised results from this.

In Wav2Lip, the generator is taught to reduce the expert sync-loss as well as the L1 reconstruction loss. In the visual quality discriminator, convolutional blocks are stacked one on top of the other. A leaky ReLU activation is followed by a convolutional layer in each block.

It is trained to minimize the following objective function:

The generator reduces the weighted total of the reconstruction (L1) loss, the synchronization loss (expert sync-loss), and the adversarial loss (Lgen) by adding all of the individual losses together.
Tortoise received special instruction to become a multi-speaker model. It achieves this by using reference videos.

These reference clips which are recordings of a speaker you supply serve as a manual for creating speeches. These samples are used to assess the output's many characteristics, including the voice's pitch and tone, speaking rate, and even speaking flaws like a lisp or stutter. The reference clip is also used to assess elements of the audio output that are unrelated to voice, such as volume, background noise, recording quality, and reverb.

V. METHODOLOGY

1. Audio Extraction from Input Video

When a request to the application will be made, the first process the input video will go through is the extraction of audio from the video for further processing.
Using moviepy [20], we process the input video with the help of this library methods for audio extraction. Using librosa [21] library, we set the sample rate of the extracted audio as mentioned in the open-source models.

2. Speech to Text (For Language Translation)

After the audio is being extracted, we use the fine-tuned open-source version of Wav2Vec2.0 [22] model from hugging face [23] for generating text from the audio.

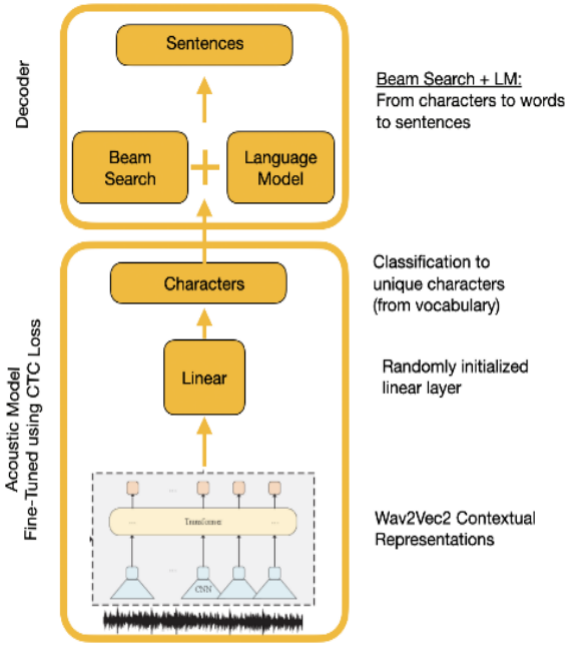

Figure 5. Speech To Text (Wav2Vec2) [24]

3. Text Translation

Once the speech-to-text process is completed, we now translate the obtained text to the language selected by the user using google trans [25] library which uses google translate to generate translation in desired language.

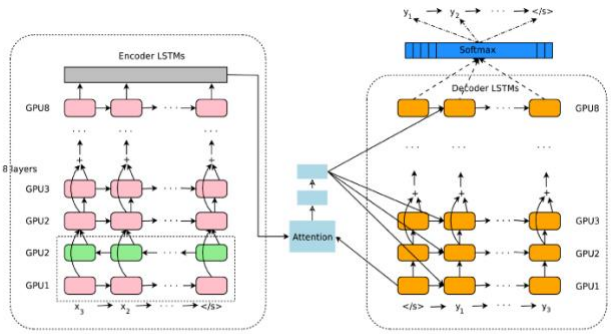

Figure 6. Text Translation [25]

4. Synthetic Audio Generation

Now, the translated text and the original extracted audio from step one is passed to a generative adversarial network model which generates an artificial voice for the given text which has similar vocal features as of original voice. For this, we are using an open-source implementation called TorToise [26].

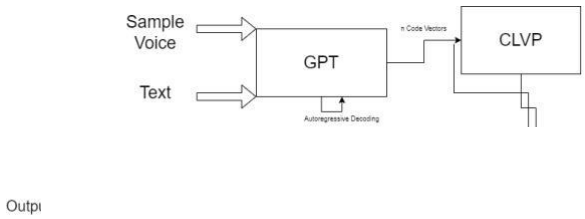

Figure 7. Synthetic Audio Generation [26]

5. Synthetic Video Generation

The separated video content is synthesized so that the lip movement of the person in the video matches the new translated audio vocabulary. The utilization of the Wav2lip model helps in achieving this feat. Give our video and the text as the input wav2lip will generate the matching lip movement [27].

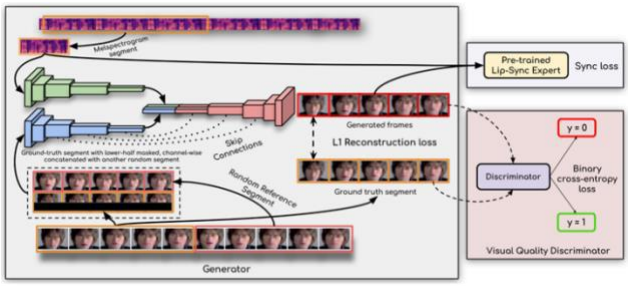

Figure 8. Synthetic Video Generation [27]

VI. IMPLEMENTATION DETAILS

To make the proposed solution accessible to people, all the above-mentioned components are modularized and connected to each other in backend by referring to the system design created and serve it as an Application Programming Interface (API). To make this service accessible a web-app has been developed.

1. Server-Side Development

For developing the backend logic, we have used Python programming language with libraries like Pandas and PyTorch. To serve this as an API we have used FastAPI framework. Its flexibility in organizing the project structure as per our preference and the ability to write async code makes it a better choice than other frameworks.

As an outcome, our proposed solution can be served on a server and can be accessed by calling the API.

2. Client-Side Development

To make our solution to general public, a Web-App needs to be developed which connects to the API developed. The web-app is developed using front-end technologies like HTML5, CSS & JavaScript. The designing part is handled using HTML and CSS and JavaScript is added to provide various functionalities to make user experience better. Here user provides the input and an API call is made with user given data and parameters, which in response returns the synthesized video.

Therefore, by leveraging Client-Server Architecture, we served our proposed solution as a web-app.

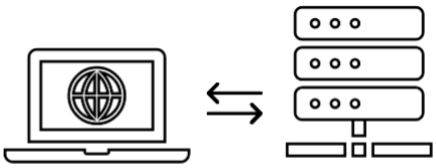

Figure 9. Client-Server Architecture

VII. RESULT AND DISCUSSION

Based on the survey carried out, we performed One Sample Proportion Hypothesis Testing from the obtained responses which validates our identified problem and the proposed idea.

1. Problem Validation

H0: Problem is not valid.: p <= 0.5
H1: Problem is valid.: p > 0.5
No. of samples = n = 110
p_hat = yes / no = 68 / 110 = 0.61
Z-Score = 2.48
p-value = 0.00657
Therefore, Null Hypothesis is rejected.

2. Idea Validation

H0: Idea is not valid.: p <= 0.5
H1: Idea is valid.: p > 0.5
No. of samples = n = 110
p_hat = yes / no = 64 / 110 = 0.581
Z-Score = 1.72
p-value = 0.04272
Therefore, Null Hypothesis is rejected.

Therefore, the developed solution, which is built by combining various techniques which are state of the art (SOTA) solutions, produces synthesized media capped at maximum video length of 1 minute.

The performance of the SOTA techniques used are as follows:

1. Wav2Vec 2.0 (for Speech Recognition) [22]

It has word error rate (number of errors divided by total words) of 5.7 which is fine tuned using only 10 minutes of labeled data from open source Librispeech corpus. On a 100-hour subset of Librispeech, the same model managed a word error rate of 2.3, 45% lower than the previous state of the art trained with 100 times less labeled data and 1.9 when fine-tuned on even more data.

2. Wav2Lip (for Lip Sync) [27]

To evaluate this model, the authors proposed a technique which is “LSED” (Lip Sync Error Distance) (lower is better) on which the model achieved score of 6.7 LSED; whereas, LipGAN achieved 10.05 LSED and Speech2Vid achieved 13.14 LSED [27].

The authors also reported that the output of Wav2Lip was preferred over existing methods or the actual un-synced videos over 90% of the time.

VIII. CONCLUSION

The problem statement and facts supporting it makes sense that this problem is apparent and does require a necessary solution. The survey results yet confirm the problem statement and the need of our solution. There are some existing solutions but aren't specifically targeted to this problem statement. These existing solutions are incomplete and need additional requirements and features to address the problem. We have made an attempt to make a unified, complete solution to address the problem statement in such a way such that there is no further language divide in the future.

IX. FUTURE SCOPE

Natural Language Processing (NLP) activities that rely on audio data, such as speech or music, rather than written text as input are referred to as textless NLP. Speech-to-text conversion is one instance of this, in which an algorithm converts spoken language into written text. Another illustration is audio-to-text creation, in which an algorithm creates text based on the information in an audio clip without the use of a formal transcript. The drawbacks of models like Bert, Roberta, and others are that they rely largely on transcripts or huge text inputs that are more laborious to create. The Generative Spoken Language Model (GSLM), however, eliminates this reliance and enables direct manipulation of unprocessed audio signals and their conversions [29]. As a result, there is no longer a need for languages without access to such data to rely on having vast text collections.

Since managing various languages from around the world is a huge challenge that must be handled, the availability of each language's data set for audio and video is crucial for this. How bias is addressed is a crucial problem as well. The language models should properly address issues like gender, toxicity, and prejudice. Therefore, iterative strategies and intrusive testing should be employed.

The TPU and GPU are essential components of the process. Up to a minute of speech may now be produced with good output from the tortoise text to speech. To complete the operation more quickly and effectively, more hardware resources are required.

Abstract: Due to the intense competition in the worldwide market, businesses are focusing on building solid client relationships and increasing consumer satisfaction. With the development of information and communication technology, it is projected that the application of video analytics would considerably enhance customer happiness and experience in service settings. to evaluate client satisfaction throughout the service cycle. Research in this field is currently challenging when attempting to recognize emotions in videos. The utilization of the audio and visual components of the video data as two sources for a thorough evaluation of emotion is one of the finest approaches to get around this challenge. With the use of deep learning models, we seek to identify a variety of solutions for consumer sentiment analysis in this article. We also investigate additional options for improving bank services, such as counting customers inside a bank or looking for theft inside a bank atm.

Keywords Deep learning, Face recognition, openCv, Cuda, video analytics, Yolo, tensorflow

I. INTRODUCTION

Banks can increase promotional acceptability and service speed with the aid of video analytics. Like other businesses, banks have customer service objectives. Don't wait in line for longer than four minutes, for instance. The Intelligent Video People Counting System counts the number of people waiting in line at any given time, the time it took for the most recent person to join the line, the average length of the line, the average wait time, and the number of people who left the line before the next person joined it. Indicates how many front desks there are, how many available counters there are, how frequently there are 3 or more people in line (for example), and how many people there are each day. For instance, 95% of people spend less than 4 minutes in line. You can compare store performance using these figures and take corrective action at underperforming sites. Enhance branch network performance through analysis, action, measurement, and iteration. The bank also keeps track of dwell time, or the amount of time consumers spend at the checkout desk. Retail shoppers are more likely to make a purchase the longer they stay in a certain area. Banks are unique. A quick turnaround time denotes effective service. Banks can compare the use of self-service ATMs and manned counters using video technology. Do you frequently use the ATM or do you pass it by to let someone else use it? All problems are revealed via data analysis. Banks can assess and improve their services for various processes by analyzing video counts.

II. LITERATURE SURVEY

Maintenance To engage with clients, offer a range of services, and learn more about personal beliefs and ideas, many businesses use social media networks. The detection of the polarity of positive or negative thoughts in text, full documents, paragraphs, lines, or subsections is done using the machine learning technique known as sentiment analysis. A multidisciplinary field called machine learning (ML) combines statistics and computer science techniques that are frequently utilized in prediction and classification analysis. In this article, general machine learning methods for sentiment analysis are presented. By conducting rigorous industry and community assessments and evaluations of white papers, academic research papers, journals, and reports, this literature analyses and discusses the concept of sentiment analysis. This paper major goal is to analytically categories and examine how research and machine learning approaches for sentiment analysis are being used in a variety of applications. This approach has the drawback of only considering the application side and leaving out hardware and theoretical exposures. The focus on applications rather than technology and theoretical parts of the topic means that this study has several limitations. This paper concludes with a research proposal for a sentiment analysis machine learning environment in e-commerce.

Current System	Objective	Study Outcome
Enhanced Video Analytics for Sentiment Analysis Based on Fusing Textual, Auditory and Visual Information. Automatic Video surveillance for theft detection in ATM machines: An enhanced approach. [Proceedings of the 10th INDIACom; INDIACom-2016; IEEE Conference ID: 37465 2016 3rd International Conference on "Computing for Sustainable Global Development", 16th - 18th March, 2016 Bharati Vidyapeeth's Institute of Computer Applications and Management (BVICAM), New Delhi (INDIA)]	The goal is to automate ATM video surveillance and create a application that looks for any potential illicit activity that might take place within the system. This significantly lowers overall system inefficiency.	The technology will analyse the video and show the user's actions, whether they were stealing or security-related. He is first captured in the original video frame using screenshots. You will then see his portion of this video frame. The trained data set is compared to this segmented frame.

An Entanglement-driven Fusion Neural Network for Video Sentiment Analysis. [Proceedings of the Thirtieth International Joint Conference on Artificial Intelligence (IJCAI-21)]	The trick is to successfully combining many modalities for emotion detection in video emotion analysis. solution offers a transparent quantum stochastic neural model as a result	constructing a shared and open quantum probabilistic neural model for sentiment analysis of videos. The model can represent both classical and non-classical correlations between modalities thanks to the idea and formalization of non-separability as quantum entanglement merging bimodalities.
CUDA-Self-Organizing feature map based visual sentiment analysis of bank customer complaints for Analytical CRM. [https://arxiv.org/ published on 2019]	A paradigm for self-organizing functional map (SOM) descriptive analysis of customer complaints is proposed. The network can also be shown using a variety of methods and automatically learns various groups of complaints.	A self-organizing card structure for sentiment analysis that examines consumer complaints. We contrasted the model's performance with that of the term frequency representation and the TF-IDF representation, two vector space model representations he used in the document.

iii. Problem Statement

Bank is using video cameras for the purpose of surveillance at many branches, ATMs and digital lobbies. Getting video analytics of different parameters from the video recording will help the bank to resolve many operational issues at the branches. The bank wants to explore video analytics for understand the customer sentiments, understand the patterns

/behaviors/actions in certain branches for proactive surveillance and provide better services to customers.

Key issues

- Analysis of sentiment of banks customers using cctv video footage.
- Building a video surveillance for checking the Tampering with the cameras / sensitive or high priority area within banks premises.
- Real-time Counting the number of people detected in cctv camera in particular frame.
- Tracking any activity with smart video surveillance system that needs any attention.
- To analyze the total time duration for any activity that needs to happen with video analytics.

III. DATA COLLECTION AND VISUALIZATION

Given the dearth of video datasets for consumer sentiment analysis in banking, a dataset was built using YouTube videos with pertinent opinions. The Banking Services Sentiment Analysis Dataset is the name of this dataset (SADBS).

- SADBS Dataset description

Statistical measure	Value
Total no. videos	63
Total no. videos expressed by male	37
Total no. videos expressed by female	26
Total no. distinct speakers	59
Total no. opinion segments	524
Total no. positive segments	274
Total no. negative segments	250
Average no. opinion segments in video	8.32
Average length of opinion segments (seconds)	5.29
Average no. of video frames	137.24
Average word count per opinion segments	12.52
Total no. words in segments	6562
Total no. unique words in opinion segments	2774
Total no. words appears in segments at least 5 times in the dataset	491

Fig 1

- SADBS Dataset statistics

Sentiment		Gender		Age-group				Dialect			
		Female	Male	AGA	AGB	AGC	AGD	Egyptian	Gulf	Levantine	Maghrebi
Positive	274	134	140	103	113	47	11	106	106	33	16
Negative	250	82	168	25	46	95	84	143	61	46	13
Total	524	216	308	128	159	142	95	249	167	79	29

- Classified sentiments of customers into final decision.

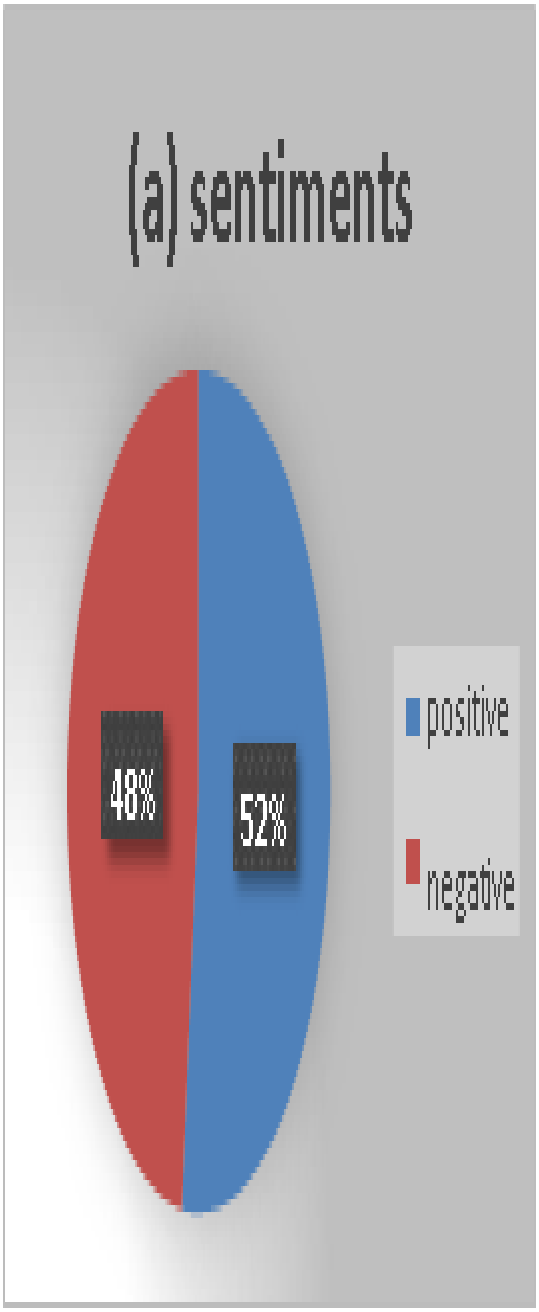

Fig 3

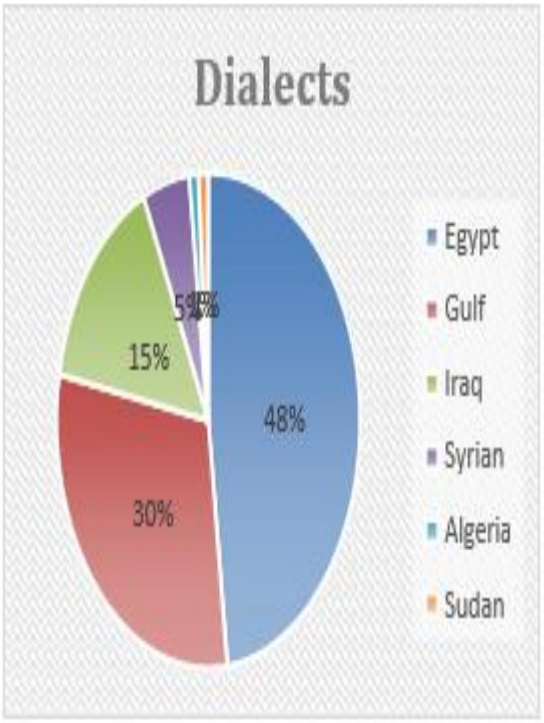
• Dialects used in dataset classified on the bases of regions.



• Number of instances of video data based on age group

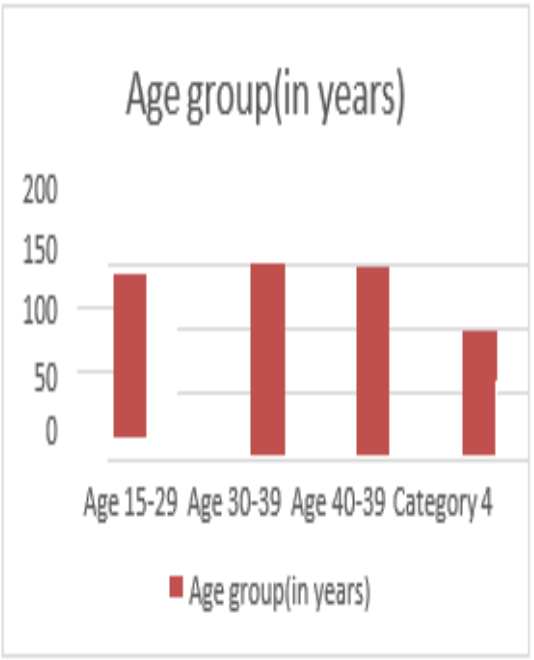


Fig 4

IV. PROPOSED SYSTEM

We must first extract visual, audio, and textual information from a video using the appropriate visual, auditory, and textual feature extractors in order to categorize the mood of the video. To accurately predict

the correct emotion, a classification model is fed with the three modality features that were retrieved. The next sections give a thorough description of the most recent models being utilized in the field as well as different kinds of visual, auditory, and textual feature extractors. The multimodal sentiment analysis technique for multimodal data is depicted in Figure 5.

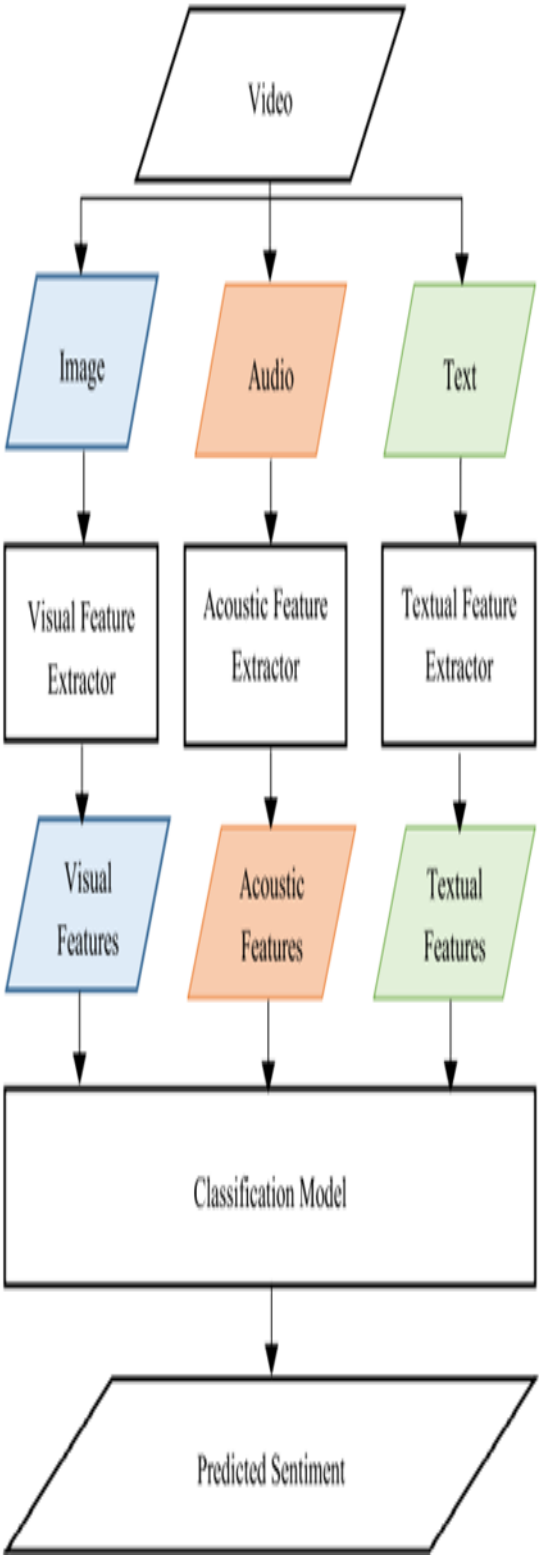

Fig 5: Sentiment analysis on a video

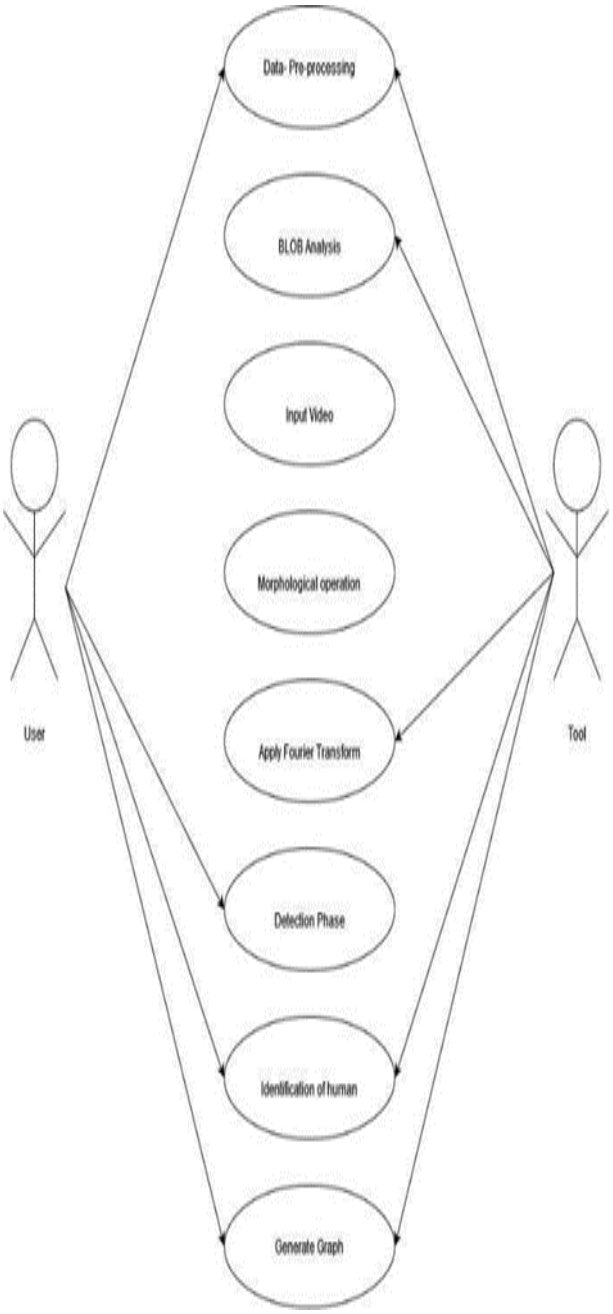


V. MODEL EVALUATION AND RESULT

These function files are provided for use in AI/ML/DL. The DL video analytics framework is highly modular and customizable. This makes the development lifecycle simple and easy. The flexibility of the Feature Extractor component makes it easy to integrate new feature extraction algorithms into the platform based on business specifications. The video data processing layer can also

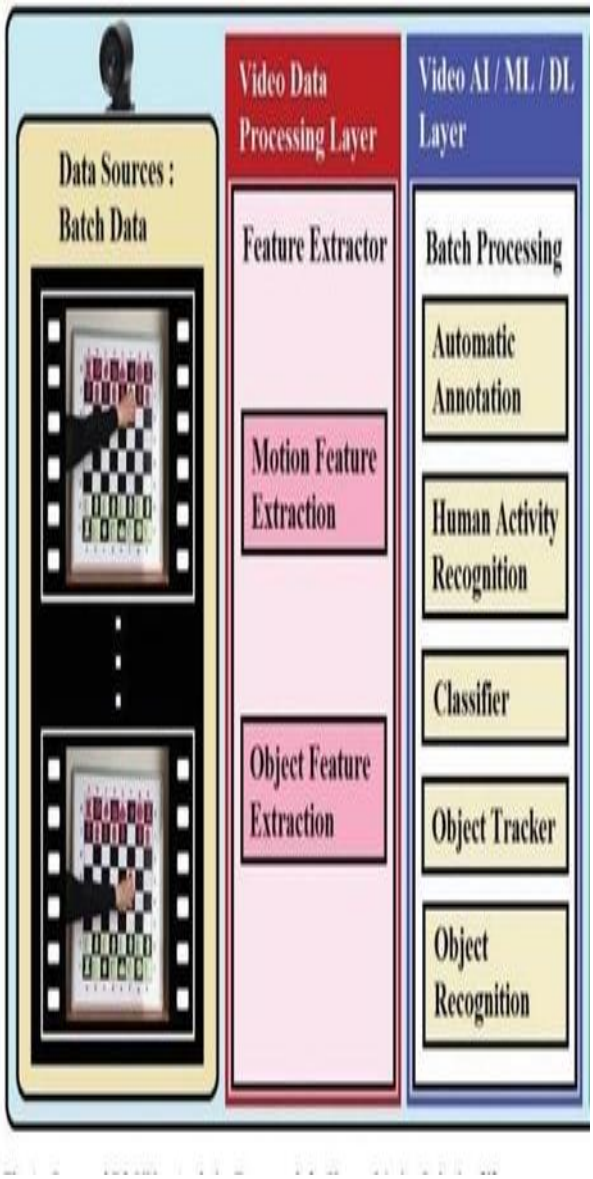
be extended.

For example, a new segmentation algorithm for 4464 videos can be created and added to the system to analyze long sequences of videos. In our work, this layer is

primarily in charge of processing raw video and image data. Her -layer Feature Extractor component also extracts significant features from image and video data.

Her two main extraction methods are object feature extraction and motion feature extraction. The Python and OpenCV libraries are used to implement the feature extraction method in the proposed hybrid deep model [1].

The feature extraction for objects is constructed using the checkerboard pattern [3] and the TensorFlow object identification API [4]. The Motion Feature Extraction API is built using a real-time portable detector [5]. The layer's input is the micro video data set, which consists of chess players' movements. This procedure generates a file that contains feature tensors as its results.



VI. ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance, and encouragement of my Dissertation Guide Associate Professor Dr. Veena Kulkarni ma'am for this novel work.

VII. CONCLUSION AND FUTURE SCOPE

Video analytics has gained a lot of interest and contributed significantly to numerous applications. The sentiment analysis of financial services is covered in this white paper using a number of multi-modal, multi-dialectical video analytics methodologies. The effectiveness and prospective contributions of speech, text, and visual modalities were analysed together with the creation of a dataset, several models, and a dataset. This paper also investigated different Fusion technologies at single and hybrid levels. To compare the significance of progress for each model, a thorough statistical analysis is offered. When multiple modalities are combined, the model is able to choose more pertinent features, producing better results than the unimodal baseline system.

In the future, we will concentrate on creating a new model that is capable of stronger analysis of human emotions. In order to generalize these models to any language while performing prediction tasks, we also put a lot of effort into making them language agnostic. We also intend to update fresh bank records in this area.

Abstract

In order to analyze video streams and extract particular features or patterns, such as object recognition, motion detection, facial recognition, or behavior analysis, video analysis employs computer vision and machine learning techniques. Analyzing video footage to spot suspicious activity or items and locate people or vehicles is part of the process. This approach comprises keeping an eye on and controlling traffic at crossings, on roads, and in highways. It entails reviewing video footage to find traffic jams and overcrowding and to offer prompt alerts or suggestions for crowd management.

Keywords-- ***Open CV, Real time, Video analysis, facial recognition, object recognition, feature Extraction***

I. INTRODUCTION

In order to conduct their investigations, law enforcement officials frequently need to spend a significant amount of time manually reviewing CCTV material. In order to make their job easier, a video analysis system is required that can automatically scan through CCTV footage for known facilitators like criminals and potential suspects. This system aims to improve object tracking and detection accuracy both in real-time and using historical data.

We are counting and locating recognized facilitators in addition to conducting real-time human detection. Real-time human detection uses either a live capture, static video, or snapshot for identification. We produce a report and analysis for it after detection.

II.LITERATURE SURVEY

Paper	Author & Year	Gap	Accuracy
Edge AI Face Recognition for Public Transport Fare Payment	Rusoke, Blaise Marvin; Musinguzi, Denis; Miyingo, Simon Peter; Katumba, Andrew (2022)	Our system's pipeline makes use of a pre-trained anti spoofmodel based off research by Costa et al. [7]. During ourdeployment tests, this model efficiency deteriorated with variations in lighting, and with low image quality	94%
Face Recognition Method for Online Exams	Sukmandhani, Arief & Sutedja, Indrajani. (2019).	further application development is expected by using updated algorithms for face recognition with a higher degree of accuracy. Trials for this method are only carried out with the same level of lighting, not yet done at different lighting levels and distances	96.3 %
Smart Surveillance System Using Face and Optical Character Recognition for Secure Environment	HarikaPalivela, Lakshmi &PM, Ashok Kumar & Krishna, V.V.. (2022).	If multiple cameras are used, additionally, the area or location at which the suspected individual was identified can also be included so as to better facilitate the authorities to apprehend that particular suspect. If a suspect is identified for a continuous protracted period of time, back-to-back emails will be sent to the authorities, which will lead to a spamming problem	98%

Table 1: Literature Survey

III. METHODOLOGY

A) Proposed Work

This is a rudimentary flowchart for a computer vision-based people detection system:

- Image or video feed capture: The system begins by taking a picture or video from a camera or sensor.
- Preprocessing: To improve the quality of the collected image or video and get rid of noise or artefacts, the data is first processed.
- Object detection: In order to identify faces or human bodies in the image or video, the system uses an object detection technique like Haar cascades and Histogram Oriented Gradients.
- Feature extraction: The algorithm collects information including shape, size, color, and location after identifying human bodies or faces.

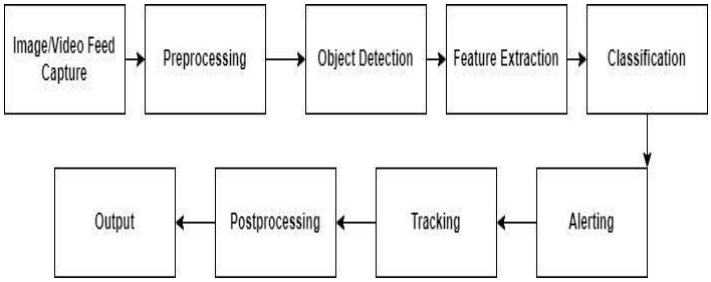

Fig.1. Flow diagram

- Classification: The system classifies the collected features as human or non-human using a machine learning method, such as support vector machines (SVM) or neural networks.
- Alerting: If a human is found, the system notifies a monitoring station, security staff, or other pertinent parties by sending an alarm or notification.
- Tracking: Using methods like optical flow or Kalman filters, the system may also follow the motion of any persons it has identified in an image or video over time.
- Postprocessing: The system then applies postprocessing to the result, such as removing false positives or enhancing the precision of the categorization, and creates a final report.

When utilizing computer vision to recognize humans, preprocessing is crucial. These are a few typical preprocessing methods for human detection:

Image normalization: is the process of enhancing an image's quality and making it better suited for human detecting algorithms by altering its brightness and contrast.

Picture resizing: is the process of adjusting an image's dimensions while keeping its aspect ratio. When the image resolution needs to be changed to meet the specifications of the human detection algorithm because it is either too high or too low, this technique can be helpful.

Noise reduction is essential for human detection systems because it gets rid of noise or other artefacts from an image or video input. The quality of the input data is increased by using methods like smoothing, median filtering, and Gaussian filtering to minimize noise.

Image enhancement By enhancing the contrast and edges in an image, one can make it simpler for human recognition algorithms to recognize the aspects of interest. Such approaches include contrast stretching, histogram equalization, and sharpness.

We looked into ways to more accurately count the number of people in movies or photographs.
Haar Cascade Classifier usage, In this case, we employ an .xml file for human detection, and with its help, we can identify people in real-time videos and photographs. We initially utilized this method to identify people, but the precision was poor.

For the purpose of object detection, computer vision and image processing employ the feature descriptor known as Histograms of Oriented Gradients (HOG). We tried this method, however we found no discernible improvement over the Haar Cascade Classifier method in terms of accuracy.

We have included a preview button in addition to the HOG description, which enables us to examine a preview of the selected image or video.
Following detection, we also displayed the maximum number of people in the window.

Finally, we used a third technique based on deep learning and convolutional neural networks utilising Tensorflow.

Using CNN and TensorFlow for Deep Learning
This is the solution to a number of computer vision issues, including object localization, object detection, and image classification.

Google's open-source TensorFlow API is frequently used to complete machine learning tasks involving Deep Neural Networks.

CNNs were a third way that was widely adopted, and we are now utilising deep learning to learn how to detect humans.
Comparing this procedure to the first, it provides greater accuracy.

To develop a personalised Haar cascade classifier for a specific object, there are only four easy steps.

1.Calculating the Haar features
2.Making Integral Images
3.Using Adaboost
4.Application of Cascading Classifiers

To recognize and help programs comprehend object detection functions, Open CV is employed. They include the methods cvtColor(), detectMultiScale(), rectangle(), and others.

Any video extension (.mp4,.mkv,.ovi, etc.) that is accepted as input for human detection can be used with the program's flexibility and human detection feature.

A big number of people are shown in the first test video's open space.Also, we have upgraded certain user interfaces and incorporated a few new functions.using other libraries like Imutils, a collection of useful functions that allow using OpenCV and Python to display Matplotlib pictures and do simple image processing operations like translation, rotation, scaling, and skeletonization much simpler.

Argparse is a module that makes it simple to create comprehensible command-line interfaces.
Work has also been done on labelling the human body that the algorithm detects with a counter that displays the number of persons in that scene in the video.

IV. RESULT

We have developed a system that can help identify known facilitators, and can identify human as well as keep a count of it. We have developed a interface where user can input image, video or he/she can make use of camera. After taking the input it's processes it, and extract features from it after which it detects the human.

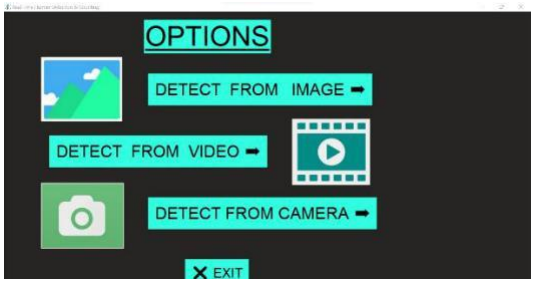

Fig.2. Fronted of human detection

Other then detecting humans, we have also developed a interface in which user can input image, and any video, after which our model will process through the video input and find that particular person in the video and will show the output in the form of image, with bounding boxes created on the person face.

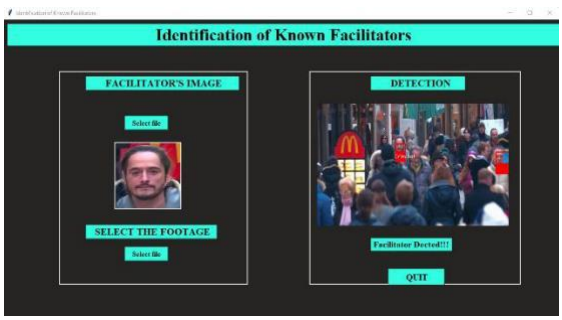

Fig.3. Frontend interface of known facilitators

Fig.4. Frontend interface of known facilitators output

We have used haar cascade and histogram orientated gradient for human detection purpose, where as for face identification we have used OpenCV etc.

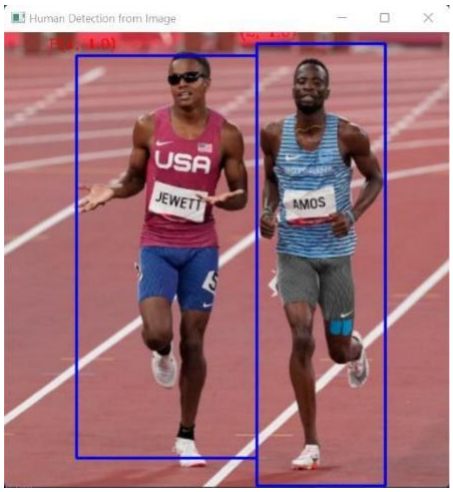

Fig.5. Bounding Box

Fig.6.Human detection output

We are also generating crowd report which shows, maximum human count, average accuracy as well as maximum average accuracy in the end it's show' s if the area is crowded or not as output.

This crowd report can be helpful for detecting crowded areas, and places.

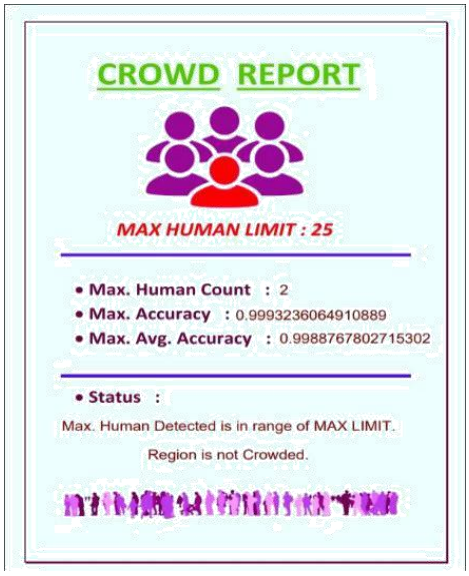

Fig.7.Crowd Report Output

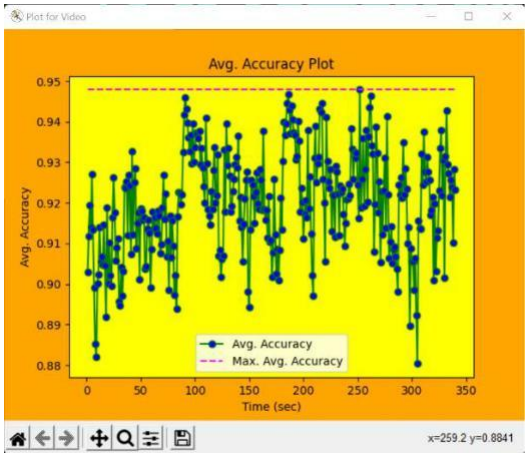

Fig.8. Accuracy Plot for Image

V. CONCLUSION

The proposed system is vital in today's world. This system can be used for various purposes such as at public areas like streets, parks, transportation hub to get rid of crime as well as to assist in emergency response. People can use for their personal use to monitor any activity, prevent theft and vandalism, and ensure safety. Also this proposed system can help identify known facilitators in case of criminal identification, where police professional can input image and check in the surveillance video and identify the criminal.

VI. FUTURE SCOPE

For future work, we can work more in image preprocessing as well improving our accuracy further. As well as we can work on to make a background running application could be made which keeps working without interfering and notifies when detects something abnormal. Accidents happening in public places could be detected. The model can further be trained in such a way that unusual events such as eve-teasing or involving any kind of violence could be detected. Can be used in the defense sector for security purposes.

VII. ACKNOWLEDGEMENT

We gratefully acknowledge our mentor Ms. Veena Kulkarni ma'am, for guiding and supporting us throughout this project work, as well as our Principal Sir, for providing us a platform to showcase our work.

Abstract – ***Facial expressions say a lot about the user's mood. Even a small change in facial expression can help us in detecting the change in the mood of an individual. Researchers have conducted a lot of studies in the field of Machine Learning and Computer Vision, where ML models are trained to detect various human emotions or moods based on the facial features that are captured.***

In this research, we propose a system that is capable of identifying the user's emotions and moods and then suggesting a list of appropriate songs that can improve the user's mood. This can be considered as an additional feature to the traditional music player apps that are already available on the internet. An important benefit of incorporating mood detection is customers' mental health condition and their personal satisfaction. The objective of this system is to capture the user's image, detect the mood of the user and suggest songs that could help improve their mood accordingly.

Keywords – ***Face Recognition, Emotion Detection, Music, Mood Detection, Recommendation System***

I. INTRODUCTION

The easiest way to understand a person in the conversation is to look at their face and body. Facial expressions are one of the most basic parts of human communication and can be viewed as a form of non-verbal communication [1]. Face recognition and emotion recognition are two concepts that have received a great deal of attention in recent research areas such as digital imaging, pattern recognition and computer vision [1]. Face recognition is a two-step process that begins with finding faces in photos or videos. It doesn't matter if the face is personal or not. Emotion recognition is used today in a variety of applications including smart card applications, surveillance, image database research, crime, video indexing, civil applications, security, adaptive human computers, and Interface for multimedia contexts.

Therefore, the main goal of this project is to develop a system that can identify different emotions of the user, from joy to sadness, from natural to shock. The proposed system then presents the user with a music playlist containing music clips of different types of music that enhances the user's mood after the emotion is evaluated. For example, if the user's facial expression is categorised as happy, the most appropriate playlist is activated: Classical Music playlist, where the user can choose from many music clips.

A. Motivation

Nowadays, music platforms make it simple to listen to a large amount of music. They are constantly working to improve music organization and search management, addressing the issue of choice, and making it easier to discover new music pieces. Recommendation systems are becoming increasingly popular, assisting people in selecting appropriate music for all occasions. However, there is still a gap in personalization and recommendation based on emotions. Music has a large influence on humans and is widely used for relaxation, mood regulation, stress and disease destruction, and mental and physical work maintenance [3]. Music therapy has a wide range of clinical settings and methods for well-being support [2]. This project will present the design of a personalized music recommendation system based on the emotions of the listener. A recommendation system is being developed using a combination of artificial intelligence technologies and generalized music therapy approaches to assist people with music selection for various life situations while also maintaining their mental and physical health.

B. Problem Definition

A user has to manually browse through his playlist and select songs that would soothe his mood and emotional experience when using traditional music players. Although these features meet the user's basic needs, the user is still required to manually browse through the playlist of songs and select songs based on his current mood and behaviour. The user suffered from the need and desire to browse through his playlist on a sporadic basis, depending on his mood and emotions.

The main goal of this project is to solve user problems and create a system that presents a music player that recommends music based on the user's real-time mood via a web camera using Deep Learning Algorithms.

C. Objectives of the Project

- To use various deep learning models and test it on the dataset and use the best model that provides the highest accuracy.
- To create a mood-based music player which performs real-time mood detection and suggests songs as per the detected mood.
- To provide appropriate music suggestions to the users based on their preferences.

D. Scope of the Project

- Only English songs will be recommended to the user using our system.
- The user should have a good camera with adequate brightness so that his/her face's emotions can be properly recognized.
- Our system will not work on a computer having an operating system less than windows 7.

E. Expected Outcomes of the Project

- The application would be able to accurately predict the user's mood based on the facial features captured.
- The recommendation engine in the application would be able to recommend the songs to the users based on the mood detected.
- The application would be able to suggest songs that would fit the user's preferences.

F. Applications of the Project

- How can it save the lives of drivers?

  Road rage occurs when a driver becomes enraged and directs his rage at other drivers on the road. Road rage diverts the driver's attention away from safety and disrupts his clear-headed thinking. It can endanger the driver as well as everyone else on the road. According to the National Highway Traffic Safety Administration, rash driving caused more than 55% of accidents (around 106,729), with anger being the most common cause.

  This mood-based music player project includes a special mode that distinguishes it from others. If the user's mood is classified as angry, it can play music to calm the user and change the user's mood to calm and cool. It may reduce the driver's aggression, preventing the driver from driving recklessly and potentially saving lives.

- How can it improve the mental health of a person?

  Our system can help improve the mental health of an individual by playing music according to his/her emotions. This can reduce the stress of an individual which can positively impact his mental health and reduces the chances of hypertension from which the user might suffer earlier.

- Other applications: Act as a plugin for the website, Smart TV, Personal Assistant etc.

II. LITERATURE REVIEW

In the research paper [4], implementation was done in two parts. First was mood detection and second was the song recommendation system. Mood detection was further divided into two modules the first being face detection and the second being mood detection. For face detection face detector class of java was chosen over Open CV library of Python since openCV is computational expensive and challenging to integrate with the android app. For mood detection Mobile net and Keras and again keras is computationally heavy and slow in android so mobilenet was used too. For the facial expression dataset, two datasets from Kaggle was used one was FER 2013 dataset and other being MMA facial expression recognition dataset. For the second part of the implementation i.e., song recommendation system, the dataset is downloaded from Kaggle which is labelled on different moods and firebase is chosen to be a dataset.

In this research paper [5], with the aim of coping with a few data and extracting only useful features from images, we propose new face cropping and rotation strategies and simplification of the convolutional neural network (CNN) to make data more abundant and only useful facial features can be extracted. Experiments to evaluate the proposed method were performed on the CK and JAFFE databases. The experiments recorded high accuracy of 97.38% and 97.18% for 7-class experiments on the CK+ and JAFFE databases. The results show that the proposed FER approach achieves competitive rests in terms of training time, testing time, and recognition accuracy. Furthermore, the proposed method can be implemented on an ordinary computer without GPU acceleration.

Another paper [6], divides the overall problem into three sections. The first one is emotion detection. CNN was used and the dataset used was FER2013. The final network was trained on 20K images and tested against 5K mages. This emotion detection model recorded an accuracy of 90%. The second section was to apply deep learning and classify the songs of the song database in different emotions. Again, CNN was used for that. The model achieved a classification accuracy of 97.6%. The third section is to recommend songs. Once the mood is detected, the User is provided with a playlist of all the songs classified as that mood.

Another Research [7] proposes an intelligent agent that sorts a music collection supported by the emotions conveyed by each song and then suggests an appropriate playlist to the user supported by his/her current mood. The user's local music collection is initially clustered and supported by the emotion of the song i.e., the mood of the song. This is often calculated by taking into consideration the lyrics of the song. Whenever the user wishes to get a mood-based playlist, the user takes an image of themselves that instant. This image is subjected to

facial detection and emotion recognition techniques, recognizing the emotion of the user. The best-matched music to this emotion is then recommended to the user.

III. PROPOSED WORK

Our suggested system is a music controller that detects emotions automatically. As illustrated in Figure 5, a camera is utilized to collect the photos that will be used as input to the proposed system, after which it is sent to the facial emotion detection model, which classifies it into: "Happy", "Natural", "Sad" or "Surprised.

Figure 1: Proposed Work

The user will be given a music playlist based on the expression or emotion identified, from which they can choose from a selection of music clips. For example, if the user's expression is classed as happy, the users will be able to select music clips from a joyful music playlist. We used a free dataset from the internet that contains 182 photos of four different emotions: joyful, natural, astonished, and sad.

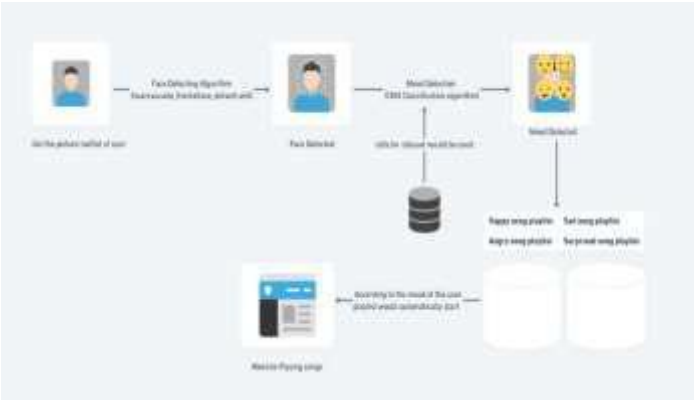

Figure 2: Proposed System Architecture

The stages that our project will follow are –

A. *Image Acquisition*

Nowadays, music platforms make it simple to listen to a large amount of music. They are constantly working to improve music organization and search management, addressing the issue of choice, and making it easier to discover new music pieces.

B. *Face Detection*

The system will begin to detect the face after obtaining the image. Simply put, the algorithm uses a sub-window to scan the photos and recognize the features of the face in the image. To improve the proposed system's performance, the image is trimmed to just contain the face once it has been determined.

C. *Emotion Detection*

Next, we must determine the user sentiment. To do so, we employ the PCA method, which is a well-known method for detecting facial expressions. The face space will be constructed using PCA, and the eigenvectors with the highest eigenvalues will be chosen. The acquired image will also be projected onto the face. The emotion is then detected by computing the scores for each emotion for the user image, and the image's emotion is chosen by taking the highest score of the calculated emotion scores.

D. *Enabling the corresponding Playlist*

The proposed system will display the appropriate music playlist based on the identified emotion. Because there are four emotions, we have four playlists with carefully selected music samples. The classical music playlist will be active for pleasant emotions, while the new age music playlist will be activated for natural emotions. For unpleasant emotions such as surprise and sadness, a designer music playlist will be enabled to improve the user's mood.

E. *Dataset*

The dataset contains 48x48 pixel grayscale images of faces with different emotions. The faces have been automatically registered so that the face is centred and occupies about the same amount of space in each image. Our job task is to categorize each face based on the expressions on the faces into the following categories (0=Angry, 1=Disgust, 2=Fear, 3=Happy, 4=Sad, 5=Surprise, 6=Neutral). The training set consists of 28,709 examples and the public test set consists of 3,589 examples.

F. *Feature Description*

- The user opens the app.
- The app gets opened and the user’s image is clicked through the webcam.
- The face gets detected then and the mood is identified.
- Some songs will be suggested to the user based on the mood of the user and if the user does not like the suggested song, then the user can click a button which will show more songs to the user from which the user can select the song of his preference.

G. *Generating the Playlist*

- The first task here is to generate the playlist.
- To do that first a random song is suggested to the user.A certain threshold (in seconds) is decided. If the user listens to the first song more than the threshold, then 20 similar songs would be taken, and a playlist would be generated. If the user skips the suggested song before the threshold is crossed, then a new random song will be suggested, and the same process is repeated until a playlist is generated of the user’s preference.

H. Alteration of the Playlist based on the mood

- Now the playlist is generated, and the user is enjoying the music. But suddenly the user skips the song. There could be 2 reasons for this: The first one could be that he does not want to listen to the song anymore (either he/she dislikes the song now or the user's mood is changed). The second potential reason could be that the user's mood has changed now and an alteration in the playlist is required now.
- This problem can be solved by clicking the picture of the user again when he/she changes/skips the song and again identification of the mood takes place.
- If the mood (which is just identified) matches the previous mood, then it can be concluded that the mood of the user has not changed yet but it's the song which no more stimulates the user and then that song then can be removed from the playlist.
- But if the new detected mood is different from the previous mood, then the playlist needs to be altered in a slightly different manner.
- This time we would add any random song of the new classified mood in the playlist, and it would be given to the user (Note: This new song would be recommended as the just next song after the user skips the previous song).
- Again, we will check for the threshold and if the threshold is cleared then 60%-70% songs of in the current playlist can be replaced by the songs like the randomly selected one.

I. Analysis at the End of the Day

Now the day is over and its midnight, the user is sleeping. A few analyses can be done now:

- Calculate the average time (in secs) of the listened music that changed the user's mood.
- To observe a particular mood, the user listened to the songs of which artist more.
- Calculate the average time (in secs) of the song listened,
- The user has which mood at what time in a day can be observed.

J. The last stage will be deployment and front end

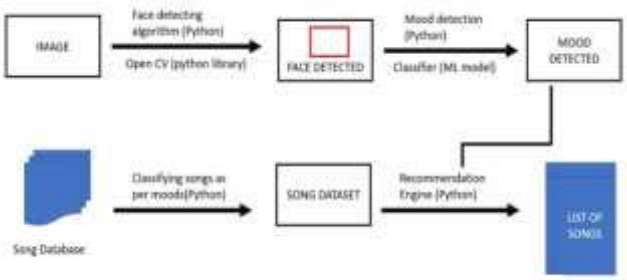

Figure 3: Methodology

IV. REQUIREMENT ANALYSIS AND PLANNING

After a careful analysis as shown in Table 1, the prime requirement of clients is to express proper unambiguous meaning of images and that will perhaps help intellectually impaired people. This analysis is done after observing responses to a survey created by us and floated among college students and elders.

Description	Criticality Level
Face detection in the Image given	4
Mood Classification using Facial Features	5
Song classification in the Songs Database	2
Recommending songs to the users from the database according to the mood detected.	5

Table 1: Requirement Specification (1-Least Critical, 2-Critical, 3-Recommended, 4-More Critical, 5-Most Critical)

A. Technical Feasibility Study

Deep learning is one of the most popular technologies used nowadays. The technology required in this project mainly surrounds the domain of deep learning. The first part of the project requires CNN (Convolution Neural Networks) for Identifying images and then classifying captions based on the image features. Creating appropriate CNN architecture or using pre-defined CNN architecture is a challenge here. Implementation would be done using the Tensorflow library of python which is an open-source library so implementing it is feasible. In the second half, a caption generator would be built to justify image captioning. Training our model to increase accuracy is a challenge. To train CNN models, we may use the GPU of Google Colab to increase the speed of training and validation. The users will be able to access and use our project via an online website.

B. Financial Feasibility Study

As of now, since the dataset is limited, no financial help is required. The online GPU provided by Google Colab is sufficient for training and evaluating the model. Though, to deploy the model on a website and to host a website online we need to buy a domain which may cost around 500 rupees per year with some maintenance costs. As a future scope, once the site is hosted and becomes popular, the number of users will increase hence the dataset increases too. With ever-increasing data, training the CNN model will become difficult on the free GPU which was provided by Google Colab hence we may need to buy Google Cloud GPU which costs around 325$ for 40Gb per GPU.

C. Technical Requirements

For implementing purposes, we used Anaconda and Jupyter as our IDEs. The language used is solely python as it is reliable for Deep Learning models. We are going to use some pre-installed python libraries to create our models and process the data.

The front-end is built using ReactJs. React is a free and open-source front-end JavaScript library for building user interfaces based on UI components. For styling, we have used modern styling methods in the web application. This is done using a Styling library known as Tailwind CSS. Tailwind CSS makes it faster and easier to build modern websites. It is a highly customizable, low-level CSS framework that gives you all the building blocks you need to build designs without any annoying opinionated styles you have to fight to override. For managing the different states of our react app components, we have made use of the React Redux. React Redux makes it easier to manage component states for big and complex React projects.

Google Colab or Google Colaboratory is a free-to-use Jupyter notebook environment that runs in the cloud. Similar to documents in Google Docs, team members can simultaneously edit the notebooks. A lot of Machine Learning libraries are supported by Colab.

Figure 4: Technologies Used

Figure 5: UI for the Music Player

V. RESULTS AND DISCUSSIONS

The first model that we created i.e., fer_1.h5 had the problem of overfitting. It happened because there were too many conv2D layers one after the other without max-pooling. The reason we removed max-pooling layers is that the image size is already too short and applying max-pooling layers was making it way less in a dimension that training the model became impossible. (20 epochs).

Now we have a slightly improved model. In this max-pooling layer are added again but this time in conv2D layers we are using padding to solve the above issue, also we have added a batch-normalizer. First, we are training our data on this model for 20 epochs initially. Still, we faced here the same problem of overfitting.

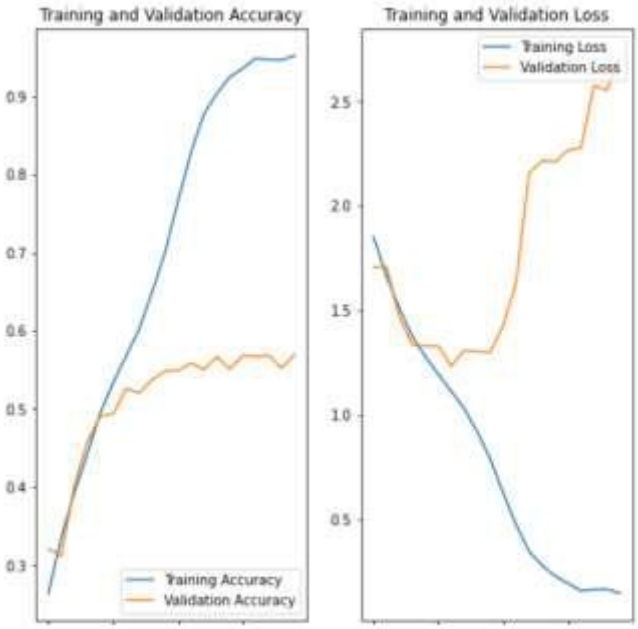

Figure 6: Results of the model with the most accuracy (57.90% accuracy on test data)

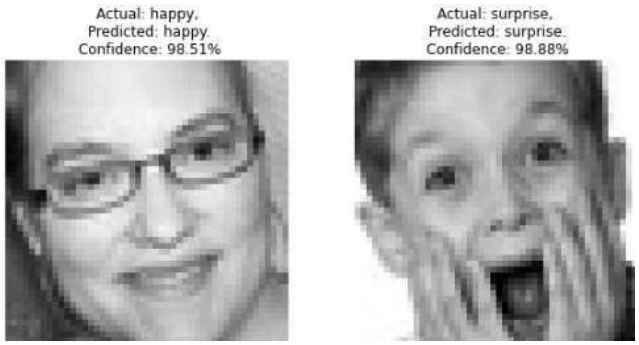

Figure 7: Predictions by the model with the most accuracy

The third training model has slight improvements from the second. We removed half of the convolutional layers and changed the number of filters and the filter size. Here also, we faced the problem of overfitting.

The fourth model is a transfer learning of the Resnet50 model trained on Imagenet for the first 55 epochs the accuracy of the model is 37% on test data. We observed there was slight overfitting after the 40th epoch as some gap between the training line and validation line was seen. After training for more than 50 epochs the accuracy for test_ds was still 37% and overfitting also increased.

The fifth model is the transfer learning of the VGG16 model trained on Imagenet for the first 55 epochs. The accuracy of the model is 46.6% on test data and the problem of overfitting persisted here too.

The sixth model is the upgradation of 3rd model. We are adding a layer of augmentation to deal with overfitting and, we are adding a dropout layer just before the flattened layer. The problem of overfitting was solved here. After 60 epochs the accuracy of the testing data is around 51%, the same for training and validation data.

The seventh model is transfer learning (pre-trained VGG16 model) with data augmentation, dropout layers and regularization (all to get rid of the problem of overfitting). This model underfits.

Sr. No.	Model	Accuracy on test data
1	Model 2 – best accuracy	57.90%
2	Model 7 – least accuracy	24.49%

Table 2: Comparison of the best and the worst trained model

VI. CONCLUSION

We present an outline of how music can affect a user's mood and how selecting the proper music tracks can improve a user's mood in this project. We also demonstrated approaches for detecting emotions. The technology that is created will be able to detect the user's emotions. The algorithm was able to distinguish happy, sad, natural, and astonished emotions. After assessing the user's emotion, the suggested system created a playlist for the user that included music that matched the mood. After researching which kind of music are appropriate for each mood, the music was picked to improve the user's emotion.

VII. ACKNOWLEDGMENT

We are extremely thankful to our project guide Dr. Sheetal Rathi for the valuable support and guidance she gave us on every step of the project execution. We also like to express gratitude to all the mentors and faculties of the Thakur College of Engineering and Technology who helped us accomplish this work.

Abstract—**Nowadays, an image caption generator has become the need of the hour, be it for social media enthusiasts or visually impaired people. It can be used as a plugin in currently trending social media platforms to recommend suitable captions or can aid visually impaired people to understand the image content on the web thus eradicating any ambiguity in image meaning in turn also free of any discrepancy in knowledge acquisition. The proposed paper aims to generate a description of an image also called as image captioning, using CNN-LSTM architecture such that CNN layers will help in extraction of the input data and LSTM will extract relevant information throughout the processing of input such that the current word acts as an input for the prediction of the next word. The programming language used will be Python 3 and machine learning techniques [21]. We have used the Resnet50 model to first extract train images features and then have run our own CNN-LSTM model on them. The model created by us has been trained for 60 epochs giving us the accuracy of nearly 80%. This paper will also elaborate on the functions and structure of the various Neural networks involved.**

Keywords— ***CNN, LSTM, BLEU, encoder, Resnet50***

I. INTRODUCTION

Generation of accurate captions for an image has been one of the major challenges to be solved by Artificial Intelligence and Deep Learning with vast amounts of applications ranging in diverse fields like commerce, marketing as well as social welfare. Its use ranges from providing accurate captions for videos in situations like security systems as well as in robotic vision aiding the visually impaired. As the name suggests, the aim is to build an optimal system generating grammatically and semantical captions for an image with minimal scope of error. Image captioning works for converting a given input image into a natural language description. It is described as one of the challenging yet fundamental tasks. This is due to it great potential impact which includes:

- Providing compact and accurate information of images in video surveillance systems.
- Helping in the generation of captions while sharing images on social networking sites.
- For better understanding of content images on the web for visually impaired people.

In this paper, we analyse a deep neural network-based image caption generation method. We can provide as input the image to obtain an English/Hindi sentence describing the contents of the image. This is done through a subfield of machine learning concerned with algorithms working like the brain, structurally and functionally called Deep learning. The techniques used will be Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN).

CNN helps in classification based on differentiation of images from one another. The neural network consists of several convolutional layers mixed with nonlinear and pooling layers such that as an image is passed through one convolution layer, the input for the second layer is the output generated by the first layer. This is continued for all subsequent layers until we receive a fully connected layer containing output information. LSTM (RNN) can extract relevant information throughout the processing of inputs such that input of one word for each LSTM layer results in prediction of the next word, thus optimizing itself by learning from captions. The CNN-LSTM architecture basically involves using CNN layers for feature extraction on input data combined with LSTMs to support sequence prediction such that combination of image feature and LSTM are added as inputs in the decoder model to generate output as caption with the length as that of dataset captions. This model is specifically designed for sequence prediction with:

- Spatial inputs, like the 2D structure or pixels in an image or the 1D structure of words in a document [4].

● Temporal structure in their input such as the order of images in a video or words in text, or require the generation of output such as words in a textual description [4].

II. LITERATURE REVIEW

Past papers have suggested neural models, which have generated captions by using the technology of recurrent neural networks, usually a long short-term memory (LSTM). A NIC model has been used to showcase an end-to-end neural network model to not only automatically see a photo but produce a reasonable description in English using CNN which can help visually impaired people understand content of any image. This is done through a given query image to join current human-made expressions retrieved by model to produce a novel description for the inquiry picture. Further, the creation technique explains the content of the images by anticipating the nearest possible nouns, preposition and verbs.

In recent years, there has been development in the process of image description which can be seen by the [1] use of attention mechanisms to allow the neural network to have the ability to focus on its subset of inputs (specific inputs) rather than the whole. The mechanism can be divided into two aspects:

- Decide the part of the input to be paid attention.
- Allocation of limited information processing resources to a significant part.

Over the time, different types of attention have been used, thus not only considering the relationship between the state and the predicted word, but also considering the image, but allowing a direct association between the title word and the image region. Therefore, recent input images have shown that the [4] trained model could detect relationships between various objects in images as well as the actions of those objects. For evaluation,[1] BLEU [14] and METEOR are used for machine translations, ROUGE is for automatic summary, and CIDEr and SPICE are used for image caption. Finally, we have CNN used for extracting features from the image using a pre-trained VGG-16 model and GTTS API is used to generate the image caption to audio. Evaluation of this model is done by generating descriptions for all photos in the test dataset and evaluating those predictions with a standard cost function which functions as a standalone module.

Past papers have revealed various tools and technologies for effective image caption generation but also have some gaps to be yet filled. In paper [3], the model is only able to generate description sentences corresponding to multiple main objects for images with single target objects and also the speed of training, testing, and generating sentences for the model are not optimized. The model [3] needs to expand its scope to train on datasets larger than 100,000 images thus producing better accuracy models on production level. Right now, it is restricted to predicting the words in its vocabulary only in a single language. One more model [5] that is studied deals with cross-lingual caption generation i.e., converting English to Japanese with cross-lingual retrieval of information. This is achieved by exploiting the English corpus with establishing a connection the dataset to be a comparable corpus. When pre-training was done ahead of time, cross lingual transfer was effective when the resource in the target language and convergence was faster in same amount of time. Paper [5] serves as a baseline for future research in the area of cross-lingual image caption generation. Another paper [6] studied deals with and end to end neural network system, NIC based on CNN and RNN such that model is trained to maximize the probability of a sentence for any given image. Evaluation like [1][3][4] is done using BLEU and ranking metrics such that as dataset for image increases so does the performance. Approximately five datasets have been used to understand the effect of dataset size on generalization. One of the challenges faced involves overfitting providing high variance. The paper classifies [13] the model into two different architecture - the merge and the inject architecture. In the inject architecture, we input the tokenized caption and the image vectors into the RNN block. The merge architecture just inputs the captions to the RNN block to merge the output with the image. Though both of the architecture guarantee accuracy equally, the merge architecture owing to its simple design leads to faster training due to reduction in hidden states.

Various other papers have been studied described by the table:

TABLE I.
LITERATURE SURVEY

Paper Name	Technology/Algorithm	Advantages	Gaps Identified
Image Caption Generator Based on Deep Neural Networks, Jianhui Chen Wenqiang Dong, Minchen Li [8]	Convolutional Neural Networks, Recurrent Neural Networks, Long Short-Term Memory	1. Proposed a simpler version of GRU having less parameters achieving comparable results evaluated using COCO caption corpus. 2. Generation of semantically correct sentences for the uploaded images. 3. End to end learning framework. 4. A deep study of the image captioning method to find out an optimal pipeline by replacement or modification of components and evaluation.	1. Has a considerable number of errors while detection of objects and generation of sentences. 2. Requires a larger amount of human labelled data which can be expensive in terms of operation. 3. Need exploration of methods to generate multiple sentences for a better understanding of the uploaded image.
Image Caption Generator Using CNN and LSTM, Swarnim Tripathi,Ravi Sharma[9]	Convolutional Neural Networks, Recurrent Neural Networks, Long Short-Term Memory	1. Shows a study of various image captioning techniques such as CNN, RNN and LSTM with their pros and cons. 2. Discusses the Vanishing Gradient problem[15] and the role of LSTMs in solving the problem. 3. Study of CNN architecture - convolutional, pooling and fully connected to generate the feature map. Study of the LSTM architecture consisting of forget gate, input gate and output gate [12].	1. The image caption generation model is a simple model with a considerable number of errors.
Camera2Caption: A RealTime Image Caption Generator, Pranay Mathur, Aman Gill, Aayush Yadav, Anurag Mishra and Nand Kumar Bansode [10]	Convolutional Neural Networks, Long Short-Term Memory	1. The technique generates well-formed sentences requiring semantic and syntactic of the language. 2. Shows high accuracy in image recognition and object detection. 3. Is computationally efficient.	1. Larger amount of training data is required. 2. Convolution Neural Network does not encode the position and orientation of the object. 3. Inability to be spatially invariant to the input data.
Domain-Specific Image Caption Generator with Semantic Ontology, Seung Ho Han and Ho-Jin Choi [1]	Convolutional Neural Networks, Long Short-Term Memory, Recurrent Neural Networks	1. Generate domain-specific image caption based on object information. 2. It makes use of semantic ontology to provide natural language description.	1. Model is not in end-to-end manner for semantic ontology.

After a careful analysis as shown below, it can be seen that the prime requirement of clients is to express proper unambiguous meaning of images and that will perhaps help intellectually impaired people. This analysis is done after observing responses to a survey created by us and floated among college students and elders.

1- Less Critical
2- Critical
3- Recommended
4- More Critical
5- Most Critical

TABLE II
REQUIREMENT ANALYSIS

DESCRIPTION	CRITICALITY LEVEL
Expressing image meaning	5
Removing image ambiguity	4
Suggesting good image captions	3
Aiding intellectually impaired people	4

III. METHODOLOGY

A. CNN Architecture

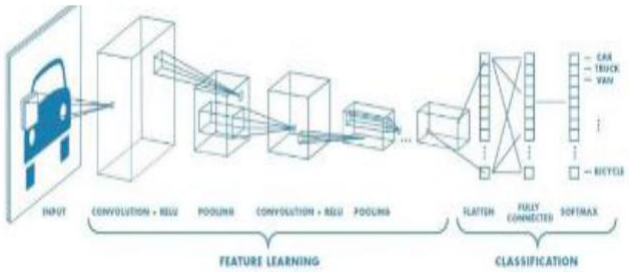

Fig. 1. Architecture of Convolutional Neural Networks for object classification.[20]

The CNN architecture consists of three layers - convolutional, pooling and fully connected. The first layer creates a features map on the basis of the input image read through the CNN. This output is passed onto the pooling layer where the feature map is broken down into simpler parts to discover critical information about the image. Depending on the picture, the two layers are practiced to get in depth information about the image creating a dense feature map. Finally, the last layer performs classification to a greater level to identify people and objects among others.
The AlexNet[20], VGGNet [20] and GoogLeNet [20] are widely used deep convolutional neural network architectures. They share the convolution pipeline explained having different shapes and connections of layers, especially the convolution layer. AlexNet is the first deep convolutional neural network used for large scale image classification. VGGNet and GoogLeNet achieves the-start-of-the-art performance in the ImageNet recognition challenge 2014 and 2015. [20]

B. LSTM Architecture

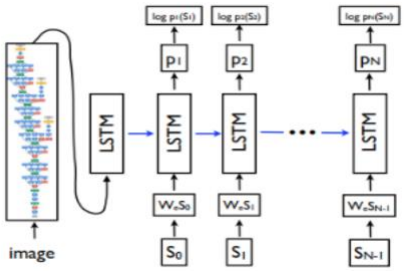

Fig.2. LSTM Model

LSTM, a discipline of Recurrent Neural Networks solves the vanishing gradient problem occurring in RNN. RNN stores the data for a fleeting time and stores only some array of data. The vanishing gradient problem is formed when RNN stores data values at each time step resulting in storing huge amounts of data, much greater than feasible. LSTM comes here to rescue. It stores the input data and generates predictions about the subsequent dataset on its own [20]. LSTM uses three main gates:

1. Forget Gate - Acts as a filter to remove the unwanted data and optimize it.
2. Input gate - Take the output of CNN as input.
3. Output gate - showing the final outcome.

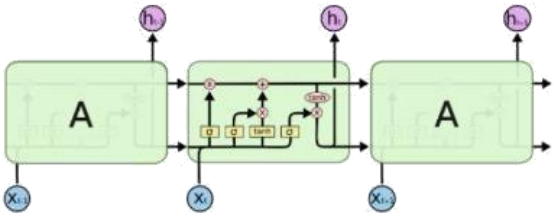

Fig. 3. The recurrent module in LSTM contains four interconnected layers[20]

LSTM uses several gates ensuring studying values again and again, mainly back propagation easier. All the gates are skilled enough to make judgment and take decisions regarding the data.

C. Workflow

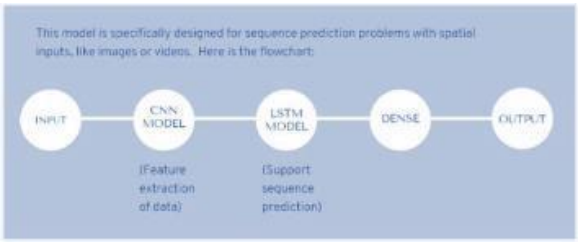

Fig. 4. Workflow

1) Dataset

The corpus that we used was the Flickr 8K dataset. There are 5 captions for each of the 8000 photos in the dataset. Understanding all the different circumstances is made easier by the single image's 5 captions. The dataset includes three prepared datasets: Flickr 8k.trainImages.txt (6,000 photos), Flickr 8k.devImages.txt (1,000 images), and Flickr 8k.testImages.txt (1,000 images) (1,000 images).

The images are chosen from six unique Flickr groups and don't feature any famous people or locations. They are nevertheless manually chosen to display a diversity of scenes. [20]

These links (thanks to Jason Brownlee) will allow you to download these datasets, each of which is 1GB in size:

Image Dataset:https://github.com/jbrownlee/Datasets/releases/download/Flickr8k/Flickr8k_Dataset.zip

Text Dataset: https://github.com/jbrownlee/Datasets/releases/download/Flickr8k/Flickr8k_text.zip

Fig. 5. Flickr8k Image Dataset

Fig. 6. Flickr8k Text File

2) Preparing Resnet50:

Here, Resnet50 which is a transfer learning model(pre-trained) is imported. The model is modified a bit by removing its last layer and thus making its penultimate layer the output layer with about 2048 labels.

3) Feature Extraction:

For each train image, the above Resnet50 model is executed to extract useful features from the image, which are stored in a python dictionary besides its respective keys which are the corresponding image addresses itself. The images are reshaped to a dimension of about 224*224*3 for feeding it to our Resnet model.

4) Text Processing:

Simple text processing techniques like converting all captions to lowercase, removing punctuations and adding a start and end phrase to each caption is performed.

5) Vocabulary Creation:

The main idea is to first count occurrences of each unique word within the captions dataset and then replace each word in every caption by their respective word count. This will convert all our captions to Integer values which is useful and interpretable to our model.

6) Data Generator:

As this is a supervised learning assignment, training the model requires giving it an input and an output. Our model is trained on almost 6000 photos, with each image containing:

1. A 4096-length feature vector.
2. A numerical value is used to represent the caption that goes with the image. Here, the variables X,Y_in,Y_out are created where:

a) X: Image Features

b) Y_in: Input Word

c) Y_out: Next Predicted Word

All the three variables are then converted to numpy arrays.

7) Model Building:

We will use 6000 training photos to train the model, creating its input and output sequences in batches before fitting them to the model. It would take a lot of training to get the model to 60 epochs. An LSTM-based model will be created with the help of the features vectors received from the Resnet50 Network in order to achieve the goal of creating a caption for the provided image.

8) Model Evaluation:

Each epoch will generate an accuracy score and the loss value which will give us an idea about the model performance.

9) Testing:

The same Python notebook can be used for testing or another one can be made. In any case, we will load the trained model that we had previously saved and produce predictions.

In addition to the tokenizer file, we made earlier, the sequence generator will now be used.

For the specific image under observation, the first stage of feature extraction will be carried out.

The function is manually supplied the path of one of the remaining 2000 test photos. A dictionary or a list can be used to keep track of the predictions for each image as you iterate through the test data set.

The start sequence and the finish sequence are used in the actual functioning of image generation.

10) Integration with frontend:

The model created will be integrated with a good user interface created via HTML, CSS and JavaScript which will support text to speech conversion as well as language translations. Flask framework will be used to integrate the same. So at the end a web application will be created where:

1. User will upload the Image from the frontend
2. The Image will be processed by our model created to predict an appropriate caption to the image.
3. The user will have an option to view the caption in different languages and also to hear the caption in case the user is visually impaired.

IV. RESULTS

A. The captions dictionary was prepared which binds image urls to corresponding captions.

```

Fig. 13. CNN-LSTM Model Summary

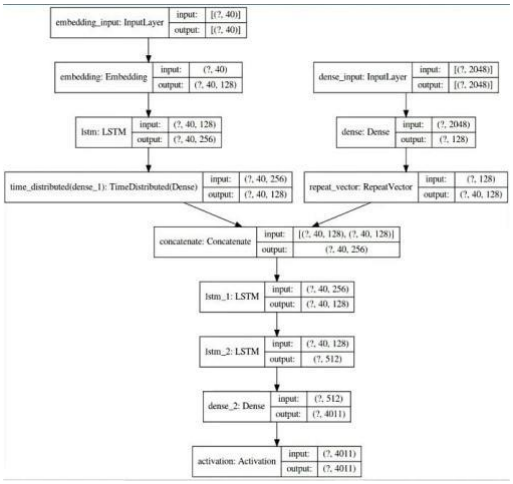

Fig. 14. Model Architecture

F. The training was done for 60 epochs with batch size of 125 images per epoch and the end result was the model being successfully trained with an accuracy of about **80%.**

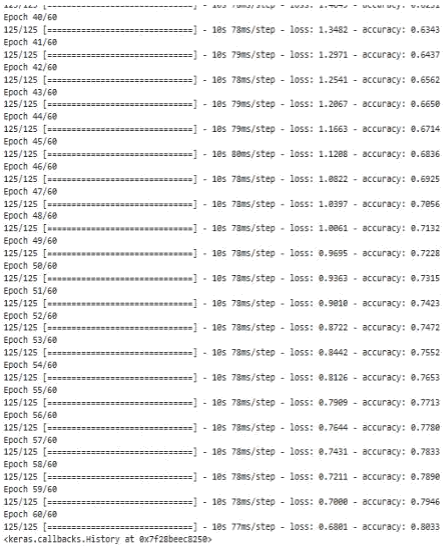

Fig. 15. Training Results

G. To validate the model, a test image is picked and the model is executed on it to predict the respective captions.

Fig. 16. Caption predicted by model for a test image

The results after running our model on different images are summarized below. The captions generated are near accurate and similar to original ones.

TABLE III.

RESULTS OF THE MODEL FOR CAPTIONS PREDICTIONS

Image	**Actual Caption**	**Predicted Caption**
	A person is riding an orange ATV in a large empty field	A man in a hat and a red helmet, holding a ATV on a dirt path
	A boy in his blue swim shorts at the beach	A young boy is standing at the camera with his hands in his arms standing in the street.
	Two girls smiling	Two girls playing in a pool

H. The final integration with the frontend using flask is done and the web application(website) is created using flask. The captions generated can be converted to different languages using Google Translate API and also captions can be heard by voice by the users. This is the page where the user will upload the image.

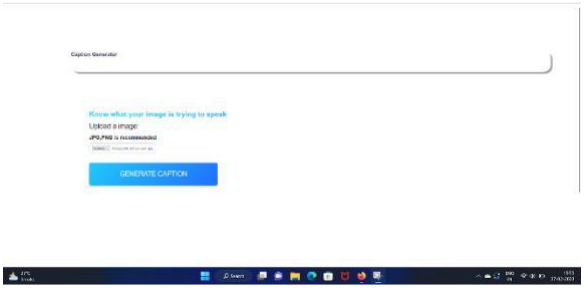

Fig. 17. Main web page

Here, the caption will be visible after the “Generate Caption” button is clicked.

Fig. 18. Caption Result

Also, the caption can be heard by clicking the “Listen your Caption” button and the caption can also be viewed in different languages.

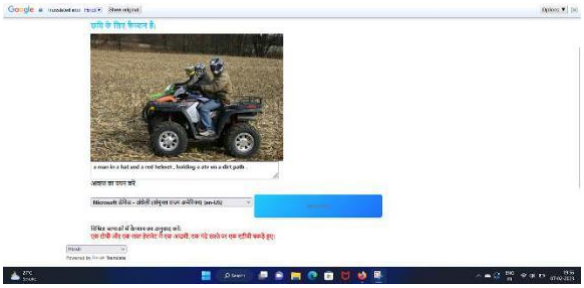

Fig. 19. Caption in Hindi language

V. CONCLUSION

As a result, we can conclude that deep learning can be used to generate image captions. We can go even further by creating a hashtag generator. Based on the findings, we may conclude that the deep learning technology employed yielded positive outcomes. Because the CNN and the LSTM were synchronized, they were able to determine the relationship between objects in images.[21]

The product can be sold as a plugin to various social media platforms due to its compact and small size nature. The features namely language translator and text to voice eradicates all possible barriers to the people with disabilities to read or understand.

VI. FUTURE SCOPE

The work done in this research has been done on an existing database on which a lot of work has been done. Here, the accuracy was improved by introducing some different techniques and model structure. However, in future we could do this same work on a dynamic dataset. Also, more images could be brought into the dataset so that the model works accurately and is even able to perform better on unseen images. The Web application created in this work can be converted into a mobile application which can enhance usability.

ACKNOWLEDGMENT

We gratefully acknowledge the support, guidance and encouragement of our guide, Mr.Shailesh Sangle sir for this work. [21]

Abstract: **Too many assumptions are baked into the conventional management accounting data processing, making it difficult to change the issue. This study employs data mining algorithms to acquire data and explore rules to increase the operational efficiency of a system using artificial intelligence information technology. Furthermore, the study employs statistical, machine learning, and other approaches to examine the relationship between attribute values and convert data into valuable information for decision-making. In addition, it identified the close relationship between corporate finance and business. This paper employs several machine learning algorithms to create an intelligent management accounting information system that, in turn, facilitates closed-loop management among financial analysis, risk management, performance monitoring, and managerial decision-making. In conclusion, this research plans studies to test the accuracy of the model. Based on the study's findings, it is clear that the system designed in this article adequately provides the sophisticated need for accounting data.**

Keywords- statistical, machine learning, Data mining, decision-making, management accounting.

I. INTRODUCTION

With the advent of AI, data has increased at an unprecedented rate. Large data sets provide challenges for conventional management accounting, and the complexity of extracting useful information from them is growing. Improving the management accounting information system's intelligence using artificial intelligence technology and combining data mining and machine learning is important to increase the system's operational efficacy.

The administration of businesses is becoming more reliant on the advancement of information technology due to the current era's rising social and economic growth levels. Management accounting's role corporate financial management is expanding in today's business world. Via the merging of financial and business data, through the study and analysis of information technology approaches, management choices that are conducive to the growth of company strategy may be found.Scientific management judgments are of great significance to the enhancement of the future economic profit of the firm. The extension of the scale of operation and the constant strengthening of comprehensive strength. At the same time, business complexity and size increase. At that point, it will depend more on management accounting for its decision-making.

II. NEURAL NETWORKS TECHNIQUE:

2.1 The neural network model has two main phases:

Training and recognition. Gathering training data, planning the network's architecture, deciding on the neural network's depth, the number of hidden nodes in each layer, and the activation function and loss function for the output layer are the primary components of the training process. Precisely, the weight matrices of each layer are adjusted based on the discrepancy between the prediction results of the present network and the goal value we genuinely desire. Acquire the Data collection process via training samples and the Learned parameters of each layer through training samples. The loss function, sometimes called the objective function, is an equation used to quantify how far off the actual value is from the projected one. Mean square error (MSE) is often used to measure how far off the actual value is from the projected one. The accuracy of a forecast is enhanced when the MSE is low. Training consists of gradually decreasing the MSE.

One kind of neural network architecture, error backpropagation, uses feedforward neural networks with three or more layers. The gradient algorithm uses the difference between the expected and actual output to adjust the weights of each link. The BP network is taught by randomly selecting examples from training samples that provide the desired outcomes. Data travels across the intermediary levels from the input layer to the output layer. Then, Compare the final result to the ideal value, and the weights of the connections between the intermediate and final layers are adjusted accordingly.

At last, the algorithm loops back to the input stage. Model weights are continually improved via repeated sample selection and training to reduce the gap between the actual and desired output values. Here are BP neural network's calculated steps:

Initialization process for the three-layer neural network:

inputs, l hidden nodes, and m output nodes. In addition, aji represent the bias from the input layer to the hidden

layer, Wjk means the weight from the hidden layer to the output layer, Wij represents the weight from the input layer to the hidden layer, and bk represents the bias from the hidden layer to the output layer. The excitation function is g, and the learning rate is (n). The excitation function g(n) is one, and it has the Sigmoid form

$$g(n) = \frac{1}{1+e^{-n}} n \in (-\infty + \infty)$$

The hidden layer's output denoted Hj, is

$$hj = g(\sum W_{ij} n_i + a_j)$$

The output layer is

$$O_k = g(\sum H_j W_{jk} + b_k)$$

Error is

$$Error = \frac{1}{2} \sum (y_k - o_k)^2$$

We may train a network with n input nodes, n1, n2,...,nn

III. MODEL DEVELOPMENT:

Big data is the foundation of the business intelligence (BI) process. Additionally, the data is saved in DW in an organized manner after being processed using ETL technology. Reveals the Data linkages after OLAP analysis, which is an excellent tool for managers to learn more about their operations. From time to time, managers must go deeper into the data to uncover the insights hiding inside. DM may assist appropriate data sources using tools like data crawlers and model libraries.

The decision's outcome may be recorded in the DW and used as a foundation for future choices. With the help of BI, the enterprise's management operations may evolve into more strategic endeavors. Figure 1 depicts this procedure [12].

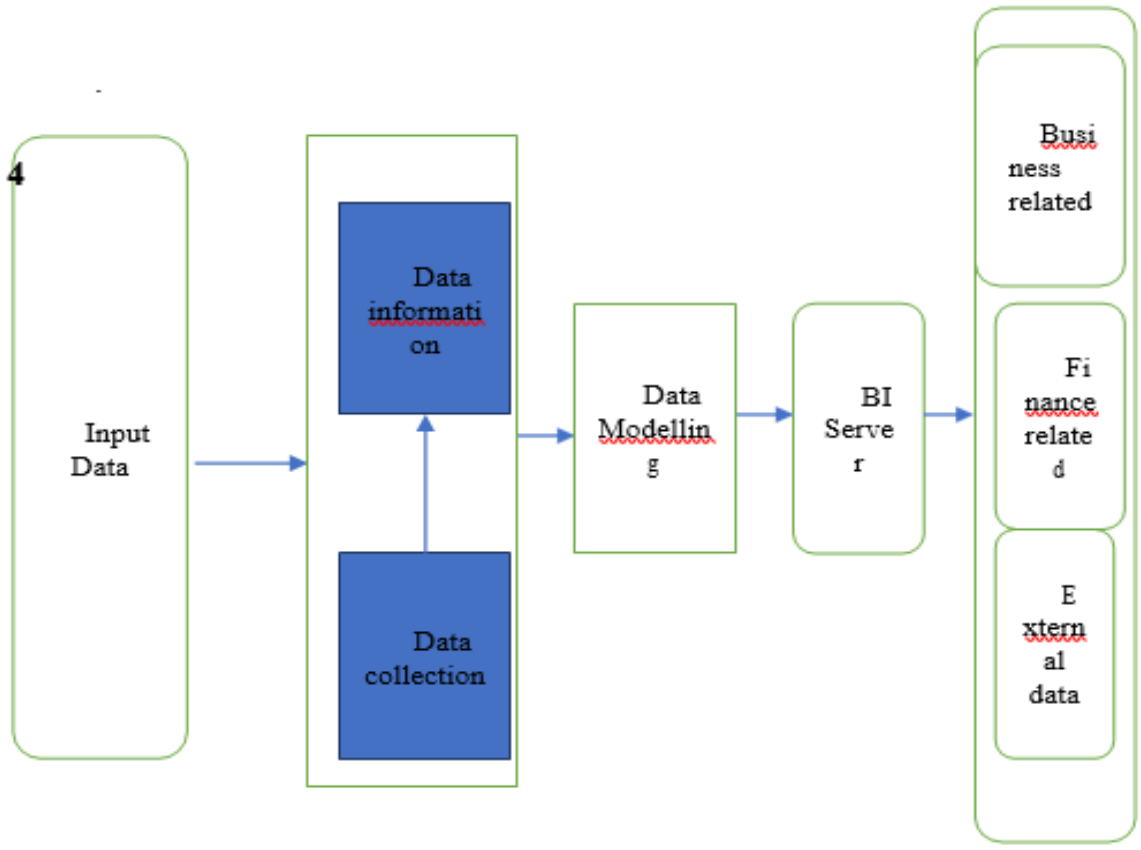

Figure 1: business intelligence (BI) process.

The Data Warehouse (DW) is the hub of an organization's data storage, offering an enterprise-wide, topic-based analytical environment. Conceptual, logical, and physical models are the three most common types of DW models. The three-tier data warehouse model's mapping connection is in Fig. 2.

• Themes in the conceptual model are conveyed via dimensions and metrics, while the conceptual model Expresses itself through topics. One's perspective, or "dimension," is the lens through which one examines the world, and one's "measure," or "measurement," is the quantitative information associated with that perspective, such as sales volume. The conceptual model may represent an information package schematic, which would include the subject's multidimensional features, the level of each dimension, and analytical indications.

• The star model and snowflake model are the most common logical models. The star model includes a fact table and a dimension table, with numerous dimension tables linked to the fact table.

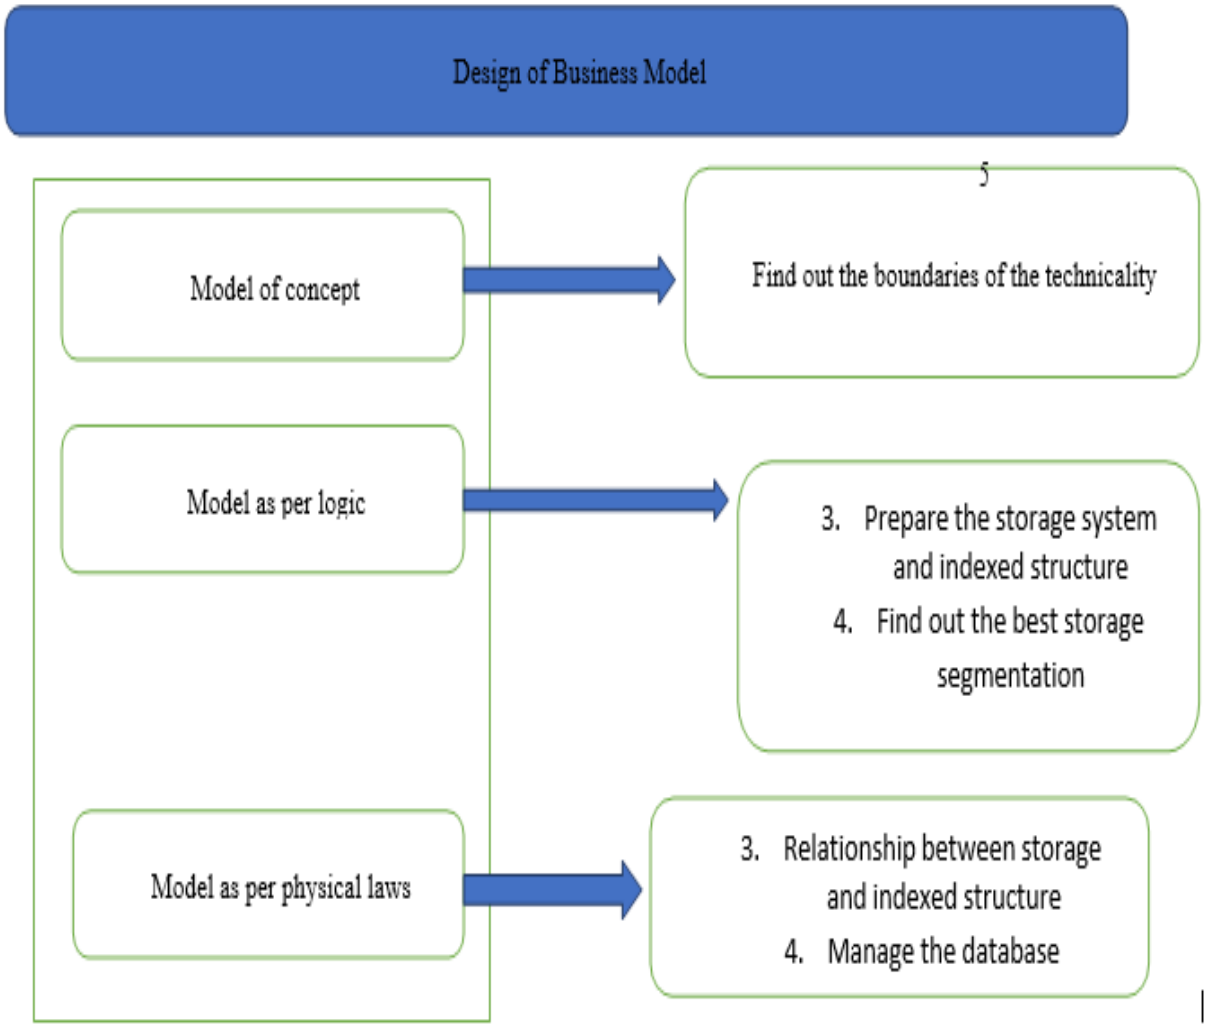

Figure 2: Relates the data model to data warehouse in layer by layer

A procurement star model in Fig. 3. The date table, the product table, the supplier table, and the logistics table are all dimension tables. In contrast, the procurement table is a fact table. Similar to how the star expanded model into a snowflake model. To reduce duplication, some data in dimension tables are divided into more specific tables. Data warehouse features, including data storage structure, data indexing technique, data storage strategy, and storage optimization allocation, are all examples of the physical model.

DW does more than collect information; it also shares news by way of a predetermined procedure (Fig. 4). Extraction of Data,

• Information in DW organizes by topic. Thus, it's essential to Before loading raw data into a data warehouse, isolate the information used for decision support. Each stage of describe extraction here.

— Information from the specified source and its interpretation; this brings us to option

— extraction. Determine which source data files or tables are accessible.

— The rate of extraction occurs at determined.

— Results. Where the information is going, and what file produce.

— Dealing with unexpected situations or how to process information when necessary information is not recovered.

• Cleaning up the data. When comparing data, the noisy data and the quiet data are filtered.

• converting data. The basic information evolves into the necessary destination data, which often entails converting formats, summarizing data, etc.

After the data has been cleansed and transformed, it is loaded into the DW using direct append and complete coverage.

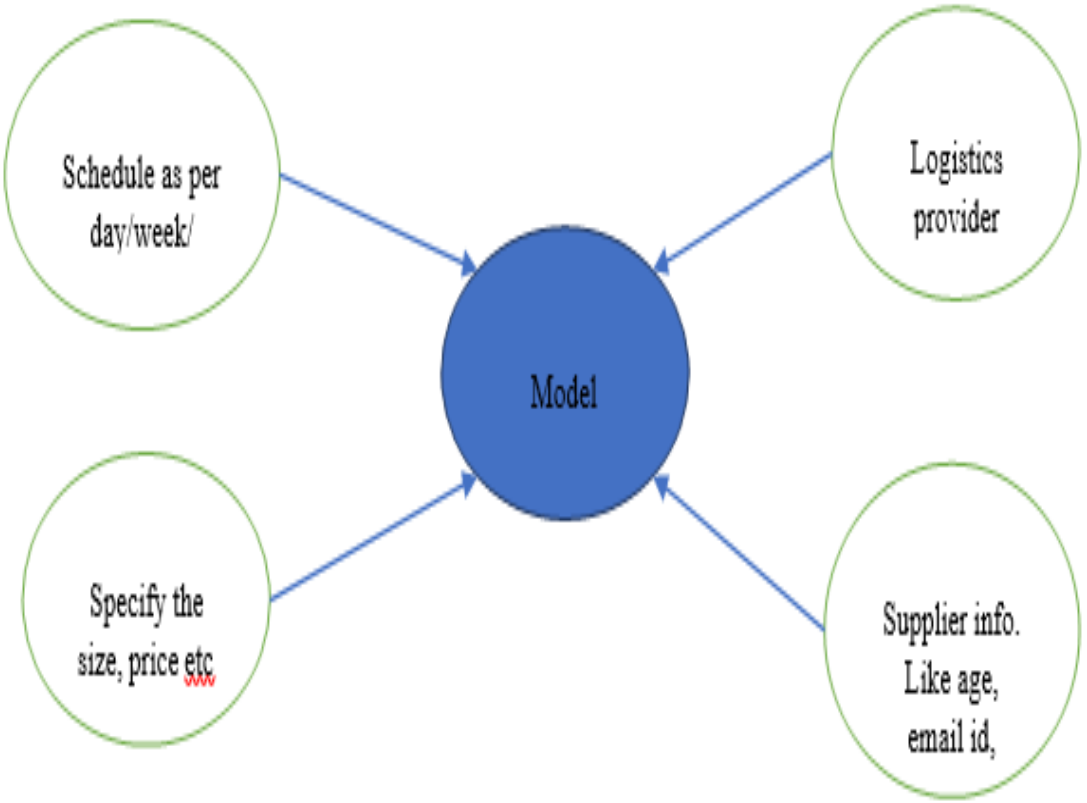

Figure 3: Model development

Figure 4: Framework of ETL process

When it comes to Online Analytical Processing (OLAP), the primary framework relies on a cube because anything can describe. In online analytical processing, the cube is a (virtual or physical) multidimensional data structure that allows for fast data processing; it also supports multifaceted in addition to intelligent data analysis and smooth operations. Develop the cube's data structure to address the shortcomings of database systems that rely on relationships between tables.

The term "data mining" (DM) describes analysing data using automated or semi- automated tools to unearth previously unknown relationships and correlations. In contrast to the OLAP described in the preceding section, data mining (DM) seeks to unearth previously unsuspected patterns in the data rather than verify the integrity of a specific hypothesis. Therefore, at its core, it is an inductive learning process. The steps involved in DM are exhaustive. The stages of data mining Fig. 5.

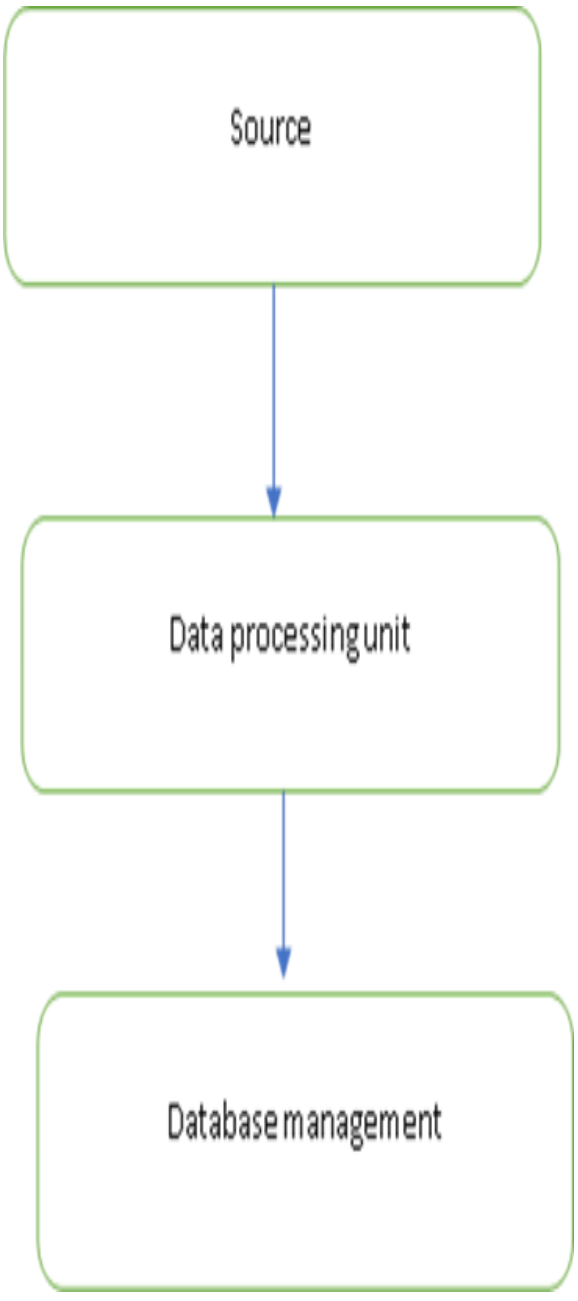

Figure 5: Data mining process

OLAP is the way to go when it comes to data analysis in DW. However, there are large-scale patterns of data. OLAP is currently unable to provide an estimate. However, The importance of predicting today's managers often requires additional support beyond what is provided by management accounting their decision-making through forecasting work to aid in constantly shifting

conditions. Right now, DM stands out as crucial in the field of management accounting The data processing system. Technology such as statistics, databases, machine learning, and others are all used in data mining. It performs a correlation analysis to determine if there is a significant relationship between two attributes. It helps businesses see previously hidden patterns in data, convert raw data into actionable insights, and competitive benefits, advantages, and merits.

Figure 7: Intelligent Accounting management system

This essay argues that a sophisticated, cutting-edge management accounting data system should have many vital components (Fig.6). One of the four components is the Accounting Analysis Management System. Risk Management Information System 2 System for Performance Management Information Fourth, a system that aids in making accounting-related decisions.

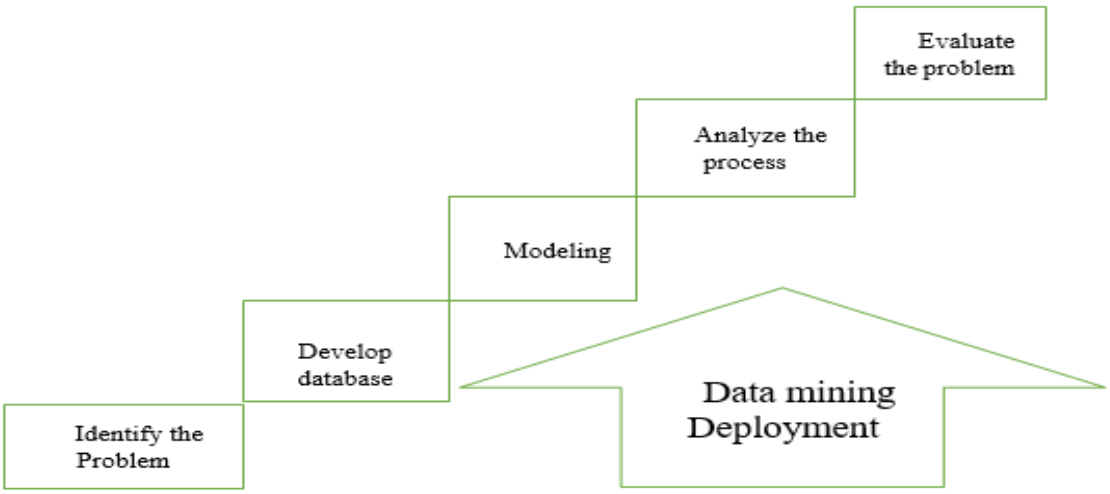

Figure 6: Data mining deployment process

In light of the account above, the authors of this study set out to create the kind of intelligent management accounting information system shown in Fig. 8. The system's primary components are a support platform with features like a data interface and system services. An accounting analysis management system with features like accounting report management, an information system for managing risks in a closed- loop fashion, a method for evaluating the effectiveness of an organization's performance, and a plan for providing decision-makers with information to guide their accounting practises. In addition, each system operates separately, takes care of its tasks, and communicates with the others to lend a hand in the enterprise's administration

IV. MODEL PERFORMANCE EVALUATION PROCESS:

This article checks the model's performance after it has been built and conducts data processing analysis according to the actual demands of management accounting. First, this study uses expert scoring methodologies to assess the effectiveness of model data mining and rank its performance—seventy-five data sets used in the simulations presented in this research. The results are in Table 1 and Fig. 8.

Sl. No	Scores	Sl. No	Scores	Sl. No	Scores	Sl. No	Scores
1	72	21	71	41	68	61	71

20	78	40	68	60	72	80	67

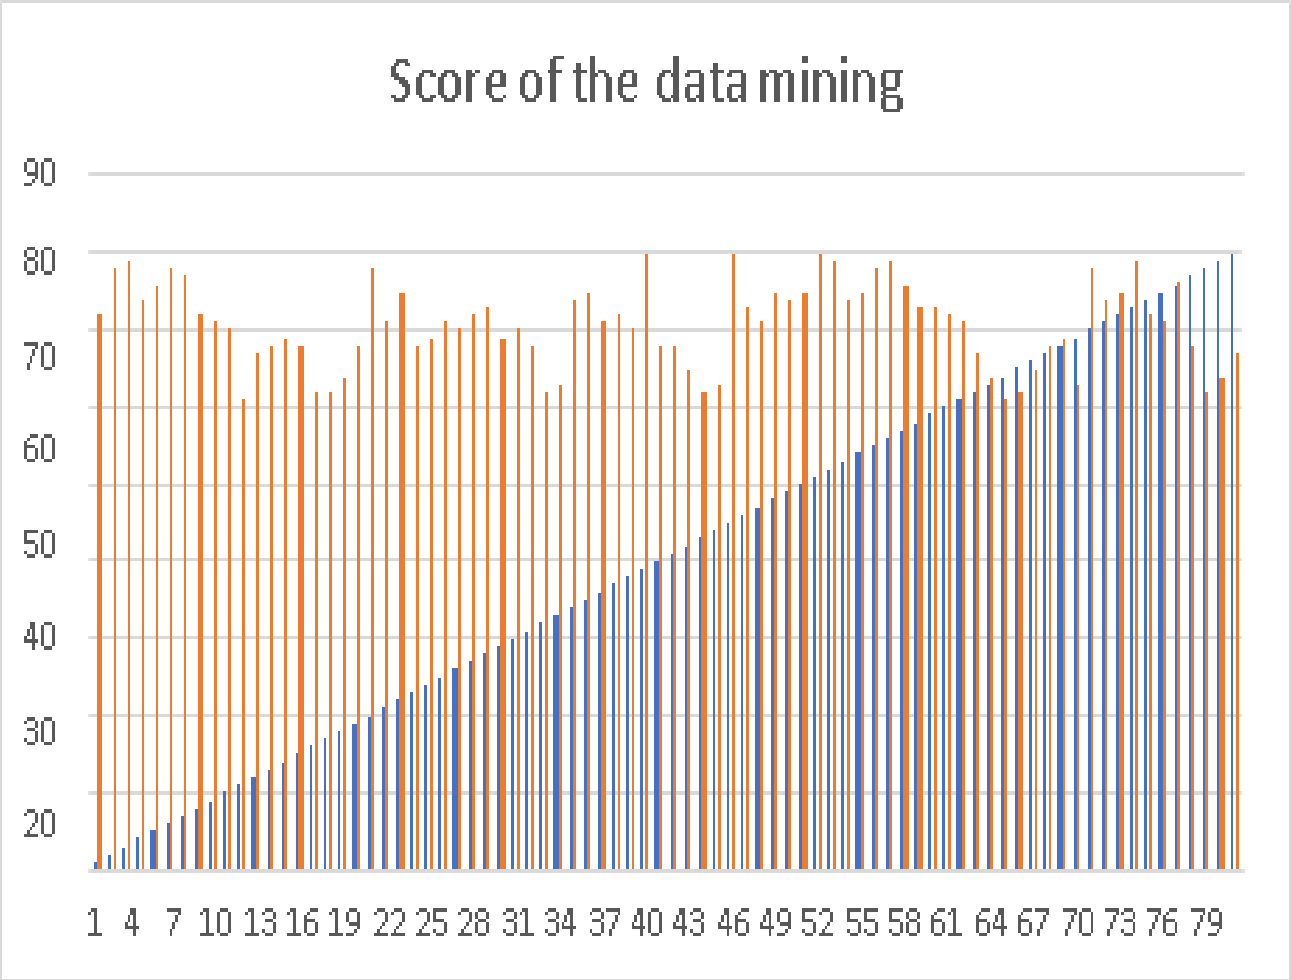

Figure 8: Statical data mining management accounting system

By examining the data above, it is clear that the management accounting information system developed in this paper has a robust data mining effect and can extract valuable knowledge from large datasets. The article then assesses the reliability of the management accounting database's data processing. Both Table 2 and Figure 9 display the findings.

Table 2: Summary statistics for MIS data processing precision

SI. No	Score s
1	99.8

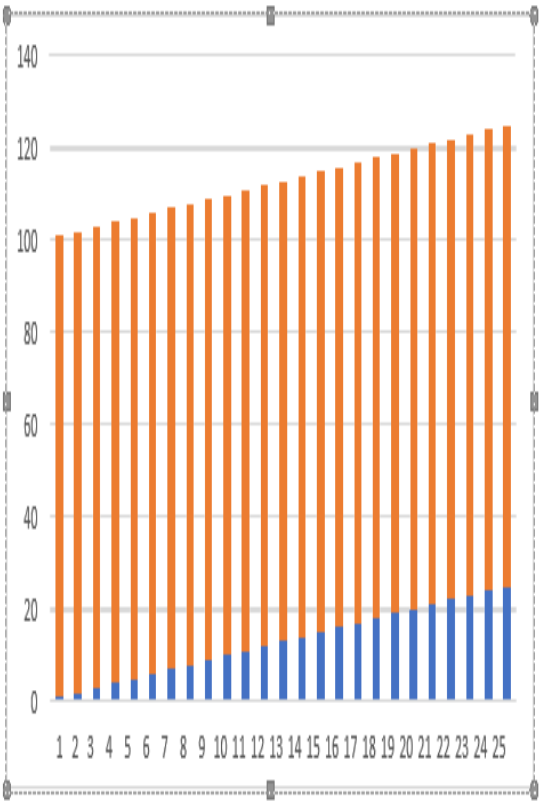

Figure 9: statistics for MIS data processing

The accompanying graph demonstrates the high precision rate of return on investment for the management accounting the data processing efficiency of this material may reach a maximum of 99.8 per cent. satisfies the stringent needs of data accounting methodical processing, so it may be used in actual settings.

V. CONCLUSION:

In this article, we employ data mining and machine learning to build a management account creation system, which is the natural next step for management accounting information systems in the AI era. Furthermore, the study argues that management accounting informatization is a natural progression in the field and that a complete management accounting information system should have analysis management, risk management, performance, and decision support modules. The various parts work separately yet are linked together. The accounting analysis management system realizes basic accounting data processing and analysis functions, enterprise-wide risks are mitigated by the risk management information system, the performance management information system paves the way for the actualization of corporate strategic goals via target decomposition and layer-by-layer implementation, and the accounting decision support system optimizes the quality of accounting decisions. In most cases, a company's ability to manage its operations may benefit significantly from the interplay between its four primary subsystems.

Abstract: . Corporations everywhere work to extract more meaning from the data they've amassed. The study's overarching objective is to explore the role of machine learning in generating lucrative business approaches. To get a competi- tive edge in today's market, corporate executives must sift through vast amounts of saved data, analyzed and easily accessible. Machine learning, a branch of AI, is used to improve business operations with little or no involvement from a hu- man operator. Financial, marketing, supply chain, human resources, and other decision-makers may all benefit from ML approaches since they allow for ana- lyzing patterns and recognition from vast data sets. Machine learning aids the changeover from physical to electronically stored data, improves memory, and assists financial decision-making. It also allows the extraction of quality patterns and database data forecasting, stimulating development. This research aims to shed light on how companies can better use machine learning to manage their finances in today's challenging market. ML has become an increasingly important tool for companies in this fast-paced environment. It has given company execu- tives new ways to profit from their access to vast data stores. The research aims to compile information from workers, supervisors, and CEOs of various sectors and analyze the impact of machine learning on financial decision-making.

Keywords- : Decision-making, finance, Machine learning, Artificial intelligence..

I. INTRODUCTION

Machine learning (ML) and deep learning (DL) are increasingly being used by top ex- ecutives worldwide because of the significant improvements they bring to the decision- making process. Artificial intelligence (AI) is the simulation of human intelligence in technological systems. Better risk management models, cash need estimates, and other estimates may be made from historical data using -e methods and other parts of artificial intelligence (AI). ML is used for enhanced financial decision-making, mainly in stock markets, to predict asset prices and manage risk [1]. Nearly $42.2 billion is invested yearly in AI, with most of that money going to the financial sector to improve decision- making. Making choices is at the core of being human and central to how we engage with the world. It's common knowledge that individuals may make both sound and foolish choices, and studies have shown both. Refrain from the best approach to helping indi- viduals make sound choices. Classes are one approach to explaining choices and getting insight into how to help others who are struggling with them. Decision-making is orga- nized, semi structured, or unstructured. For a long time, structured decision issues have which there is a single, best answer; these cases do not need help making decisions. A choice, for instance, finding the shortest path between two places, is a precise answer to an analytical problem.

In contrast to structured issues, which have established criteria and solutions, unstructured problems need the decision maker's preferences. For instance, choosing a life partner is a haphazard choice. A large variety of semistructured situations fall be- tween these two extremes, often having some agreed-upon criteria but still requiring human input. Criteria-based decision-making input or preference-based decision-mak- ing input. For instance, the company's choice to enter international markets may have a loose framework to guide it. With this in mind, semi structured choice issues might benefit from decision assistance, which entails the approach that uses user feedback and data analysis to create viable options about best practices and criteria. For example, when AI methods are used, the process of coming up with different options is called "decision tree learning," and the resulting system is called an "intelligent decision mak- ing." system of support.

II. LITERATURE SURVEY:

Since thematic modelling is a kind of ML applied to Natural Language processing , we include a mutually-beneficial element in our research by making use of ML methods to comprehend ML studies in the financial sector [7]. Research on ML's use in financial decision making was conducted for the first time, with a focus on neural networks as a tool for economic decision making. Preliminary research evaluating whether ML may enhance lending choices and credit risk management were published in the 2010s in the Journal of Banking &

Finance, suggesting prospective advantages for the banking in- dustry [8]. When ranking Italian enterprises for the likelihood of financial troubles, researchers employed neural networks but also used genetic learning algorithms. Re- search published in financial journals has shifted its emphasis from traditional ML methods like linear regression to more cutting-edge ML approaches like deep learning. Some of the most recent software packages deal with modelling the investment climate, learning the coverage rates for the best alternatives, and gaining a better grasp on how quickly defaults are recovered.

Risk management with the help of AI and ML by doing more precise risk assessments in advance. When it comes to risk management, ML is most beneficial to the company, and the most significant connection is seen in cash flow management. To handle these risks, we equipped financial institutions, for instance, with artificial intelligence and machine learning to enable choices based on prior correlations between the prices of various assets [9]. The system as a whole may benefit significantly from risk-mitigating tools for drivers. [5]. Artificial intelligence and machine learning achieve better risk management by prior anticipation and identification of potential fraud, suspicious trans- actions, late payments, and cyber-attacks. However, AI and ML-based technologies might miss emerging threats and events if they "over-educate" themselves on historical data [10]. The current innovations in artificial intelligence and machine learning imply that these tactics still need to be evaluated to manage risks in fluctuating economic conditions. Still, they have the potential to enhance risk management in the meanwhile significantly. This scholarly essay follows the following structure: The literature review is discussed in Section 2, while Section 1 represents the introduction. Section 3 explains the procedure followed. Section 4 summarizes the results and consequences, and Sec- tion 5 discusses the conclusion and prospects.

When AI and ML are used to make decisions, they create "black boxes" of risk, which might lead to difficult situations, particularly in retrospect. Financial users, especially regulators, may need help making sense of complex choices, such as those involving trade and investing. The lack of transparency around AI and ML is just part of the issue; the approaches may pick up biases from human assumptions and hidden artefacts in training data, leading to unfair or inaccurate decisions. Furthermore, human operators of such systems may need help monitoring due to the incomprehensibility of these in- struments' communication methods [11]. Users of these AI and ML systems may all pull the "shut-off switches" (manually disabling the tools) simultaneously if they have any lingering doubts. Users may only revive the systems after an event if they get con- firmation from most of the market's users. The potential for system-wide voltage con- cerns and the need for adequate switches may rise with -it.

By analysing large amounts of data, AI and ML may pave the way for "more personal" financial services [12]. Extensive data analysis, which AI and ML may aid, can help businesses better understand their customers and investors so they can create more per- sonalized products and services. However, there are potential privacy and security risks associated with using customer data. Additionally, it would be essential to think about customer outcomes as analytical artificial intelligence and machine learning data may analyse the characteristics of specific consumers using public data. It has to be guarded while also ensuring that customers' privacy is preserved and big data is used effectively and securely to improve service delivery [13]. Deep learning algorithms are particularly beneficial to organisational decision-making, which may aid workers in analysinginformation, boosting their analytical abilities and easing the shift to greater design out- put. Further, it would be essential to set up well-designed governance frameworks for financial service providers leveraging AI and ML to safeguard customers and investors

III. METHODOLOGY:

This research examines how machine learning may apply to company finance. The re- searchers have considered several criteria in selecting private banks and financial or- ganizations from India and data is collected from them. In the financial industry, ma- chine learning algorithms have shown to be necessary due to their capacity to identify fraud, improve trading procedures, and give individualized financial counsel to con- sumers. In contrast to more conventional education techniques, machine learning may rapidly examine vast data sets in search of patterns and enhance performance [14]. As a result of machine learning's importance in economic decision-making for low-income nations, researchers have begun to focus on it using a descriptive approach. In addition, CEOs are looking to adopt new technologies that will help them optimise risk manage- ment, cash inflows and outflows, asset pricing, and the identification of profitable busi- ness opportunities.[15]

The researchers obtained data using a questionnaire administered to respondents; they used a nonprobability sampling strategy to compile their sample of 3241 responses from the sample population used in the analysis. Researchers may efficiently collect answers from the sample population by using closed-ended questionnaires; Translate the aggre- gate replies into quantitative aspects by the Likert scale concept [1 = strongly disagree, 5 = strongly agree]. Test data using descriptive analysis of demographic factors and then implement the structural equation model (SEM) using AMOS [12]. The SEM model allows for the comprehensive evaluation of the correlation between independent and reliant variables.[16,17]

3.1 Hypotheses testing:

Ho: Effective financial decision-making in the organization correlates significantly with machine learning in risk management.

H1: The use of machine learning to analyze ways to improve financial performance correlates with something other than better financial decision-making inside an organ- ization.H2: The company's ability to make sound financial decisions differs from how well it handles its cash flow.

3.2 Data collection process:

The data acquired by the authors are analyzed in depth in this part, with the most critical analyses being percentage analysis, correlation analysis, and structural equation modelling. From Table 1 sample population was composed of: 30.79% of males and 69.23% of females; 14.79% of the respondents were be- tween the ages of 37-50, 30.61% were under the age of 25, 15.30% were over the age of 50, and

Variable		**In Number**	**In %**
Gender Con- sideration	Male Female	20 45	30.79 69.23
Age consid- eration	Less than 25 26-36 37-50 Above 50	60 77 29 30	30.61 39.28 14.79 15.30
Type of in- dustry	Banking sec- tor Finance sec- tor	148 91	61.92 38.07
Management grade	Low level Mid level Head level	69 139 41	27.71 55.82 16.46
According to Experience	Less than 3 years 4-10 11-15 16-20 More than 20 years	64 62 29 17 76	25.80 25.00 11.69 6.85 30.64
According to family	Combined family Nuclear fam- ily	124 112	52.54 47.46

This study examines how machine learning might help businesses make better-in- formed choices. Table 2 shows that nearly half (43.66%) of respondents strongly agree that machine learning provides more opportunities for management to make better de- cisions. In comparison, another 20.42% approve, and 11.26% disagree (plus 9.85% who strongly disagree). Introduce the possibilities afforded by machine learning through a chart in Figure 1.

were under the age of 25, 15.30% were over the age of 50, and the remaining respondents were in the age range of 26 to 36. About half of them (47.46%) were members of a nuclear family, another 61.92% were employed by financial institutions and the remaining 38.07% were employed by businesses outside the banking sector. In the existing organizations, around 16.46% were in upper man- agement, 27.71% were in lower management, and the remaining 55.82% were Mid- level Management. 25.80per cent have less than three years of experience, 25per cent have between four and ten years of experience, and 11.69 per cent have between 11- 15.

Opportunity	**In Number**	**In %**
Highly Disagree(1)	14	9.85
Disagree (2)	16	11.26
In neutral (3)	21	14.78
Agree (4)	29	20.42
Highly agree (5)	62	43.66
Total	**142**	**100**

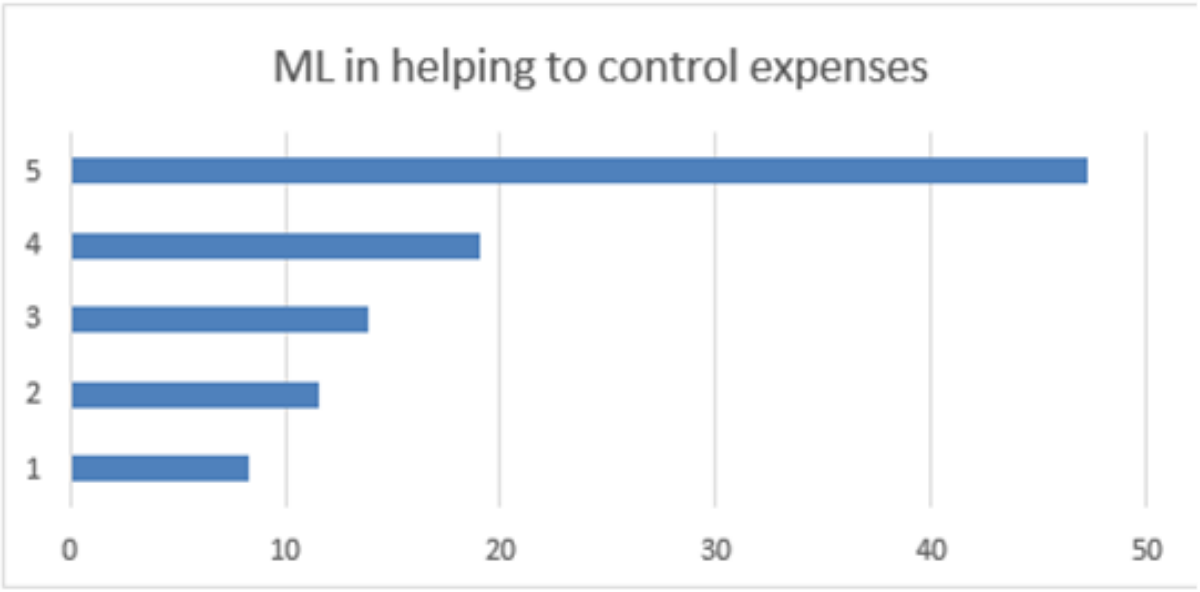

Figure 2: Usefulness þf ML in helping to control expenses

Where machine learning comes in handy since cheap and abundant computing re- sources make this technique feasible, the proliferation of affordable and powerful com- puting has fueled the explosion in the amount of data we're able to collect and the im- provement in machine learning algorithms performance.

The authors have also ran surveys to gauge respondents knowledge of whether or not machine learning aids in controlling overhead expenditures. Table 3 shows that 47.22 per cent of respondents strongly agreed with the statement, while 30.1 per cent agreed. While 9.6% of respondents disagreed and 8.33% strongly disagreed.

Figure 2 demonstrates the usefulness of ML in controlling expenses. The bars in this diagram show the percentages of respondents who strongly disagree, disagree, are neutral, agree, or agree.

Opportunity	In Number	In %
Highly Disagree (1)	18	8.333333
Disagree (2)	25	11.57407
In neutral (3)	30	13.88889
Agree (4)	41	18.98148
Highly agree (5)	102	47.22222
Total	216	**100**

3.3 Correlation Factors:

In this study, the researchers considered three crucial independent variables: risk man- agement, areas for improving financial performance, and cash management, and dis- covered that all three had favorable effects on the dependent variable. Correlation anal- ysis is a useful statistical tool that assesses the overall association between variables.

Table 4 shows that variables have a strong positive link if their values are above

+0.64. ML helps the organization make better risk management choices since financial decision-making and risk management are highly correlated. Machine learning tech- nologies allow organizations to make

reduce expenses and enhance earnings from sales and other sources.

Table 4: Results of a correlation analysis

	Risk management process	Performance of finance	Effectiveness of management process	Decision making system
Risk management process	1	0.76	0.82	0.94
Performance of finance	0.76	1	0.76	0.73
Effectiveness of management process	0.82	0.76	1	0.84
Decision making system	0.94	0.73	0.84	1

IV. RESULT AND DISCUSSIONS:

3.4 Structural Equation Modelling Approach (SEM):

SEM is a comprehensive multivariate technique that allows the researcher to apply fac- tor and regression analysis. It also evaluates the global structural relationship between the variables and the constructs. This model has widespread scholarly and practical support because it estimates multiple and other dependencies via analysis considering both endogenous and exogenous factors. Figure 3 demonstrates this. We reject the null hypothesis and accept the alternative idea because Table 5 shows that none of the independent variables has a P value higher than the 5% threshold of significance (deal at 0.05) about the made financial decisions. This leads us to Table 6, which serves as the hypothesis statement.

Therefore, critical, independent variables, such as risk management and area analysis to improve financial performance and cash management using machine learning, help make quick monetary judgments. When making financial decisions, business leaders are in a prime position to focus on risk management and the areas that will impact the corporation's revenues —used machine learning tools and techniques to predict the outcomes. In addition, managers recognize that cash flow is one of the most critical aspects of production, and it must be appropriately handled by analyzing operational costs and expenditures. Management can make informed choices by better anticipating financial needs and with the help of machine learning algorithms.

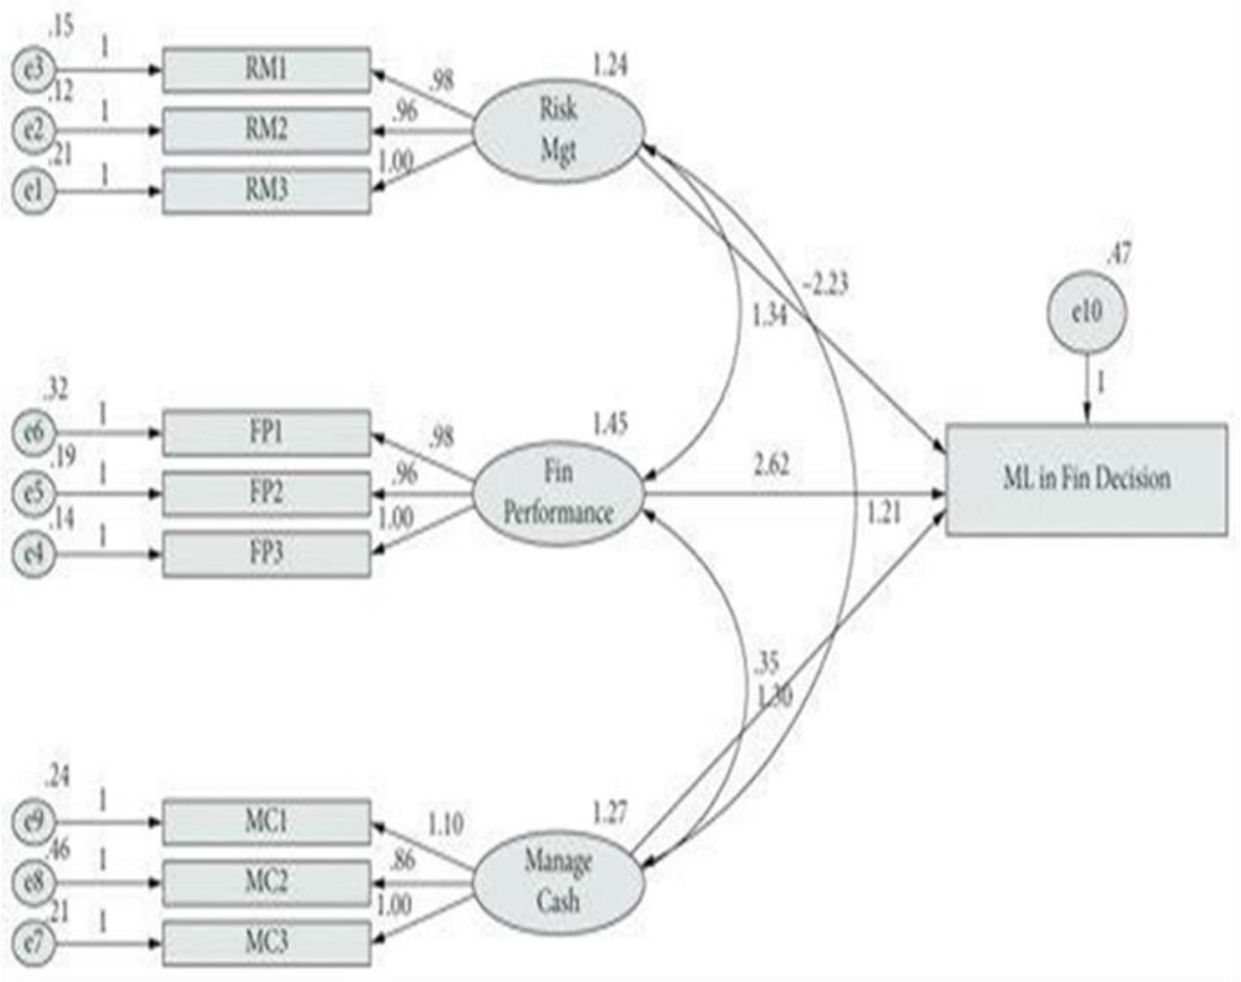

Figure 3: Graph showing the structural equation model (SEM) between the independent and de- pendent factors

V. CONCLUSION:

Machine learning is often defined as a branch of AI that seeks to automate the optimization of commercial procedures. Management can get the insights they need to make sophisticated choices in various financial, marketing, and supply chain domains thanks to ML technologies that analyse and identify the model from huge data. Artificial intelligence's ability to apply algorithmic transactions, handle risks, facilitate process automation, and manage cash flow effectively are all essential features. Machine learning is the most critical part of the AI approach since it helps to make predictions based on historical data. In addition, ML-based technology improves consumer interactions by providing more accurate responses to their inquiries. Better ideas can be found, data can be analyzed more efficiently, and better financial choices may be made with the help of machine learning algorithms. Employees and management often design such strategies to identify the pattern, zero in on the value of securities, and implement the necessary steps for successful risk management. Saving money, increasing productivity, mitigating risk, and encouraging prudent spending are all aided by ML techniques. Also, ML algorithms often provide custom reports based on existing data, giving management at all levels clear and concise information in a streamlined style from which to make decisions.

Abstract **Quality standards are rising as people's disposable incomes, and their reliance on the market for necessities like food and clothing are increased. The main objective of the research is to apply AI expertise and computerization to accounting analysis and its information. In this paper, we use the principle of subsystem combination to develop an AI accounting information web system and conduct a theoretical and technological feasibility study of this system. It has a positive impact that speeds up the dissemination of all types of informa**

tion and encourages a shift in the approach used by businesses to manage the account. The organization's total management level is enhanced, enterprise's overall competi-tiveness and save costs have up to an 8 % improvement in the correctness of the system model compared to the standard system algorithm.

Keywords: Account management, Artificial intelligence, cost, information

1 Introduction:

Influence modern businesses by swiftly and accurately extracting helpful infor-mation from a wide variety of data and information sources of varying sorts and densi-ties in light of the rapid advancements in science and technology. Audit plays an essen-tial role in every organization. Modern businesses risk the crisis of enterprise annexa-tion if they rely

on old-fashioned methods of handling the vast quantities of data and many formats of information created by their operations. Accordingly, how to increase productivity and guarantee the correctness of audit information has become a focal point of study in the domains relevant to the current, ever-shifting information land-scape.

May quickly assume the accounting data and expertise thanks to develop-ments in big data. In today's advanced economies, businesses want to become "intelli-gent firms," focusing on increasing their value via knowledge production. China's na-tional economic growth policy makes clear proposals for sustainable development information, and scientific advancement in light of the country's rapid progress in in-formation technology. The question of how Chinese businesses may best use IT to boost their competitiveness in the fast-paced "information economy" and "knowledge econ-omy" is one of the most pressing issues facing the country's business community. With the advent of modern information technology, data mining has emerged as an essential aspect of knowledge acquisition and business intelligence, despite its origins as a mul-tidisciplinary field spanning both computer science and management science. The In-ternet's widespread adoption and use have resulted in a dramatic increase in the volume of data and information available. This, in turn, provides a wealth of data and infor-mation resources and an easily accessible interactive communication platform to aid in decision-making and encourages the inclusion of more knowledgeable parties in the process. In another way, all the workers need to concentrate more on the data mining process to develop the new learning things and to get the decision-supporting data to the decision-supporting system. It is a hot issue in educational and corporation systems how to convert the business information to the primary resource information to get the massive achievements.Accounting information management is critical to the development and prof-itability of modern enterprises, which is why companies must use artificial intelligence technologies like big data information processing. Consequently, this work's original contribution is combining a decision support system with an expert system to create an interactive accounting information system (IAIS).Furthermore, include accounting data and auditing expertise in the IAIS-based management information model for account-ing. Finally, assess its usefulness as a resource for the evolution of accounting data via examination of its performance and feasibility.

Basic information about Account management and information system:

How an individual or group uses the accounting system's tools to determine the perspective on accounting's fundamental nature. Organization management authorities supply management accounting and financial accounting information; however, the former is used mainly for internal purposes. Accounting information providers and con-sumers work together as one. Management accounting information and financial ac-counting information do not need societal regulation. Management accounting data is isolated and can only be utilized internally and not shared with other departments. The foundational idea is that society cannot care about management accounting principles, but that cannot imply that management accounting is devoid of accounting standards. Compared to the uniformity, legality, and coercion of financial accounting principles, the uniqueness, discretion, and awareness of management accounting principles stand out. Because of this, management accounting data is not only a made-up system. It may be built and tailored to meet specific needs and can-do comprehensive data analysis.

Most definitions of a system emphasize its holistic nature, defining it as a collec-tion of parts that work together to perform a single purpose. This framework includes systems, elements, structures, and functions. It illustrates the interconnectedness of

interdependence of eco-systems, perspective of system theory to describe these connections. To this end, as knowledge and technology advance, employees must apply system principles to their everyday work in areas as diverse as operations, finance, planning, compensation, and performance. Individuals need to learn to see management from the viewpoint of sys-tem integrity to make informed decisions about how to strengthen best the management capacity of their company and usher in a new era of effective management.

Basic theory on AI and implementation process:

Artificial intelligence (AI) studies how to programme a computer to do tasks that previously required human intellect at a high level of competence by deducing the rules governing how human intelligence works and then modelling those rules in an artificial system.

Artificial intelligence (AI) researchers are working to develop computer pro-grams that can compete with humans in areas where human intellect is often required, such as solving complex problems. The human brain, for instance, is the first to tackle complex mathematical and scientific issues. This advancement has made it possible for computers to out-calculate humans and does it more quickly and precisely. With the passage of time and the promotion of technology, the definition of complicated labour changes, and so must include the precise purpose of AI.Artificial intelligence and theoretical science are like practice and theory. Arti-ficial intelligence (AI) is a subfield of cognitive science that operates at the technology's application level. For AI to make significant strides forward, it must consider not just logical thinking but also picture thinking and inspirational thinking. Numerous fields look to mathematics as their foundational science, and the subject permeates other do-mains, such as linguistics and philosophy. A place for found may result in both tradi-tional logic and fuzzy mathematics. All branches of AI should use mathematical instru-ments; this will encourage collaboration and speed up progress. Variety of Artificial Intelligence-Related Research Areas.individual components, the interdependence of systems and the

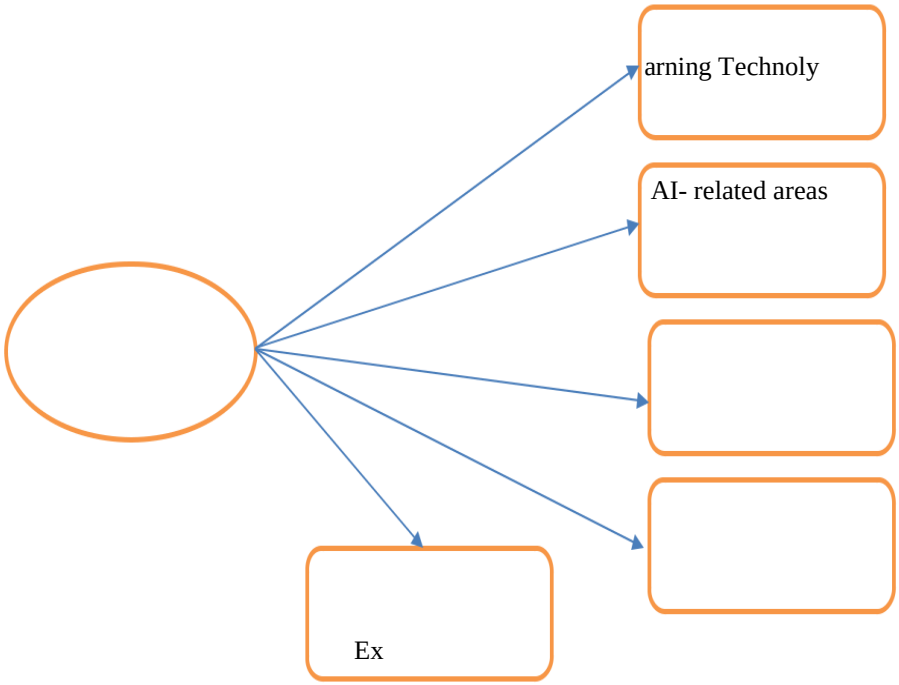

Figure 1: AI related areas

4 Methodology:

4.1Integrating the AI with Management accounting system:

If we assume that information technology continues to develop as it has, then the accounting information system will be complete and transparent. Accounting trans-actions resulting from the circulation of money in a firm are the basis for this network-based framework. In finance, it may educate, aid in analysis and forecasting, and im-prove decision-making and control. Advances in artificial intelligence To remedy the accounting information processing systems to integrate shortcomings, network tech-nology. By incorporating a feature for prudent professional judgement in accounting, strengthening the intelligent decision support function of accounting information pro-cessing within the decision support system, and erecting a network interconnection sys-tem for the accounting information system, they have created a new design that is both intelligent and open. The newly implemented accounting information system (IAIS) now has a much-enhanced capability, allowing for the fast and reliable sharing of ac-counting information.

Given the pervasiveness of AI's use, it's just a matter of time before it is put into finance. These days, AI is a particularly relevant area of study since it uses statis-tical approaches in finance and accounting. The purpose of an expert system, for in-stance, is to have a computer mimic experts' knowledge, reasoning process, and prob-lem-solving skills in a particular subject. In this sense, an expert system is a highly specialized informational system. Making intelligent financial management and deci-sions is possible via its implementation in the accounting information system and the construction of the computer-aided system. This method Using accounting information systems may be successfully adapted to serve as a tool for management and decision-making in addition to accounting. Under the influence of AI, the accounting infor-mation system must become an integrated application of people, machines, data, and software. A basic accounting package and a more includes an advanced accounting decision support system in its user-friendly interface.

The present state of accounting information system has certain glaring flaws, such as a lackluster decision-support function and a simulation of a manual accounting system. Business accounting and finance systems cannot handle the complexity and rigour of modern decision-making challenges. As the need for precise financial records continues to increase, businesses must emphasize centralizing their management in-formatization efforts around their accounting information system. As a result, develop-ers have ramped up their efforts to create a high-performance, high-level accounting information system as quickly as possible, including cutting-edge technology and inte-grated processes into the accounting information system.

4.2 Development and integration of management accounting and AI:

The key to limiting the growth of accounting information to a higher level lies in the difficulty of intelligent judgement by computer programmes, which is at the heart of modern accounting—the following steps in accounting work. The first step in preparing accounting vouchers is verifying and measuring economic transactions from the origi-nal coupons. The second thing must be to certify the registration of accounting vouch-ers.

Third, it's crucial to double-check all financial reports and documents for cor-rectness. Finally, while producing transfer vouchers, validating and measuring the cost accounting and fixed asset depreciation is necessary after the period has ended. Finally, reset when book value, proof and measurement in accounting are still required. Ac-counting judgement, in a word, permeates the three phases of accounting verification, recertification and size.

This study aims to create an intelligent accounting system in IAIS that incor-porates the expert opinion of accountants. The accounting

information system shown in Fig. 2 uses artificial intelligence.

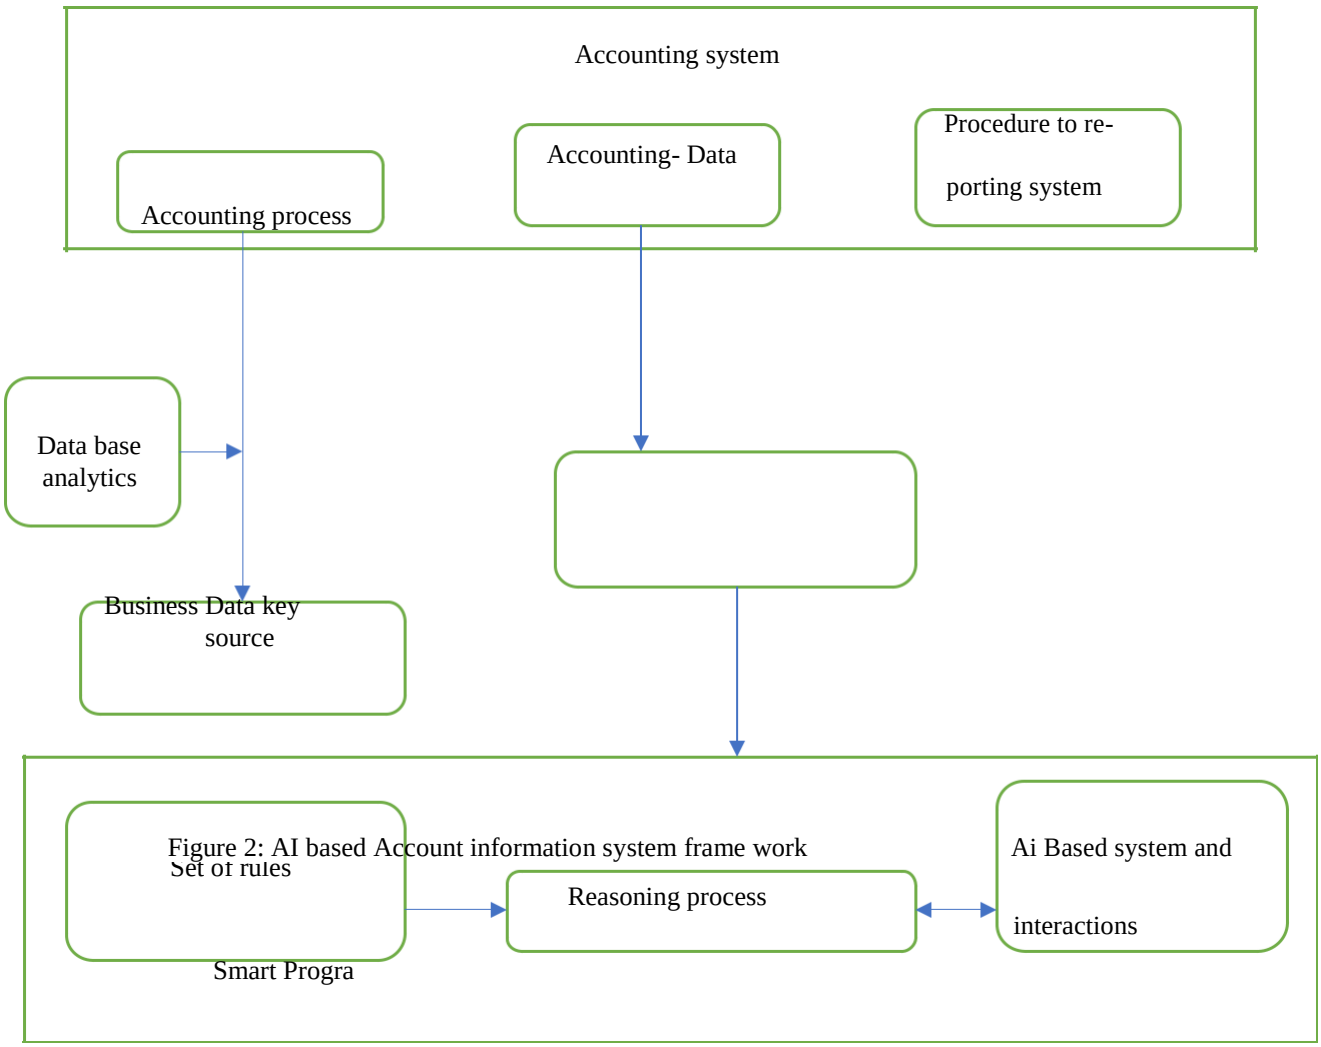

Figure 2: AI based Account information system frame work

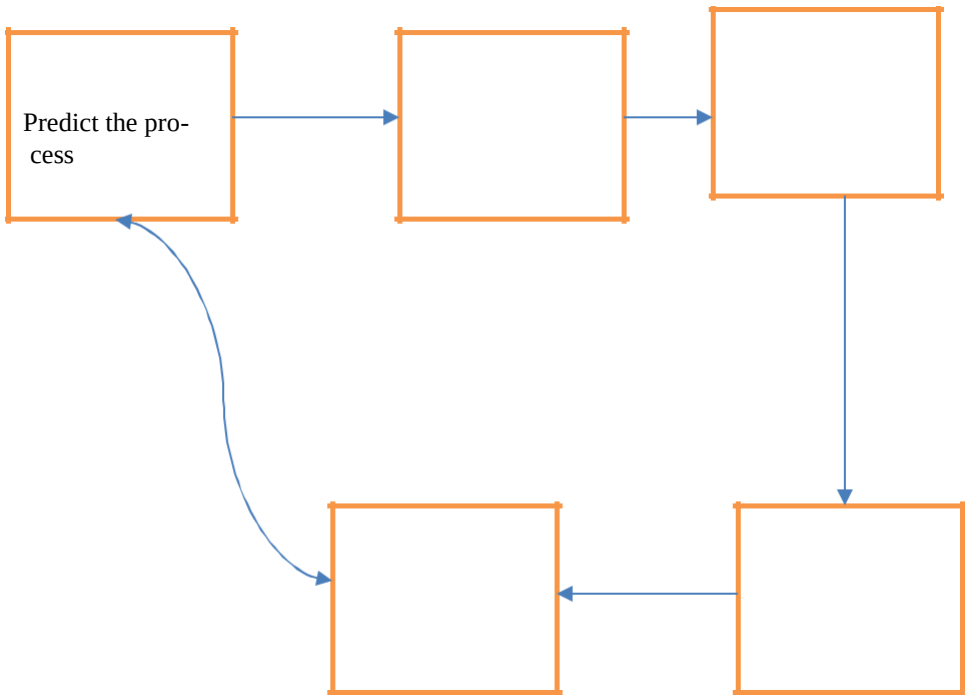
Technology from artificial intelligence and database management forms the basis of this system paradigm. Divide into two modules: a formal accounting system and an informal logic engine. An organization's financial transactions are handled automatically by the accounting system. The keep result data in the financial accounting database serves as a reliable and consistent basis for the system's ability to generate its accounting statements.

4.3 Decision making process based on AI with Account information system:

The IAIS intelligent DSS combines features of a conventional DSS with an expert system driven by AI. The basic concept is to add artificial intelligence-based knowledge processing and information representation to the existing accounting decision support infrastructure. If you're making a decision based on a model, you can utilise that system to do some severe numbers crunching. Fig. 3 shows the data processing flow imple-mented into the financial subsystem. With the addition of a knowledge base, manage-ment system, and inference engine, the system may do a qualitative analysis of deci-sion-making based on the knowledge and experience of experts to help in both unstruc-tured and semi-structured decision-making.



4

.4 Smart accounting information process:

As the competitive environment in which businesses operate gets more nuanced, the use of conventional internal management and a closed, isolated accounting information system is at a catastrophic disadvantage. Companies must have access to timely market data to choose their next course of action and thrive despite intense competition.This research aims to build an accounting information system that integrates and is exceptionally open to the information of all departments inside an organization and pertinent information from outside the organization. The plan for an architectural build-ing is in Fig. 4.

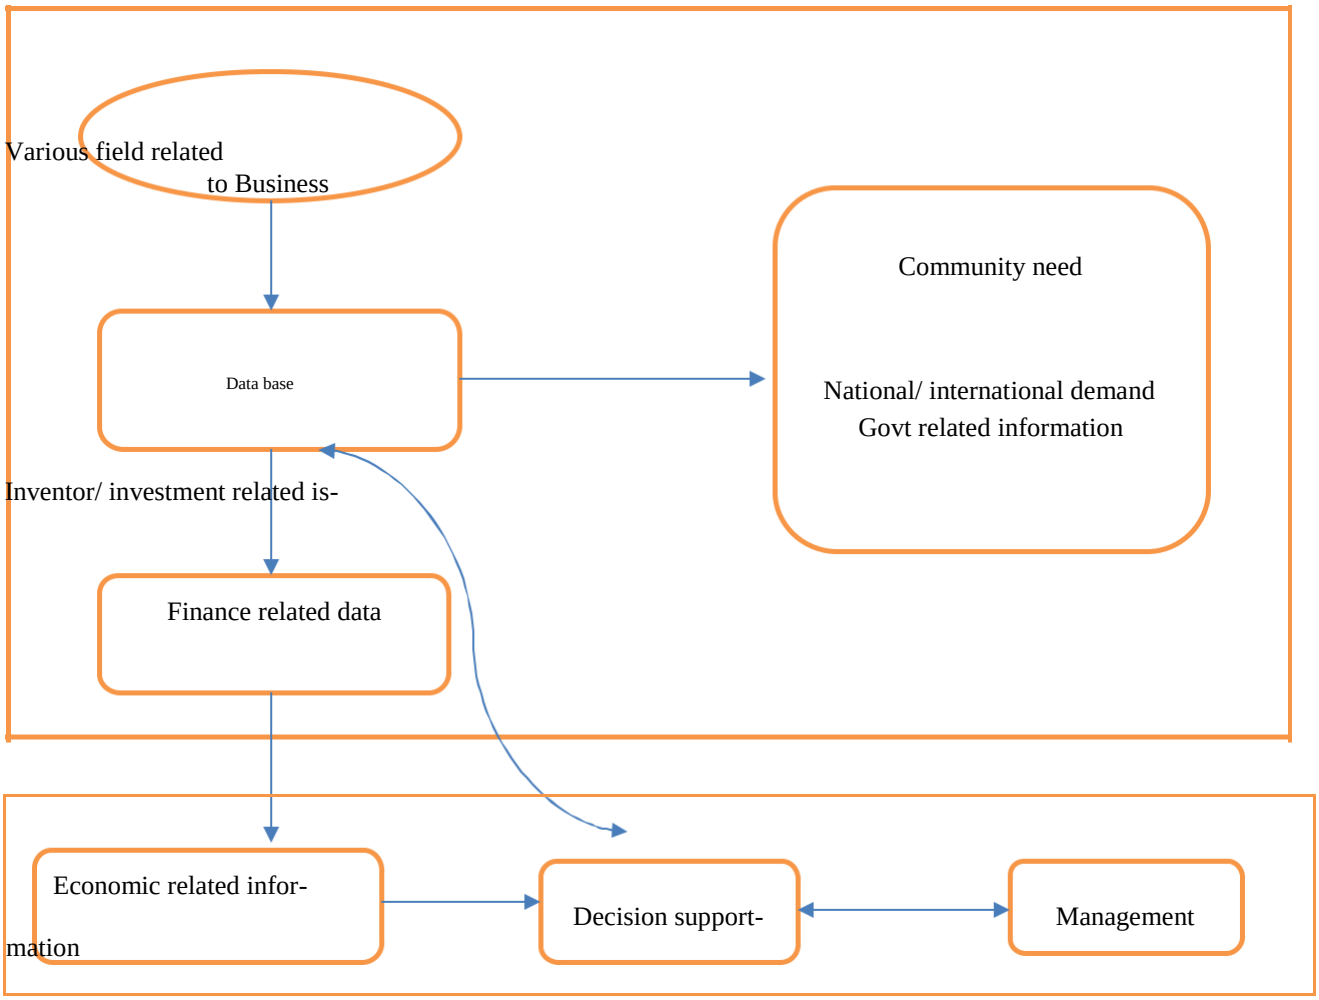


Figure 4: Information process- Accounting process

Intelligent accounting information systems gather data on an enterprise's daily business operations and use that data to automatically process the day-to-day accounts, including creating vouchers, journals, detailed reports, and ledgers. After the internal accounting data has been sorted and processed, it is sent to an intelligent decision sup-port system, which then generates the necessary financial statements for the company. Meanwhile, IAIS will feed economic data into the company's smart decision support system through the system's internal and external network interface, empowering man-agers to make well-informed judgments . The intelligent decision support system (IDSS) collects three different types of data, which then analyses and evaluates the data and the significant decision-making challenges before proposing a solution to the prob-lems facing firm management.

Companies may also use the Internet to disseminate their financial data. En-terprises make it simple for approved, registered users of external accounting infor-mation to get actionable accounting data they can use in their decision-making pro-cesses. Connecting IAIS to other networks improves its intelligence and allows sharing of accounting data in real time.

Theoretical and practical AI management accounting information system analyses rely heavily on arithmetic. The accuracy and latency of the newly built system are investigated and compared to the standard management accounting information analysis platform.

In this study, we will use the core logical structure of the theory underlying intelligent information processing to conduct a theoretical feasibility analysis. The ac-ademic deduce of the foundation of intelligent information processing is analyzed as follows. I, the quantity of physical information, is the integral of r, an ordinal scalar or scalar.

= ∫ ( )

Where n(r) represents the density of information, the data found by solving equation

(1) is neutral data. J is equal to iV is the revised value of the information I, which is the genuine practical information J.

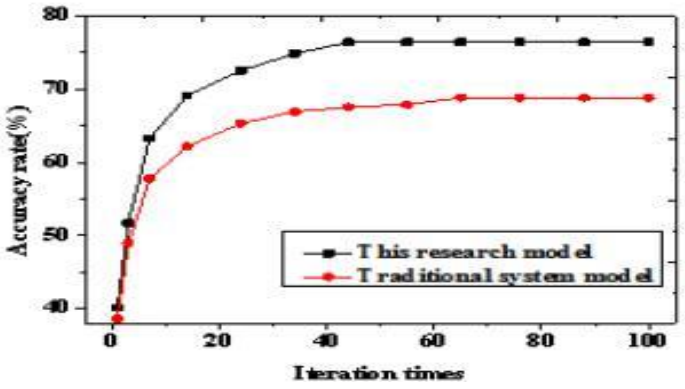
5 Result with discussion:

5.1 Theoretical analysis:

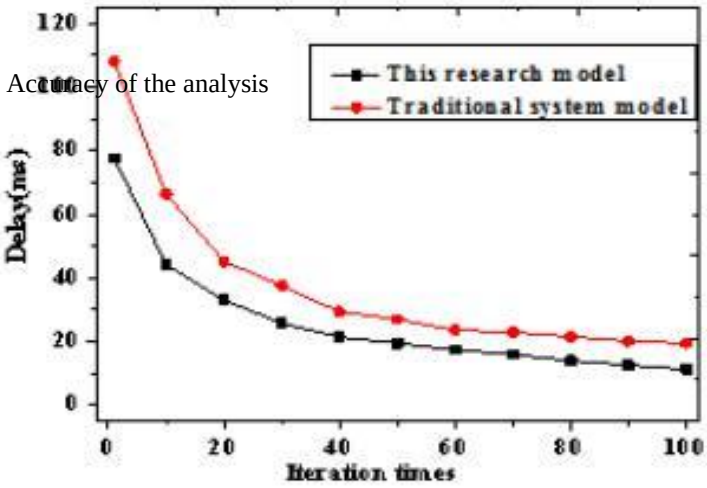
The Decision-making system will suggest the correct prediction of the sub-jective information with the knowledge values through the perfect analysis of the right input information(I) found in the subject knowledge in intelligent information pro-cessing. Knowledge (K) is the goal of a knowledge innovation process (KIP) that uti-lizes the inputs of knowledge (K), information (I), and judgement (J). To function, ex-pert systems are predicated on intelligent information processing. The IAIS system is based on the notion of an expert system. To integrate the AI, Network information with
the traditional accounting system to get the connection with an intelligent decision-making accounting system. Develop a smart expert system for growing IAIS.

5.2 Performance analysis:

It then evaluates the built model against the standard management accounting data analysis method—the precision and delays analysis in Fig. 5.



Accuracy of the analysis



Delay of the time

Figure 5: precision and delays analysis

The created model of the system compared to the conventional model in terms of its correctness and time delay. The suggested model provides a more accurate system representation than the standard model. At 110 iterations, its accuracy may reach 75.89%, while the accuracy of the classic model drops to below 71%; at 100 iterations, the suggested model has a time delay of 11.19ms, while the traditional model has a hold of 19.5ms. Therefore, the proposed system model based on AI is superior to the previ-ous system in accuracy and time delay.

5.3 Technical Analysis:

Since the capacity of traditional operating system limits to the processing of account-ing and its information in the traditional sense, intelligent processing of accounting data is not possible. Recent advances in artificial intelligence (AI), electronic commerce, data warehousing (DB), remote communication (RC), and Internet/Intranet network technology (INET) have bolstered support for IAIS, allowing for the development of system capable of performing sophisticated data processing tasks.

The use of AI allows for enhancing the intelligence of the conventional ac-counting information system. We must focus on these three areas to build an intelligent information processing system. The first is the information repository, which Indicates that all of the relevant information in the subject of analysis is compiled in a structured, machine-readable format. Semantic networks and ontology knowledge trees are two ways to convey this. It helps to boost expertise in analytical reasoning about data. Rule-book, second. In this case, "if... then..." use clauses since the analytical technique is stated as a set of rules. The goal is to make the analysis process more uniform so that the system can

do analyses following predetermined criteria and the information in-cluded in its knowledge base: the knowledge base and use of the ruleset to develop the inference engine. Decision-making generates recommendations when the data is ana-lysed and evaluated using prior knowledge and rules.

6 Conclusion:

To achieve the vision of an intelligent corporate management system, this study employs the expert system technology of artificial intelligence in the context of financial data analysis. A model of AI-powered accounting develops the information system and a method built for making data-driven decisions.

At the theoretical and practical examination viability of the performance of accounting. Both the system's accuracy (which has increased by 6%) and its latency (which is now just 11.17ms) demonstrate significant advancements in theory and tech-nology. Shortly, the system will play a more substantial part in society's accounting work, management level, and businesses that rely on artificial intelligence.

Inadequacies in the studies, however, persist. For instance, artificial intelli-gence is still in the conceptualization phase when analyzing financial data. As a result, the improvement of research on intelligent accounting information systems and its linked challenges would encourage the fast growth of information technology in society as science and technology advance.

Abstract. In general, today's society relies heavily on the electric grid. The traditional grids must be transformed into smart grids due to increased problems. Problems due to traditional grids can be lessened by using smart grids, which are more intelligent. The Smart Grid can considerably increase the efficiency and dependability of future power systems as the need for renewable energy sources rises. However, as large power plants become more integrated through commu-nication networks, cyber security in the Smart Grid is becoming more critical. Cyber-attacks can result in severe catastrophes, such as widespread outages and the destruction of power network infrastructure, because they can potentially de-stroy energy data, starting with releasing personal information from grid users. We suggest implementing a secure, decentralized intelligent energy management system based on blockchain to solve this issue. The blockchain is a network of computers that shares and updates a decentralized database. The Smart Grid can manage energy data more securely by integrating blockchain technology; this could be advantageous for the developing intelligent energy sector.

Keywords: Smart grid, cyber security, energy management, blockchain

1 INTRODUCTION:

1.1 Conventional Electrical grid system**:**

The conventional electrical grid [1] uses integrated, long-distance transmission and lo-cal distribution networks to transmit electricity from a few large power plants to indus-try, households, and local
ommunities. The traditional electrical grid was forced to be created since electricity cannot be stored in the grid's distribution network.
Con sumption and production must constantly be in sync. Throughout the day, con-sumption varies, reflecting both industrial and human habits.
Demand-based power systems end this disagreement: Market procedures plan generat-ing capacity based on anticipated future demand—plans for production pro ject industry consumption. Private home use can be evaluated using "Standard profiles", but this cannot be the plan. They represent the annual energy consumption of a typical home for each period of each day.
When expected consumption and production differ from actual usage, an alternating current frequency change indicates either a surplus or a shortfall of energy. These var-iations and consumption peaks are lessened by standby generation capacity. Extra-ca-pacity power plants are adaptable and can quickly ramp up/down production, although they could be more economically efficient. In conventional grids, frequency change is the only means of communicating supply and demand.
The typical power system connects several central generators with dispersed users. It forecasts consumption variations and responds to them using a demand-oriented ap-proach.
Because blockchain technology monitors and validates transactions transparently, many users may profit from it. One illustration is the utilisation of energy or "smart" grids. The power produced by a solar array is the same as that produced by burning coal when it reaches the home. Therefore, determining the energy source is challenging [1].

However, the current certification system and green energy market make it difficult for businesses and consumers to verify that the power they purchase is gener-ated from renewable sources. Tracking the quantity of energy produced by renewable energy sources like solar arrays, hydroelectric dams, and wind turbines and recording the findings by hand may be challenging and depressing in the modern day. The certi-fication process involves recording the data in spreadsheets and sending them to a cer-tifying organisation, may take several weeks. Furthermore, after the agency verifies the validity of the findings, it produces green energy certificates that the business may use to sell the certificates on the open market. Energy users and producers strive to locate one another on the open market to exchange certificates, but the procedure is cumber-some. [2]

After years of widespread blackouts and the associated costs, there is a renewed focus on how to best manage energy

resources to end the world's chronic lack of elec-tricity. To add insult to injury, we need to reduce the pollution from burning fossil fuels like coal and oil before they are all gone. Further, a method is required to effectively manage and use renewable energy sources like wind and solar power. The Smart Grid, an infrastructure that lessens damages while increasing energy efficiency, is of interest as a result of problems with the power grid, the supply and demand for energy, envi-ronmental pollution, and the use of renewable energy sources.

1.2 Smart grid system:

It is difficult to define the smart grid in a way that pleases all stakeholders. This part defines the smart grid's most important consumer privacy and privacy-enhancing tech-nologies for the rest of the dissertation. The European Commission and Ontario's
Privacy Commissioner defined the smart grid in the following section. These two opin-ions were picked for their relevance to European law and smart grid privacy, respec-tively.

"A smart grid is an electricity network that can cost-efficiently integrate the behaviour and actions of all users connected to it—generators, consumers, and those that do both—to ensure economically efficient, the sustainable power system with low losses and high levels of quality, security, and safety."

The Smart Grid, or intelligent grid, is the next generation of power grid technology that has evolved for efficient and dependable energy management. With innovative ICT(Information Communication Technology Automatic control, high power conver-sion, optimal energy demand management, and renewable energy management tech-nologies are all components of the Smart Grid[1, 2]. The Smart Grid's connectivity to both electricity generators and consumers allows it to function as a real-time energy management system that shares data optimally. However, there is a need for initiatives to detect and handle security risks to energy data supplied by grid members and pro-cesses due to the potentially catastrophic repercussions of ignoring them.

2 Existing smart grid:

There is often a surplus of electricity produced by the current power grid. Since it is challenging to predict the demand for power from consumers in real-time, excess energy is created so that users always have access to electricity, even if consumption is higher than expected. Under such a system, the cost of constructing and supplying new power plants with the required fuel would rise. Underutilized electrical power reduces energy efficiency and increases pollution from fossil fuel combustion. Innovative meth-ods of exploiting renewable energy sources like wind and solar have been developed as the world's supply of fossil fuels dwindles. A brand-new energy platform is required to efficiently and meticulously track numerous electrical power sources.

There has been an increase in power plants to meet the demand for power that began in the 1970s and persisted through the 1990s. The initial system went live in 1886. The rapid urbanization and infrastructure development taking place all across the world may be a manifestation of this change. As shown in Figure 1, the current system for distributing electricity from power plants to end users is strictly hierarchical at the top. Electricity and data move in one way and are created using fossil fuels at the power plant, which serves as the system's nerve center. Since the present grid structure pre-cludes it from collecting and interpreting real-time data on the services provided to consumers, it could be more efficient in terms of power loss and excess pow

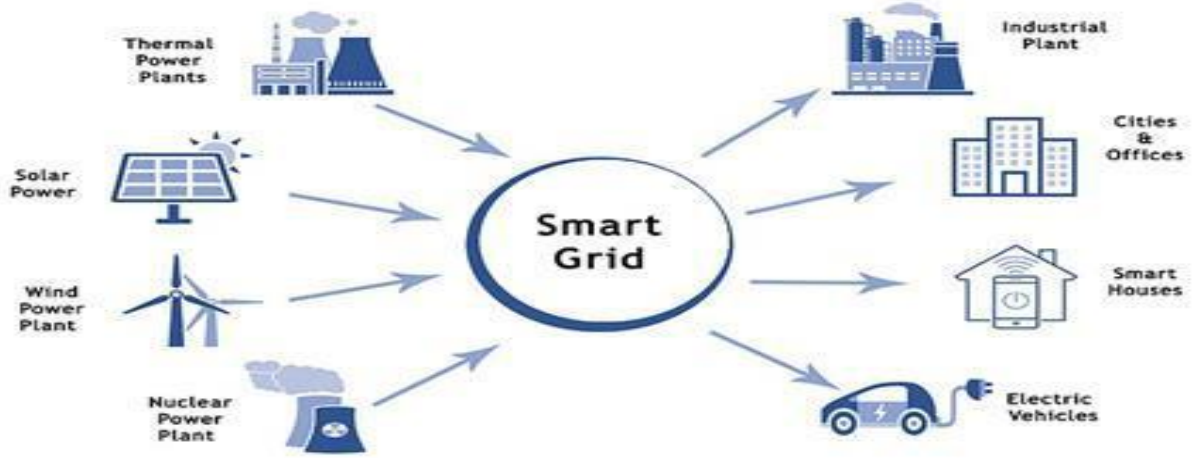

Figure 1: Smart grid- distribution system and generation system

The "Smart Grid," a portmanteau of the terms "smart" and "grid," is a catchall phrase for many components of the electrical power distribution system. Users have greater "situational awareness" of the grid's health because the Smart System integrates cutting-edge information and communication technology into the existing power grid[5]. In other words, it's a technology that facilitates two-way, real-time communi-cation between the utility and the end user to improve energy efficiency. Connecting power plants, substations, and consumers to a shared network. Smart Grid facilitates two-way communication and real-time data sharing for more efficient energy manage-ment. The existing system only allowed for electricity production, distribution, and sale in one direction. Several critical aspects of the current grid are compared to the Smart Grid in Table 1.

Table 1: compares the current grid and the Smart Grid

Si.no	Existing traditional grid	Smart grid
	Electro-mechanical systems	Smart sensors are used
	Only one way communica-tion system proposed	Two-way communication sys-tem proposed in smart grid.
	All are centralized from one part.	All are distributed from differ-ent aspects.
	Very less sensors are used.	Very huge sensors are used for proper response
	No proper monitoring sys-tem.	Monitoring system in all as-pects.
	Manual monitoring system.	Smart monitoring by sensors and IoT.

	Old/ very limited controlling system	Very new technological control system
	Testing's are done manually	Testing's are done by remote ac-cess.

Again, the Smart Grid is a secure two-way system that combines electricity. The secu-rity system will need the data production rate in the meantime, the system's transmis-sion, substation established under the smart grid, distribution system of the power grid, and consumption data making use of ICT for cyber security, communication, and AI.

[7]. Smart Grid users may reduce energy usage and expenses by improving energy management system reliability, efficiency, robustness, and transparency.

1. Reducing global fossil fuel use.
2. Promoting green energy.
3. Pollution mitigation.

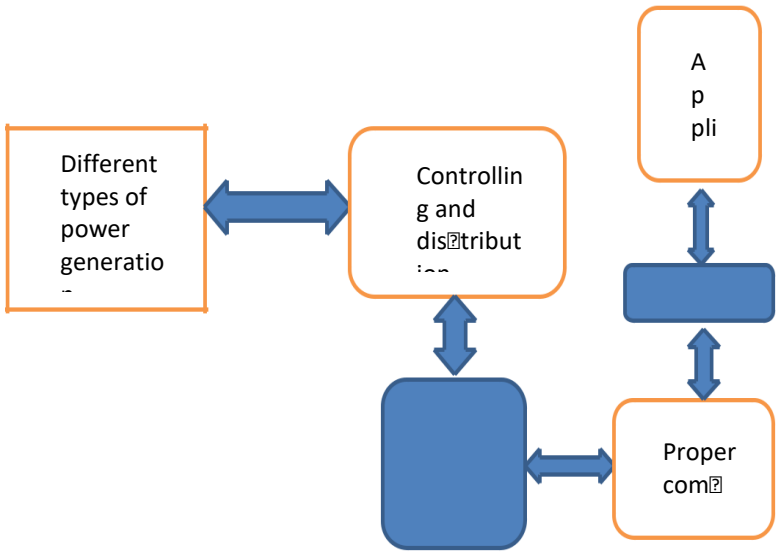

Figure 2: The Smart grid outlook

3 Basic aim and objective of the smart grid:

A smart grid basically aims to develop a dynamic and efficient energy management system. Smart grids integrate intelligent meters and networking systems. Intelligent meters contain a significant speed monitoring system, and networking systems have two ways.However, the communication and networkin technologies on which smart grids depend leave them open to various risks.

The Smart Grid's ultimate objective is to construct a dependable, safe, and optimal power system, yet this goal might paradoxically endanger the power system's function-ing. In this part, we'll discuss the potential dangers the Smart Grid faces, such as cyber security concerns and the accompanying need for a response.

3.1 Existing smart grids- challenges- security threats:

The term "threat" is used to describe a wide range of behaviors that may be neu-tralized via the use of either artificial or natural systems[10]. Theft, hacking, terrorism, natural catastrophes, and other similar dangers all pose problems for the security of the Smart Grid's design and infrastructure [11]. Power outages, faulty consumer products, unstable energy markets, threats to human safety, and other problems might all be caused by flaws in the Smart Grid's information technology architecture.

Smart Grid security issues and dangers have been studied in the past. Below is a list relates potential Smart Grid-damaging risks and related difficulties, compiled from existing research. Most hackers will damage the security system and steal the smart grid's ethical work.

3.2 Smart grid- cyber-attacks:

A specialist in control system security has estimated that 188 cyber events have resulted in power outages, three considered severe (in 2015). This section will discuss the most serious cybercrime incidents against the Smart Grid and the associated dangers.

3.3 Stuxnet attack :

In July 2010, Stuxnet launched its most well-known assault to date. Stuxnet is malicious software designed to reprogram and conceal modifications to certain kinds of industrial control systems. This assault demonstrated the viability of cyber-attacks on such sys-tems.

3.4 Data and Grid intellectual property theft attacks:

The Night Dragon is a malicious piece of malware that aims to acquire sensitive infor-mation relating to industry rivalry; it was first reported in November 2009 and is thought to have originated in China, primarily focusing on oil and electric power busi-nesses. This incident highlighted the risks associated with intellectual property and data theft.

3.5 Hackers' attacks:

A cyberattack on a computer system led to a blackout in January 2008. Although this assault did not affect a large geographical region, it did raise concerns that a hacker-caused blackout may occur.

4 Smart grid security system by Block chain Management:

The smart grid relies significantly on computer networks.

Information on energy generation, energy consumption, and energy trade among prosumers may all be compromised or altered due to cyber assaults on the Smart Grid. May mitigate Damage caused by data leaks on the Smart Grid with a system that safely stores and transmits all data created and exchanged on the network.

The term "information security" refers to a broad category of tools, many of which are used by the Smart Grid. However, a secure system for safe energy trading has become necessary as a result of the rise of the prosumer(prosumer + consumer)[13]. This person is capable of both producing and consuming energy. To ensure the security of all Smart Grid operations, Blockchain-based energy management is our suggestion.

4.1 Block chain with Management system:

Blockchain is a decentralised record that stores encoded data and information regarding each and every transaction without a trusted third party like a bank. Block-chains are decentralised information handling units where all the network operators share and store data without a central server or trusted third party [3]. The smart grid relies significantly on computer networks.

Information on energy generation, energy consumption, and energy trade among prosumers may all be compromised or altered due to cyber assaults on the Smart Grid. May mitigate Damage caused by data leaks on the Smart Grid with a system that safely stores and transmits all data created and exchanged on the network.

However, a secure system for safe energy trading has become necessary as a result of the rise of the prosumer(prosumer + consumer)[13]. This person is capable of both producing and consuming energy. To ensure the security of all Smart Grid operations, Blockchain-based energy management is our suggestion.

Data is encrypted and stored using a hash with the preceding block data, and linked in a chain-type connected structure, as illustrated in Figure 3. Therefore, updat-ing the data is challenging since it must change the prior nodes to

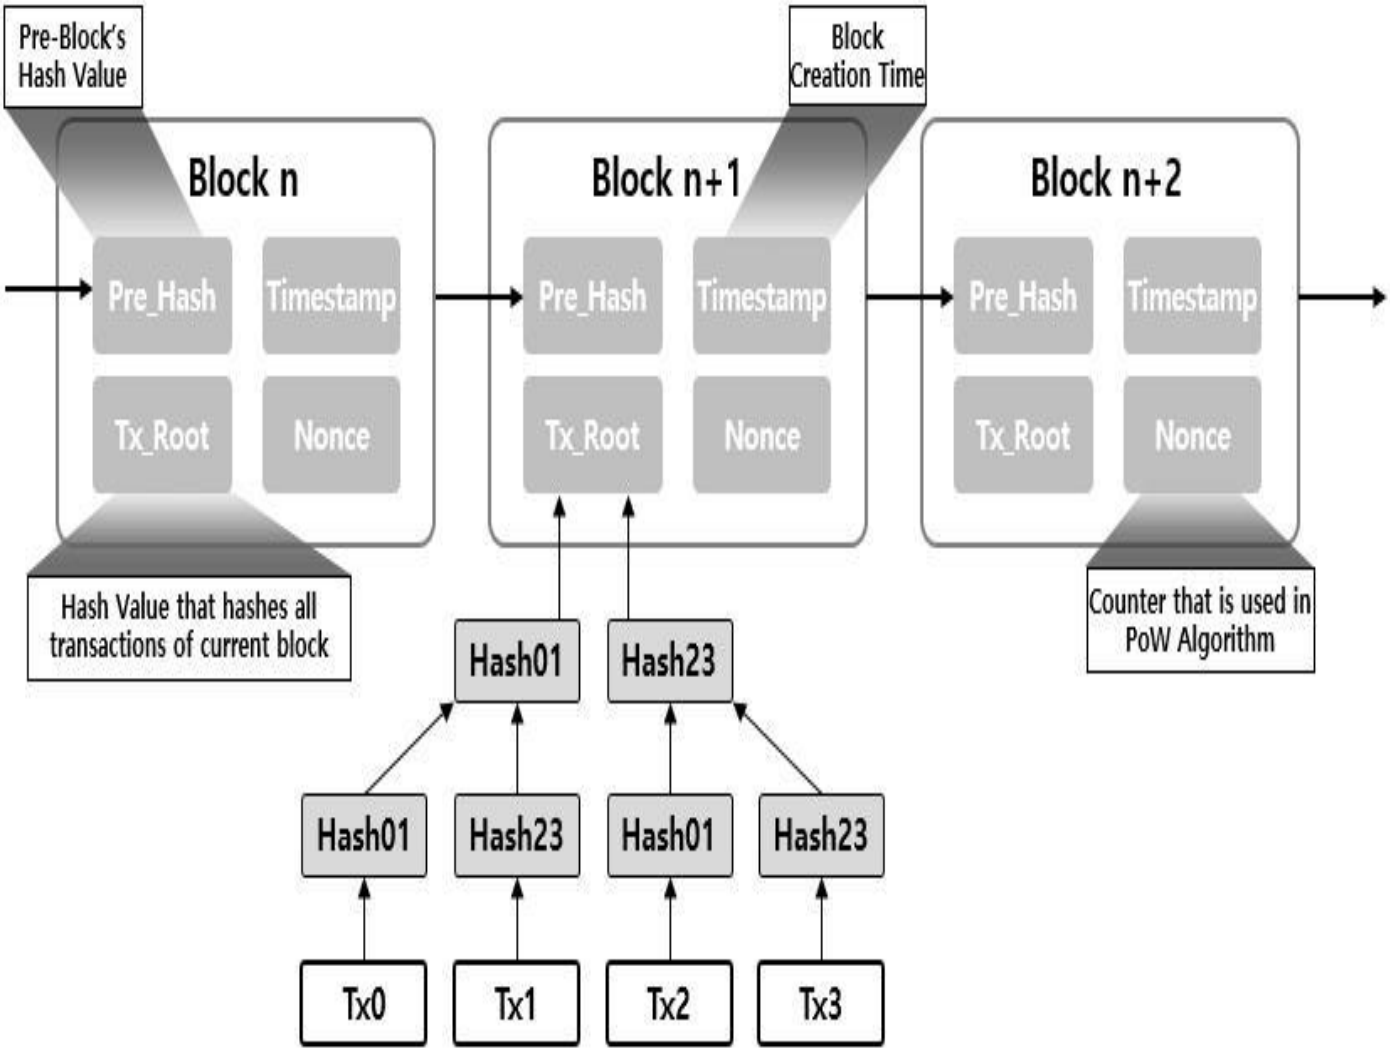

Figure 3: Block chain with management system framework

Result with analysis:

The purpose of this study is to propose a blockchain-based intelligent energy manage-ment system and to describe its operation and anticipated outcomes.

While power plants will still contribute to the Smart Grid's ability to generate and distribute energy, solar panels on every roof will allow residents and business own-ers to develop their clean power. Therefore, the system will make recommendations based on the premise that all homes and businesses will generate power independently.

Figure 4 depicts the bidirectional flow of real-time energy data across all Smart Grid nodes, including traditional power plants, renewable energy power plants, households, buildings, and industrial facilities. The approach might expose sensitive information to cyberattacks. As a result, encrypt these records inside a block before saving and linking to the blockchain in

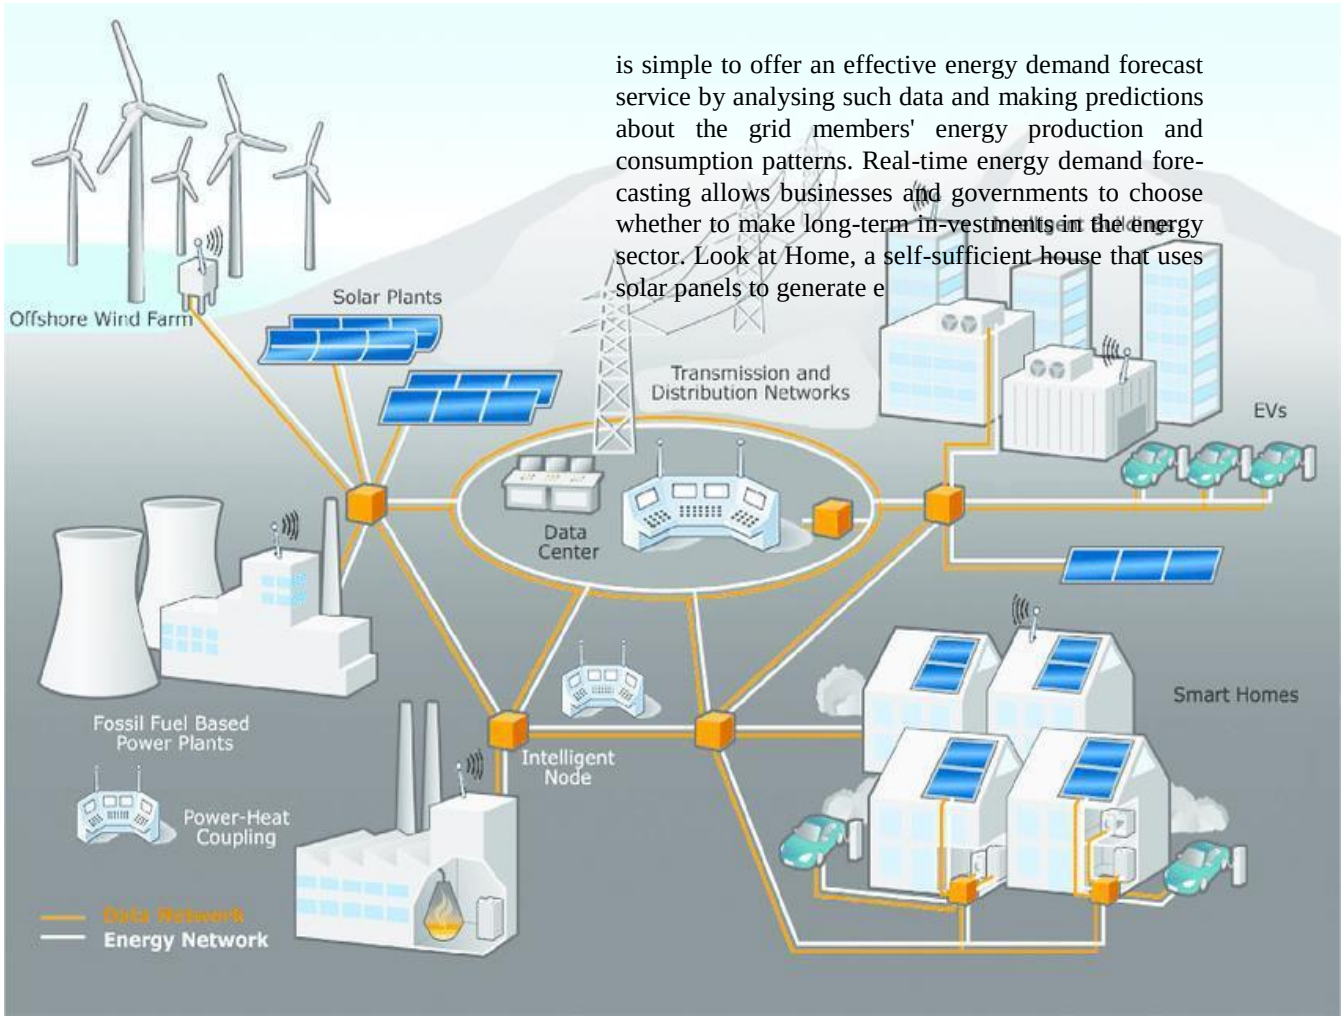

Figure 4: Bidirectional flow of real-time energy data across all Smart Grid nodes

Look at Home, a self-sufficient house that uses solar panels to generate electricity. Since it generates its electricity, the ledger will include its power output and details of usage; the latter enables the storage of any energy excess (production minus consump-tion). Future Smart Grids will also keep data on energy transactions since prosumers on the same grid will trade power on an as-needed basis. To ensure the integrity of the data and facilitate communication across nodes in the same grid network, this is rec-orded in real-time and added to the linked blockchain.

This technology stores all Smart Grid energy data in an encrypted form inside a block and on a distributed ledger (chain) to prevent forgery and theft. That's why it will be a far more secure and trustworthy method for storing information than we have now.

Because users in the same grid network can share data, an organisation (like a government) that manages a Smart Grid can quickly and easily understand the amount of energy generated over a given period, the amount oself-production of buildings and buildings, and the amount of usage. Therefore, it is simple to offer an effective energy demand forecast service by analysing such data and making predictions about the grid members' energy production and consumption patterns. Real-time energy demand fore-casting allows businesses and governments to choose whether to make long-term in-vestments in the energy sector. 6 Conclusion:

This study looked at the Smart Grid and outlined several possible dangers and hacks.

We anticipated the severity of a cyberattack on the smart grid.

Therefore, a way to make intelligent energy management more secure against cyberat-tacks is provided when implementing the smart grid.

The smart grid's stored data can be shared and secured using blockchain. Energy data will be carefully stored and used by this system. Thus, it will encourage the growth of the Smart Grid energy industry.

A blockchain-based infrastructure is developed to operate and monitor the smart grid securely and intelligently. After the development of the design, IoT devices will gather energy data and upload it to the storage system via the blockchain.

Following the simulation, the blockchain can examine the shared information. Apply our technique to the actual Smart Grid once it succeeds. Therefore, a way to make intelligent energy management more secure against cyberat-tacks is provided when implementing the smart grid.

Voice Personal Assistant For Windows Using Rnn

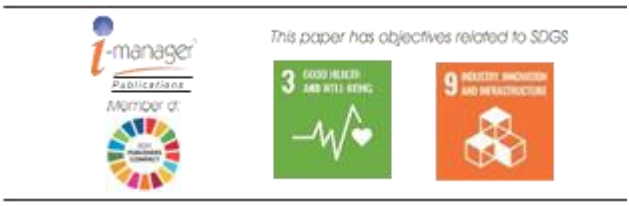
Saransh Singh , Ananya Shetty, Arpana Rit, Dr.Manish Rana
Thakur College of Engineering and Technology, Mumbai, India

Abstract— **The goal of this work is to build a personal voice assistant for Windows users. Speech is understandable by humans easily but it is difficult for computer to realize. For the detection of speech we have to consider the physical properties of sound waves. Different people got different sound which makes the sound distinct. Background noise, type of microphones are the variables one has to consider for speech module. Neural network is used to analyze to build the model for speech recognition.**

Keyword- Speech Recognition, Neural Network, Voice assistant.

I. INTRODUCTION

A voice assistant can be a digital assistant that uses human voice, language process algorithms, and synthesis to pay attention to particular voice commands and come applicable information or perform particular functions as appealed by the user supported commands, commonly known as intents, tell by the user, voice assistants will come applicable information by hearing for particular keywords and filtering out the close noise. One of the most popular voice assistants are Siri, from Apple, Amazon Echo, which responds to the name of Alexa from Amazon, Cortana from Microsoft, Google Assistant from Google.



The primary goal of this work is to build a local voice assistant that performs the work of human and the daily task that a human needed to do in day-to-day life. The users can ask their assistants questions and devices, media playback via voice and they manage their basic tasks such as g-mail account, calendars with verbal commands. It will also basic and common features of today's voice assistants. As voice assistants are become more widely used to deliver the library services and materials. Voice control is major growing feature. The voice assistants will gather the audio voice as input the human beings from the microphone and it will be converted into text and it will sent the output google text to speech. The voice recognition technology is evolving rapidly to expected to become default input from for smartphone presently the modern voice recognition technology has been very useful to users as it provides uses with various app and resources from the any where in the world. And most systems are allows the user to train the software to understand their voice and it can translate speech to text more precisely. And speech recognition is a keyboard typing it is easily understand your talking to the machine and your voice or your talking words shown on the screen.

Voice assistant are widely used to developed to consumption of time. The voice assistant provides the command to the system and it is giving to the message replay as text and it will directly connect to the web browser.

II. PROBLEM STATEMENT

"Google Voice Search" which is used for in Android Phones. But this Application mostly works with Internet Connections. Cortana, Siri, Google Assistant and many other virtual assistants which are designed to aid the tasks of users in Windows, Android and iOS platforms. But to our surprise, there's no such complete virtual assistant available for Core Windows platform consisting of 70% of the users. So, this is actually a major problem for users where there could be internet instability, server problems and places where internet is not accessible. , there is no universal assistant who would do all tasks equally well.

III. OBJECTIVE

The primary technologies are voice activation, automatic speech recognition, Text-To-Speech, voice natural language understanding and named entity recognition. The data is collected in the form of speech and stored as an input for the next phase processing and input voice is continuously processed to converted to text using STT. The ability of computers to read text aloud and converts written text to a phonemic representation using TTS engine. The use of dynamic base Python pyttsxwhich is a text to speech conversion library in python andunlike alternative libraries, it works offline.

IV. LITERATURE SURVEY

The field of voice-based assistants has observed major advancements and innovations. The main reason behind such rapid growth in this field is its demand in devices like smartwatches or fitness bands, speakers, Bluetooth earphones, mobile phones, laptop or desktop, television, etc. Most of the smart;/// devices that are being brought in the market today have built in voice assistants. The amount of data that is generated nowadays is huge and in order to make our assistant good enough to tackle these enormous amounts of data and give better results we should incorporate our assistants with machine learning and train our devices according to their uses. Along with machine learning other technologies which are equally important are IoT, NLP, Big data access management. The use of voice assistants can ease out a lot of tasks for us. Just give voice command input to the system and all tasks will be completed by the assistant starting from converting your speech command to text

command then taking out the keywords from the command and execute queries based on those keywords. In the paper “Speech recognition using flat models” by Patrick Nguyen and all, a novel direct modelling approach for speech recognition is being brought forward which eases out the measure of consistency in the sentences spoken. They have termed this approach as Flat Direct Model (FDM). They did not follow the conventional Markov model and their model is not sequential. Using their approach, a key problem of defining features has been solved. Moreover, the template-based features improved the sentence error rate by 3% absolute over the baseline [2]. Again, in the paper “On the track of Artificial Intelligence: Learning with Intelligent Personal Assistant” by Nil Goksel and all, the potential use of intelligent personal assistants (IPAs) which use advanced computing technologies and Natural Language Processing (NLP) for learning is being examined. Basically, they have reviewed the working system of IPAs within the scope of AI [4]. The application of voice assistants has been taken to some higher level in the paper “Smart Home Using Internet of Things” by Keerthana S and all where they have discussed how the application of smart assistants can lead to developing a smart home system using Wireless Fidelity(Wi-Fi) and Internet of Things

V. CONCLUSION

This paper provides a basic knowledge and difference between various voice assistant present. Also it gives a brief idea on how we could incorporate neural networks to build the acoustic model. Linguistic model uses beam search which is an rescoring algorithm that deals with the probability distribution of the most probable word which could occur in a sentence which makes a sense in the sentence. Recurrent Neural Network handles the time sequence series of speech as it is light weight in process and could work with various speech dataset with great efficiency.

VI. ACKNOWLEGEMENT

This paper on "Voice Personal Assistant for Windows" has been possible only because of the kind of cooperation lent by our professor and project guide Dr. Manish Rana, without which this would have not been possible. We would also like to thank our parents, who have provided us with all possible resources to gain the best possible knowledge and understanding in our enlightened journey.

Design and Development of Accessible Video Chat Application for People with Disabilities

Ninad Patil, Siddhesh Mane,,Akash Maurya Zahir Aalam
Department of Computer
Engineering,
Thakur College of Engineering and
Technology,
Kandivali (East), Mumbai
npradeeppatil2001@gmail.com,siddheshmane025@gmail.com, akashamaurya@gmail.com

Abstract—**Communication has been a struggle for everyone since the outbreak and in the aftermath, people have had to get accustomed to video conferencing applications. However people with physical or mental limitations are still unable to use video conferencing apps and their interfaces. This necessitates the development of web-based video chat applications that can aid those who are unable to communicate verbally and/or operate using standard mouse and keyboard inputs but yet need to feel close to others when they are apart. The proposed application incorporates various accessibility features such as speech-to-text and text-to-speech, gaze tracking and pictorial speech interfaces. It enables individuals with disabilities to participate in virtual meetings on an equal footing with their peers. The application's goal is to remove barriers and promote inclusiveness in remote work and collaboration for all users, regardless of their abilities.**

Keywords—***Video Conferencing, Accessibility, Assistive Technology, Gaze Tracking***

I. INTRODUCTION

Video conferencing is a type of online meeting where two or more people engage in a live audio-visual call. With a strong internet connection, the participants can see, hear, and talk to each other in real-time, no matter where in the world they are. In business, people typically use video conferencing to communicate and collaborate within and outside an organization. One just needs to set up the necessary hardware and software to get the most out of the experience. There was a time when video conferencing was a luxury that only large corporations could afford. Smaller businesses lack the resources to deploy complex equipment and hire technical experts using other forms of communication. But video conferencing has now become more accessible and affordable. This is mostly thanks to the continued development of Voice over IP or VoIP. These days, one can literally carry this powerful communication and collaboration tool inside the pocket. With more companies incorporating video conferencing into their daily operations, ensuring everyone can connect online through video is a significant aspect.

However, for individuals with disabilities, access to these apps can often be limited by a lack of accessibility features. This can make it difficult for these individuals to fully participate in virtual meetings and events, and can even limit their career and educational opportunities.With the wrong tools, a person with a disability may actually experience new barriers. WCAG (Web Content Accessibility Guidelines) is the industry benchmark that provides support for web users living with various levels of conditions. Making a platform more accessible can assist not only users with physical, visual, photo-sensitive, auditory, or auditory impairments. But also people with temporary disabilities such as a broken arm or lost glasses or "situational limitations" such as language barriers, geographical position or poor network conditions.

To address this issue, many video conferencing apps have begun incorporating accessibility features, such as closed captioning, voice-to-text transcription, and keyboard shortcuts, to make the technology more accessible to everyone. By providing these features, video conferencing apps are helping to close the digital divide and ensure that individuals with disabilities have equal access to the same communication and collaboration tools as everyone else. However, there is still much work to be done in terms of making video conferencing apps truly accessible for all. Some apps may still lack certain accessibility features or may not implement them in a way that is usable for everyone. As such, it is important for developers, users, and organizations to continue to push for greater accessibility in video conferencing technology, in order to create a more inclusive and equitable virtual world.

Our approach aims to develop a universally accessible and free video conferencing application. By integrating 4 Modes to the video chat software, the solution aims to add practical and pertinent interfaces and bring Augmentative and Alternative Communication (AAC) to video conferencing, enabling people with disabilities to connect and speak with those who are important to them.

II. LITERATURE REVIEW

A 2020 study by the Royal National Institute of Blind People found that only 45% of visually impaired people in the UK use video conferencing, compared to 75% of the general population[1]. A survey by the National Association of the Deaf found that approximately 70% of deaf and hard of hearing people in the United States experience communication barriers on video conferencing platforms.[2] According to a 2019 survey by the charity AbilityNet, only 52% of people with disabilities in the UK feel confident using video conferencing, compared to 69% of the general population [3].

A study by the United Nations Department of Economic and Social Affairs (2019) found that people with disabilities face significant barriers in accessing and using digital technologies, including video conferencing[4]. A 2020 survey by the charity Scope found that only 55% of disabled people in the UK have access to the equipment needed for video conferencing, such as a computer or smartphone, compared to 82% of the general population [5]. The World Health Organization (WHO) reports that only 37% of people with disabilities globally have access to assistive technologies, such as closed captioning or sign language interpretation, which can greatly enhance their experience with video conferencing [6].

These statistics highlight the digital divide faced by people with disabilities when it comes to using video conferencing, and the need for increased access to assistive technologies and inclusive design to improve the experience for all users.

Sr. No	Paper Details	Methodology and Outcomes	Gaps and Bridging the Gaps
1	**Title:** Implementing Deep Learning Model in Human-Computer	**Methodology:** The paper attempts to use eye movements and facial expressions as the basis for a handless mouse	**Gaps:** Translation of conventional mouse actions like moving the cursor and clicking is done by tracking the user's

	s Recognition using Convolutional Neural Network [7] **Conference Name:** International Research Journal of Engineering and Technology (IRJET) 2022 **Conference Year:** 2022	The proposed procedure in this paper works based on the following actions: a. Blinking b. closing both eyes c. Head movement (pitch and yawning) d. Opening the mouth **Outcomes:** The mouse control system works and the user can move the cursor and click at will The cursor is moved by moving the eye right, left, top, and down as per the requirement Click action is initiated by opening and closing the mouth	facial orientation and mouth movements respectively These detections require going beyond the segmentation of the eyes **Bridging the gap:** Instead, the actions can be translated as follows: **Cursor Navigation:** Gaze Tracking using the position of specular reflection in the user's cornea **Click:** Blinking Eyes / Persistent Gaze
2	**Title:** Non-Intrusive Gaze Tracking Using Artificial Neural Networks [8] **Conference Name:** School of Computer Science Carnegie Mellon University **Conference Year:** 1994	**Methodology:** The training data for the ANN is 2000 image/position pairs (High-resolution images of the subject's **cornea and pupil**) **Steps:** 1. Find the specular reflection of a stationary light source in the subject's eye 2. Find the pupil center 3. Find the relative position between both to determine the gaze direction **Outcomes:**	**Gaps:** The model relies on the geometric model of the eye, and hence relies heavily on parameters such as cornea radii, cornea center, etc. which are often noisy in a webcam feed Expensive Hardware Systems accuracy: **0.75 degrees** This method: **1.5 degrees** **Bridging the gap:** Instead of using just eye patches for gaze prediction, The model can also incorporate Head Orientation The use of offset tables, generated

		In a gaze tracking system, the most important attributes are speed and accuracy **Speed**: 15 Hz **Accuracy**: Using only cornea and pupil: 2.1 degree Additionally using Eye socket position: 1.5 degrees	after model training can improve the accuracy

3	**Title:** Accessible Education for Autistic Children: ABA-Based Didactic Software [9] **Conference Name:** Universal Access in Human-Computer Interaction **Conference Year:** **2011**	**Methodology:** This paper discusses various techniques and design of physical interfaces for autistic children **Outcomes:** The educator can make use of this physical interfaces namely the carousel, digital core boards, circle of icons and color-coded sheets to teach autistic children	**Gaps:** The mentioned system makes use of physical interfaces thereby reducing the reach of the interfaces among masses No Online centralized application **Bridging the gap:** Due to poor motor skills they cannot use Sign Language or type on a keyboard A pictorial phrase selection based layout to implement to help autistic users build and convey sentence
4	**Title:** Conversation of Sign Language to Speech with Human Gestures[10] **Conference Name:** 2nd International Symposium on Big Data and Cloud Computing **Conference Year:** 2015	**Methodology:** This paper recognizes hand gestures and converts its into speech and text output **Steps:** 1. Image Capture 2.Gray Scale Conversion 3.Contour Detection 4.Convex Hull 5.Analyzing and Identification of Alphabet The OpenCV function determines the edge points. 6.Existing OpenCV Algorithms find features of Contour 7.The set of points in the contour forming	**Gaps:** The existing system is only able to recognize the sign gestures for letters only Colloquial Sign Language also uses representations for syllables and words **Bridging the gap:** By using a densely labeled dataset our Mode will attempt to implement sign language implementation with the ability to recognize not just letters but syllables and words too

		an N-dimensional polygon is Hull **Outcomes:** Recognize hand gestures and convert them into speech and text output Camera captures images of hand and Contour feature extraction recognizes the hand gestures and on the basis of it, the recorded soundtrack is played	

5	**Title:** Accessible Video-Call Application on Android for the Blind [11] **Conference Name:** Lecture Notes on Software Engineering vol. 4 **Conference Year:** 2016	**Methodology:** Screen reader is essential software that allows blind users to interact with smartphones. Web Content Accessibility Guidelines (WCAG) is to suggest a standard for web content accessibility that meets the needs of individuals, organizations, and governments internationally, be they people with disabilities or others Understood outcomes by blind and non blind persons perform the same experiment. **Outcomes:** The paper implemented an application for Android smartphones to help people with visual disabilities to communicate with their assistants for navigation help and more. The paper showed that the existing applications failed to serve this group of users, and this led to the later parts where we proposed the guideline as a solution and simulated it to compare with those popular applications.	**Gaps:** Unable to locate functions. Eg. Hidden option menus Unable to proceed / Unknown status. Eg. System halted when the input was incorrect or loss of call signal Use of Non-standardized or confusing terms. Eg. Tango uses "Discover" to mean "Contacts" **Bridging the gap:** Must have descriptions or announcements for every error handling and change of status. Use terms that can be understood by most and add description in captions. Every button and function must be visible on the screen, can be read out loud by the screen reader, and be accessible by a swiping motion.

Table 1 : Literature Review

III. PROPOSED SYSTEM

Our proposed solution aims to cater to this aforementioned problem by integrating 4 interactive modes to the video conferencing application with each mode serving a special disability.

These Mode are as follows:

- Mode-1 - Voice Based Control
- Mode-2 - Graphics Based Control
- Mode-3 - Eye Gaze Based Control
- Mode-4 - Automatic Sign Language Translation

Fig. 1 contains the component diagram of the system to show the relationship between different components in a system. Other aspects of the application related to the area of implementation, type of the solution, category of the disability are mentioned below:

- Situation Category: Daily Life
- Disability Category: Multiple type
- Disability Type: Open
- Software / Hardware: Software

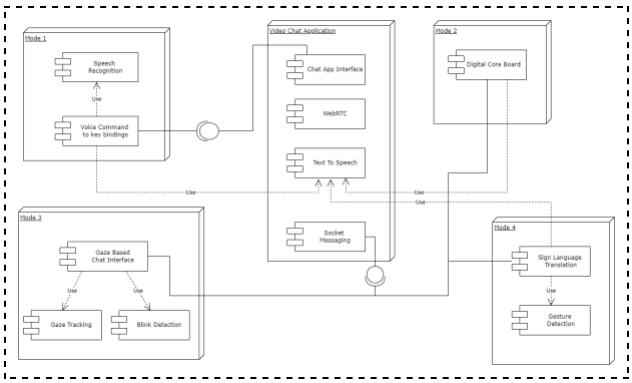

Fig. 1 : Component Diagram

Further is a detailed deep dive into each of the modes of the application.

Mode-1: Voice Based Control

The Target Demographic for this Mode are people suffering from Visually Impaired Ability or Physically Disability. Using Mode-1, users can use voice-based commands to interact with the video chat interface and get voice-based feedback. This helps users

who are unable to use conventional input devices like a keyboard and mouse.

Mode-2: Graphics Based Control

The Target Demographic for this Mode is people suffering from Autistic Spectrum Disorder. Due to poor motor skills, Autistic children cannot use Sign Language or type on a keyboard. Mode-2 provides them with a pictorial word & phrase selection-based layout to help autistic users build and convey sentences.

Mode-3: Eye Gaze Based Control

The Target Demographic for this Mode are people suffering from Severe Physical Disability or Locked in Syndrome. Using Mode-3, Users with severe disability or Locked in Syndrome can use their eyes to interact with the interface. The user's gaze location on the screen will be tracked using the webcam and accordingly, the mouse cursor will be positioned.

Mode-4: Automatic Sign Language Translation

The Target Demographic for this Mode are people suffering from Deafness / Muteness. Often people who communicate using Sign Language need a communication assistant for video conferencing interactions. We can overcome this by training models that can intercept the webcam feed and convert Sign Language into Spoken Language

IV. METHODOLOGY

Mode-1 and Mode-2

The Mode-1 and Mode-2 of our solution is a complete web centric approach powered by WebSockets and leveraging the WebRTC technology.

Earlier, It was quite common for most web apps to have a closely connected backend and frontend, so the apps served data with the view content to the user's browser. Nowadays, typically loosely coupled, separate backend and frontends are developed to maintain a two tier architecture and are connected by a network-oriented communication line. For example, developers often use the RESTful pattern with the HTTP protocol to implement a communication line between the frontend and backend for data transferring. But the HTTP-based RESTful concept uses simplex communication (one-way), so we can't send data directly from the client (frontend) to the server (backend) without implementing workarounds such as polling. The WebSocket protocol solves this drawback of the traditional HTTP pattern, offers a full-duplex (or two-way) communication mechanism between the client and the server over a single TCP socket connection, and helps developers build real-time apps. The WebSocket protocol has only two agendas: To open up a handshake and to help the data transfer. Once the server accepts the handshake request sent by the client and initiates a WebSocket connection, they can send data to each other with less overhead at will. WebSocket communication takes place over a single TCP socket using either WS (port 80) or WSS (port 443) protocol. Almost every browser except Opera Mini provides admirable support for WebSockets. In order to use WebSockets, We employed a Node.js WebSocket server that handles the video conferencing backend logic and a React app that connects to the WebSocket server for real-time features.

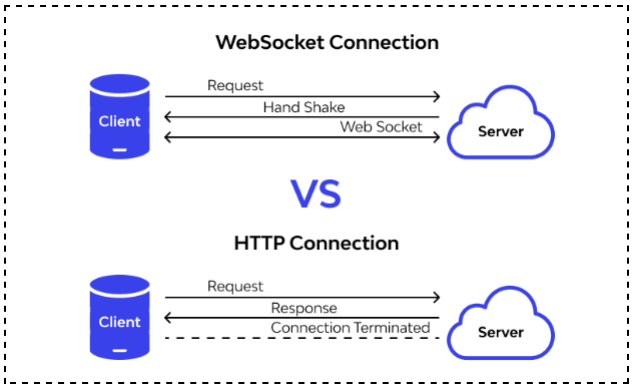

Fig. 2 : WebSocket vs HTTP Connection

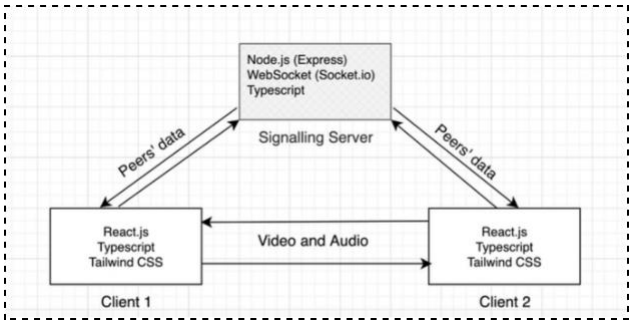

Fig. 3 : Video Chat App Data Flow

Mode-1 of our solution targets the community which are suffering from Visually Impaired Ability or Physical Disability. For example, a person with delocated arms. Such people are not able to use the traditional video

chat apps with their motor arms, thereby making the physical touch a barrier for them. Our solution solves the problem of touch by controlling the entire application using our voice assistant. Each and every step that is being involved right from room creation to sending chats and handling the video audio options, everything can be operated just by the specified voice commands like create a room, join a room, enter the user details, turn off and on audio and video, sending messages in the chat window and also mailing someone the meeting link, basically each and every activity that a normal user does can be performed by the disabled too.

Fig. 4 : An instructor interacting with a student with ASD using Vocabulary Core Board

Mode-2 of our solution targets the community which are suffering from Autistic Spectrum Disorder. In simple terms, the children suffering from this disorder are not able to communicate either verbally or via sign language communication due to poor motor skills. So, in the current scenario, instructors of such children make use of the below shown physical board called as Vocabulary Core board. These are physical boards that serve as a collection of tiles in which 50% of a child's daily vocabulary is represented in a chart pictorially in a color code fashion. The tiles are grouped on the basis of category so that the child can point on a sequence of tiles in order to form a sentence and can communicate with the co-person. In our application, we have digitized this physical load in the form of a digital core board in a similar manner with color code groups such as pronouns, alphabets, letters, adjectives, emojis, etc.The child can click on any tile and that tile is included in the word tray.

Fig. 5 : Vocabulary Core Board (Physical / Paper)

In similar fashion, the child can construct the sentence by clicking on the tiles and once the sentence is ready, the child can click on the speak icon to convey his/her sentence to the instructor over the call using socket programming.

Mode 3

Mode 3 of our solution employs Gaze Tracking to act as a substitute for conventional keyboard and mouse controls as well as a conveying medium for verbal communication. Gaze tracking software is used by individuals who have disabilities or limited mobility that make it difficult or impossible for them to use traditional methods of computer control, such as a mouse or keyboard [12]. This software can provide an alternative method of control that is based on eye movements, which can be especially useful for people with conditions such as:

- Motor disabilities, such as cerebral palsy or multiple sclerosis, that impact the ability to use a mouse or keyboard.
- Neurological conditions, such as ALS or spinal cord injuries, that affect muscle control and mobility.
- Visual impairments, such as macular degeneration or glaucoma, that make it difficult to use a mouse or keyboard.

Web Gazing refers to the act of using eye-tracking technology to control a computer or other electronic device. This technology uses a webcam or other type of camera to track the movement of a person's

eyes and translate that movement into commands for the device. Web gazing technology works by detecting changes in the position and gaze of the eyes, and translating this information into commands for the device. The technology can be used to perform a wide range of tasks, such as scrolling through a web page, navigating menus, and even typing.There are several types of web gazing technology available, each with its own unique features and capabilities. Some systems use webcam-based eye-tracking, while others use specialized hardware that is built into the device. However specialized hardware for gaze tracking is expensive and hence heightens the barrier of inclusion. Hence for our solution we use Web-Cam based gaze Tracking using an Open Source library - WebGazer.js.

WebGazer.js [13] :

WebGazer.js is an open-source library for web-based eye tracking. It works by using a webcam to track the movement of a user's eyes and translate this movement into commands for the computer. The library uses machine learning algorithms to identify the user's eyes and determine the gaze direction. It tracks the position of the eyes over time, and uses this information to determine where the user is looking on the screen. The library can then translate this information into commands, such as clicking a button or scrolling a page.

WebGazer.js runs in a web browser, which means that it can be used on any device with a webcam and an internet connection, without the need for any additional hardware or software. The library is designed to be easy to use and integrate into existing web applications, and it can be used to build a wide range of interactive applications and experiences.

One of the benefits of WebGazer.js is that it provides a low-cost and accessible solution for web-based eye tracking. Because the library runs in a browser, it eliminates the need for specialized hardware or software, and it can be used with a wide range of devices and operating systems. Additionally, the open-source nature of the library means that it can be freely modified and extended to meet the specific needs of individual users and applications.

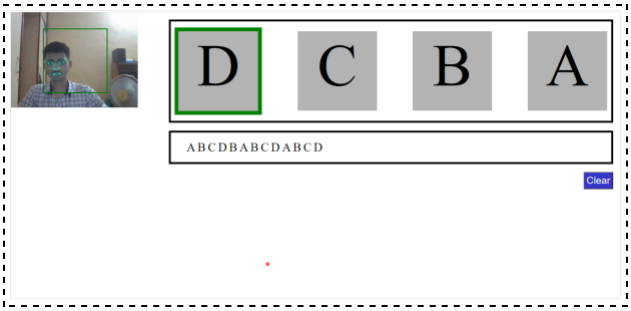

Fig. 6 : Demonstration of typing words by selecting buttons on the screen solely using Gaze Tracking

Internally WebGazer is agnostic about face and eye detection algorithms, it incorporates three different facial feature detection libraries: clmtrackr [14], js-objectdetect [15], and tracking.js [16]. All three implement different vision algorithms in JavaScipt. Js-objectdetect and tracking.js detect the face and eyes and return rectangles that enclose them. Instead of using the whole video frame we first perform face detection for finer-scale eye detection on its upper half, speeding upgaze prediction and suppressing false positives. Clmtrackr a more realistic fitting of the facial and eye performs contour. To provide consistent input for WebGazer, the smallest rectangle that fits the eye contour is used. This is followed by pupil detection and eye feature extraction (120D feature). Then a regression model is used to map these 120D features to 2D screen coordinates.

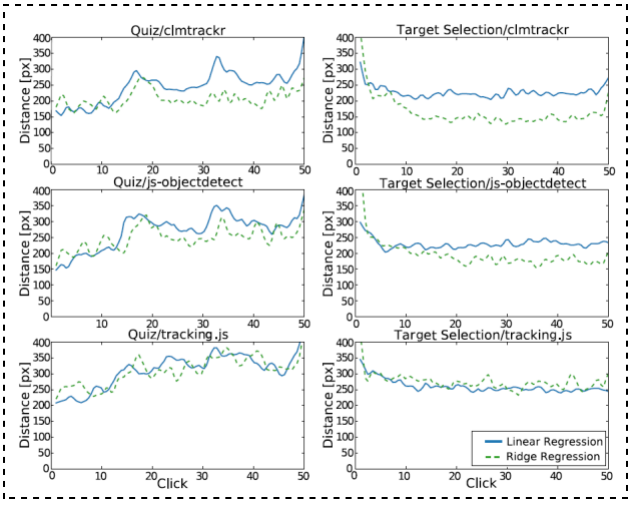

Fig. 7 : Average Euclidean distance in pixels between the click location and the predictions made by the simple linear (solid blue) and the ridge regression model (dashed green).

Interface Design :

Using WebGazer's abilities the interface for Mode 3 can help the user form sentences and communicate them to their chat partners using Text-to-Speech. The size and layout of the buttons that are triggered by Gaze Tracking has been carefully decided so as to combat any errors in the gaze prediction. Also for smaller buttons on the interface Blink Detection has been used as a trigger.

Mode 4

Mode 4 of the solution uses the webcam video feed to detect non-verbal communication like Sign Language and convey it in the meeting via Text-to-Speech.

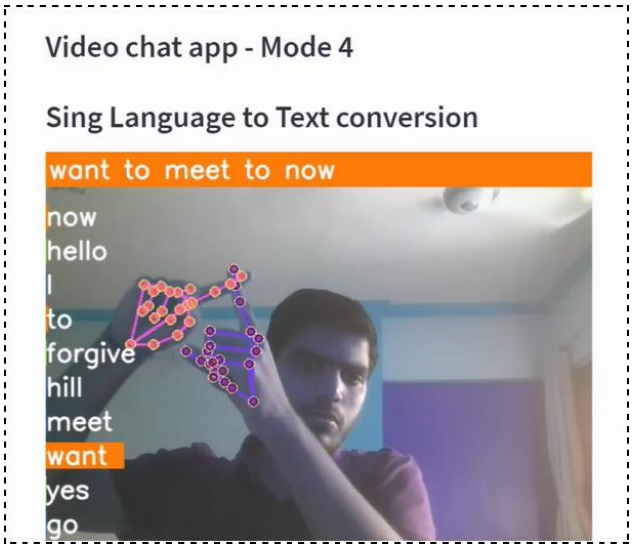

Fig. 8 : Mode 4 Demo

(For demonstration purposes we built our Sign Language Detection model on a limited vocabulary of 20 words)

Mediapipe is a library for building cross-platform multimedia processing pipelines. It provides a framework for integrating and processing image, audio, and video data in real-time. MediaPipe contains a massive array of human body detection and tracking algorithms that have been trained on Google's vast and diverse dataset. They track critical spots on different body sections as the skeleton of nodes and edges or landmarks. All coordinate points are normalized in three dimensions. An overview of how the Sign Language Detection works:

1. Input data: To start, we capture video data of a sign language gesture, by using the webcam.
2. Pre-processing: Before the data can be processed, it may need to undergo some pre-processing steps, such as resizing or cropping the image, converting it to grayscale, and normalizing the brightness and contrast.
3. Sign language detection: Next, we used the Mediapipe library to build a pipeline for sign language detection. The pipeline will include a series of computer vision algorithms, such as edge detection, object detection, and feature extraction, to identify and analyze the sign language gestures.
4. Recognition: Once the sign language gestures have been identified and analyzed, the pipeline uses machine learning algorithms, such as decision trees, support vector machines, or deep neural networks, to recognize the signs and match them to predefined sign language symbols or words.
5. Output: The final step is to output the recognized sign language, either as text or speech. The output can be displayed on the screen, sent to a text-to-speech engine, or saved to a file for later use.

V. RESULTS AND DISCUSSION

Fig. 9 : Website Landing Page

Fig. 10 : Mode 1 Interface

Mode 1 interface imitates any generic video chat interface, but with additional speech recognition capabilities. Common meeting control actions like Creating a Meeting, Turning off video, Unmuting microphone, Leaving a meeting etc. can be done using voice commands. Moreover one can also use the text chat using voice commands.

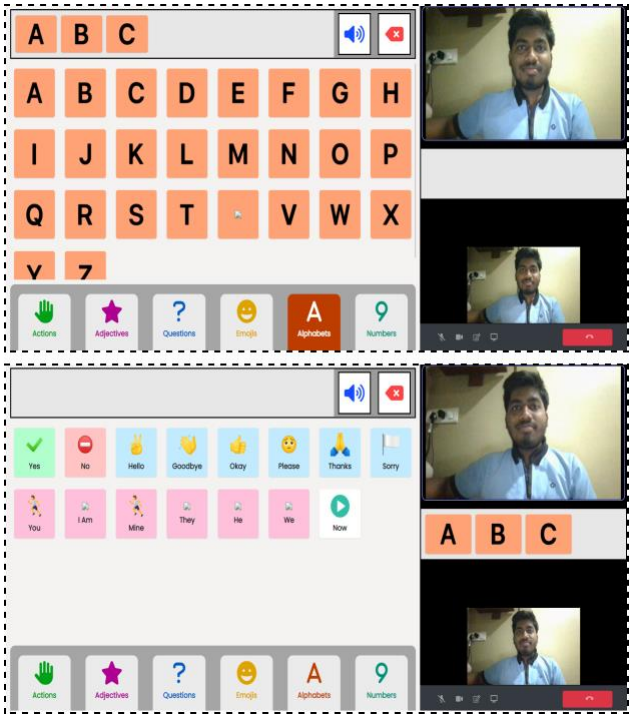

Fig. 11 : Mode 2 Interface

Mode 2 interface implements a Digital Vocabulary Core Board on the left with the video feeds placed on the right of the screen. Users can select tiles from the word tray which are then added to the sentence tray. Once a sentence is formed the user clicks on the Speak button, and the formed sentence is communicated to the meeting partner via Text-to-Speech. The contents of the word tray can be modified using the array of options on the bottom. Also the messages sent by the instructor are displayed on the right in the same word tiles format.

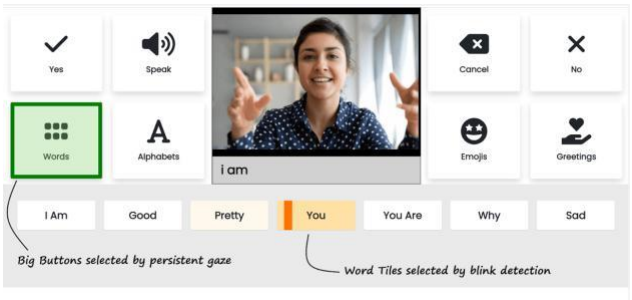

Fig. 12 : Mode 3 Interface

Mode 3 Interface consists of two types of buttons, each being triggered by a computer vision based detection event. The larger buttons in the upper portion of the screen are triggered based on Gaze Tracking. Persistently staring at a button leads to a click event on it. The placement of the video feed at the center and buttons on the sides is deliberate and meant to utilize the comparatively better gaze prediction on the sides of the screen. Similar to Mode 2, in Mode 3 we have a sentence tray. The word tray in the bottom portion of the screen is used to populate the sentence tray. Once activated, a cursor traverses through the tray from Left to Right. When the cursor is on the desired word, the user must blink. The blink is detected and the word is added to the sentence tray. Using the Speak button the contents of the sentence tray are communicated to the meeting partner via Text-to-Speech.

VI. CONCLUSION

The problem statement and the facts that back it up provide the impression that the problem is evident and does call for a necessary solution. The employment of an inclusive video chat application that accommodates various disabilities will lessen the drastic cutoff of offline resources, have a greater reach, and be simple to use in a centralized fashion.

VII. FUTURE SCOPE

The accuracy of Computer Vision models can be improved using extensive training data and more browser performant models. The interfaces created can be decoupled from the core video chat application and can be offered as add-ons to existing video chat applications, thus increasing the potential for inclusivity.

VIII. ACKNOWLEDGMENT

We sincerely appreciate the assistance, direction, and encouragement provided by our mentor Zahir Aalam for this evaluation work. Additionally, we are grateful to the project managers for setting up the facilities required to complete the job.

Abstract- **Every student in school, every student at university, and every professional in the workforce relies on Word documents on a daily basis. These documents may be used for conveying ideas, projects, and even taking notes. Keyboards and mice are useful for most but there are some individuals who have unsupportable conditions such as Arthritis in the hand, Parkinson's, Carpal Tunnel Syndrome, or Essential Tremor for which keyboard is painful. Speech docs aim to solve such problems by enabling only voice to interact with the documents. By using their voice, users can perform any operation, such as creating, editing, opening, writing, or replacing words in a document.**

Keywords- Speech recognition, Voice recognition, Speech-to-Text, Feedback mechanism

I. INTRODUCTION

Voice-controlled systems have revolutionized how humans interact with computers. Users can make hands-free requests to computers with voice or speech recognition systems, which process their requests and respond appropriately. With years of research and development in machine learning and artificial intelligence, voice-controlled technologies have evolved to be more efficient and are widely used in many fields to enable and improve human-to-human and human-to-computer interactions [1].

Word processing software did not develop out of computer technology. It evolved from the needs of writers rather than those of mathematicians, only later merging with the computer field. The history of word processing is the story of the gradual automation of the physical aspects of writing and editing, and the refinement of the technology to make it available to individual and corporate users [2]

. Word processing software can be used in daily life and business to create professional-looking documents such as resumes, letters, applications, forms, brochures, templates, business cards, calendars, reports, eBooks, and newsletters in speed with high quality.

In this paper, we present Speech Docs which is a voice-controlled word processing software and is designed for those who are unable to type on a keyboard. With SpeechDocs, you can create a new document, update its contents (Replace, delete, clear, enter title, type body, etc.) and save it, or download or export the document to a word file to share it with anyone.

II. LITERATURE REVIEW

1. Voice Controlled E-Commerce Web Application

A preliminary prototype of a voice-controlled e-commerce web application using IBM Watson STT, and TTS services is presented, along with performance comparisons of some of the more well-known SRSs from the literature and a taxonomy for classifying SRSs based on their functionality.[1] It also studies some cutting-edge SRSs. Increasing website accessibility is essential for the e-commerce-dependent economy of today. In order to increase accessibility of web applications for visually impaired users so that they can use their voice to manage the application, authors created an SRS-based e-commerce web application. By encouraging easy interaction and multitasking and supporting a lean environment where users may make requests using

natural language, SRS enabled programmes can improve usability for all users.[4]

Results after comparison of some popular SRS available today.

Cloud-based SRS	WER (%)	PRR (%)
Google	15.8	73.3
Nuance	39.7	44.1
IBM	42.3	46.3
AT&T	63.3	32.8
WIT	63.3	29.5

Fig 1. SRS comparison

$$PRR = \frac{\text{Number of Words} - \text{Substitutions} - \text{Deletions} - \text{Insertions}}{\text{Number of Words}}$$

$$WER = \frac{\text{Substitutions} + \text{Deletions} + \text{Insertions}}{\text{Number of Words}} * 100$$

Fig 2. PRR and WER formula

In terms of quality, Google proved to be superior to the other systems as it was able to identify 73.3% of the text with only 15.8% WER and 73.3% PRR. Nuance's The Dragon system achieved around 39.7% WER with a PRR of 44.1%. IBM Watson recognized 46.3% of the text with a WER of 42.3% and 46.3% PRR.

a) Gaps Identified

There are no specifics on how visually challenged users are supposed to login and navigate to different pages on the e-commerce website. Because the entirety of the website cannot be voice controlled, visually impaired individuals are still not independent.

b) Findings

A unique vocabulary is maintained which is frequently used in application,which helps in better recognition of words / sentences. We can populate the vocabulary according to a specific application and can train a model on those specific words and this might help with better speech recognition.

2. Voice Based Email System

The proposed method is usable by both normal people and people with disabilities. The system is pleasant to all user types, whether they are normal, visually challenged, or illiterate, however it concentrates more on regular users.[3] The system directs the user in carrying out the action that is desired. The main benefit of this system is that the user doesn't have to worry about using the keyboard because all actions are voice-based or based on simple mouse clicks, so there's no need to learn keyboard shortcuts in order to provide speech inputs. The technique will also be very helpful to those who are illiterate and cannot read or write.[5] This e-mail system can be used by any user of any age group with ease of access. It has features of speech to text as well as text to speech with speech reader which makes a designed system to be handled by visually impaired persons as well as blind persons.

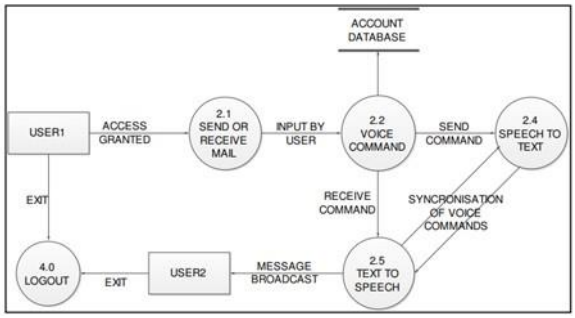

Fig 3. Voice Based Email System Architecture diagram

a) Gaps Identified

Voice-based authentication is used in the planned voice-based email system. Users must speak out their email address and password, which can cause security problems. There is no discussion of how to fix the security problem. Traditional login systems may not work with voice based input as someone can hear the email and password and it can cause severe security issues.

b) Findings

Offers a very good feedback mechanism that can be used to improve user friendliness, particularly for those who are impaired. The system continuously directs the user as to what actions to take next. This can be very helpful for speechdocs user's.

III. PROBLEM STATEMENT

According to WHO, nearly 15% (i.e 1billion population) of the world have some form of disability. Out of 1 billion around 200 million have limb amputations or handicapped. In some cases, they are forced to make do with imperfect hacks such as sending audio files, using keyboards painfully, or avoiding typing altogether. Speech Docs offers users a powerful, fully-featured voice-controlled document

editing system where they can do everything the same way as on MS Word or Google Docs without touching the keyboard or mouse.

IV. PROPOSED SYSTEM

The system mainly consists of three views: landing page, dashboard, and main sheet. The navigation between all the pages will be fully voice controlled with a feedback mechanism. There is a navigation to the authentication page on the landing page. We are going to use facial recognition authentication instead of voice authentication to protect user credentials. The dashboard page will have navigation to the main sheet page and also have the section where users can see all the history of all the past documents. The users can also favorite their documents and see them under the tab 'favorites' again all the processes will be fully voice-controlled. The main sheet area will have commands displayed in an organized manner equally on the left and right of the sheet.

1. Architecture Design

The speechDocs web application receives voice commands from the user and internally recognizes the voice using a speech-to-text converter. The text is then translated using natural language processing. Each command in a speech document is mapped to a specific function. The collection of commands is then compared to the interpreted text. The function mapped to that command is carried out if any of the commands match. If there are any changes to the data, the database's state is updated. Additionally, SpeechDocs features a feedback mechanism, and for each successful command, the user receives feedback that internally implements text to speech.

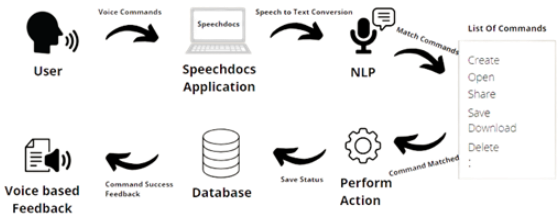

Fig 4: SpeechDocs Architecture Design

2. UI Design

(A) Dashboard Design

The dashboard allows users to open a new document as well as view all their previously edited documents. By saying the unique document id, they can open documents. There is a recent section where users can view the latest version of the document, making it easy to open the latest version. Users can also favorite a document, which can be viewed in the favorites tab.

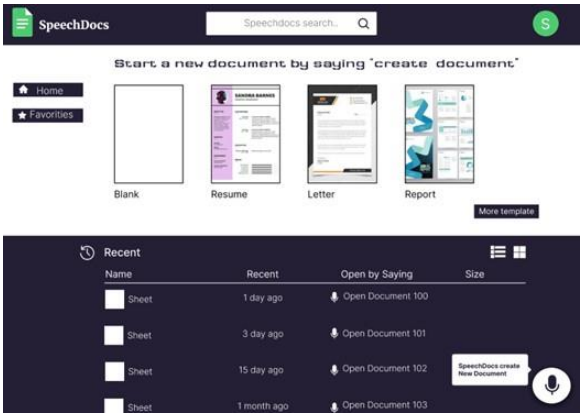

Fig 5. Dashboard Page

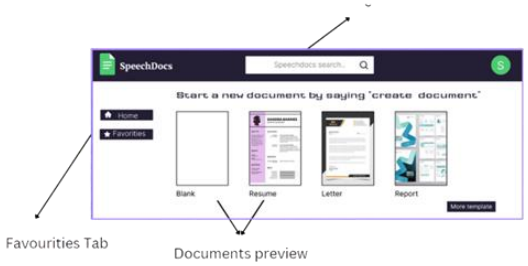

Fig 5 a. Dashboard top Section

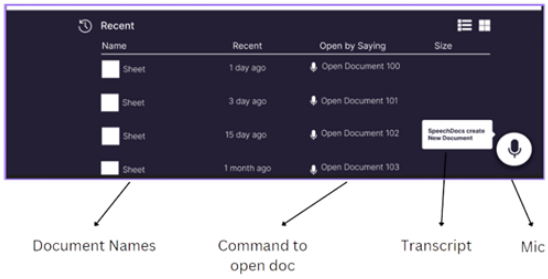

Fig 5 b. Dashboard Bottom Section

(B) Main Page Design

The main page design consists of navbar and main sheet. The navbar has different modes such as select mode, edit mode, etc. wherein each mode has commands associated with it which will be shown

equally distributed on left and right of the main sheet on request.

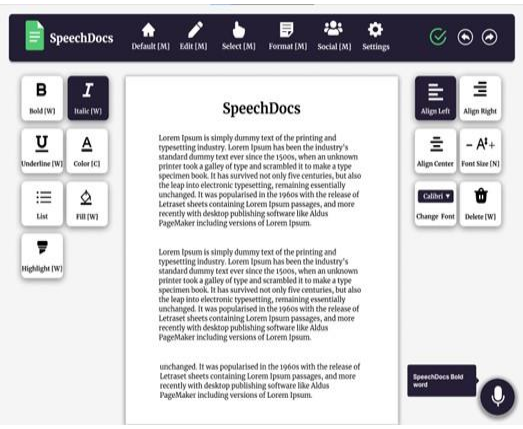

Fig 6. Main Page

Navbar consists of all different modes like default, edit, format social etc.

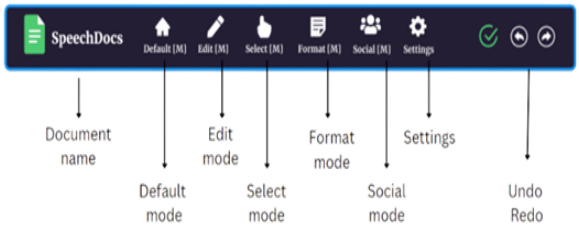

Fig 6 a. Main Page Navbar

Left and right section is equally distributed by commands. Each command is in form of a tile which consists of an icon and actual command which user needs to utter

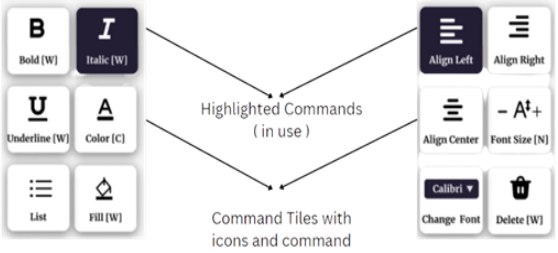

Fig 6 b. Main page Command Tiles

(C) Use Case Diagram

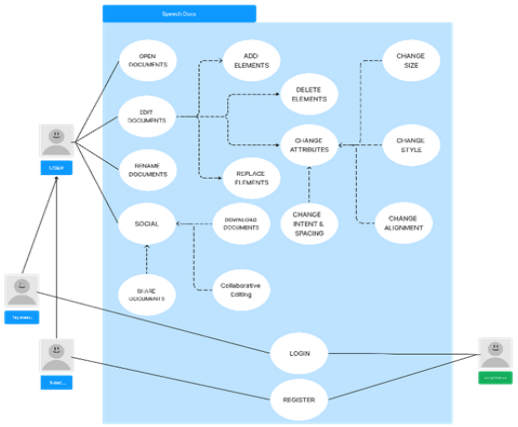

Fig 7. Use case Diagram

V. RESULT AND DISCUSSION

A basic functionality has been implemented where users can change titles, add words, remove words, share, and download documents, among other things. With the implementation of a small prototype, we have found that the ability to capture speech is much slower. It can misinterpret words if you don't speak clearly and when the user is in a noisy environment it sometimes fails to perform desired actions. But the few parts that are successful are the user will be able to navigate between pages by voice and a facial recognition authentication system will be used to ensure the security of their credentials. There will also be support for multi-language systems (mainly English and Hindi).

VI. CONCLUSION

In the past, it was only those with a profound understanding of word processing who benefited from the advantages of word processing; those without such knowledge and unsupportable conditions such as Arthritis in the hand, Parkinson's, Carpal Tunnel Syndrome, or Essential Tremor were denied the benefits. We present a solution to the above with a speechDocs where navigation to different pages and opening documents to editing documents are fully voice controlled. Also, to protect the user's credentials we have looked at facial recognition authentication systems. In order to reach more users, we will have an additive advantage to the software.

VII. ACKNOWLEDGEMENT

We would like to thank Dr. Prachi Janrao for all of his invaluable guidance and support throughout the project.

Abstract. Using a variety of sensors, automatic activity recognition systems can continuously monitor a wide variety of physiological signals from sensors con-nected to the user or the user's surroundings. When applied to healthcare, this can greatly benefit areas like automated and intelligent monitoring of everyday ac-tivities for the elderly. This article represents a novel approach to analysing the data using Artificial intelligence. The data was collected from the smartphone's internal sensors using the feature ranking algorithm. These sensors collect data regarding human activities. Classify the collected information using random for-ests, ensemble learning, and lazy learning techniques. The suggested method may lead to intelligent and autonomous real-time development, as shown by extensive tests utilising a public database1 of human activity using smartphone inertial sen-sors. Human activity tracking for use in eHealth situations, including the elderly, the handicapped, and other populations with unique healthcare requirements.

Keywords: Security, random forecasting, machine learning, smartphones

1 Introduction:

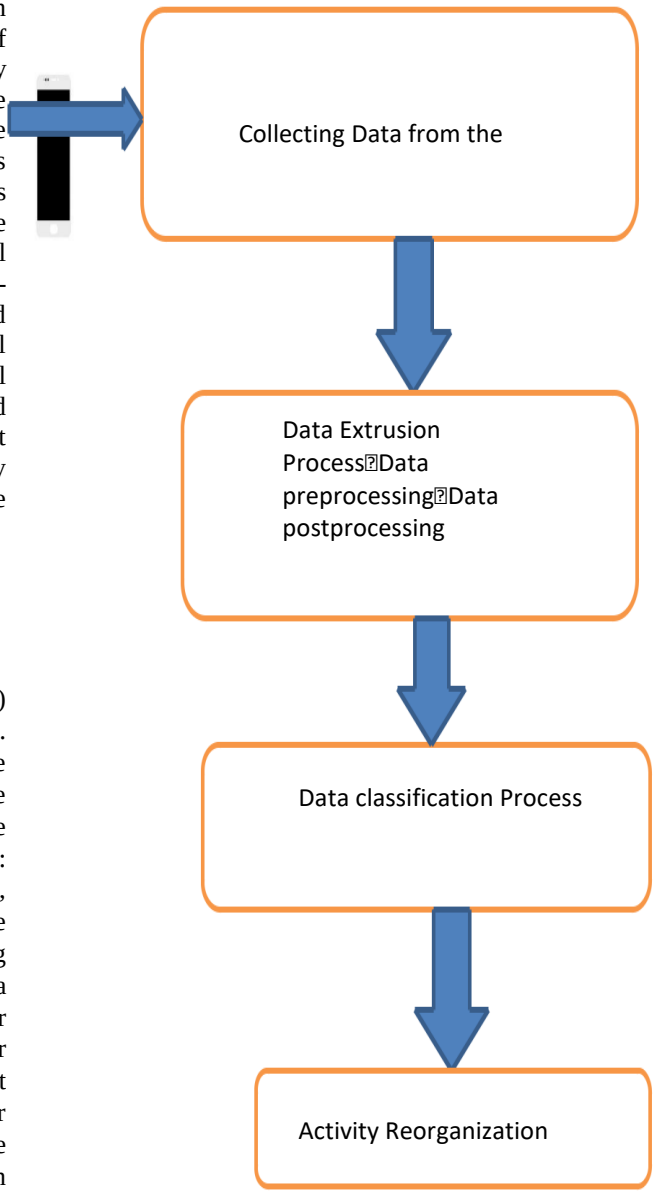
Most app developers and smartphone owners have helped propel the mobile application (app) ecosystem to the forefront of global economic growth. According to recent sta-tistics, the most downloaded apps in 2022 by users will be according to their require-ments. continuously monitor a wide variety of physiological signals from sensors con-nected to the user or the user's surroundings. When applied to healthcare, this can greatly benefit areas like automated and intelligent monitoring of everyday ac-tivities for the elderly. This article represents a novel approach to analysing the data using Artificial intelligence. The data was collected from the smartphone's internal sensors using the feature ranking algorithm. These sensors collect data regarding human activities. Classify the collected information using random for-ests, ensemble learning, and lazy learning techniques.

Studies show that although internet users are increasingly dependent on smart mobile devices (such as smartphones and tablets) for their day-to-day activities and demands, they may not always be aware of or able to influence the processing of per-sonal data using these tools. Moreover, it is frequently difficult to analyse apps' privacy and security features because of the complexity involved in understanding how they function because of their dynamic environment, reuse of software libraries, and inter-action with other networks and systems. Inadequate data protection and security proce-dures are often the result of app developers' lack of awareness, expertise, or understand-ing of how to properly arrange for and engineer privacy and security needs into their products, rather than any deliberate neglect of such standards.

The General Data Protection Regulation governs the collection, storage, and disclosure of personal information using applications (EU)

The present Data Protection Directive 95/46/EC [2] is being replaced by a new one that is immediately applicable in all Member States. While The General Data Protection Regulation (GDPR) strengthens the privacy and security guarantees estab-lished by the Data Protection Directive. offers supplementary safeguards that give users more say over their private information, is extremely difficult to do on a mobile device or the internet5 . Beyond the requirements of GDPR, this also applies to The EU's Di-rective on Privacy and Electronic Communications also has implications for mobile applications. Transmissions EU Directive 2002/58/EC (ePrivacy) [3] are being revised at the moment and compliant with the General Data Protection Regulation. In January this year, the European Commission proposed a new ePrivacy Regulation. Commission and is being discussed at the moment in the European Parliament and the Council. Ees-sential safeguards for users' personal information in mobile applications, including pro-cedures for ensuring the anonymity of users' data and the prevention of data breaches exchange of messages and information, installation of apps and files (cookies) on end-user gadgets and rules governing tracking's effect on users' privacy preferences. Combining these numbers with the blurring of barriers between personal and company-owned mobile devices, it's clear that mobile app analysis is becoming more vital for businesses. In reality, these applications may expose sensitive information about workers, which cybercriminals might use for social engineering, the practice of tricking people into giving up sensitive information to steal it, or even for exfiltrating data or installing

malware (malware). Companies are right to be wary of the ever-ex-panding cyber threat environment, which now includes mobile apps, due to the sensi-tivity of the data they collect from their customers (personally identifiable information, or PII). The term "mobile device management" refers to a method businesses use to deploy and control mobile devices like smartphones and tablets. Rules and an applica-tion make up this framework usually, with the latter used to manage policies that limit an employee's access to install mobile apps and enforce security measures. These reg-ulations are implemented to prevent unauthorised access to sensitive information, such as financial records, social security numbers, and intellectual property, and to ensure that malware is updated and cannot compromise systems (IP). An incident responder or mobile device manager may remotely erase all data on a lost or stolen employee's mobile device



Experimental validation with Activity recognition process:

We utilized a public activity recognition (AR) database1 for experimental validation of our method. This Thirty people between the ages of 18 and 50 have provided labelled data for this database. Every single individual performed. Wearing a smartphone belt case while doing six things, including but not limited to: walking on level surfaces, climbing stairs, swimming, playing a video game, and playing a board game sitting, standing, and lying down, as well as walking up and down stairs. In this case, we uti-lized a smartphone to sensor package with 3-axis linear acceleration measuring accel-erometer and angular velocity measuring gyroscope angular velocity, both at a fixed rate of 50Hz, which is more than enough for recording human motion. The two com-ponents of the database are the raw sensor data that has not been processed and the collection of features data that is processed ex

Figure 1: Frame work- Activity reorganization in step by ste

At first, 2.56-second fixed-width sliding windows with 50% overlap were used to sam-ple the noise filters of the raw data. There are 17 parameters, that may be extracted from the time- and frequency-domain analysis of accelerometer data.

Another data set has 2.32-second-long vectors with 552 features apiece. Each vector stores information about the interval, including the average, maximum, lowest acceleration and angular velocity along all three axes and other, more advanced features like the Fourier, transform and autoregressive coefficients. We utilised this dataset to test our activity recognition method's efficacy. Figure 1 depicts the block diagram for this dataset's processing. The preceding section will go on to discuss the relevant con-text.

3 Motivation of the research work:

There are several benefits of using cell phones for automated activity identifi-cation, including the convenience of the device's mobility and the absence of the need for bulky, unpleasant permanent equipment.Other well-established methods of activity identification include body sensor networks and dedicated hardware configurations. For example, While such sophisti-cated setups may improve the effectiveness of activity detection, it is unreasonable to expect individuals to wear them regularly in most residential settings due to the effort, time, and convenience involved in doing so. Smartphones have a leg up on the compe-tition for activity detection because of their portability, simplicity of use, and the ability to utilise the phone's many sensors. Smartphone sensor outputs need the development of practical machine learning and data mining technologies for automated and intelli-gent activity detection. While several machine learning approaches are developed, the best algorithm for recognising mobile phone activities remains unclear. It would be a massive boon to the eHealth field if automated activity identification systems could be constructed using the intelligent processing of numerous smartphone sensor character-istics. They focus on remote activity monitoring and recognition in the elderly and dis-ability care sectors. This article compares the naive Bayes classifier and the unsupervised k-means cluster-ing method. The comparison for activity recognition on several novel machine learning and data mining approaches in smartphones, Adopting the random forests and random committees on the decision tree method. A publicly available smartphone activity iden-tification database 1 reveals that integrating machine learning and data mining signifi-cantly increases recognition performance over earlier smartphone-based activity detec-tion methods. I'll explain the machine learning methods that allowed a mobile app-based activity recognition system.

Data Mining approach to classify the Activities:

In the next stage, work will organize in the form of data mining. Initially, based on the ranking system preprocessing is implemented. For preprocessing technique, Con-sider real-time smartphones (561 parts). In this case, the data is used to determine the relative value of various constituents, with less important ones being disregarded. In the setting of our very high-dimensional datasets, our attribute selection technique has performed exceptionally well, allowing us to employ almost half as many characteris-tics as before while maintaining the same level of recognition performance. A battery of tests was conducted using a range of feature rankings derived from an information-theory-based ranking technique. These varied from the use of a Naive Bayes classifier as a starting point to those of Decision Trees, Random Forests, Ensemble Learning, and Lazy Learning. Several different classifiers were evaluated for this work, and we offer summaries of each below.

4.1 Bayesian Classifier:

This classifier uses Bayes' theorem at its core to make inferences based on probabilities. Naive Bayes, the most straightforward Bayesian approach, is explained as a specific example of an algorithm that requires no modification for continuous data. Since it is supervised learning and easily trained, it provides a valuable starting point for evaluat-ing other methods in terms of accuracy and generalization.

4.2 K-Mean classifier approach:

In this case, the dataset may be unlabeled since clustering is an unsupervised learning technique. Instances are stored into two categories: those that are the same or connected and those that are distinct. K-Means is the most well-known and straightforward tech-nique for determining whether instances may classify based on some criteria. Because of its ease of use and the fact that it can process unlabeled data, it might serve as a benchmark against measuring the performance of other classifiers.

4.3 Decision tree-classifier approach:

The dependent variable, or the desired outcome for a new sample, is calculated using a decision tree classifier based on predictive machine-learning algorithms. Here, the internal nodes of the decision tree represent distinct qualities, and the branches between the nodes represent the range of values that each attribute may take in the data samples being analyzed. The terminal nodes further indicate the dependent variable's ultimate values (classification). In statistics, the word "dependent variable" refers to the variable whose value is being predicted; in this context, it is the attribute whose values are being anticipated. Consequently, the independent characteristics are the independent varia-bles in the dataset, contributing to predicting the dependent variable's value. The J48 Decision tree classifier employed in our tests has a straightforward algorithmic ap-proach. Whenever it has to categorize anything new, it must first generate a new deci-sion tree using the attribute values from the existing training data. Attributes that differentiate across samples are used to identify the next batch of items added to the train-ing set. This attribute gives us the most helpful data since it allows us to easily distin-guish between different occurrences of the data, which is essential for accurate catego-rization.

4.4 Random forecasting approach:

When it comes to ensemble learning techniques for classification and regression, Ran-dom Forests are a decision tree ensemble. Additionally, they may be seen as a kind of closest neighbor predictor, as they build many decision trees during training and use the class mean as their output. Random Forests is an ensemble of decision trees (a term used by Leo Breiman15). Through averaging and balancing the two extremes, Random Forests aim to mitigate bias and variation problems. In addition, there aren't many knobs and dials to fiddle with in a Random Forest; in most cases, you may get good results by just utilizing the default settings. Because of these benefits, Random Forests may frequently be used directly from the box to produce a decent, quick, and efficient model, without the requirement for extensive handcrafting or modelling in comparison to other classifiers.

- A time and frequency domain vector of 561 features. That describes its function.

Individual subject identification for the researcher conducting the study.

4.5 Random type forecasting approach:

As with other types of ensemble learning methods, the premise of the random commit-tee is that the addition of more classifiers will lead to better overall results. Each indi-vidual classifier in this sort of classifier is built from the same underlying data but with a distinct random number seed. To determine the final output class, it takes the mean of the predictions made by all of the basic classifiers.

4.6 Lazy learning classifier:

Classifiers based on lazy learning store the training instances during the training period and use them later for classification. The IBC classifier resembles the k-nearest neigh-bor classifier in many respects. However, there are ways to speed up the determining closest neighbors by utilising various search methods since most of the learning occurs during the classification phase when these models are often at their slowest. While this study used a linear search strategy, the performance may have been improved using kD-trees, commonly known as cover trees. As the measure of separation, we used Eu-clidean distance. There was no distance-based weighting applied, and just one neigh-bour was utilised.

5 Result:

Use the 2.56-second chunk of data from dataset 1 that has been pre-processed to include a collection of 561 characteristics to evaluate the efficacy of the recommended data mining approach for independently identifying human activities from smartphone data. Each track displays the following traits:

Body acceleration estimation and triaxial acceleration from the accelerometer.

- The gyroscope's reading of the triaxial angular velocity.

Figure 2: Difference between the classifier

In Figure 2, we see the relative merits of various features, as measured by their contri-bution to the Model's performance and the amount of time spent on its construction under various classifier learning strategies. This chart displays the results of our
analysis of2,8,16,32,64,128,256, and 561 features (all features), ordered by infor-mation gain. About 10,000 samples were used in total throughout training and testing. Because there were so many samples in this dataset (10,000 total), we utilised fivefold cross validation to split it into separate training and testing sets. Figure 2 depicts each classifier's Accuracy in Classification and Model Building Time, while Tables 1-3 pro-vide additional metrics, including TPR, FPR, PR, RC, F-m, and ROC. Table III displays the confusion matrix for the best-performing IBk classifier with 128 and 256 ranked features, respectively.

The Naive Bayes Classifier takes the least amount of time (5.76 seconds) to finish building the model, and its 79% accuracy on the massive dataset is seen in Figure

2. Among the ensemble learning methods, however, random forests provide the best combination of accuracy (96.3% on average) and speed (14.65 seconds on average) when developing a model. The other classifiers in the ensemble learning system also perform well in classification accuracy (96%) (random committee and random sub-space). As an unsupervised method, K-Means clustering does poorly, with a classifica-tion accuracy of just 60% and a time to solution of 582 seconds.

In contrast, the slow-learning-based IBk classifier outperforms all other classifiers by a wide margin (90%+ accuracy for 128 and 256 features). To attain maximum perfor-mance, a smartphone-based activity identification system must trade between accuracy and the time it takes to create a model since real-time activity monitoring requires a model to be generated dynamically from the obtained data. Aside from TPR and FPR, other performance measures include Precision, Recall, and F-measure.

Since real-time activity monitoring necessitates the construction of a model dy-namically from the obtained data, an activity identification system implemented on a smartphone must strike a balance between accuracy and the time required to create the model. Additional measures such as false positive rate (FPR), false negative rate (FNR), precision, recall, F-measure, and ROC area should be considered when choosing an algorithm for an automated activity identification system. Table I displays these addi-tional indices of productivity.

Table-3: well developed

The top-performing IBk classifier's confusion matrix on datasets with 128 and 256 sorted features is shown in Table II. The confusion matrix (Actual Class (AC-0 to AC-5) versus Recognized Class) displays the classifier's ambiguities and misclassifications (RC-0 to RC-5). Class 1 (walking) and Class 6 (lying) exhibited the fewest discrepan-cies in the classifier's identification of the six activities tested. There is some ambiguity between sitting and standing, and it's downright impossible to differentiate between ascending and descending flights of steps. When compared to earlier attempts at activ-ity identification using a single smartphone worn at the waist, this is a significant ad-vancement.

6 Conclusion:

In this article, By using machine learning, identify smartphone activities. Based on the ranking theory, machine learning automatically takes actions and records. This work is validated using well-known techniques like Lazy learning, random forests, and ensem-ble learning. For analysis purposes, prepare datasets according to the classification technique. Due to the classification technique, the dataset will develop accurately, con-cerning time, and a well matrix will create. Data mining technique is implemented in different smartphone to analyse various activities. An unsupervised algorithm is needed to construct intense real-time work on smartphones. At end of the research IBk classi-fier performed well at 128 and 256 features.

Abstract— **Crop diseases are a major threat to food security, but their rapid identification remains difficult in many parts of the world due to the lack of the necessary infrastructure. The combination of increasing global smartphone penetration and recent advances in computer vision made possible by deep learning has paved the way for smartphone-assisted disease diagnosis. Using a public dataset of 54,306 images of diseased and healthy plant leaves collected under controlled conditions, we train a deep convolutional neural network to identify 14 crop species and 26 diseases (or absence thereof). We employ latest advancements in computer vision field by using transformer based models and using techniques like one cycle learning rate policy and discriminative learning rates. Our project aims to achieve high accuracy when our model is tested on a set of images collected from trusted online sources i.e. taken under conditions different from the images used for training - the model. Moreover, real world datasets are very hard to collect and training our model with small datasets is the major challenge. Overall, the approach of training deep learning models on increasingly large and publicly available image datasets presents a clear path towards smartphone-assisted crop disease diagnosis on a massive global scale.**

Keywords)- — ***classification model, Convolution Neural Networks,*** **computer vision ,** ***infected crop. Neural network, Transformer, ResNET, efficentNET, VIT, plant disease detection***

I.INTRODUCTION

Agriculture and farming has been one of the oldest and most profitable professions until today's date. Computer and Technology has made an evolutionary change year by year in order to yield out maximum profit and also to reduce the human effort. Significant changes in farming techniques has been observed with increase in technology and have also led to the ease of farmers.

Although, there are still some factors leading to loss of cultivation and not only affecting the farmers wages and salaries but is also contributing to disruption of the eco- system. Some crop diseases are contagious and may also lead to infertility of the soil upon which the crop's foundation is based. These menace would gradually lead to poor fertility of the land and may no longer be hold enough moisture and other constituent nutrients required for an ideal growth. A huge amount of effort has been put in to reform the cultivation methods once again and make the work of the famers convenient to some extent this may not only inhibit the soil for withstanding the cultivation but also damage the plants in the nearby vicinity.

Infected plants can be hazardous to the consumer in a certain way wherein, they may not be fit enough for the consumption, these lost soil nutrients do not replenish quickly. Hence, not making them fit enough for harvesting throughout the year.

For the farmers, the ones who are experienced tend to solve the solution by adding appropriate fertilizers or any other remedy which would not be suffice the situation significantly and the crop has already been infected and these infected crops are sold which in turn breeds numerous diseases.

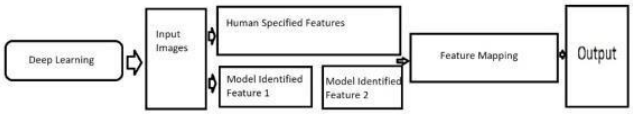

Figure 1: Deep Learning Approach

Therefore, to tackle this situation a technology has been introduced which would classify the infected crops using Convolution Neural Networks which comprises of several layers and each subsequent layer treats the previous layer's result as an input. This filtration goes through multiple stages before the final result is generated a diagrammatic representation i.e. Fig 1 illustrates the procedure.

Till now many researchers have shared multiple techniques for detecting disease from plant leaf using CNN. In the below section we have reviewed the others paper work and we have tried out to explain the recent advancement which are done in the CNN technique for disease detection. We hope our this work will be helpful for the people who are looking forward for the exploring of this field more.

Benefits of Convolution Neural Network for detection of crop disease:

1. ***Works well for internal representation of two dimensional images.***
2. ***It is self reliant and works well without any human intervention.***

We upon reviewing multiple researcher's paper have come up with few incites which would help us to identify which one is the best method of detection of crop disease.

II. LITERATURE SURVEY

In the paper[1], First, leaf images are captured, then image processing techniques are applied to extract features useful for disease detection.

A. Image analysis

To detect the disease, the image of the infected leaf needs to be examined in a series of ways. The input image is preprocessed and its features are extracted according to the dataset. Then, in order to classify the disease according to a specific data set, it is necessary to use some classification method.

B. Image capture

Image capture is the process of capturing and converting it to the desired output format. In this application, the analog image is first captured, then converted to a digital image for further processing.

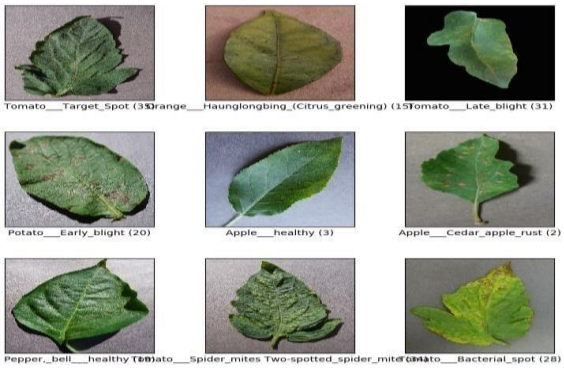

Figure 2: Training Dataset

C. Image preprocessing

The following pre-processing steps are performed on the captured image. Freeze frame or use active binarization, look-up table, or image plane separation to increase image contrast. Reduces image resolution degradation through binning. Rotate Image Converts a color image to a grayscale image.

D. Feature extraction

The goal of this phase is to extract features such as color and shape. Two geometric features, such as area and perimeter, are extracted from the binary segmentation image. Color feature is extracted from the color segmentation image. The color characteristics include the average gray value of the R /G/ B component, the distribution of the gray value of the R / G / B component, the R / G / B component, the color ratio in RGB color model, -H. / S / V component gray value average, H / S / Vgray value distribution H / S / V- component gray value component and skewness.

E. Leaf image classification

In the classification between the affected leaf, the classifier relied on Bayes' theorem, and SVM was used to distinguish between the classification and the affected leaf.] First, the captured images are classified into infected leaves and unaffected leaves. The color distribution is the same for the unaffected leaves, but the color distribution for the affected leaves is not uniform. This is because the pixel values of the affected leaves were completely different from the pixel values of the normal leaves.

The image quality of the leaf is improved by applying an averaging filter after the where image segmentation is performed by Otsu's threshold algorithm. After extracting features from a given leaf image, a recognizer is required to recognize the disease in the leaf image from the stored database. In this paper, we proposed a detection method using the back propagation network (BPN). Back propagation can train multilayer feed forward networks which consist of a forward pass and a backward pass as shown in Fig. 3. In the forward pass outputs are calculated and compared with preferred outputs.

Errors from preferred and actual output are calculated. In the backward pass this error is used to alter the weights in the network in order to reduce the dimension of the error. Forward and reverse paths are repeated until error is low. Normally, the user sets the value of the accepted error. When the trains the NN, it feeds the network a set of sample with inputs and desired outputs. If you choose a learning rate, your swing will help you adjust your weight.

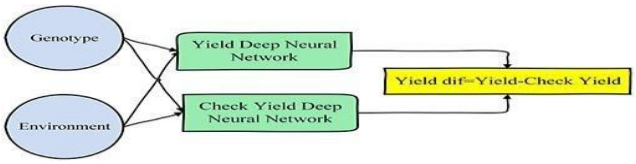

Figure 3: Crop Neural Network

The output layer contains neurons. Support Vector Machine (SVM) is a supervised machine learning algorithm that can be used for classification. This algorithm plots each data item as a point in n dimensional space n is the number of features you have with a feature value of for each leaf.

An approach based on image processing technology has been proposed in to help detect plant diseases. Disease detection is primarily the purpose of the proposed approach and can detect leaf disease with little computational effort. This proposed approach consists of four phases.

Accuracy is improved by using various image processing techniques such as image analysis, preprocessing, feature extraction and classification. Speed and accuracy are two main features of plant disease detection using deep learning techniques that must be achieved. With the proposed method, accuracy of up to 92% can be achieved. With the more featured SVM classifier, you can improve the recognition accuracy by significant amount. This approach can be used for applications such as disease classification of plant parts such as leaf .

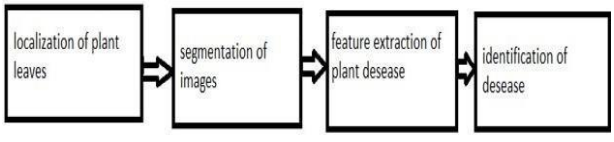

Figure 4: CNN Approach

III. PROBLEM STATEMENT

India being one of the major cultivating centres. Farmers grow varieties of crop in order to make out the most profit. But there is one of the factors which are yielding out low profit and that is crop disease which is not only hazardous but also contagious to the crops in the nearby vicinity. Hence spoiling the quality of the soil foundation .Hence a solution has been drawn out by creating an android application making using of neural networks and yielding out results for the same also making use of machine vision simultaneously.

Making use of CNN and also considering Vgg architecture with depths of 16 and 19 but it was found out to be vgg uses 3X3 convolution layers stack on top of each other and training those models where not feasible because of the issues with respect to convergence and training deeper networks Hence it was slow to train and consumed a lot of bandwidth .Hence to overcome these issues ResNet comes in ResNet does this by connecting nth layer to (n+x)th layer. This implies that Training of this form of network is easier than the other form of networks and also solves the problem of error rate as it decreases the error rate.

In [2] For early detection of disease, capture images taken days or weeks before plant disease becomes visually observable and train Model to detect plant disease early. It has been proposed to be used for. When implementing this framework, it is necessary to experiment with Combinations of different image bands, including bands beyond the visible spectrum, to determine the optimal band combination that can be used to model the deep learning train that can detect Plant diseases even before they are visible to the naked eye.

This is based on the assumption that the disease can be detected before it becomes visually observable, as the spectral reflectance of diseased leaves and canopies is known to be more pronounced in the invisible part of the spectrum. (Campbell & Wynne, 2011). In fact, recent research results show that infections in tomato Botrytis cinerea leaves can be detected 9 hours after infection (long before visual symptoms appear) using near-infrared and redrimmed sensors. (Fahrentrapp et al., 2019). As shown in 3.2, pre- illness Images should be categorized

Image Acquisition: In photo acquisition step, pix are different deep learning CNN architectures that is obtained thru excessive decision virtual digital digicam or from numerous reassets of internet .Few fashionable datasets like Plant Village, APS etc. also are to be had for the researchers The pix are amassed beneath wild, managed or out of control conditions.

Preprocessing: Preprocessing is a way of casting off noises or distortions in a photo to enhance its quality. Various preprocessing techniques consists of Contrast Stretching, Noise filtering and Histogram adjustments etc. “Various filters like low pass, excessive pass, etc. are implemented to cast off numerous kinds of noises

according to the time steps (e.g., days) captured before the illness becomes visually observable. This shows how healthy and diseased crops are displayed in natural colors and in a virtual false color composite of bands extracted from aerial images.

The first row (RGB view 1) shows an image of a healthy crop, and the Image in the second row (RGB view 2) also shows a healthy crop, except for the last image (TN). As Shows, diseased crops are displayed in natural colors (RGB). The third line, (False color view), is an example of what the second line looks like. A combination of virtual false color bands in which existing disease classes exist. In this view, the first three images (T0 to T2) represent a view of a healthy herd of, and the next three Images (T3 to T5) are displayed in false colors, thus indicating the disease class. Represented, is the last image. (TN) displays the same diseased crop on the second line as it appears in this fictitious false color view. As an example of, only one pre-disease class is shown here, but many other classes can be identified during model experimentation and training.

The trained disease Classification model should be continually updated to include "newly discovered" ones. Early stage illness class. 3.3 shows the key components of the proposed framework for early detection and continuous monitoring of plant health. Rounded rectangles indicate common Machine learning tasks, and connection arrows indicate user workflows.

The green Rounded rectangle represents the new disease early detection task developed by this Study. This framework is intended for use by, for example, regional and national Government agencies to monitor the health of a wide range of plants. Such institutions are expected to monitor this The Seasonal crops are in the growing season and the perennial crops are annually maintained in the health of the plants of various crops.

The agencies should use trained crop Classification models at the beginning of the growing season to identify and map the Areas where specific crops are sown, and then deploy trained crop diseases classification Models to images covering only those areas planted with the identified crops.

In [3] The basic “structure of plant ailment detection system” includes numerous stages defined ultimately as: photo acquisition, labelling and pre-processing of statistics accompanied with the aid of using statistics augmentation. After this section education and trying out of dataset executed thru numerous getting to know strategies and class thru deep Convolutional neural networks.

Data augmentation: Since maximum of the datasets aren't to be had easily. In order to create huge datasets, statistics augmentation strategies implemented at the smaller datasets for enhancement. Big datasets reduces the hassle of over fitting.

Training and Testing of statistics: Training and trying out of statistics consists of splitting of datasets into numerous train-check splits. The version is educated through numerous getting to know strategies like baseline education, great tuning or switch getting to know.

Classification: Classification of illnesses is primarily based totally at the predefined dataset values. “For class section, unique type of system getting to know strategies are being hired to allocate a category to a fixed of unclassified statistics”. The fundamental strategies used for class are Support Vector Machine (SVM), Neural Networks, Fuzzy Classifier, Linear Discriminant Analysis, KNN etc. Deep getting to know is a rising studies region with inside the area of system getting to know in addition to in convolutional neural network. It is a subset of system getting to know strategies. Various deep getting to know processes had been used for photo class and recognition. In deep getting to know, CNN is one of the maximum outstanding approach. It includes middle structures: a convolutional layer and a pooling layer. This paper concentrates in particular at the plants that have been categorized thru deep getting to know convolutional neural networks.

In [4] author has developed the model based on convolution neural network (CNN) for detecting the diseased plant images. They have taken the public dataset which is freely available on PlantVillage. 54,306 images of different plant including health and diseased dataset of 14 crop species on 26 diseased have been collected in this dataset.

When model was tested it gives the accuracy of 99.35% which is considered to be good accuracy overall. But when model was tested under different dataset compare with normal dataset it performs accuracy of 31.4% which was still good compare with traditional random selection.The model was developed using two AlexNet and GoogleNet. These architecture are most popular among CNN architectures for image processing and video processing. For getting the best accuracy different methods of training were also implemented that is TRAINING FROM SCRATCH for AlexNet and TRANSFER LEARNING for GoogleNet architecture. The transfer learning outperforms over training from scratch.

Three versions of plant image dataset was taken (color, greyscale, segmented) to test the model. And the 30 epochs(parameters) where used for feature extraction. The colored dataset gives the best accuracy compare with greyscale and segmented but to overcome the inherent biases of neural network in lightening conditions the model was tested on greyscale and segmented versions also. To check the role of a background on image dataset segmented version was taken. The segmented version performs good and gives greater accuracy as compared to grayscale version but perform less with colored version. And the grayscale version of dataset performs worst among all three version of dataset.

To test the models performance to any unseen data the four different trainingtesting approaches were implemented. That is 20%-80%(20% for training and 80% for testing), 40%-60%(40% for training and 60% for testing), 50%50%(50% for training and 50% for testing), 60%-40%(60% for training and 40% for testing) and 80%20%(80% for training and 20% for testing). the accuracy was found out for AlexNet architecture is 97.36%, 98.60%, 98.96%, 99.07%, 99.27% respectively and for the GoogleNet it was is 98.20%, 99.14 %, 99.16%, 99.24%, 99.34% respectively for the Colored version of dataset. We can see here as the training size increases the accuracy is also increased. And from here it can be seen that the GoogleNet architecture gives better result over the AlexNet architecture.

When the model was evaluated on the dataset other than PlantVillage it gives less accuracy of 31.4%. since the PlantVillage dataset taken under ideal condition the real leaf image will be directly taken in different circumstances in more complex environment. While the accuracy of 31.4% is still good with traditional random selection approach but more diverse image data can help to train the model. But when this model will be applied to different datasets then this will eventually increase it’s performance and the accuracy will also increase. and another limitation is model only performs on the single leaves images on the homogeneous background only while it should also perform on the plant leaf itself

In [4] the author has proposed a model based on RPN(reason propose network), chen-vese algorithm and transfer learning for developing the model for disease detection. RPN was used to localizing the leaves into complex background. Chen-vese algorithm for segmentation of images from RPN algorithm input and the transfer learning model which is pre- trained model on multiple diseased dataset with normal background for disease recognition. This model archives accuracy of 83.57%.

Around 1000 leaf image dataset in complex background is taken from the plant photo bank of China(PPBC) including many plant at various growth stage. And the PlantVillage public dataset is also being used here. And the transfer learning is pre-trained on 537 black rot, 1032 bacterial plaque disease, 293 rust and 2852 healthy leaves.

The plant disease recognition in the complex environment is performed with three steps.

1.desease leaves image segmentation.

2.feature extraction

3. disease identification

1. image segmentation : the segmentation of images in the complex background is a tedious task. So the author has also reviewed multiple approaches to overcome with this challenge. delta E-color difference algorithm can be applied for separating the infected area on diseased leaves.

some of the researchers have used the region of interest(ROI) for segmentation of images. And another approach would be the leaves can be divided into multiple parts with diseased spots as a parameter for the segmentation process.feature extraction: different different images have different texture, shape, motion-related attribute, color of leaves this puts up challenge for feature extraction of all the images. But several methods are easy to use and we also gets desired outputs.

- color and texture feature
- Dempster Shafer (D-S) theory for feature extraction and for prediction the result improved local binary pattern (LBP) for Greyscale image and processing over it.

Disease Identification: researchers have developed multiple methods to detect the disease info with images.

- Hybrid clustering For Detection
- CBIR(content-based image retrieval) for feature extraction and then SVM for classification.
- novel approaches such as with use of mobile device for image segmentation and them improved k-means clustering for disease information.
- trained CNN with 1632 corn images for detecting the disease of a corn leaf.
- improved CNN with AlexNet and VCG-16 net architecture for detecting the disease on maize leaves.

Bayesian discriminant method was used for classification of

This is the general flow of model which is suggested for detecting the disease on plant.

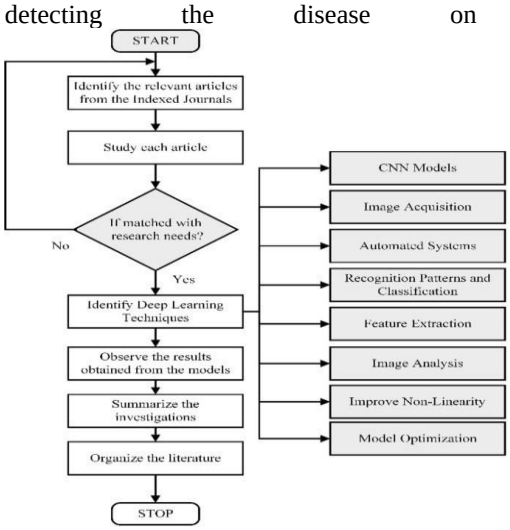

Figure 5: CNN Approach

Leaf localization: RPN algorithm is trained with convolution neural network to classify the boundary of image. Classification neural network is used to detect the leaf image present in picture is boundary or an object. Basically it uses intersection over union for detecting the boundary. If IOU is
0.5 then the image is object and for IOU greater then 0.5 will be background.

Leaf Segmentation: chen-vese algorithm is used here for the segmentation of leaf images.

Disease Identification: the model which is used for detecting the disease information is transfer learning. First it is pre- trained with the diseased images on simple background and then output of the previous method is tested for finding out the correct disease information.

RPN algorithm is used for the training of image dataset in complex environment and the CNN will be used for retrieving the diseased plant leaves and these inputs is given to chen-vese algorithm for the segmentation purpose and finally the output of these all steps is test under the transfer learning model for identifying the disease which is present on the leaf or plant.

In [6] the author has reviewed multiple research papers and presented current trends and difficulties which are present in the plant image disease detection with CNN.

In another method for the same apple leaf detection the BP neural network model was performed for classification and accuracy was found around 92.6%.with 63 parameter selected for feature extraction of rice leaf. And the

diseases. The model has perform the classification with 97.2% of accuracy.

Traditional methods can detect the diseases with good accuracy but they lack in detecting with more diverse dataset and also early detection of diseases was not specified in the traditional approaches. instead of taking whole leaf images the single spots or lensions can be used with augmented data. And when this applied on GoogleNet architecture the model is able to detect disease with accuracy of 94% which is greater than when using whole images 82%. another method was to focuses on diseases diseased area. And when Mask R-CNN model with [ResNet 50 or ResNet 101 feature extraction] was used to detect the diseases. the accuracy was found out to 92.01% on test dataset.transfer learning gives more accuracy over training from scratch on AlexNet architecture for detecting the diseases correctly. The accuracy can reach upto 95.53%.

Corn leaf diseases detection in the complex background with small sample dataset with CNN (VGG 16) on transfer learning model performs 95.33% of accuracy.

ResNet 50 pre-trained on ImageNet dataset when used for identifying the apple leaf diseases gives accuracy of 97% for simple background and accuracy of 51% for a complex background images. New DL architectures for leaf detection

When multiple CNN classifiers was combined and used the accuracy was high compare with single and double classifiers. And the accuracy was 97.8%.

for some tomato leaf with problems of having shadow, occlusion and light integrity on images the Deconvolutional Guided VGG network can identify plant diseases with 99.10% accuracy.

In ResNet18 architecture when convolutional 1 layer of ResNet18 is combined with multiple convolution kernel & SETNet module addition the model is able to solve low recognition issue of grapes due to different degree of diseases and this model achieves accuracy of 90.83%.another model which is developed on CNN with adding 3 convolutional layer, 3 pooling layer, 2 fully connected layer it is able to detect different diseases on tomato leaves. And this developed model has an accuracy of 91.2%.

IV. ACKNOWLEDGEMENT

We the students of TCET, with a collaborative effort with **Dr. Rashmi Thakur** we have been successful in designing a full length research paper with topic named **Crop Disease Detection Using Deep Learning.** We feel delighted and would also like to thank all the concerned faculties for teaching us the basic structure and overview of the Deep Learning models and convolutional neural network with the help of which we were able to draw out meaningful conclusions of the numerous authors around the world.

Abstract -**Object detection and tracking is one of the most important and demanding fields in computer vision and have been widely distributed applied in various fields such as health care monitoring, autonomous control, anomaly detection and so on. With rapid development deep learning (DL) networks and GPU computing power, the performance of detectors and object trackers was very high improved. Understand the main development status of the object detection and monitoring of pipelines thoroughly, in this survey, we have critically analyzed the existing DL object network methods detection and tracking and described various reference datasets. This includes recent developments in granular DL models. We have primarily provided a comprehensive overview of the various species both general object detection models and specific object detection models. We have obtained various benchmarks to get the best ones detector, tracker and their combinations. In addition, we have stated traditional and new object detection and tracking applications showing its development trends. Finally, challenging problems, including the relevance of granular computing, in the domain mentioned are developed as a future scope of research along with some concerns**

I. INTRODUCTION

In recent years, object detection and tracking has gained increasing attention due to a wide range of applications and recent breakthrough research. In both real-world and academic applications, object detection and tracking are of equal importance. Imaging technology has made tremendous progress in recent years. Cameras are cheaper, smaller and better than ever before. At the same time, computing power IS increasing dramatically as proposed in [47]. In recent years, computing platforms have focused on parallelization, such as multi-core processing and graphics processing units (GPUs). Such a hardware version enables CV for object detection and tracking for real-time implementation. Rapid development in deep convolutional neural network (CNN) and improved GPU computing power are the main reasons for the rapid development of CV-based object detection and tracking.

In a detection network, a deep CNN is used as a backbone to extract key features from an input image/video. These features are used to locate and classify objects within the same frame. Then, in object tracking, these detected objects are tracked based on the proximity of the object from frame to frame. Object detection refers to scanning and searching for objects of certain classes (eg human, car and building) within an image/video.

Object detection can be done using either image processing techniques or DL networks. Image processing techniques usually do not require historical data for training and are unsupervised. However, these techniques are limited by various factors such as complex scenarios, lighting effect, occlusion effect, and interference effect. All these problems are better solved in DL-based object detection. The working principle of DL networks is inherently supervised and limited by the huge amount of training data and GPU computing power. Many reference datasets are already developed in the field of object detection, such as Caltech, KITTI, ImageNet, PASCAL VOC, MS COCO, and V5. Due to the availability of such a huge amount of data and the development of GPUs, object detection based on DL networks is widely accepted by researchers. Object detection is followed by object tracking. The goal of object tracking is to locate the trajectory of the detected object and connect it to it. An efficient and robust system design is required for object tracking in a domain-specific or general scenario. Recently developed DL networks meet this goal. For example, consider the research on DL networks for image classification that was conducted in the ILSVRC 2012 competition. Here, the error rate is reduced by 10% compared to conventional methods. Then, new deeper learning networks are gradually developed for image classification. They are well accepted by the human vision community due to their effectiveness Multiple Object Tracking (MOT) is Deep Learning in detecting and tracking multiple objects which is more complex than single object tracking and more applicable in real-time scenario. That is why research at STK is overwhelmed by researchers. Although DL has been observed to be effective for MOT problems, the tracking performance is purely based on the success of correct image localization and classification.

II. LITERATURE SURVEY OF OBJECT DETECTION AND TRACKING ALGORITHMS

In [1], Qiang Ling et.al, developed feedback-based object detection algorithm. It adopts dual layer updating model to update the background and segment the foreground with an adaptive threshold method and object tracking is treated as an object matching algorithm. [BACKGROUND MODEL BASED DETECTION AND TRACKING]

An algorithm for tracking multiple objects in the presence of partial object occlusion was proposed in . However this, algorithm may not successfully track feature points with different velocities[2]. Therefore, this algorithm needs a more flexible

representation of objects, and they also used a static camera to capture the video. [POINT DETECTION AND TRACKING].

In computer vision systems, the basis of object detection and tracking is the background structure. The traditional background modeling method often requires complex calculations and is sensitive to lighting changes. Therefore, a new hierarchical method based on coarse to fine textures for background modeling was proposed in [3]. It has the following advantages: (1) tolerance to illumination changes, (2) low computation, and (3) excellent description for each block when the multimode method is applied. This method is quite effective. [DETECTION BASED ON BACKGROUND MODELING].

Integrating a camera system into a mobile robot is very demanding and computationally intensive. High-quality image data only provides accurate information about the environment. However, it requires high computational demands [4]. Hannes Bistry and Jianwei Zhang proposed an object detection algorithm based on SIFT. They created a distributed SIFT vision algorithm, and the intelligent camera architecture can be used to integrate a complex vision algorithm. [SEGMENTATION BASED OBJECT DETECTION].

III. OBJECT DETECTION AND TRACKING

In this section, we briefly discuss various approaches, both conventional and DL-based, for the detection and tracking of multiple objects along with their characteristic features. As already mentioned, both object detection and tracking are important in the field of CV [3]. In general, object detection is performed in two steps: finding foreground entities (using features) that are hypothesized to be an object, and then validating these candidates (using a classifier). We divide object detection into three board categories; i) based on appearance, ii) based on movement and iii) based on DL. Appearance-based approaches use image processing techniques to recognize objects directly from images/video [3]. However, these approaches usually fail to detect occluded objects. Whereas in motion-based approaches, a sequence of images is used for object recognition. These methods may not work well for object detection in complex scenarios. DL-based approaches use either appearance features or motion features or a combination of these to detect objects in images/videos. Due to recent technological breakthroughs, DL-based object detection approaches has received much attention compared to appearance- or motion-based approaches. Deep CNNs are used as the backbone in DL-based object detectors to extract features from the input image/video. These features are used to classify objects. DL-based approaches have two categories: i) two-stage detectors [43] and ii) one-stage detectors [44]. In two-stage detectors, approximate object regions are first designed using deep features, and then these features are used for classification as well as bounding box regression for the object candidate. On the other hand, for single-stage detectors, bounding boxes are predicted on images without a region design step. This process consumes less time and therefore can be used in realtime devices. Two-stage detectors achieve high detection accuracy, while single-stage detectors have high speed. Different backbone networks (feature generation networks) used in DL-based object detection are: i) AlexNet [45], ii) ResNet [46], and iii) VGG16 [43], among others. With the development of backbone networks and the increasing capabilities of GPUs, remarkable progress has been made in the field of two-stage object detectors. Recently, the concept of granular computing has been incorporated into deep networks to greatly increase the computation speed and balance with the detection accuracy. Some such networks are granular CNNs [3] and granular RCNN .

IV. GENERIC OBJECT TRACKING

General object detectors aim to locate and classify objects in an image and mark them with rectangular bounding boxes to show certainty of existence. Generic object detectors are of two types: two-stage detectors and one-stage detectors. Two-stage detectors follow the traditional pipeline of object detection, i.e. object localization and its classification. While single-stage detectors treat the task of object detection as a regression/classification problem. For both detectors, the classification task is performed based on some features that are generated using a feature generation network, called a backbone network.

Recent advances in deep learning [1,2,3] and the availability of computing power [4,5] have revolutionized several fields such as computer vision and natural language processing (NLP). Object detection [6,7] is a well-developed field in computer vision [18]. Object tracking is typically the next process after object detection that receives an initial set of detected objects, inserts a unique identification (ID) for each of the initial detections, and then tracks the detected objects as they move between frames.

Multiple Object Tracking (MOT) is a subset of object tracking that is designed to track multiple objects in a video and represent them as a set of high-accuracy trajectories. However, object tracking usually has one big problem when the same object does not have the same ID in all frames, which is usually caused by ID switching and occlusion. ID switching is a phenomenon where an object X with an existing ID A is assigned a different ID B, which can be caused by many scenarios, such as a tracker assigns another object Y an ID A because it resembles object X. Another problem is occlusion, which is when another object partially or completely covers one object for a short period of time.

Figure 1 illustrates the MOT process. Initially, objects in the current frame are detected by the detector. The objects are then tracked as they are loaded into the MOT algorithm. Figure 2 then visualizes the process of tracking multiple tracked objects from the current frame to the next frame. Both figures show the MOT's tendency to accurately track a large number of objects

FIGURE 1

Figure 1. Using the MOT15 [8] reference dataset, ID allocation based MOT papers published in the last three years.

ID	Ref.	Year	Contributions
1	[9]	2021	• Offers a comprehensive review of object detection models. • Shows the development trends of both object detection and tracking. • Describes various comparative results for getting the best detector and tracker. • Categorizes deep learning based on object detection and tracking into three groups.
2	[10]	2020	• Reviews the previous deep learning-based MOT research in the past 3 years. • Divides previous papers into five main sections, which include detection, feature extraction and motion prediction, affinity computation, association/tracking, and other methods. • Shows the main MOT challenges.
3	[11]	2020	• Shows the key aspects in a multiple object tracking system. • Categorizes previous work according to various aspects, and explains the advances and drawbacks of each group. • Provides a discussion about the challenges of MOT research and some potential future directions.
4	[13]	2020	• Reviews the past five years of multi-object tracking systems. • Compares the results of online MOTs and public datasets environment in the deep learning model. • Focuses mainly on deep-learning-based approaches.

TABLE 1

In recent years, many new MOT studies have been proposed to address existing tracking issues such as real-time tracking, ID switching, and occlusion. In addition, deep learning is increasingly applied to MOT to improve its performance and robustness. Table 1 details the contributions of some previous surveys on MOT [18]. Overall, each survey focused on a specific MOT issue. Recently, Pal et al. focused on the deep learning method and explained detection and tracking separately so that readers can easily focus on their part of interest. However, due to the description of many parts related to detection, the description of tracking is insufficient.

On the other hand, Ciaparrone et al. reviewed deep learning-based methods, one of the core concepts of MOT, is explained. They use the described online methods that work in real time and batch detector to detect objects in the current frame first. The detected methods that can use global information and compare results are passed to the MOT algorithm to assign an identifier to experimental results. However, they only focused on MOT benchmarks and did not provide any comparisons for each object. other benchmarks. In another review, Luo et al. described the MOT methodology in two categories and the evaluation focused on the PETS2009-S2L1 sequence of the PETS benchmark. Finally, Kalake et al. reviewed MOT documents for the last 5 years.

Although they covered many aspects of MOT, it was difficult to determine an exact rating for each monitoring method due to limited evaluation

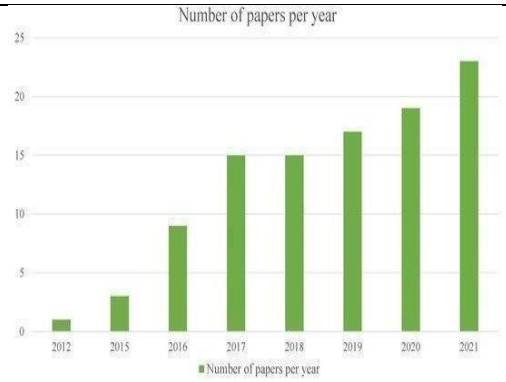
.

FIGURE 2

Figure 2. Object tracking visualization for
the next frame using the MOT algorithm on the MOT15 test dataset. Objects in the next frame are detected first. The detected result is passed to the MOT algorithm
to compare objects in the current frame with objects in the next
FIGURE 3

frame. Finally, based on the current frame, each object in the next

frame is assigned an ID as shown in [46]. **Figure 3**: Figure 3: Shows the total number of articles reviewed in this review.



In general, there is an increasing number of MOT articles presenting various deep learning-based MOT frameworks, new hypotheses, procedures, and applications. Previous surveys have partially addressed tracking, specifically the topic of MOT. However, some existing parts of MT were not covered in these reviews. For example (1) mostly

the surveys concentrated on the detection part rather than the tracking part, and (2) a limited number of benchmarks were mentioned. As a result, a comprehensive survey on recent MOT work is meaningful for stakeholders and researchers who want to integrate MOT into the existing systems or start new MOT research. This survey summarizes the previous work and covers many aspects of MOT. The main contributions are as follows.

V. THE EMERGENCE OF DEEP MODULAR LEARNING

Compared to other machine learning methods, deep learning is remarkably modular. This modularity gives it unprecedented capabilities that put Deep Learning head and shoulders above any other conventional Machine Learning approach. However, recent research points to even more modularity than before. It is likely that monolithic deep learning systems will soon become a thing of the past.

Before I discuss what's coming in the future, let me first discuss the concept of modularity. This is a concept familiar to software engineering, but the idea is not as commonly found in machine learning. In informatics, we build complex systems from modules. One module assembled from several simple modules. This allows us to build our digital world based only on NAND or NOR gates. Universal Boolean operators are necessary but not sufficient to build a complex system. Complex computing systems require modularity in order to have a manageable way to manage complexity.

Here are the six main design operators that must be supported in a modular system:

- Partitioning — Modules can be independent.
- Substituting — Modules can be substituted and swapped.
- Expansion – new modules can be added to create new solutions.
- Inverting — Hierarchical dependencies between modules can be rearranged.
- Porting — Modules can be used in different contexts.
- Excluding – Existing modules can be removed to create a usable solution.

These operators are generic in nature and are inherent to any modular design. They allow the modification of an existing structure to new structures in well-defined ways In the context of software, this can mean refactoring statements at the source code level, language construction at specification, or component models at construction. These operators are perfect in that they can generate any structure in your computer design. The six-statement definition focuses on functional invariance in the presence of design variations. More clearly, allows you to use these operators and does not affect the function as a whole as shown in . In the context of deep learning, modularity operators are accepted as follows

- Splitting — Pretrained autoencoders can be split and reused as layers in another network.
- Substitution — Through transfer learning, student networks can serve as substitutes for teacher networks.
- Extensions — New meshes can be added later to increase accuracy. You can combine training networks to improve generalization. In addition, neural network outputs can be used as neural inputs, which can be used as representations for other neural networks.
- Porting — A neural network can be "ported" to another context by replacing the upper layers. This works in cases where the

domains are similar enough. Further research on domain matching is needed to understand the limits of this method.

The two remaining modular operators are not available for current monolithic DL systems.

- Inverting — Layers in the network cannot be rearranged without catastrophic consequences. The layers of a monolithic DL system are too tightly coupled to allow this.
- Exclusion – There is no mechanism to “forget” or exclude functionality from a monolithic DL system.

However, despite these two drawbacks, DL systems have an unrivaled advantage over competing machine learning techniques. One of the reasons for the tight coupling of layers in a monolithic DL system can be traced back to Stochastic Gradient Descent (SGD). SGD works in lock-step mode with training. It is a very highly synchronized mechanism that requires coordination of behavior across all layers. However, this monolithic structure is replaced by an even more modular system. Here are two interesting events related to this. DeepMind has explored a method called "Synthetic Gradients" that points the way to looser layers. The method essentially inserts a proxy neural network between the layers to approximate gradient descent

A second development that may lead to greater modularity is the concept of generative adversarial networks (GANs). Typical GANs have two competing neural networks that are essentially separate but contribute to the global objective function. However, now in research we are seeing the emergence of more complex configurations such as this Where you have a ladder network of separate encoders, generators anddiscriminators. The general pattern is that all normal functions of neural networks have also been replaced by neural networks. In particular, the SGD algorithm and objective function have been replaced by neural networks. All analysis features are gone! This is what happens when you have deep meta-learning as shown in [45].

Another very impressive result, also recently published with the same name (i.e. StackGAN), shows how efficient multiple separate GANs can be: The task here is to take a text description as input and generate an image matching the description. Here we have two GANs staged one after the other. The second GAN is able to refine the fuzzy image into one with a higher resolution. Modular networks have the ability to factor capabilities that would otherwise be entangled in an end-to-end network. In software engineering, we have the concept of API. That is, a restrictive language that communicates between different modules. In the above scenario, a neural network that "learns to communicate" acts as
an API bridge between networks

We consider the problem of multiple agents sensing and acting in an environment to maximize their shared utility. In these environments, agents must learn communication protocols to share information needed to solve tasks. By adopting deep neural networks, we are able to demonstrate end-to-end learning protocols in complex environments inspired by communication puzzles and multi-agent computer vision problems with partial observability.

Another recent paper titled "Generative Adversarial Parallelism" explores this further in relation to GANs. In this work, the authors attempt to address the difficulties in training
GANs by extending the usual two-player generative adversarial games to a multiplayer game. They train many GAN-like variants in parallel while periodically swapping the discriminator and generator pairs. The motivation here is to achieve better separation between pairs. Much work remains to be done to determine whether separate interfaces between
networks lead to better generalization

VI. COMPARISON

ImageNet images typically have one large object [18]. Thus, our non-prediction-based methods, such as image-box, which treats the entire image as a bounding box, are suitable for ImageNet. To test whether our loss works with different distributions of multi-object images, we test it using the Conceptual Captions (CC) dataset. Even on this challenging dataset with multiple objects/labels per frame, Detic provides a gain of ∼2.6 points in new class detection over the best prediction-based methods. This suggests that our simpler Detic method can generalize to different types of image- tagged data. Overall, the results from Table 1 indicate that complex prediction-based methods that rely heavily on model prediction scores do not perform well for open dictionary detection. Among our non-prediction-based variants, max size loss consistently performs best and is the default for Detic in our following experiments

	IN-L		CC	
BOX SUPERVISED(BASELINE)	30.0±0 .4	16.3± 0.7	30.0±0. 4	16.3 ±0.7
YOLO9000	31.2±0 .3	20.4± 0.9	29.4±0. 1	15.9 ±0.6
WSDDN	29.8± 0.2	15.6 ±0.3	30.0±0 .1	16.5 ±0.8
Detic (Max-object-score)	32.2± 0.1	24.4 ±0.3	29.8±0 .1	18.2 ±0.6
Detic (Image-box)	32.4± 0.1	23.8 ±0.5	30.9±0 .1	19.5 ±0.5
Detic (Max-size)	32.4± 0.1	24.6 ±0.3	30.9±0 .2	19.5 ±0.3

VII. APPLICATIONS

Major One of the key safety concerns on construction sites is ensuring that workers wear the appropriate personal protective equipment (PPE), such as hard hats. However, monitoring compliance with PPE requirements can be a challenging task, particularly on large construction sites with many workers.

This technology could be used to address this challenge by automating the detection of hard hats worn by construction workers. By training a THIS model on images and videos of workers wearing hard hats, the model could accurately detect when a worker is not wearing a hard hat or is wearing it improperly. This would enable safety managers to quickly identify and address compliance issues, reducing the risk of injuries and accidents on the worksite.

In addition, This technology can be used to monitor the compliance of individuals with safety regulations, such as the wearing of safety gear, in both school and office settings. For example, in schools, This could be used to detect whether students are wearing safety goggles or lab coats in a chemistry lab. In offices, it could be used to ensure that employees are wearing safety gear, such as helmets and safety shoes, in manufacturing and construction areas.

Another potential application of This technology in schools and offices is for environmental monitoring. By analyzing images and videos of classrooms and office spaces, This models could be trained to detect potential safety hazards, such as overcrowding, blocked exits, or fire hazards. This could help safety managers and facilities personnel identify and address potential safety hazards before they become serious problems.

VIII. CONCLUSION

Major advances in deep learning methods have been made in the areas of image recognition, object detection, and person re-identification, which also benefit from the development of multi-object tracking. In this article, we summarize the deep learning-based multi-object tracking methods that rank high in public benchmarks. The contribution of this article lies in three aspects. First, the use of deep learning for multi-object tracking is organized, and the mechanisms of deep feature transfer, neural network embedding, and end-to-end network training are analyzed based on existing methods, and the rules for designing a new tracking framework are analyzed. they are inspired. Second, we examine the roles of deep networks in surveillance and investigate the training issues of these networks. Third, comparisons between these multi-object tracking methods are presented and reorganized according to common datasets and evaluations. Advantages and limitations of the methods are highlighted. From the analysis of the experimental evaluation, it can be seen that there is a lot of room for improving the tracking results using the deep learning paradigm. This document provides some useful insights. On the one hand, there are not enough labeled datasets to train satisfied tracking models under all conditions. A possible path can be paved by generative networks, which are excellent for supporting the generalization of deep learning models. On the other hand, to cope with adverse tracking results in a complex environment such as a moving platform, it is necessary for integrated network models to learn the features of these dynamic scenes. In addition, to further adapt to changing conditions, higher-order feature learning or online transfer features are expected for tracked object

ABSTRACT -**This paper discusses a system that collects data in order to provide reliable weather updates and predictions. This study proposes a method that will collect data from a large number of users using an Android application and an Arduino- based device with a GPS system. Our system collects microlevel data from thousands of users and also gives meteorological information. The report explained how the system works, how it was implemented, how data was analyzed, and what work will be done in the future. Java was used to create the Android app, while Weka 3.8 was used to simulate data analysis.**

Keywords: -Weather forecasting, Quantitative data.

1. INTRODUCTION

Weather forecasting dates to the nineteenth century. Weather forecasting is defined as the analysis of atmospheric variables such as temperature, radiation, air pressure, wind speed, wind direction, humidity, and rainfall.

A large amount of data must be collected or generated in order to predict the weather. In addition, the information is jumbled. As a result, using meteorological data to predict the weather is a difficult process with too many variables to consider. These variables change in response to rapidly changing weather

conditions. To propose a weather forecasting algorithm, we must take into account the algorithm's unique properties, such as continuity, data intensity, and multidimensional and chaotic behaviors. Weather forecasting evolved from a human-intensive effort to a computational process, which necessitates the use of high-tech equipment. The precision of forecasts can be affected by a number of things. Season, geographic location, input data accuracy, weather classifications lead time, and validity time are only a few of the effective elements.

According to the National Oceanic and Atmospheric Administration (NOAA), the National Centers for Environmental Information (NCEI) is now the largest provider of weather data. Land-based stations, marine, radar, weather balloons, satellites, and paleoclimatic data are only a few examples of data sources. To obtain the most precise data, a variety of equipment are utilized to measure different columns of the atmosphere. The data is transmitted to the satellites from terrestrial weather stations that are typically hundreds of kilometers or even further apart.

2. TOOLS AND TECHNOLOGY

The key device required for developing the entire device is Arduino, which is a device that is designed in such a way that it contains a physically programmable circuit board.

On computers, software that runs an IDE and can be used to write and burn the code in the actual device Also included is the computer. interacts with the board and follows the steps which were written there. BMP180, DHT11, and other sensors are used in this project. Modules for GPS and RTC from Venus.

The Bluetooth module HC-05, which employs the Bluetooth Serial Port Protocol, was utilized to transmit data from the android phone to the server database. We used Bluetooth to accept data into the programmed and send it to the server because it

creates a wireless connection. The entire device's data will be transferred to the database. For that purpose, an Android application has been created that receives data over Bluetooth.

The time period selected for each string of value to transit from device to android and finally to the database is 5 seconds for quantitative measurement. As a result, each device may communicate 12 rows of data every minute and 720 rows per hour. The application is responsible for triggering the insert query.

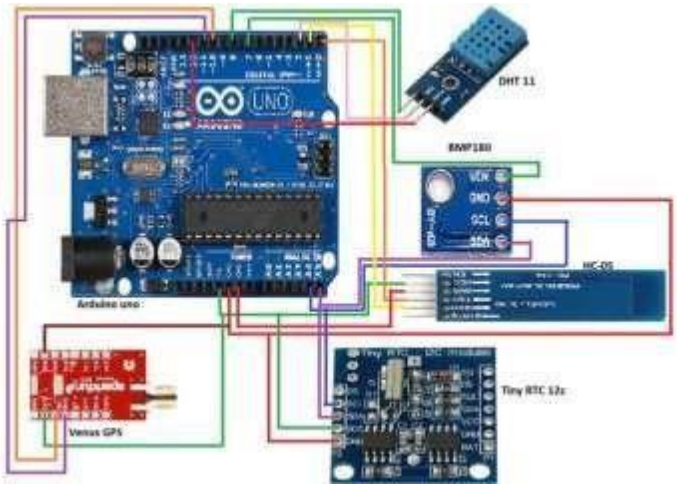

Figure 1: Connectivity between Arduino, Bluetooth and sensors.

I. Implementation and flow

Figure 1 depicts the connection between the devices. Each sensor has a corresponding piece of code in the Arduino code that generates the desired output. The portions of code that is burned in the Arduino device that receives and prints data for each device is represented below

1. BMP180

The section of code in responsible of reading the pressure from BMP180 is sensors_event_t event; bmp.getEvent(&event);

2. DHT11

The section of code in responsible of reading the temperature and humidity from DHT11 is float h = dht.readHumidity(); float t = dht.readTemperature();

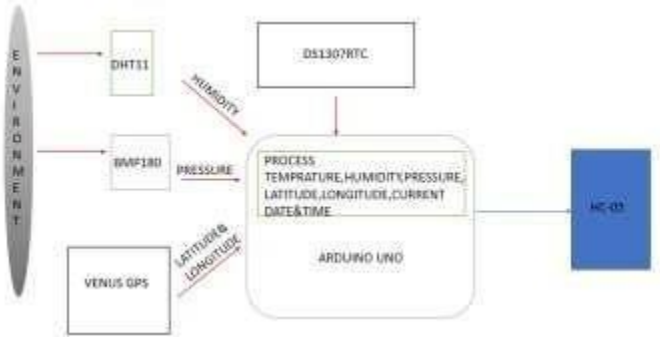
3.Printing string

The code that prints the text that is later used in the Android application to transfer data to the database is included.

```
Serial.print('#');
Serial.print(t); //temperature
Serial.print('+');
Serial.print(h); //humidity
Serial.print('+');
Serial.print(event.pressure); //pressure
Serial.print('+');
Serial.print('~');
```

4.Temperature and humidity are calculated using the "t" and "h" values, whereas pressure is calculated using "event pressure."

Dr. Dmitry Korkin says “The body networks such as disease systems are so complex and dense that they look like a big mess.” He is currently working on developing new ways to see these complex networks using HoloLens. HoloLens is also being used to reconfigure operating rooms so they can better handle the needs.



II .Literature Survey

On a global scale, a significant number of attempts have been undertaken by various researchers to reliably forecast Weather using various methods.

Techniques.

However, because of the nonlinear structure of

Accuracy of weather prediction obtained by these

Techniques are still in need of improvement. Ali, Lin, and others [1] created an ANN technique.to calculate the heat potential of tropical cyclones (TCHP) is a tool for calculating the Cyclone and Prediction of intensity. They calculated TCHP.1) an artificial neural network (ANN), 2) a two-layer neural network a multiple gravity model, and 3) a reduced gravity model. We used the regression technique and compared the results.

Estimates based on in-situ observations They discovered that out of the three approaches, The ANN method produced the best results. The findings point to the ANN's value. a method for calculating TCHP that is more accurate precision in the north

3. CONCLUSION

Unpredictable weather and being trapped in traffic have become a way of life for us. As a result, if we apply our approach, we can make our lives easier by forecasting road conditions. Data is now an indispensable part of our life. The application is simple to comprehend and operate. Users gain vital knowledge while also providing us with data. To prove that the data we collected have a high association, we used Data Mining tools such as Trees.M5P and Hierarchical Clustering. A tree and rules were built to forecast the data.

Abstract: **There has been an increase in the number of vehicles on the road within the past two decades. Thus traffic control and vehicle owner identification has become a major problem, sometimes it becomes difficult to identify vehicle owners who violated traffic rules or caused unexpected accidents, etc. In order to overcome these problems, an intelligent and automated traffic monitoring system is required. The system should be able to detect Moving vehicles, Number plate detection and character recognition. And these records should be maintained for any further usage and referencing. The proposed system provides a method for detection and identification of vehicle number plates along with the functionality of storing these details on the cloud. The system basically has three steps: Getting the image from the videos through processing, Image processing till number plate segmentation and lastly character recognition and storage of the data on the cloud.**

Keywords- Number Plate Recognition (NPR), Optical character recognition, Automatic number plate recognition, Image Processing, Machine learning.

I. INTRODUCTION

The last few decades have seen a sharp increase in the number of vehicles all over the world.This situation has led to an increase in traffic congestion, and with it comes traffic problems. The modern city needs to build an effective and efficient automatic traffic system for the management of traffic law enforcement. Due to the difficulty in locating the owner of the car, numerous offences ranging from minor traffic infractions to major and violent felonies may go unpunished.The solution to it is monitoring done by computers using machine learning and image processing. The key factor to tackle this situation is number plate identification.Vehicle plate number recognition system was invented by the British in 1976 at the police scientific development branch in the UK. Through the use of a variety of techniques, such as image processing, character prediction, character segmentation, and character identification, the Number Plate Recognition system can identify characters on number plates. It helps in accomplishing some complex tasks like counting vehicles on highways, parking violation alerts, database management, blacklisted and stolen vehicle alerts etc.Management of vehicles and transportation are tedious and time-consuming tasks. If it is completely operated manually that could reflect enormous errors and difficulties. In recent years computer vision technology has made great strides in dealing directly with real world problems. This enables us to foresee a new era of machine vision applications. The aim is to explore the current challenges in machine vision applications and to stimulate the exchanges of knowledge in highly effective and practical machine vision techniques.

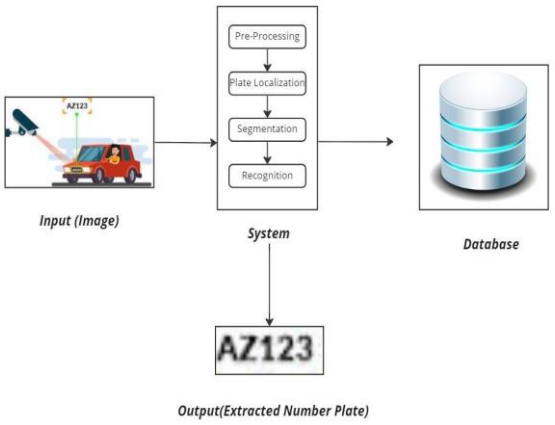

Figure 1: ANPR System

As in figure 1, the first step is to capture the image of the vehicles using any hardware capable such as cameras,etc. Then the second step is the processing part where various methods are applied to overcome the challenges of light, size, clarity of the number plates,etc. to produce the image of the number plate.In the third step character segmentation is done for the algorithm to be able to compare it with the characters.In the last step the character recognition is done using algorithms and methods that can produce result with the highest accuracy.

This paper focuses on the goal of providing a way to tackle vehicle identification and creating an automated and well documented number plate record system and thus keeping a shackle on traffic violations and any other crimes that can be prevented by using this technology.

II. Literature Survey

The following paper [1], provides us with the implementation and accuracy of Otsu method and K nearest neighbor (KNN) algorithm in the field of number plate recognition systems. The provided system uses Otsu method for converting RGB image into binary image and thereby extracting the characteristics of the image.Firstly, feature extraction is done by Otsu method that converts pixels into binary form. As the Otsu method is based on a pattern recognition process, it uses a binary vector without influencing the threshold value. Adjustments are made to the pixel values of images to get good results and better binary segmentation.Then, it uses KNN for classification and noise cancellation. It classifies this data by comparing neighborhood test data to training data. This system proved to be a great step in recognition of vehicle number plates. The following paper[2], provides us with a system using supervised K-means machine learning algorithm and Support Vector Machine (SVM). The proposed system uses K-means machine learning algorithm to segregate the characters into subgroups and then it is further classified using Support Vector Machine (SVM) which recognizes blurred license plate images and improves accuracy Support Vector Machine (SVM) which recognizes blurred license plate images and improves accuracy.The system proves to be helpful in overcoming problems such as the angle of the camera, the speed of the vehicle and the surrounding light and shadow. The usage of supervised K-means eases the classification of hard recognizable characters.

The following paper[3], gives a system that recognizes the number plate along with updating of the details related to the number plate on the server.The image of the vehicle number plate is extracted using various image processing techniques. Then the process of compartmentalizing the characters from the number plate is completed and lastly KNN is applied to extract the characters from the image. These extracted details are then stored on the server .

The following paper[4] focuses on the issue of Number plate recognition in India, it discusses the various issues that can arise in the process due to ranges of font sizes, different colors , double line number plates etc.It emphasizes on a lot of the problems that can be found in Indian road conditions and proposes a system using ANN (used for character recognition) and SVM (used to detect plate contour).The system also uses various algorithms to remove noise and enhance plate recognition. Neural networks are also used in the system for best results with easing lots of camera constraints.

The following paper[5], proposes a system that can tackle challenges such as unclear number plates, high speed vehicles and different traffic situations, which can result in increasing the difficulties in the process of extracting vehicle number plate's details.It also suggests about the hardware aspect along with the algorithms used for extraction. This system uses a dataset that includes images from various paths from different road, street and highway, daytime and nighttime, inclement weather environment and different number plate clarities. The system provides solutions to deal with the light, size, clarity of the number plates. The techniques and algorithms in the system along with the dataset helps in finding solutions to the number of problems faced while creating a number plate recognition system.

III. Problem Statement

The proposed paper focuses on tackling the issues faced during traffic and vehicle management via creating an automated system that can monitor and store the details of every vehicle passing through that checkpoint. Also the problem of vehicle record maintenance by creating a system which can maintain proper records of vehicles that could be used for any process such as speed tickets, robbed vehicle searches, etc. And all this could be done without any human intervention and thus limiting the errors that could be its product.

IV. Dataset

A comprehensive dataset with a wide variety of characteristics and an acceptable amount of data is necessary for the process of constructing an automated system for number plate identification, just as it is for any other machine learning project. There are several datasets available for Vehicle licence plate detection. The number of characteristics and the contrast of the data in these datasets varies. The dataset may include photographs from numerous pathways on different roads, streets, and highways, daytime and evening, adverse weather, and varying number plate clarities, among other things.

V. Methodology

The proposed system can be described through the process:

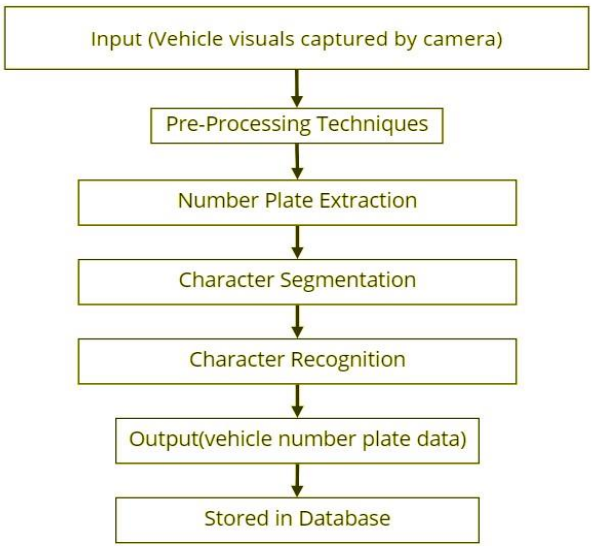

Figure 2: Methodology

1. Input: The input will be in the form of a video. These videos will be then converted in image form from frame to frame.These images then undergo a pre-processing process in the next step.

2. Pre-processing: The automatic number plate identification system has numerous difficulties, as was previously indicated. In order to improve the input image and make it more suited for the following processing processes, this step is crucial. Preprocessing starts with applying a minimal filter to the image in order to improve the dark values by expanding their region. This is mostly done to reduce the effect of the light diagonal strips that appear in the letters and edges and to make the characters and plate edges bold. Following this step, the image's saturation is increased to improve color separation. The image is then made grayscale. The contrast of the image is then increased to make the background distinct.

3. Localization of the Number Plate Region : The most crucial and significant step for ANPR systems is the successful extraction of the number plate from the picture or video. This stage determines where the licence plate is located, and the result is a sub-image that just shows the licence plate. There are two primary steps in this process. searching for a sizable bounding rectangle above the licence plate. This stage involves locating a rectangle that houses the licence plate (this rectangle might also include some excess pieces from the four sides), and this rectangle serves as the input to the following step for additional processing (removing the extra parts, character segmentation then recognition).The sub-image from the previous stage, which contains the licence plate with any additional elements, is used for the further processing. As a result of the camera's angular position during picture acquisition, the licence plate may be distorted. Furthermore, it is crucial to restore the plate's original skew so that it may be made to read correctly.

4. Character Segmentation: Character segmentation serves as a link between character recognition and number plate extraction. Multiple characters that are joined because of picture artefacts must be separated for per-character OCR; single characters that are fragmented because of artefacts must be connected. In this, various characters on a number plate region are divided into segments. Numerous factors, including variations in the illumination, plate frames, and rotation, are those that obstruct the segmentation process. Boundary box analysis is another name for a segmentation technique. This approach assigns characters to related components, which are then extracted via boundary box analysis. When the image's noise level is reduced, segmentation is finished.

5. Character Recognition:

characters are segmented, the next step is to recognize the characters.The character recognition step is accomplished by extracting the characteristics of characters and their various categorization procedures using feature extraction. EasyOCR is used to recognise characters from the license plate.

6. Data storage:

In this phase, the output from the character recognition stage is stored in the database together with a timestamp in order to maintain an exact record of the cars. This will make it easier to discover vehicles that have disobeyed traffic regulations or been linked to crimes since data can be retrieved more quickly and with less effort.

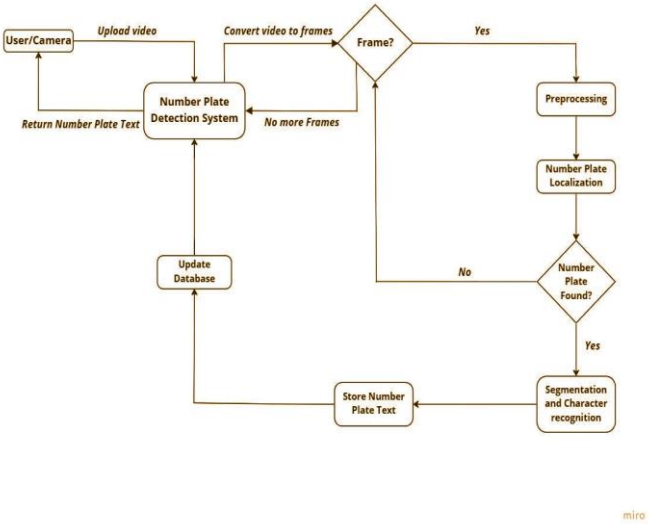

Figure 3: Flow of system

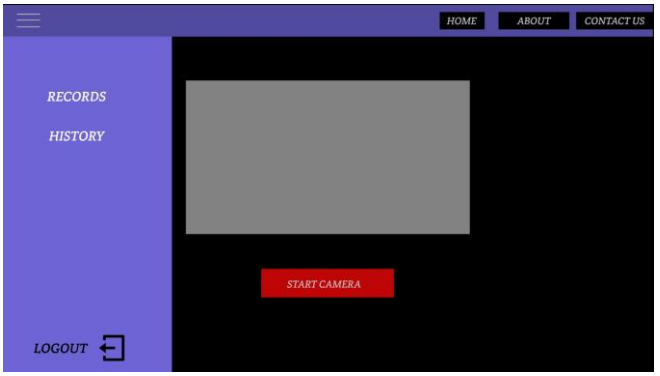

Figure 5: Dashboard

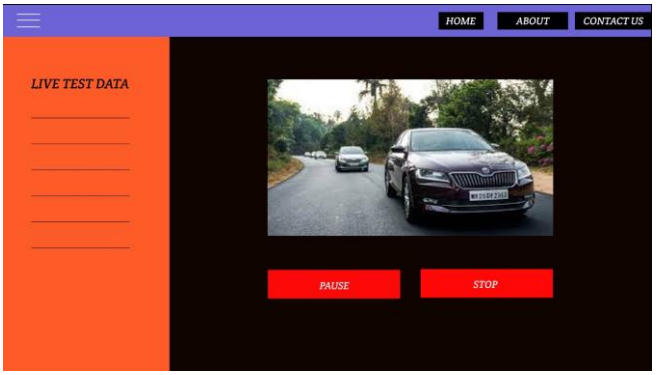

Figure 6: Live Recording Page

Observing the given figure 3 will help you comprehend how the system functions. The flowchart provides the flow of data from the image to the database of our system and the working of the system.

The Prototype of the UI of the proposed solution is given below:

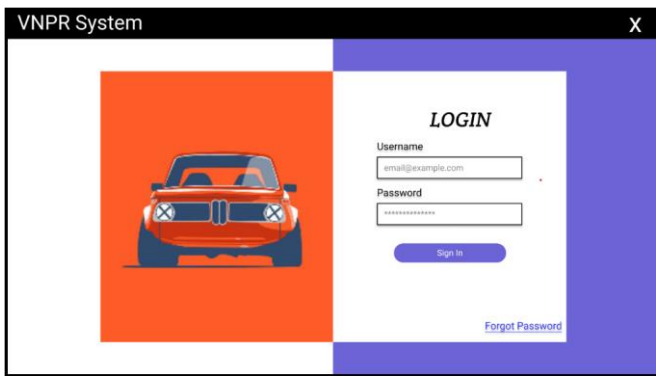

Figure 4-Log In page

Primarily , the system utilizes Python as the environment for data loading, data pre-processing, training and deployment. Numpy Library is used for performing Mathematical Operations and Matrix Operations. Pandas Library is used for dataset loading and pre-processing. Matplotlib Library is used for plotting graphs of training-validation curves, dataset visualizations, image plotting and other visualizations. Tensorflow is opted for building models of object detection and training of models.

The proposed system consists of primarily object detection which is done by the assistance of tensorflow object detection model to identify vehicles from the different frames of videos and then accompanys the number plate extraction of the vehicle.

The number plate extraction is further divided into two parts: the first part is concerned with number plate detection and the other for number plate identification. The first section uses the template matching approach to extract the number plate region from the recorded image of the car. There are three activities in the number plate identification section. (1) In the number plate region, the super resolution method is utilised to transform a low-resolution image to a high-resolution image. The picture is then converted from RGB to grayscale. (2) The bounding box approach is utilised for character segmentation. (3) Finally, EasyOCR is used to extract features from the segmented alphabets and numbers.

Additionally, the system after extracting the text from the number plate, saves the extracted number plate with current date and time, into the database.The database provide the user feasibility to look for a specific car by number plate and separate records for blacklisted vehicles.

VI. Result and Discussion

The dataset employed for the suggested system was a large dataset containing a range of photos with varying backgrounds, intensity, clarity, and so forth. As seen in figure 7, the technology produced an accuracy of roughly 90%, providing us with a superior outcome and correct number plates.

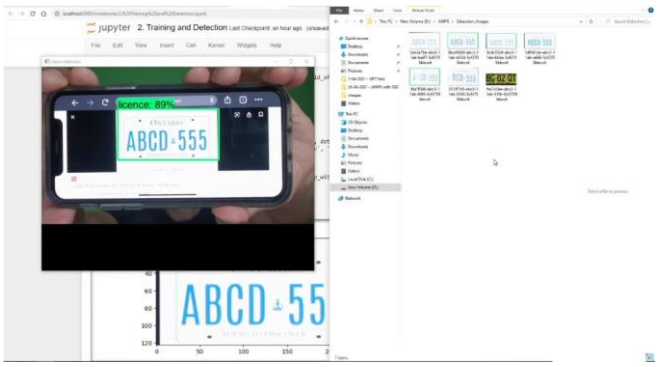

Figure 7. Results

The system is general enough to be capable of detecting and classifying vehicles while requiring only minimal scene-specific parameters, which can be obtained through training.

VII. Conclusion

Our work mainly proposes a system that can.extract the number plate and then can classify the characters of the number plate and then store it in the cloud.Firstly extraction of plate location, then separation of the plate characters individually by performing different pre-image processing techniques and segmentation, finally the segmented numbers is correlated with the standard templates in the library. It can be further exploited for vehicle owner identification, vehicle model identification traffic control, vehicle speed control and vehicle location tracking. It can be further extended as multilingual ANPR to identify the language of characters automatically based on the training data and various other features can be added.

VIII. Acknowledgment

I gratefully acknowledge the support, guidance and encouragement of my Guide Professor Ashwini Patil ma'am for this novel work.

Abstract— **The Internet of Things (IoT) has opened up new avenues for medical patients through its applications. The IoT app plays a crucial role in enhancing medical performance. This paper focuses on a real-time remote monitoring system that leverages IoT technology and has practical applications, low power consumption. Due to the increasing number of people requiring healthcare each year, traditional in-person monitoring systems within hospitals can create unhealthy environments for patients, especially those with serious health conditions. IoT and modern electronic devices offer a promising solution to this challenge. This study proposes using IoT platforms to remotely monitor ECG signals, heart rate, SPO2, blood pressure, and body temperature in patients. The symptoms are measured and processed using high-speed microcontrollers. The results of the study are displayed on a smart mobile app.**

Keywords—***IOT, Healthcare, Medsync, realtime-health monitoring, Microcontroller, ECG, Cloud.***

I. INTRODUCTION

In this modern world, it's becoming increasingly difficult to manage one's health. Health care is a crucial aspect of life that helps prevent, diagnose, and treat health problems. Although it's available through healthcare professionals, the cost of postoperative care and post-hospital care is high and it's important to monitor a patient's recovery even after they've been discharged. By incorporating the Internet of Things (IoT) into healthcare, we can enhance patient care, minimize human error, and maintain a constant watch over health conditions. The aim of this paper is to present a real-time health monitoring system that utilizes IoT and a mobile application. The system comprises of various sensors such as a temperature sensor, ECG sensor, pulse oximetry sensor, that monitor different health parameters such as body temperature, electrocardiogram, heart rate, and oxygen saturation levels. The same data is easily accessible to users on the MedSync Mobile application.

The paper is divided into nine sections, starting with an preface. The coming section contains problem statement & objects. The review of applicable literature outlined in section three, followed by the methodology in section four. Section five details the hardware, software conditions and flowchart. The working of the system are bandied in section six, with the results in section seven. The future scope is given in section eight followed by conclusion in the final section nine.

II. PROBLEM STATEMENT

Health monitoring has become crucial in today's world due to the growing concern about health issues. People are facing numerous health problems due to their hectic and stressful lifestyles. With an increasing number of patients in hospitals and skyrocketing doctor fees, it has become more challenging for individuals to receive adequate medical care, especially for those who are unable to pay or who don't know the costs until after their treatment.

Remote health monitoring offers a solution to this issue by providing an opportunity for individuals to monitor their health at home. This is especially beneficial for elderly or chronically ill patients who would like to avoid hospital stays. The system should be capable of collecting data on heart disease diagnosis, blood pressure, body temperature, and other parameters.

This health monitoring program offers better health care through self-monitoring and consultation with specialists. The customized app will be accessible and easy to use for individuals of all ages. The user-friendly interface of the app will be crucial to its success.

The proposed paper has the following objectives:

1. To remotely measure body temperature, blood pressure, and pulse rate using wearable sensors.
2. To transmit the gathered data to the relevant hospital and doctor.
3. To ensure that the sensor data is easily readable, allowing anyone to understand the individual's health status without any technical knowledge.
4. To provide a fast-responding alert mechanism and timely medical assistance for critically ill patients.
5. To make the proposed health monitoring system compatible with multiple wearable sensors to gather medical data on pulse rate, blood pressure, body temperature, ECG, and other parameters.

III. LITERATURE SURVERY

This paper [1] outlines a proposed approach that utilizes smart phones as a key device in health monitoring. The author highlights the various types of sensors commonly included in smart phones, such as accelerometer, GPS tracker, and temperature sensor, which are useful in collecting health information.

In paper [2], the author suggests a sensor-based health monitoring system that gathers health status data through an electronic signal and alerts the patient through an alarm. This system makes use of body temperature sensors, heart rate sensors, and temperature sensors.

Paper [3] proposes cost-effective research to create a photoplethysmography (PPG) sensor using a combination of LED and photodiode. The sensor is capable of measuring a

variety of blood volume, including heartbeats, to diagnose atrial fibrillation.

The author in paper [4] focuses on the study of various methods used to monitor patient health and the limitations of medical care through the internet of things. The paper also provides information on existing health monitoring programs for chronic patients or those who are at risk of illness.

In paper [5], the author suggests a system that combines temperature, circulatory difficulty, and patient stroke rate to monitor patient health. The system uses data from ten patients to assess their condition and informs the patient of necessary action.

Paper [6] proposes research on microcontrollers, commonly used equipment in health monitoring systems, as a means of rapidly processing raw sensor data. The proposed system is an Arduino-based parameter monitoring system controlled by a smart phone app.

Paper [7] outlines a proposed remote health measurement system that can measure bio signals, such as heart rate and body temperature, in real time with high resolution. The system is flexible and can be applied in various areas. In paper [8], the author conducts a comprehensive literature review on ECG feature extraction, resulting in a wellorganized health monitoring system. This system enables physicians to monitor patient health parameters, such as fever and heart rate, using ZigBee technology.

Paper [9] outlines a proposed IoT-based patient monitoring system that continuously monitors a patient's heart rate through an ECG sensor implanted in the patient's chest. The system is capable of quickly detecting unusual conditions for the benefit of the patient.

Finally, paper [10] proposes a health monitoring system using IoT and Raspberry Pi. The system is capable of detecting any unusual conditions in the patient's health and communicating it to their relatives. The proposed system is easy to understand and use for both the patient and the doctor.

IV. METHODOLOGY

The proposed system is to record various sensory information and present it to users in an easy-to-use interface. Recorded data that can be accessed through the app will show that the reading is within the normal range. It will also inform the user and their contacts regarding medication requirements such as dosage, meal time etc. In the next section, the building blocks will be specified.

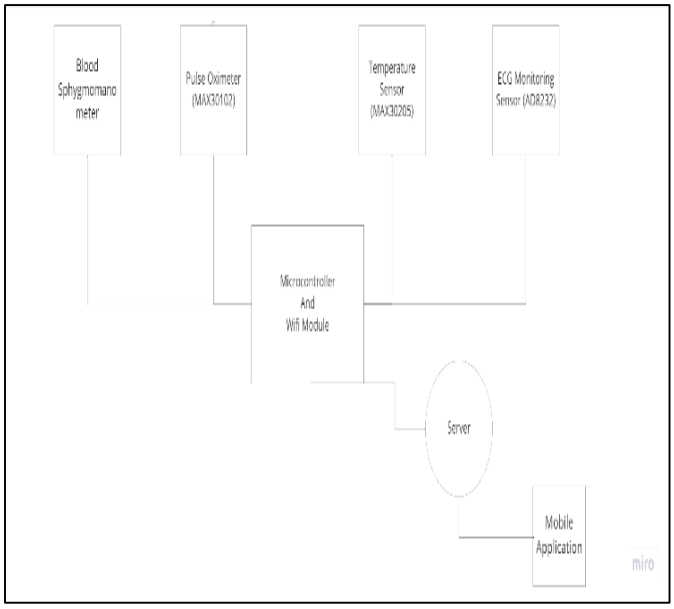

Fig.1 Block diagram of smart mobile App for remote health monitoring system

The proposed system consists of sensors that monitor various health parameters, namely heart rate, blood pressure, electrocardiogram (ECG), body temperature and oxygen saturation (SpO2).

V. HARDWARE AND SOFTWARE REQUIREMENTS

A. Hardware Requirements

The proposed system requires a sphygmomanometer (for measuring blood pressure), temperature sensor, ECG sensor, and pulse oximeter, along with the MedSync App as the software for implementation.

a. Blood Sphygmomanometer

A blood pressure sensor (shown in figure 2), also known as a sphygmomanometer, is a device used to measure the pressure of blood flow in the arteries. This information is critical in determining an individual's cardiovascular health and is used to diagnose and monitor conditions such as hypertension, heart disease, and stroke. With the increasing prevalence of cardiovascular diseases and the importance of maintaining cardiovascular health, the use of blood pressure sensors has become increasingly widespread. Today, blood pressure sensors come in a variety of forms, ranging from traditional manual devices to digital and wearable devices that provide real-time monitoring and tracking. These sensors play a vital role in the early detection and management of cardiovascular conditions, enabling individuals to take proactive measures to maintain their heart health.

Fig.2 Blood sphygmomanometer sensor [15]

b. Pulse Oximeter (MAX30102)

The MAX30102 pulse oximeter is a small, low-power, and portable device used to measure an individual's oxygen saturation levels and pulse rate. This information is critical in determining the individual's respiratory health and is used to diagnose and monitor conditions such as sleep apnea, chronic obstructive pulmonary disease (COPD), and pneumonia. In today's world, where respiratory health has become increasingly important due to the COVID-19 pandemic and other respiratory illnesses, the use of pulse oximeters has become widespread.

The MAX30102 is particularly popular due to its compact size, ease of use, and compatibility with a variety of devices such as smartphones and laptops. It enables individuals to monitor their respiratory health from the comfort of their homes and provides critical information to healthcare providers in the early detection and management of respiratory conditions.

Fig.3 Pulse Oximeter Sensor [14]

c. Temperature Sensor (MAX30205)

The MAX30205 temperature sensor is a small, low-power device used to measure temperature. It is a critical component in a wide range of applications, from consumer electronics and wearable devices to industrial and medical applications. In today's world, temperature measurement has become increasingly important in the context of the COVID-19 pandemic and other infectious diseases, as elevated body temperature is one of the most common symptoms. The MAX30205 is particularly useful in these applications due to its high accuracy, small size, and low power consumption, making it ideal for use in handheld devices, wearable devices, and other compact systems. It also has the ability to interface with a variety of microcontrollers and microprocessors, making it a versatile component in a range of applications. The MAX30205 temperature sensor plays a critical role in ensuring the accurate and reliable measurement of temperature, enabling individuals and healthcare providers to make informed decisions about their health and well-being.

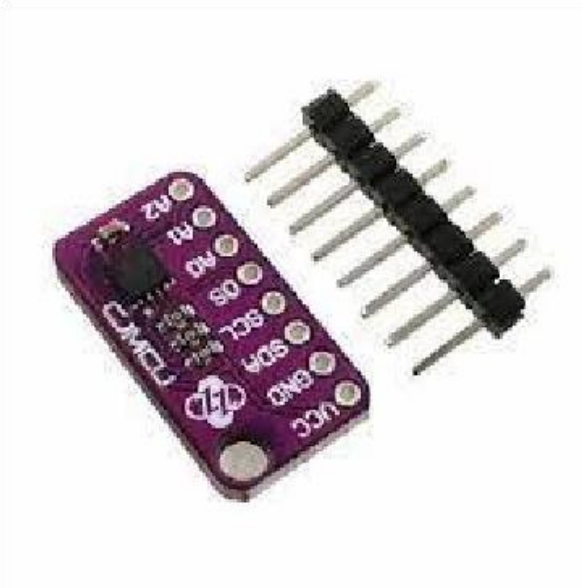

Fig.4 Temperature Sensor [13]

d. ECG Monitoring Sensor (AD8232)

The AD8232 ECG Monitoring Sensor is a vital component in today's healthcare world. It is an integrated circuit that allows for the measurement of the electrical activity of the heart in real-time, providing critical information for the diagnosis and treatment of heart conditions. The compact design of the AD8232 makes it ideal for portable or wearable devices, enabling healthcare professionals to continuously monitor their patients' heart activity in both clinical and home settings.

With the rise of telemedicine, ECG monitoring has become increasingly important for remote patient monitoring, reducing the need for in-person visits and allowing for more timely and effective treatment. The AD8232 ECG Monitoring Sensor plays a vital role in improving patient outcomes and health monitoring.

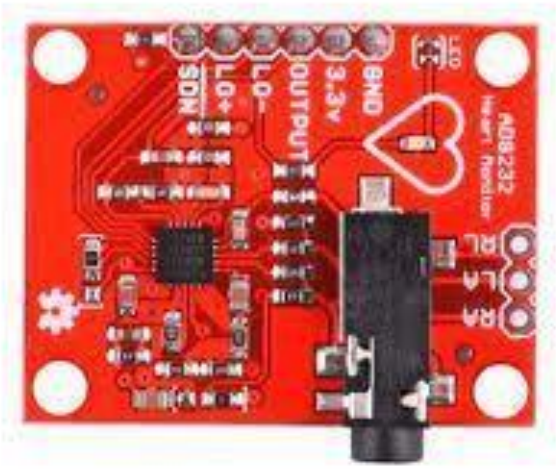

Fig.5 AD8232 Sensor [12]

e- Micro-Controller

The Raspberry Pi is a low-cost, small sized computer or a microcontroller that was first introduced in 2012. Raspberry Pi has the processing power of a desktop computer and can run a variety of operating systems, including Linux and Windows. It has a range of inputs and outputs, including USB ports, GPIO pins, and an HDMI port, allowing it to be connected to a variety of sensors, cameras, and other devices. The Raspberry Pi's versatility, affordability, and ease of use have made it a popular choice for a wide range of applications, from home media centers to robotics and the Internet of Things (IoT).

The Raspberry Pi microcontroller is widely used in health tech devices due to its small size, low cost, and high processing power. Its versatility and open-source nature make it an attractive platform for developers to create health monitoring systems, wearable devices, and other health tech applications. Focusing on this product it can be used to collect , process and transmit vital signs data to healthcare professionals, or as the brain of a wearable device that tracks fitness and health metrics. The Raspberry Pi can also be integrated with other sensors and devices to create comprehensive health monitoring systems, providing valuable information for diagnosing and treating various health conditions. Its widespread use in health tech devices demonstrates its versatility and the growing importance of technology in the healthcare industry.

Fig.6 Raspberry PI Microcontroller [11]

B. Software Requirements

a. Python

Python is a high-level, interpreted programming language that was first released in 1991. It is known for its simple and easy-to-read syntax, making it a popular choice for beginners and experienced programmers alike. Python is used in a wide range of applications, including web development, scientific computing, data analysis, and artificial intelligence. The language's standard library includes a vast collection of modules and tools, which makes it easy to perform complex tasks with minimal code. Additionally, Python has an active and supportive community, which contributes to its ongoing development and improvement.

One of the main advantages of python is its versatility and ability to handle a variety of tasks with ease. It has a large number of libraries and frameworks that can be used for machine learning, data analysis, web development, and more. Python's simple syntax and high-level abstractions make it easy for programmers to express concepts and ideas clearly, making it easier to maintain and read code. The language is also platform-independent, meaning that code written in Python can be run on different operating systems without modification. These and other factors have made Python one of the most popular programming languages in the world, and it continues to be a go-to choice for many developers and organizations.

b. MEDSYNC APP

MedSync is a cross-platform mobile application that integrates various Health-tech sensors and devices under a single roof. The app connects to the cloud to fetch and process the data received from the sensors and microcontroller. This data is then analyzed by the app and presented to the user in an easy-to-read dashboard format. The app also summarizes the data and sends it to the user's doctor, making it easy for both the user and the doctor to keep track of the user's vital signs. This continuous monitoring allows for early detection and management of potential health

issues, improving the overall healthcare experience for the user. The integration of various healthtech devices and sensors through MedSync makes it a valuable tool for anyone looking to keep track of their health and well-being.

VI. WORKING OF SYSTEM

The system for real-time monitoring connects sensors to a Raspberry Pi microcontroller, which is also connected to a Wi-Fi Shield for internet connectivity. The microcontroller is powered by an external battery and is linked to the hearing unit's components and WIFI Module. The sensors gather the user's vital information and send it to the microcontroller. The end product is a real-time monitoring system.

The mentioned system captures the user's sensory readings through an app and adjusts them based on time variation. The system then forwards these readings to the cloud via a microcontroller where they are evaluated. Using cloud computing, the analyzed data is then conveyed to the user's android and iOS apps and kept for individual supervision. The app can instantly alert the patient in case of an emergency, and the user's physician can receive the information to monitor their condition and provide a realtime analysis of their vitals.

The MedSync app presents the measured parameters, such as blood pressure, pulse rate, body temperature, and ECG of an individual. The sensor details are continuously updated on the mobile application. The MedSync app enables us to monitor our body parameters regularly. Even from afar, the doctor can recommend medications using the app and even book tests for the user for any diagnosis.

The mobile app includes a user interface that enables individuals to manage their medication schedules and set reminders for when they need to take their medications. The app's notifications inform the user when it's time to take their medicine. This feature can help people remember to take their medication on time, which can be crucial for managing chronic conditions, avoiding adverse health outcomes, and staying on top of complex medication regimens.

The app may also provide additional information about the medications, such as possible side effects, interactions with other drugs or foods, and other relevant details to help individuals stay informed and make informed decisions about their health.

VII. RESULT & DISCUSSION

The real-life health monitoring system for a range of health metrics, including blood pressure, heart rate, body temperature, and ECG collected by nerve endings, is designed in this suggested study. Temperature and SpO2 sensor details are sent to cloud . Details of the cardiovascular measurement are shown on the app. The remote display of the estimated physical parameters in the MedSync app is displayed in Figure 7. The MedSync App, depicted in Figure 8, also displays ECG sensor details. Overall, real-time health monitoring systems have the potential to transform healthcare by providing continuous monitoring and early detection of health issues, improving patient outcomes, increasing patient engagement, reducing healthcare costs, improving healthcare delivery, and enhancing public health.

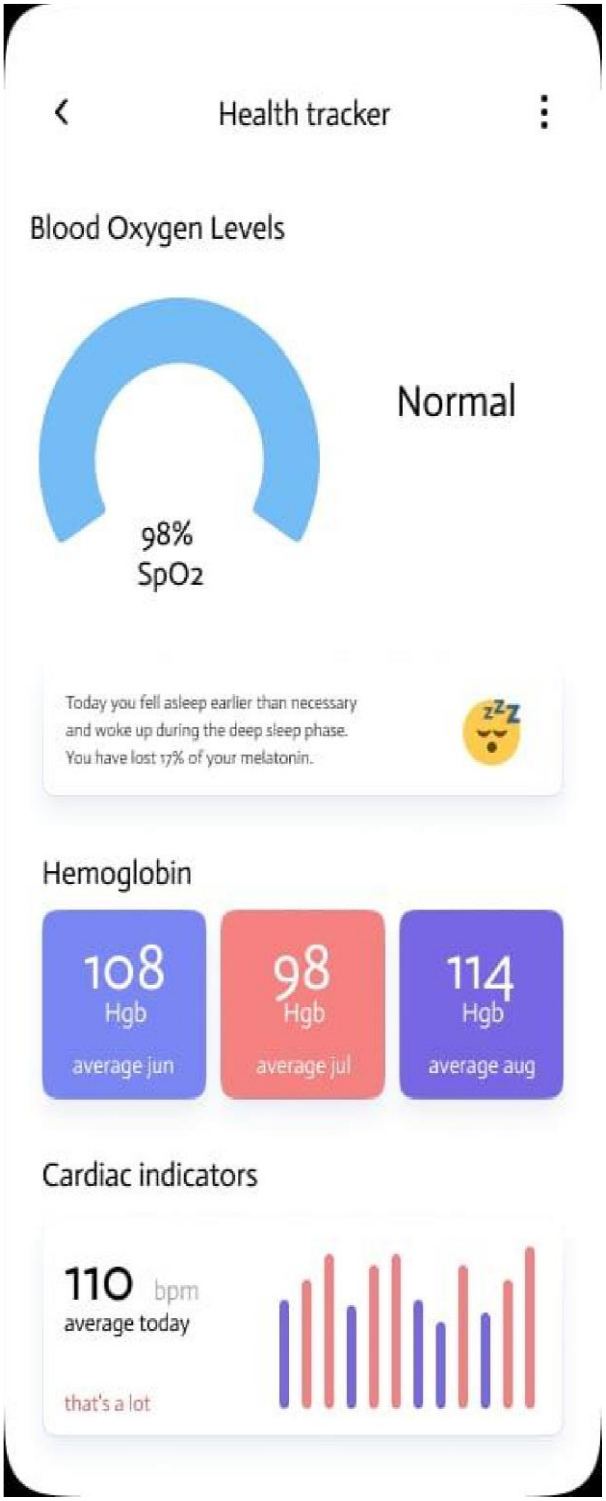

Fig 7 Various health parameters shown on Medsync app remotely

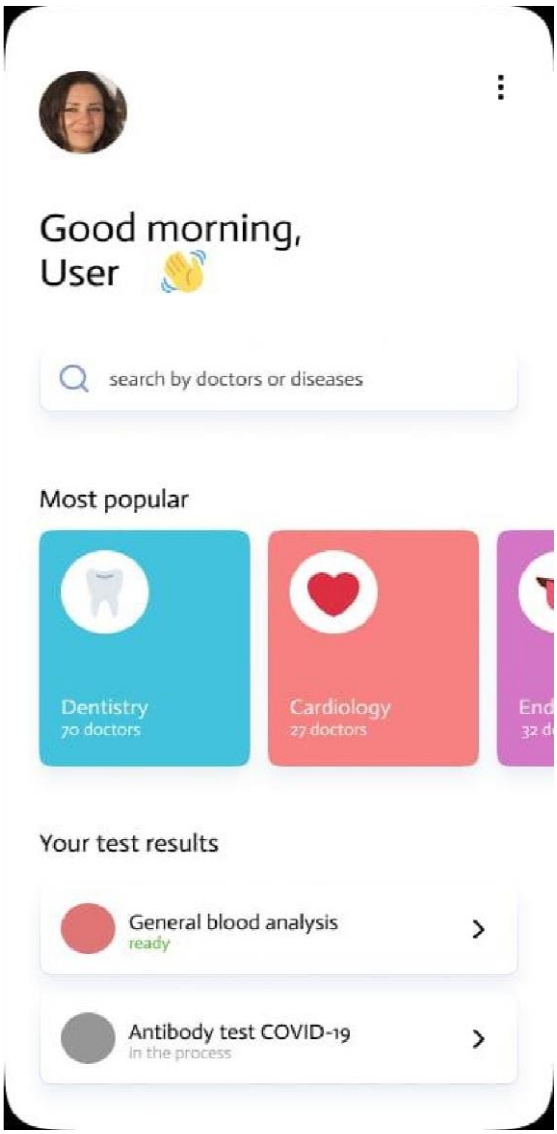
Fig 8 Detailed results on Medsync app



VIII. FUTURE SCOPE

The primary benefit is a relatively straightforward user interface attempting to provide hassle-free personalized healthcare. The power of Artificial Intelligence (AI) and Machine Learning (ML) algorithms can be leveraged to analyze data and detect patterns and anomalies through realtime data in order to forecast future human health situations. It is obvious that putting an alarm system in place will aid in the early identification of uncommon occurrences of cardiovascular disease and the mitigation of its negative effects.

IX. CONCLSION

An IoT-based remote health monitoring system that is affordable, portable, and energy-efficient has produced positive results. The system uses sensors in addition to an ESP32 microcontroller and the MedSync App. With the aid of Wi-Fi shield, the bodily parameters of a person are sensed by sensors, and the sensor details are shown on the MedSync mobile application, which comes preinstalled on iOS or Android devices. Senior adults in particular benefit greatly from the proposed system because it allows them to regularly check their health while remaining in the comfort of their own homes. It can improve patient outcomes, increase access to healthcare, and enable personalized and proactive care. By using our products, doctors can prevent serious lifethreatening situations for their patients by acting quickly.

ACKNOWLEDGMENT

We warmly recognize our Mentor, Dr. Vidyadhari Singh, for her assistance and direction in assisting us in successfully going forward while developing the solution.

Abstract— ***One of the most promising areas for mHealth is in vaccination and doctor's appointment scheduling. Vaccines are one of the most effective ways to prevent the spread of infectious diseases, but access to information about available vaccines and scheduling options can be challenging for many individuals. Similarly, regular doctor's appointments are crucial for maintaining overall health and well-being, but scheduling and attending appointments can be difficult for some individuals.*** ***This research aims to explore the potential benefits and challenges of an android application for vaccination and doctor's appointment. The app aims to provide users with easy access to information on available vaccines, scheduling options, and nearby vaccination clinic. Additionally, the app allows users to book appointments with doctors, view their vaccination records, and receive reminders for upcoming vaccinations. The study will investigate the user experience and usability of the application, examine the effectiveness of the app in increasing vaccination rates and reducing missed doctor's appointments, assess the security and privacy of personal health information stored in the app, and study the impact of the app on healthcare systems and providers. The findings of this research will provide valuable insight into the potential of mobile technology to improve healthcare accessibility and outcomes.***

Keywords—***Vaccine, Medical record, certification, Medicine suggestions.***

I. INTRODUCTION

Vaccination is an important tool to handle the pandemics and hence it is very important to ensure mass vaccination wherever possible. The concept of herd immunity is used to tackle infectious diseases using mass immunization. Recently, the coronavirus pandemic has made the need for a proper system of vaccination more important. Record of vaccination can be managed using a centralized ledger and physical proof of vaccination can be provided to individuals. But in that case, there is a question about the integrity of the records of vaccination, also, various enforcing authorities can manipulate the data or records as they have the authority over the records. The world will be in the utmost need of a mechanism that stores the immunity status of a person with guaranteed security and verifies the vaccination status of a person wherever needed. This paper attempts to address the above-mentioned challenge of storing the vaccination status data and verifying the immunity status of a person at different checkpoints, wherever necessary, to establish a security system for the people to create a trusted vaccination report.

II. LITERATURE SURVEY

Maintenance of proper vaccination has been a challenge since long and continuous developments have been made to come up with new solutions. Initially, records were stored physically with physical records of vaccination provided to individuals but the problem with such a solution is the integrity of the data and because of this, various enforcement agencies, like governments, ask for certificates from individuals. Studied the need for standardization and simplification of vaccination records. The authors also emphasized on the need to have a digital universal record for vaccination so that it is easier to provide a universally accepted record wherever necessary. Even though the need for a standardized system is important, there are always concerns of data security while storing centrally and hence a decentralized system is a more suitable one. Groom et al. Studies how having knowledge of vaccination records effects on increasing the vaccination rates.

A literature survey on android applications for vaccination and doctor's appointment would involve reviewing existing research on the topic to gain a deeper understanding of the potential benefits and challenges of this type of technology. Some potential areas of focus for a literature survey on this topic could include: The usability and user experience of android applications for vaccination and doctor's appointment scheduling. Studies have shown that user-centered design can increase the effectiveness of mHealth applications.

The effectiveness of android applications in increasing vaccination rates and reducing missed doctor's appointments. Research has shown that mobile technology can be an effective tool for promoting vaccination and preventive health behaviors. The security and privacy of

personal health information stored in android applications. Studies have found that privacy concerns are a significant barrier to the adoption of mHealth applications and

Current System	Overview	Gap
A study piloting maternal use of Immunize CA, a Pan-Canadian immunizatio n app.	To evaluate if the use of an app could change beliefs and behaviors related to vaccination, users were asked to attempt surveys before and after 6 months of using the app.	Integration with medical treatment was not attended to in any way.
Vaccine Prioritization Using Bluetooth Exposure Notification	An app was developed to use Bluetooth exposure for contact tracing, and based on	The accuracy of the user data was not checked very thoroughly.

Apps	that, prioritizing vaccination for people.	
An Intelligent Baby Care System Based on Smart Phone Application.	This app was built with modules about information, benefits, and schedules of vaccines, along with age groups. The users are reminded about upcoming vaccines using push notifications.	The confidentiality and safety of the users were not protected.
Vaxign: the first webbased vaccine design program for reverse vaccinology and applications for vaccine development.	This app integrated opensource tools and developed modules with user-centric interfaces. Users can add their vaccine information and questions which would be processed by PHP/HTML/SQL. The result is the given to the user.	This website that provides information about vaccinations was developed using obsolete technology, and because it makes extensive use of open-source software, the user data it contains is extremely vulnerable to being exploited.
Smartphone app uses loyalty point incentives and push notifications to encourage influenza vaccine.	A quiz was developed in the app, about the influenza vaccine to educate the users about its importance. If the users were within 200m of a pharmacy, they would be informed via notifications and visiting would give bonus points.	This application did not concentrate on the process of vaccination as a whole and did not integrate itself with any healthcare systems in order to validate the data it collected. Instead, its primary focus was on a single vaccine.
Vaccipack, A Mobile App to Promote Human Papillomavirus Vaccine Uptake Among Adolescents aged 11 to 14 Years: Development and Usability Study.	An app was developed, consisting of a vaccine tracker. Basic details about the vaccine were also included. Additionally, 26 stories were included in the app, to promote vaccination	When building this programme, user demographics were not taken into consideration at any point.
Immunization and technology among newcomers: A need assessment survey for a vaccinetracking App.	Refugees attending a healthcare camp in Canada were requested to attempt a survey that had 17 questions about languages, homeland, demographics, and vaccination history if known.	The user interface of the programme is rather complicated, and it does not give any information on the most recent vaccines or provide any vaccination recommendations to the user based on their age group.

Table 1. Literature Survey

that robust security and privacy measures are essential to ensure the protection of personal health information. The impact of android applications on healthcare systems and providers. Research has shown that mHealth applications can lead to more efficient use of healthcare resources, but it is also important to consider the potential challenges and limitations of this technology.

Adoption and engagement of android applications by marginalized communities. Studies have shown that mHealth applications tend to be adopted more by higherincome and younger individuals, thus it is important to consider the accessibility of the app for low-income, elderly, and other marginalized communities. Some examples of relevant studies in this area include A study that found that an mHealth application for vaccination scheduling increased vaccination rates among participants. Another study that found that mHealth interventions, such as text message reminders, improved vaccination rates among adolescents Research that found that mHealth interventions for vaccination and doctor's appointment scheduling improved health outcomes and reduced healthcare costs.

Overall, the literature on android applications for vaccination and doctor's appointment suggests that mobile technology has the potential to improve healthcare accessibility and outcomes, but that it is important to consider the potential challenges and limitations of this technology to ensure that it is used in an effective and responsible manner.

In addition to the studies mentioned previously, other research has also highlighted the potential of android applications to improve vaccination rates and reduce missed doctor's appointments. For example:

A study published in the Journal of Medical Internet Research (JMIR) found that an mHealth application for vaccination scheduling increased vaccination rates among participants and improved self-reported vaccination knowledge.

Another study, published in the Journal of Medical Systems, found that mHealth interventions, such as text message reminders, improved vaccination rates among adolescents and increased the likelihood of completing the vaccination series.

A study published in the Journal of Medical Internet Research (JMIR) found that an mHealth application for vaccination scheduling improved vaccination rates and reduced healthcare costs.

A study published in the Journal of Medical Systems found that mHealth interventions for vaccination and doctor's appointment scheduling improved health outcomes and reduced healthcare costs.

Other research has also highlighted the importance of usercentered design in the development of android applications for vaccination and doctor's appointment scheduling. For example:

A study published in the Journal of Medical Internet Research (JMIR) found that user-centered design principles can be used to improve the usability and user experience of mHealth applications and increase the likelihood of adoption.

Another study published in the Journal of Medical Systems found that user-centered design can be used to improve the effectiveness of mHealth applications for vaccination and doctor's appointment scheduling.

It is also important to consider the privacy and security of personal health information stored in android applications. Research on this topic has highlighted the importance of robust security and privacy measures to ensure the protection of personal health information. For example:

A study published in the Journal of Medical Internet Research (JMIR) found that privacy concerns are a significant barrier to the adoption of mHealth applications and that robust security and privacy measures are essential to ensure the protection of personal health information.

Overall, the literature on android applications for vaccination and doctor's appointment suggests that mobile technology has the potential to improve healthcare accessibility and outcomes, but it is important to consider the potential challenges and limitations of this technology to ensure that it is used in an effective and responsible manner. It is also important to ensure the accessibility of the app for low-

III. PROBLEM STATEMENT

The biggest flaw in today's medicine sector is that most vaccines are administered during childhood. Vaccination records are important documents to be kept for a lifetime, but the documentation of immunization events is poorly standardized. At the point of care, paper records are often unavailable, making it impossible to obtain accurate vaccination histories. Vaccination records should include batch specifications to allow the tracking of licensed vaccines in cases of recall.

Key issues

- Standardized vaccination records are needed on a global level.
- Standardized vaccination records should income, elderly, and other marginalized communities.

be universal, safe, flexible, durable, and available in emergency situations.

- To increase accessibility the whole appointment system is being converted to a digital system to get rid of the conventional method of sitting in line for long hours waiting for turns.
- Simplified digital vaccination records provide significant advantage over paperbased systems, including universal access in cases of emergency.
- User-centered vaccination records should empower patients to keep track of their vaccination record and to ask for professional advice, when needed.
- Regulatory agencies and standards organizations should be involved in the development of digital records to ensure semantic interoperability.

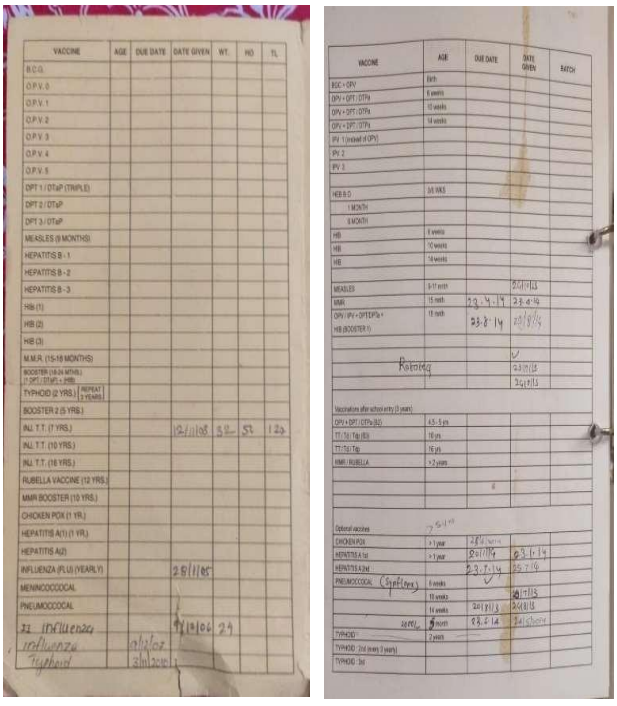

Fig 1. Vaccination Card

IV. Methodology

User testing, surveys, and statistical analysis will all figure into this study's approach. In order to gauge how well the application works for its intended audience, user testing will be carried out. In order to gauge the app's success in boosting vaccination rates and decreasing missed doctor's visits, surveys will be sent out to users. The privacy and confidentiality of users' health records will be evaluated through data analysis, and the app's effect on healthcare delivery and financing will be investigated through empirical research. The study's findings will be used to inform the app's ongoing development and pinpoint potential trouble spots. The overarching goal of this research is to add to the expanding body of literature on healthcare's adoption of mobile technologies and to provide insightful information for healthcare professionals and policymakers.

V. Data Collection And Visualization

This research aims to explore the potential benefits and challenges of an android application for vaccination and doctor's appointment. The following research questions will guide the study:

How usable and user-friendly is the android application for vaccination and doctor's appointment scheduling?

How effective is the android application in increasing vaccination rates and reducing missed doctor's appointments?

How secure and private is personal health information stored in the android application?

What is the impact of the android application on healthcare systems and providers?
Methodology:

The methodology for this research will include a combination of user testing, surveys, and data analysis. User testing will be conducted to evaluate the usability and user experience of the application. Surveys will be distributed to gather feedback from users on the effectiveness of the app in increasing vaccination rates and reducing missed doctor's appointments. Data analysis will be performed to assess the security and privacy of personal health information stored in the app, and to study the impact of the app on healthcare systems and providers.

The sample for the study will be chosen according to the inclusion criteria. Participants will be recruited through various channels such as social media, flyers, etc. Data collection will be performed through user testing, surveys, and analyzing data from the application.

The findings of this research will provide valuable insight into the potential of mobile technology to improve healthcare accessibility and outcomes. The results of this research will be used to identify areas for improvement and guide future development of the application.

The data is collected from questionnaire which was created in google forms and circulated to various aspects of people. The following are the questions asked in the survey:

- Age:

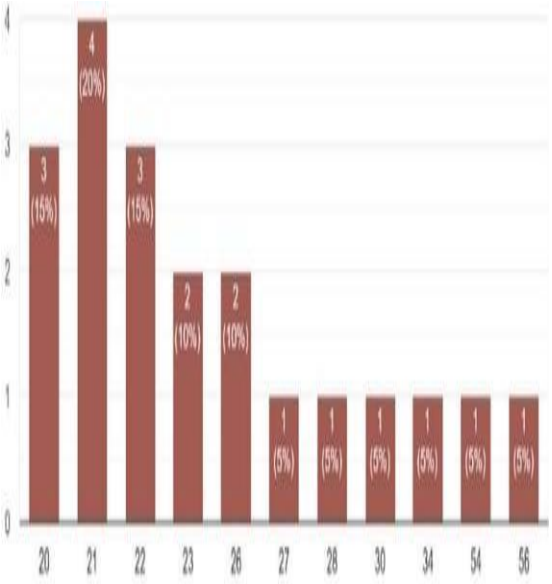

Fig 2

- Are you fully vaccinated from birth?

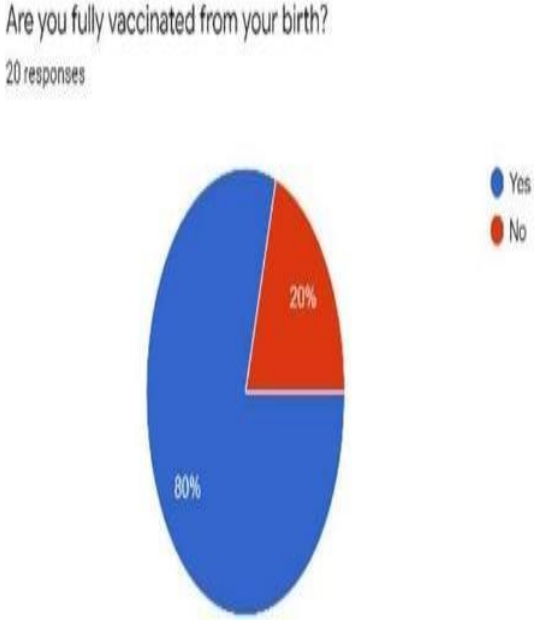

Fig 3

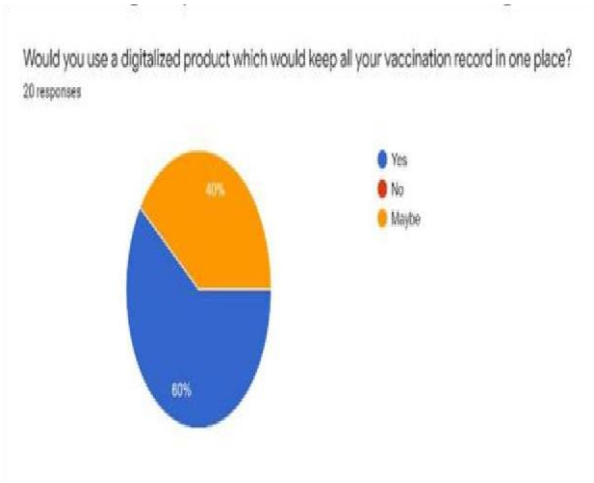

Fig 5

VI. PROPOSED SYSTEM

- Do you keep any type of record for your vaccination?

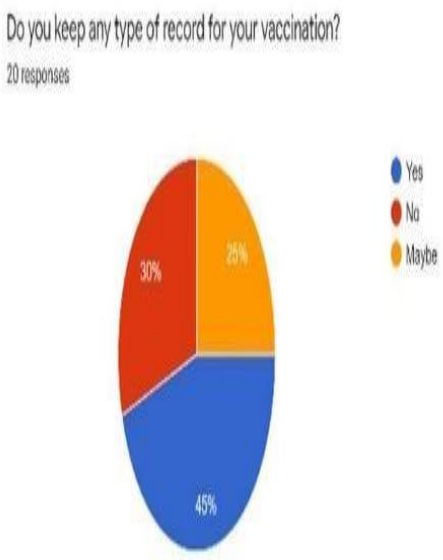

Fig 4

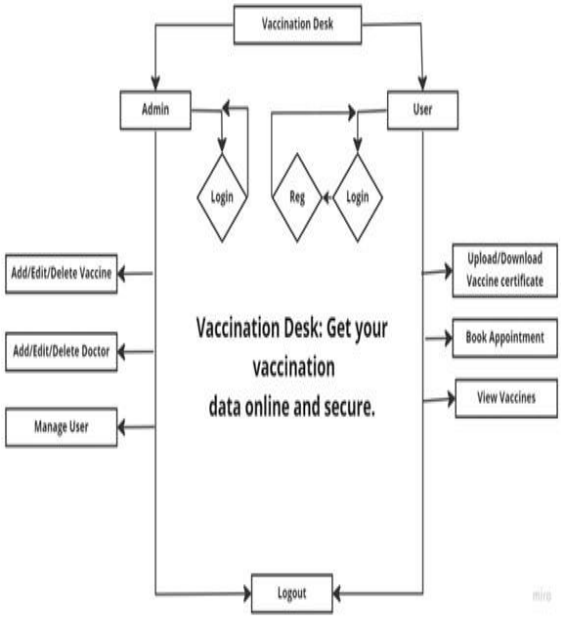

- Would you use a digitalized product which would keep all your vaccination record in one place?
- This The proposed system for an android application on vaccination and doctor's appointment scheduling would aim to provide users with easy access to information on available vaccines, scheduling options, and nearby vaccination clinics. Additionally, the app would allow users to book appointments with doctors, view their vaccination records, and receive reminders for upcoming vaccinations.

The system would be designed with a user-centered approach, focusing on usability and user experience to ensure that it is easy for users to navigate and understand. The system would include the following features:

- A booking feature that allows users to schedule appointments with doctors and vaccination clinics.
- A reminder feature that sends notifications to users about upcoming vaccinations and doctor's appointments.

- A record feature that allows users to view their vaccination records and track their vaccination status.
- A security and privacy feature that ensures the protection of personal health information stored in the app.
- A feedback feature that allows users to provide feedback on the app and its features.

The proposed system would be designed to be easy to use and navigate, providing accurate and reliable information to users. Additionally, the system would be designed with security and privacy in mind, to ensure the protection of personal health information stored in the app. The system would be tested and evaluated in real-world settings to ensure that it meets the needs of users and healthcare providers. The system would be continuously monitored and evaluated to identify areas for improvement and guide future development.

Fig 6: Block Diagram

Fig 7: Phases of Implementation

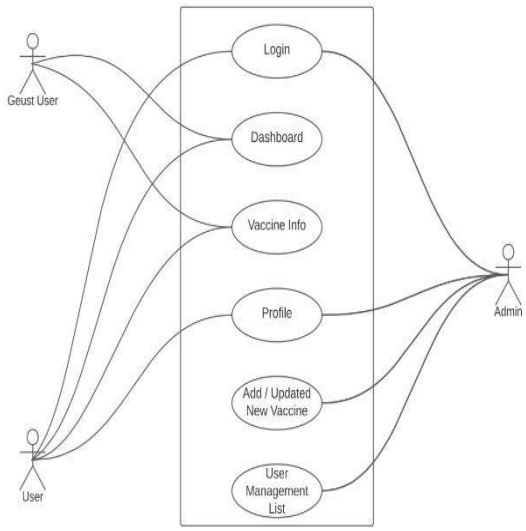

Fig 8: Use Case Diagram

VI.

VI.

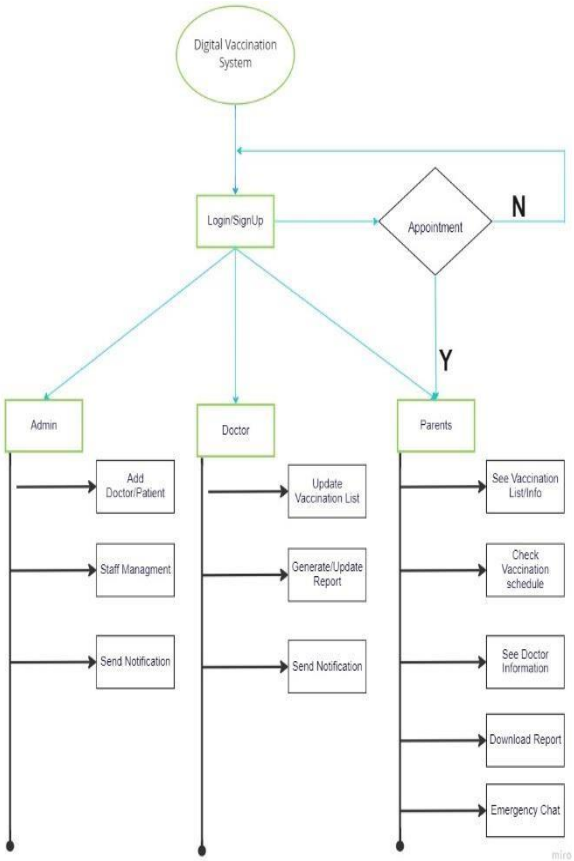
MODEL EVALUATION AND RESULT

This paper was intended to explain the full functionality of our application. It shows the bifurcations in our implementation based on working and internal securities which will lastly lead to better user experience. The highlight features of our product would be safe preservation of our client's vaccination records and make availability to our users would be our topmost priority.

This application would also try to reach its max capacity to make aware of the new vaccination coming up to the market. The last attraction in this product would a live chat-bot setup to serve the emergency setup and contact the doctor in case of urgent matter which may turn to events in past to late-nights almost eliminate waiting in queue for their turn and can arrive just prior to their allotted or selected time. The old conventional methods would still be available to the users till they get used to the updated system.

The distinguishing factor which sets our product out of the current market would be a feature to introduce new clinics as well as doctor to the application as they subscribe and approve of our service and facilities provided by us. This would make it more authenticated as more and more verified doctors approve this application and help us to make aware of the new vaccination coming up to the market.

The diagram ahead will show full functionality of our product, this current design shows us all the services



provided is divided into three major parts. Each having its own unique features.

Fig 9: Architecture Diagram

VII. ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance, and encouragement of my Dissertation Guide Associate Professor Dr. Harshali Patil ma'am for this novel work.

IX. CONCLUSION

This research aims to explore the potential benefits and challenges of an android application for vaccination and doctor's appointment. The app aims to provide users with easy access to information on available vaccines, scheduling options, and nearby vaccination clinics. Additionally, the app allows users to book appointments with doctors, view their vaccination records, and receive reminders for upcoming vaccinations. The study will investigate the user experience and usability of the application, examine the effectiveness of the app in increasing vaccination rates and reducing missed doctor's appointments, assess the security and privacy of personal health information stored in the app, and study the impact of the app on healthcare systems and

providers. The methodology for this research will include a combination of user testing, surveys, and data analysis.

The widespread adoption of smartphones and mobile devices has had a significant impact on many aspects of daily life, including healthcare. An android application for vaccination and doctor's appointment scheduling could have a significant impact on improving vaccination rates and reducing missed doctor's appointments. However, there are also potential challenges to the development and use of this type of application, such as privacy concerns, the need for accurate and reliable information, and the impact on healthcare systems and providers. This research will provide valuable insights for healthcare professionals and policymakers and contribute to the growing body of literature on the use of mobile technology in healthcare.

VIII. FUTURE SCOPE

Our existing solution has room for development and enhancement in the form of additional features, such as Aadhar verification for the user, which will help prevent any fraudulent activity with the user's paperwork. Even a degree verification might be provided for the physicians, allowing them to accept a charge receipt for any user once they have received their vaccination dosage.

More additional features which could be included for enhancement of our product would be as follows:

- Improving the user experience of the application, such as through personalized recommendations and reminders.
- Integration with existing healthcare systems and databases to improve data accuracy and accessibility.
- Development of algorithms to predict vaccine efficacy and side-effects based on demographic and health data.
- Analysis of the impact of the application on vaccine uptake and hesitancy, and the development of strategies to address these challenges.
- The application of machine learning techniques to optimize vaccine distribution and allocation, and to predict and prevent outbreaks.
- Examination of ethical, privacy and security concerns related to the storage and use of personal health information in the application.
- Study of the impact of the application on vulnerable populations, such as rural or lowincome communities.

***Abstract*— Even in the 21st century, Mental Health remains a taboo despite the fact that Mental Health directly affects our emotional, psychological and social well-being. Previous surveys conducted on public health suggest that people with disabilities (PWDs) have higher risk of morbidity and mortality as compared to adults without disabilities. The inordinate levels of poor mental health observed in people with disabilities in contrast to those without accentuate the importance of delivering timely mental health screening and treatment/intervention during and after the COVID-19 pandemic to such people. We aim to create a platform that will provide early screening, psychological support, mental well-being and support from mental health experts. The aim is to help people who are suffering from stress, anxiety, depression, panic attacks, post-traumatic stress disorders, substance abuse, suicidal ideation, pandemic-induced psychological issues, and other mental health emergencies. It will provide people in need of assistance across the country with first-stage advice, counselling, and referrals in various languages according to their convenience. The emphasis will also be on user friendliness of the UI to engage more users and maximize the benefits obtained from the system The project also focuses on creating an audio- sign language converter that recognizes and comprehends speech ultimately converting it into analogous Indian sign form for PWD.**

Keywords—Mental Health, professional assistance, disability, PWD, user interface design

I. INTRODUCTION

The World Health Organisation (WHO) perceives mental health as a “State of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community” [1]. Therefore, mental health goes far beyond the mere absence of a mental health condition. It spans over a wide complex spectrum and each person may experience it differently with differences in levels of distress, symptoms and other social and cultural outcomes. Mental health conditions include mental disorders and psychological maladies as well as other mental states associated with significant distress, trauma, dysfunction, or risk of selfharm. People who are suffering from mental health issues are more likely to experience morbidity or lower levels of mental happiness. Exposure to unfavorable social, economic, political and environmental conditions including poverty, violence, inequality, substance abuse, pollution and environmental deprivation can increase people’s risk of experiencing mental health disorders [2].

Mental health risks can evince themselves at different stages of life, but those that occur during developmentally significant

phases, especially early childhood, are particularly detrimental. For example, authoritarian parenting and physical punishments are known to undermine the health of children. Similarly, bullying can severely affect a child's mental health and lead them to lose their self-confidence. It is observed that symptoms related to emotional disorder are mostly seen in children [3]. It

is also responsible for disability among adolescents as well as children. An important and critical stage of human’s life is last years of childhood and adolescence, wherein changes pertaining to physique, cognition and psychology take place. This is a matter of concern, and extreme care should be taken so that a complete development of individual’s personality takes place. As per 2011 census, about 2.21% population of India has some kind of disability, which indicates 2.68 crore people in India are disabled. Out of total 62.32 crore male Indian citizens, about 1.5 crores are disabled and out of total 58.76 crore female Indian citizens, about 1.18 crore are disabled. Under RPWD Act 2016 a total of 21 types of disabilities are recognized of which 19% people are known to have vision related disabilities, another 19% people have auditory disabilities, 7% people have speech impediments, 20% of people have locomotor disabilities, 6% people are affected by mental retardation, 3% of people are suffering from mental illnesses, 8% people have multiple disabilities and around 18% people have other types of disabilities [4]. Surveys regarding mental health suggest that issues experienced by people with disabilities is 5 times higher than a normal adult [5]. According to a study, an estimated 17.4 million adults i.e., 32.9% adults who were physically disabled, experienced mental health issues frequently, where for past 30 days for 14 or more days they experienced mental distress. This is associated with more than required use of mental health services, presence of a chronic disease, limitations due to their physical disability, etc. [6].

The data thus emphasizes the need for professionals to provide mental health services and to attend to their emotional needs. Despite the urgency, there is a dearth of such programs and facilities that foster well-being and positive emotions [7]. In this respect, modern technology and multimedia devices can be employed to considerably improve the quality of life of people with mental health issues and include them in the society. The Internet offers various benefits for users and researchers alike, such as ease of use, a greater disclosure for individuals and better access to people. However, existing technical solutions applied so far in such devices only partially fulfill the needs of people with disability. Some studies have shown the usage of Internet

in school settings to support the screening, detection and identification of mental disorders, showing that the Internet can play a significant role in facilitation of promotion, prevention and interventions of mental health in adolescents [8]. There has been an increase in the number of people with mental disorders, but, a shortage of online screening or therapy programs that prevent mental disorders and promote mental health in adolescents and people with disabilities. This stresses on the need for development of a system which involves routine check-ups to the prevention of mental distress and the promotion of psychological and emotional well-being in both adolescents and people with disabilities by providing a screening assessment that can be conducted by schools, family or pediatric physicians prior to consulting psychologists or psychiatrists [10]. Therefore, there is a requirement that such cases should be handled with an approach that is specifically designed for them. Since, there is a dearth of online screening and mental health assessment tools especially the ones that cater to the needs of adolescents and those that make such tools easy to use for people with disability, we aim to create a web app that focusses on the user friendliness and provides a one stop destination for users that involves all the activities starting from early mental health screening to consultation with professionals.

OBJECTIVES:

This project aims to serve the following purposes:

1. To implement improved Healthcare system using AI and ML.
2. To make a user-friendly system
3. To make best mental health services available at the fingertips of users.
4. To create awareness among people about mental health through blogs and social forums.
5. To connect patients with experts for diagnosis.
6. To make communication easier by incorporating audio-sign language translator.

II. RELATED WORK

Gathering related information in the form of research papers is an essential step in research that helps to understand the perspectives of various authors and the research conducted by them. It helps in deriving insights and generate better ideas considering the previous research results and outcomes. Lately, there has been an increase in the research for potential applications of technology-based applications in the healthcare domain ranging from physical to mental health conditions. Surveys suggest that consumers are increasingly opting for technology-based applications or at least try out new health apps. As per an international consumer survey of adults conducted in 2018, about 50% of the participants reported to having used a health app which indicated a threefold increase in the utilization of health apps since 2014 [17]. Surveys that specifically focus on mental health apps suggested that the usage is around 10% of total participants coming from different population groups [18, 19]. Health apps seem to be extensively consumer-driven based on the fact that people discover such apps through social media, personal searches, and word of mouth, rather than professional recommendations [20]. Currently, mental health professionals are trying to understand how apps can be incorporated into clinical practice. In this respect, the gaps identified can help us to enhance the application.

In paper [9], the authors have focused on secondary schools because they think that it is an ideal setting to recognize young people undergoing mental health problems such as anxiety, depression, eating disorder, sleeping disorder etc. According to their research, current methods for identifying mental health problems highly depend on paper-based assessments which are very lengthy, time-consuming and for the school it is very difficult to manage such data. So, they have proposed a prototype for a web app named Artemis-A which uses computerized adaptive testing technology that reduces the time of the mental health assessment and gives schools a feasible and easy way for assessing mental health among students. The purpose of this research was to build the web app with stakeholders' consultation to enhance the user experience, to conduct usability testing and to finalize the app design and functionalities and check if the app is suitable and acceptable in schools. The findings indicated that young generation students found the app visually appealing and easy to operate. However, school staff found the app difficult to use so they suggested that few more features should be added to the app which would provide them more flexibility for data visualization.

In paper [10], the authors have proposed a system for detection of mental health in children and adolescents. In this paper, the authors have focused on the bi-dimensional model which conceives psychological problems and psychological wellbeing as two parts of mental health that provide a comprehensive grasp of individuals unlike the unidimensional model that determines mental health based the presence/absence of psychological problems. Further, the authors have proposed The DetectaWeb Project which is a web-based assessment for early detection of mental health issues in children and adolescents and aims to provide a web-based platform for screening of both psychological problems and personal strengths and also analyze key determinants of mental health issues. The paper focusses on developing a system only based on data samples collected from a region in Spain hence, its external validity is limited. Also, in the system the assessments are conducted on LimeSurvey platform which is an online platform for the creation and implementation of online surveys. The collected data is then transformed using SPSS statistical software for further analysis. This indicates a lack of user friendliness and a systemic user interface of the application.

In paper [11], the authors have discussed about big data in healthcare especially in management, analysis and future developments. The authors feel that visualization of big data in a user-friendly manner will be a critical factor for development of the society. They have developed technically advanced applications and software that can utilize fast and cost-efficient high-end computational power for such tasks. As per the authors, big data analytics leverage the gap within structured and unstructured data sources. The gaps identified are that revolution in healthcare is further needed to group together bioinformatics, health informatics and analytics to promote personalized and more effective treatments. New strategies and technologies

should be developed to understand the nature (structured, semi-structured, unstructured), complexity (dimensions and attributes) and volume of the data to derive meaningful information.

In paper [12], the authors have developed a web based mental health detection and get cured application. This solution is user friendly which makes it easy to use by people of any and every age group. The method used for screening the mental health issues makes it easy for the user to get the possible cures for their mental health issues. It asks certain questions and based on the algorithm and previous data on which they have trained their model, the possible cures are suggested. Its improvement can be done by focusing on people with disabilities. The scope of functionality can be increased so that users can also take expert advice and other related benefits.

Reference [13] has explored the ways of achieving student wellbeing and used various machine learning algorithms for the prediction based on the data of commercial capability in university students. This paper investigates the mental disorders among university students across various courses. 30 out of 100 students reported mental disorders which is in line with the work that university students are at higher chances of depression and anxiety.
The paper discovered three predictive modelling techniques Decision Trees, KNN and SVM for prediction of mental disorders based on the features in the dataset. The performance metrics deemed Decision Trees as the most suitable algorithm for this prediction problem in the current dataset. The drawback was the data size which is considerably small consisting of 219 rows affecting the performance of the predictive techniques. However, this could be enhanced using the appropriate dataset that will justify the performance. The results indicate the choice of major and gender has a noteworthy impact on a student's comfort. Thus, Decision Trees perform better than KNN and SVM giving an accuracy and F1-score of 0.64 and 0.61 respectively as shown below:

Model	Accuracy	Precision	Recall	F1-Score	AUC
DT	0.64	0.61	0.62	0.61	0.65
KNN	0.59	0.45	0.56	0.49	0.61
SVM	0.44	0.31	0.25	0.26	0.0

Figure 1. Predictive Table with evaluation scores as obtained from the experiment.

In the paper [14], the authors have proposed a web-based application on which people can express their emotional state of mind anonymously, without any fear of being judged. The authors believe that Indian society has made it difficult for younger generation people to express their mental status by continuously neglecting mental health issue. In this paper, the authors came up with an application which is suitable for all age groups and can be used by anyone. A questionnaire has been used to collect data from users. All the collected data is added to dataset. Further, the data collected helps to determine the severity of user's condition using technology like Machine Learning. Based on the severity of the user's condition, appropriate treatments are recommended to the user. Overall, various machine learning algorithms have been used for predicting the severity of the condition. In future, Doctors can also be recommended in this application to better treat the user's mental health.

III. PROPOSED METHODOLOGY

The identification of mental health disorders is considered difficult due to the considerable symptom overlap between the disability and mental health conditions and the problems faced while distinguishing between the conditions [21]. The review also highlighted how research being conducted behind app development has been insufficient. As per studies conducted, majority of mental health apps available for download are not supported by any evidence-based research and may not be following prescribed treatment guidelines.
Considering these aspects, the Project aims to provide early screening, psychological support, mental well-being and support from mental health experts in adolescents and PWDs by rendering the ability to detect and intervene prematurely and to prevent future mental disorders, as well as to promote mental well-being.

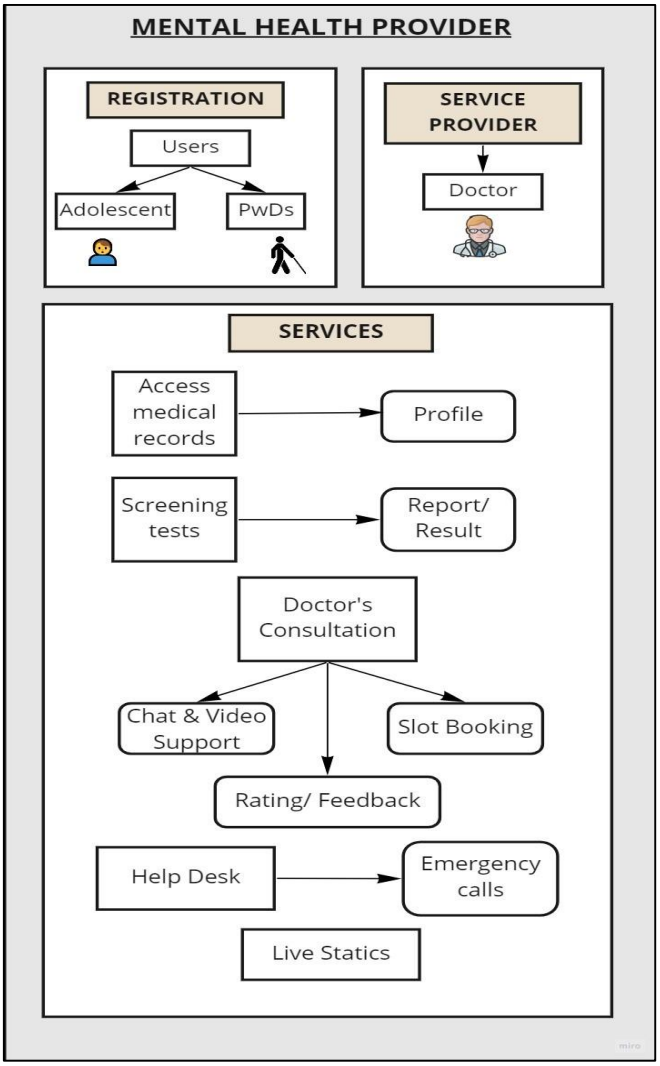

Figure 2. Flow of the proposed system

After studying and gaining knowledge on our topic through literature survey, we were able to design and think about the

proposed methodology. This survey has helped us go beyond our limits and come up with a solution that can eradicate as many gaps as identified by us.

Our aim is to focus on ML or other AI technologies that could help address a number of challenges, by improving access to quality healthcare, particularly for adolescents and PWDs also keeping in mind low-income groups; addressing the scarcity or non-availability of skilled mental health professionals; improving the access and increasing awareness about various mental health conditions and mental well-being; and enabling the delivery of personalized healthcare, at scale also considering the current pandemic situation.

Our idea is to design a platform that will provide early screening, psychological support, mental well-being and support from mental health experts. The aim is to help people who are suffering from stress, anxiety, depression, panic attacks, post-traumatic stress disorders, substance abuse, suicidal ideation, pandemic-induced psychological issues, and other mental health emergencies. It will serve as a lifeline, providing adolescents and people with disabilities in need of assistance across the country with first-stage advice, counselling, and referrals in various languages as per their convenience.

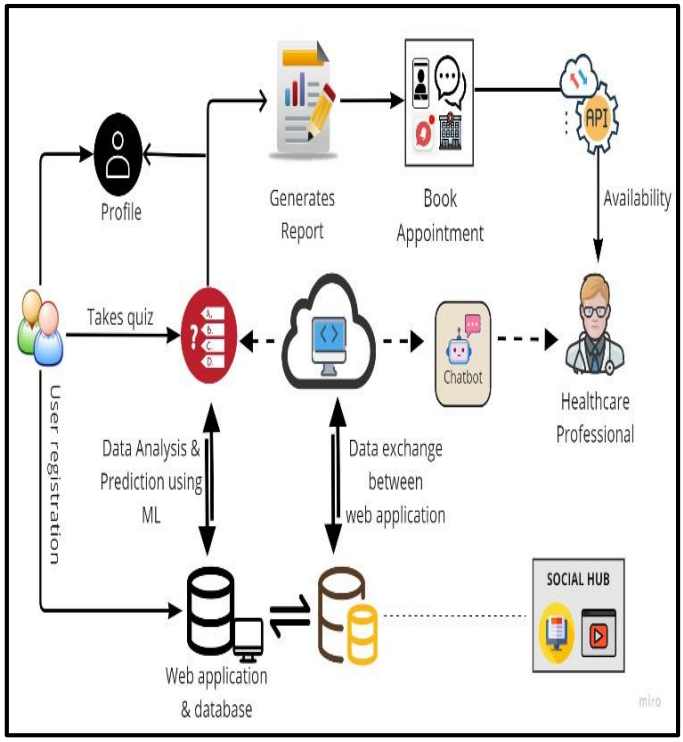

Figure 3. Architecture of the proposed system

A web-based portal will be designed using python frameworks for a smooth experience by the users. The system will consist of various sections, each depicting its own importance in regards to mental health.
The system will be implemented using HTML, CSS, Bootstrap, JavaScript for frontend and Python Flask for backend. We will be using APIs to provide the facility of audio-video calls. Also, planning to design chatbot for assistance using Microsoft Azure.

We are going to collect mental health problems related live data on which we will apply various Machine Learning algorithms and predict suggestive features before-hand as a precautionary measure to help youngsters. The entire system will be deployed on the cloud server – Heroku for ease of access.

IV. RESULTS & DISCUSSIONS

There is a need for further research for developing cogent and regulated measures of mental health problems among adolescents and people with disabilities (PWD). Concomitant mental health disorders are more prevalent in the disabled population as compared to the normal population. Mental health disorders result in reduced functioning and an increased need of assistance in everyday life be it at home, at school, or at work, in addition to difficulties due to the disability itself. These impediments are associated with reduced quality of life for the person and the family. Consequently, careful assessment of mental health should be an essential goal for benefit all people with disabilities and should be incorporated into clinical practice. Though there are a large number of apps that exist currently, the evidence base is scarce, especially for adolescents and PWDs. But a well-designed, appropriately tested, evidencebased system would prove to be very effective for detection of mental health disorders.

Figma is a collaborative interface design tool which helps to brainstorm ideas into virtual reality. This gives a blueprint of the whole system before its execution. Below is the prototype for our proposed system that has been designed using Figma.

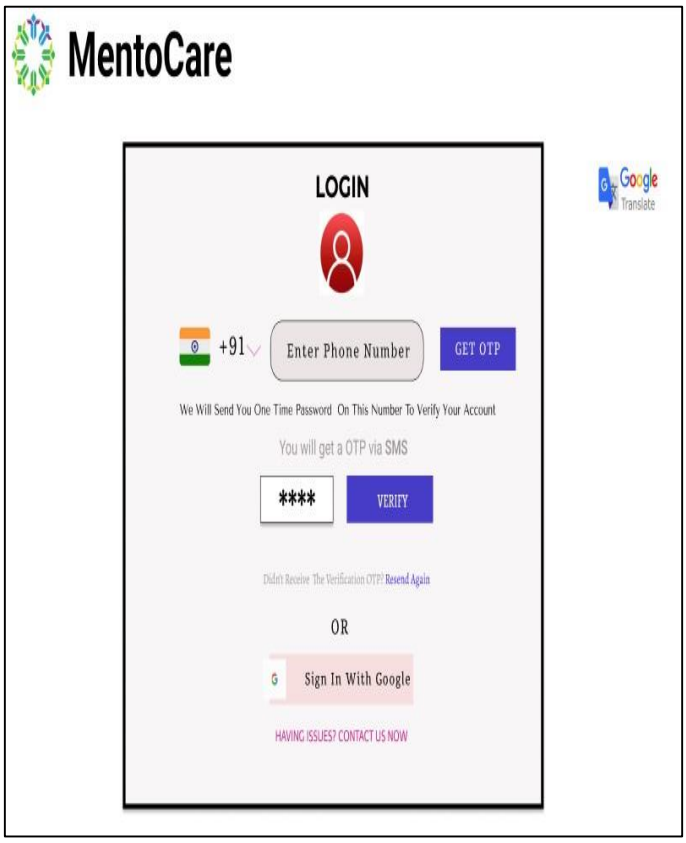

Figure 4. User's Registration page

The users will have hassle-free access to the system - On the login page, we will give an option for google translate so that the user can login in their native language conveniently through OTP verification.

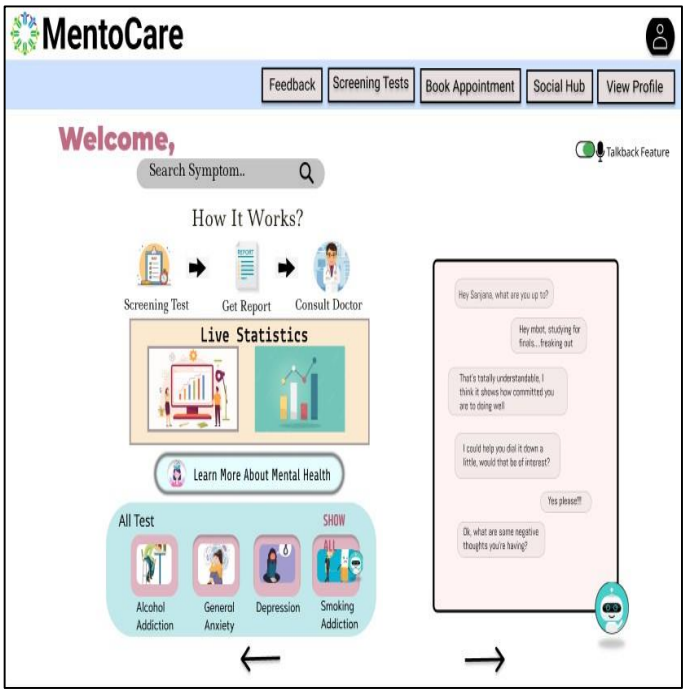

Figure 5. Home page

User friendly interface – Our main focus is to build an application which has user friendly interface. All age groups should be easily able to use the application.

Audio-sign language conversion – A unique feature incorporated to help PWDs communicate. It takes in live audio or speech recording as an input, converts it into text and then displays the corresponding Indian Sign Language images or GIFs accordingly.

Given below is the flowchart for an easy understanding of the processes:

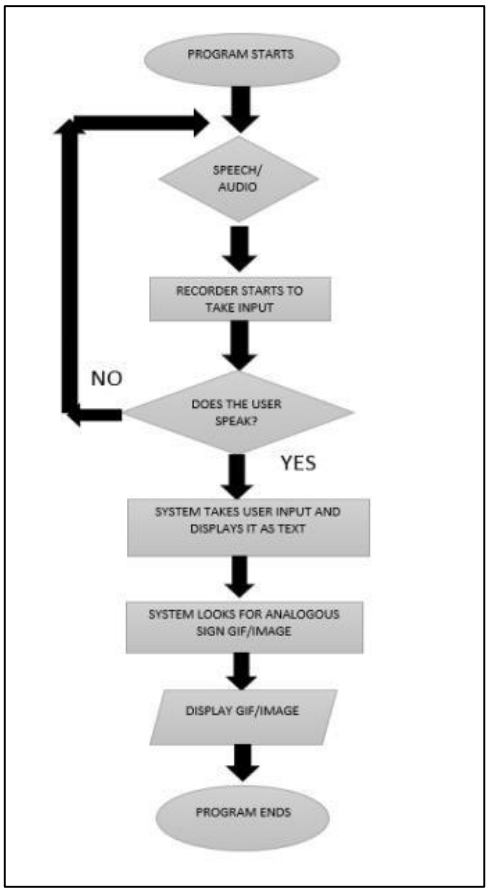

Fig 6. Flowchart representation of the audio to sign converter.

Chatbot - The chatbot will be designed for basic help i.e., basic solution of user's problem will be provided.

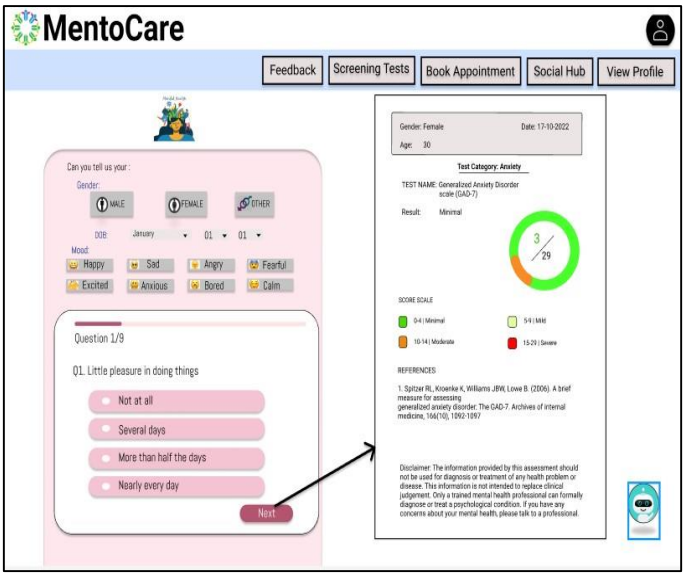

Figure 7. Screening test page

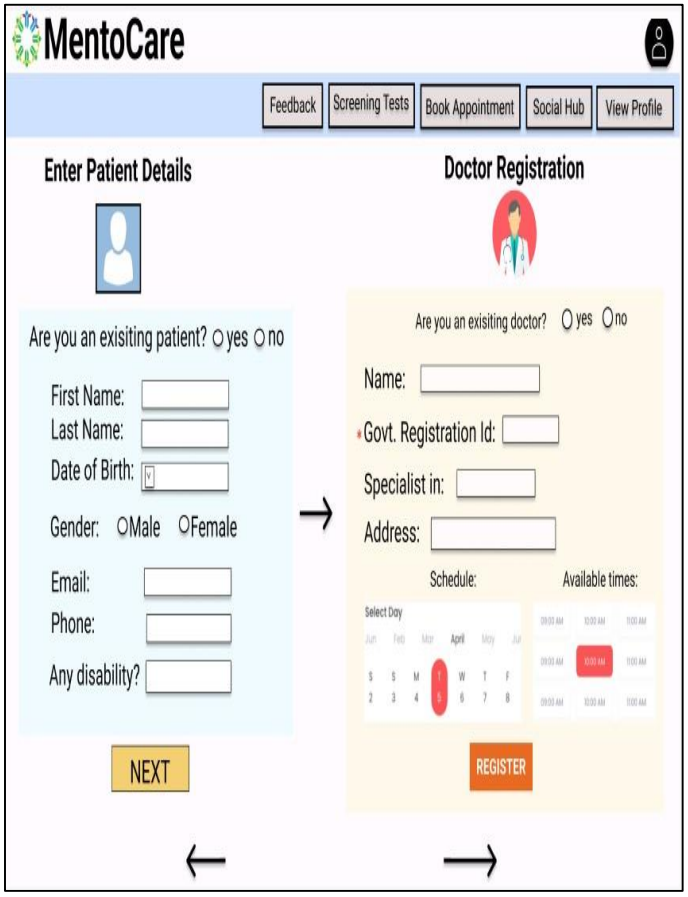
Screening test quiz – This section will contain various tests like - depression, anxiety etc. The test will start with a general questionnaire based on the responses of which the user will be redirected to a questionnaire pertaining to specific mental health issues. After ending the test, the user will get their report.

Report Generation – Based on the test given by the user, a report will be generated. This report will consist of the score, test's name, patient's basic details and reference.



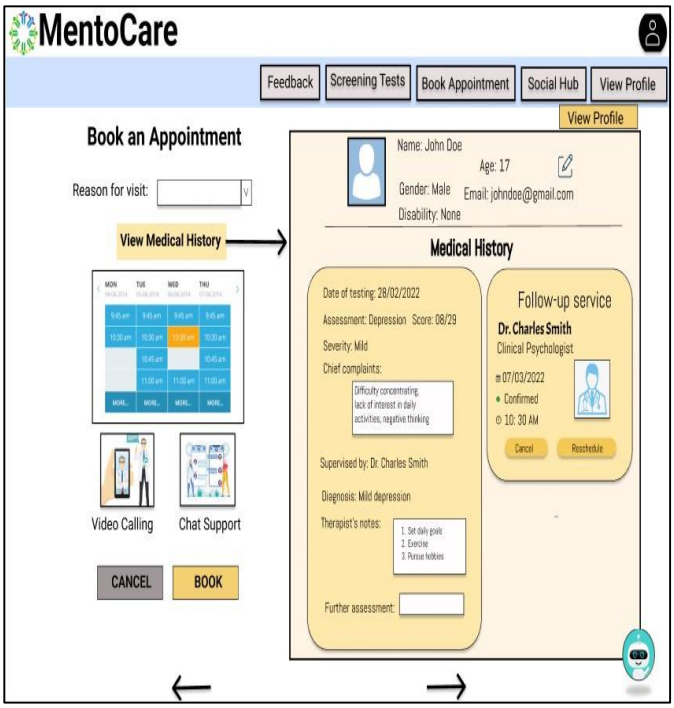


Figure 8. Appointment Booking page

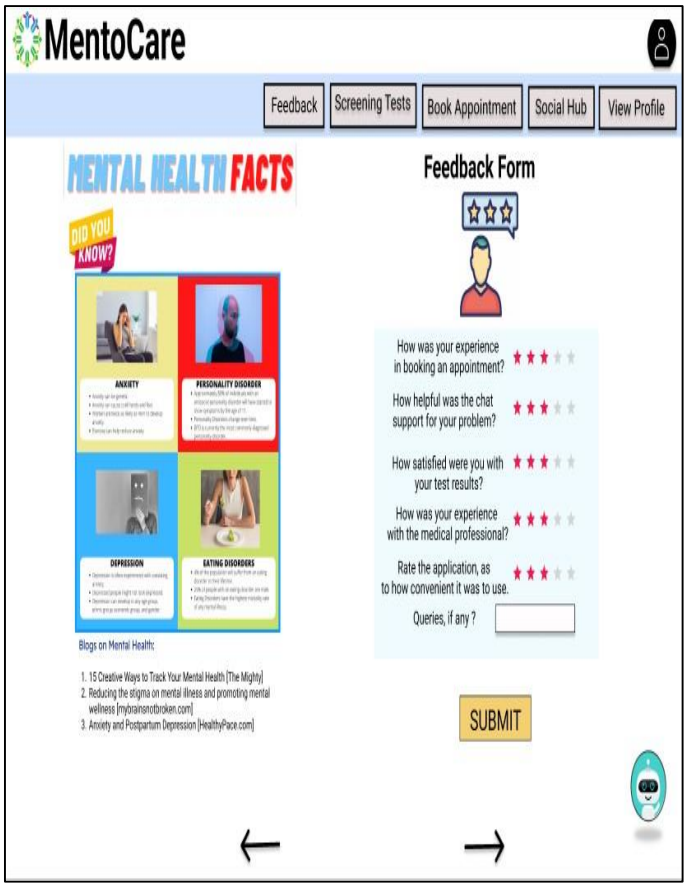
Connect to doctors – After getting the auto generated report, the user can book an appointment. The appointment booking part will be done using API. The user can consult doctor by live chat, video and audio call facility. We will try to incorporate audio-sign language translator in live chatting to make communication easier for wide range of users.

Figure 9. Doctor's Registration page

Appointment booking - The users can get in touch with doctors



App name	MentoCare	Dr. Mind	MoodMission	Headspace
Supports (Target audience)	PWDs, Adolescents and general public	All age groups	people dealing with stress, anxiety, or depression	For novice meditators and people new to the concept of mindfulness
Attractive features	Talkback feature for PWDs, Social Hub to learn more about symptoms, Chatbot for solving basic queries	Get help from nearby centers, Share test results with friends and family	In-app rewards, CBT based activities in the form of missions	Progress tracking, guided meditation tracks, online forums
Doctor consultation facility	Yes	No	No	No
Cost structure	All the features are free, but Doctor consultation is paid	Free	Paid	Paid (Discount for students)
Offline features (If any)	Screening tests, Emergency helpline	Read about different mental health problems	Missions can be used offline once downloaded.	Sessions can be viewed offline once downloaded.
Gaps	- No help from nearby centers	- Not very user-friendly for adolescents & PWDs -Only available in standard languages	- Activities limited to missions - Time consuming activities - No professional help	- No mood assessment ratings - Exercises may feel repetitive - May not be very appropriate for clinical usage

Figure 11: Comparison of various existing apps with the proposed system

by submitting the required details as per their convenience.

Figure 10. Social Hub and Feedback page

Social Hub – This section will consist of various blogs and videos related to mental health. Users can visit this section to get a broader idea about mental health and its symptoms. Also, users can share their stories or experiences and connect to people having similar mental issues.

Discussion Forum – Feedbacks are very important part of any system as it gives us glimpse inside our user's mind, and we can use the feedback to improve the user experience. In this section users and patients can give application feedback. In this section users and patients can give feedback of doctor's consultation and also the application's feedback.

Thus, we have also compared our proposed system with the existing ones and tried to finalize a solution that can overcome the problems with the existing apps.V. CONCLUSION AND FUTURE SCOPE Web apps have the potential to act as a safe and effective medium for detection and treatment of a wide range of mental health conditions provided the approaches followed for screening and treatment are evidence-based. Consequently, the use of an online assessment tools lays out several advantages such as cost reduction, increase in accessibility, evidence-based assessments and counselling. Apart from this due consideration is required of the patient data privacy and security, clinical approval and safety of the app content [27]. Our proposed methodology will be useful for a wide range of community. It will be an inclusive approach that will provide mental health facilities by keeping in mind the concerns of PWDs as well. Through our system we will try to provide a healthy environment which will give mental peace to the users, where doctors can be easily connected to the patients. Patients can easily approach the best mental health facilities at their fingertips. This platform can act as a tool for early screening, to determine the symptoms and severity, to decide which professional has to be referred to for treatment, to learn more about mental health conditions and well-being in a more inclusive way than what was conventionally followed. This will ensure less damage and an improvement at earliest to the mental health of patients. We will try to keep the UI user-friendly. Efforts will be needed to improve the user friendliness of the application along with incorporation of quality content of data to increase the engagement of users to maximize the benefits of the application. Although, proper integration of these online tools with the existing methods is important, technical implementations are never the largest barriers and digital healthcare tools already exist in the market [28]. In spite of the extensive research and progress in the field of Artificial Intelligence (AI) and Machine Learning (ML), the implementation of ML to solve real world problems is often perplexing. There is also a need to understand the risks and challenges involved in the incorporation of ML in healthcare and try to bridge the gap between ML and Healthcare. ML is currently doing miracles in healthcare systems as well [29]. Thus, we will try to incorporate this to help our users get better first aid results. The implementation of digital tools in enhancing patient care, reducing machine runtime, and minimizing care expenses have given an impetus to growth of technology in healthcare industry. When it comes to our healthcare industry, especially in the matter of life and death, the promise of technology to improve healthcare outcomes are very interesting and fascinating.

The usage of technology is associated with a number of moral and social issues pertaining to the lack of transparency and trustworthiness among the general mass. Many issues amongst these superimpose with the issues raised by the use of data and healthcare technologies more broadly. A key challenge for future governance of digital tools will be ensuring that it is developed and used in a way that is clear and suited with the public interest, whilst driving innovation in the sector. This match of demand and supply coupled with development will enable both fields to advance significantly in the foreseeable future, which will ultimately ameliorate the quality of life of people in the society.

Abstract - **Mental health illnesses are a worldwide concern that affects one out of every four people at some point in their lives. Depression is a prevalent mental illness. This paper explores the use of human voice as a valuable indicator for automated mental health assessment, particularly with regard to depression. There are several barriers to getting mental health checkups, including cost and stigma. In order to learn how voice signal behave in terms of frequency and amplitude, speech signals were processed to create spectrograms. To categorise individuals based on their traits, speech signal patterns of depressed and non-depressed individuals were examined. As a result, mental health assessments can be automated using the Convolutional Neural Network model, a machine learning technology that uses speech samples as a biomarker to enhance diagnosis and therapy. It can help in early detection of signs of depression and take the necessary actions in order to become mentally healthy.**

Keywords—Speech, Biomarker, Acoustic feature, CNN, Machine Learning, STFT

I. Introduction

According to the World Health Organization (WHO), more than 300 million people worldwide suffer from depression [1], and the number is rising, particularly among the elderly. Depression, also known as Major Depressive Disorder (MDD), is a mental illness characterised by a persistent bad mood, low self-esteem, loss of interest, low energy, and pain with no obvious reason. It has an adverse effect on a person's family, job, sleep, and food habits. According to [2] ,half of all completed suicides are linked to depression and other mood disorders in extreme circumstances. As a result, many researchers have focused on building mechanisms to diagnose and prevent this mental condition so that psychiatrists and psychologists can help patients as effectively as possible.

Currently, the assessment and monitoring of psychiatric illnesses is based mostly on reports from affected individuals or their carers on an as-needed basis. Patients' retrospective recall biases (e.g., to downplay or overestimate symptoms), cognitive limitations (e.g., remembering of incidents and environment, causal inference), and social stigma all play a role in these reports. Individuals with mental diseases require immediate objective diagnosis, long-term monitoring, and evidence-based interventions, especially those who are unable to receive standard psychological or psychiatric services owing to geographic, financial, or logistical limitations. Remote assessments and improved personalization of care would be made possible by this systematic and objective assessment, which would improve clinical services across the medical practise.[18]

The majority of us communicate without comprehending the degree of coordination required to do so. Speaking entails more than just moving the lips. It's a highly organised display of human communication that expresses thought, intent and emotion.

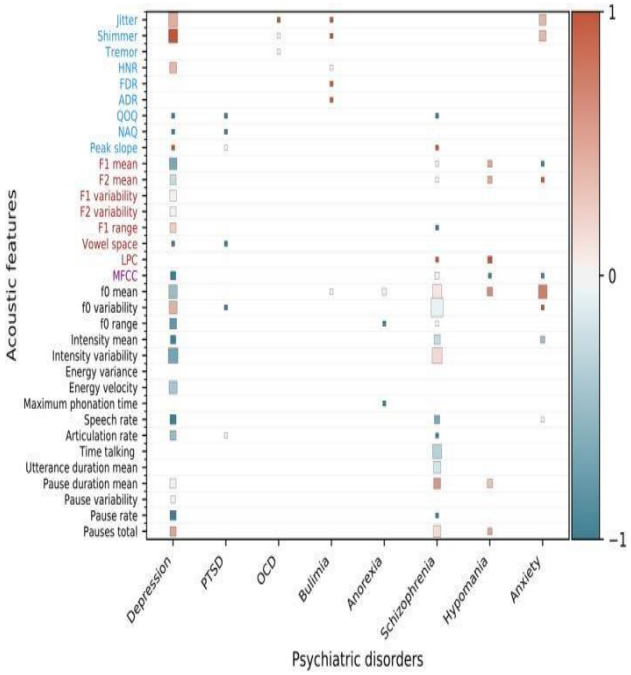

Fig . 1 . Acoustic Features [18]

II. Literature survey

Depression and human behaviour have been linked in studies. A shift in the brain's basal ganglia causes a reduction in motor coordination (also known as laryngeal control), which is one of depression's features. Malyska and Quatieri [3] showed that vocal source qualities can be employed as biomarkers of depression severity and that voice quality carries information about a person's mental condition. They proposed that commonly used voice quality measures in depression detection, such as jitter, shimmer, small cycle-tocycle variations in glottal pulse amplitude in voiced regions, harmonic-to-noise ratio, and the ratio of harmonics to inharmonic components, could be borrowed from signalprocessing methodologies. These characteristics were linked to the vibration of the vocal folds, which was influenced by vocal fold tension and subglottal pressure. The study of laryngeal biomarkers and psychomotor retardation assessment led to a better understanding of the

neurophysiological foundation for changes in voice quality associated with depression and human speech deterioration.

Several additional scholars have described how depression affects common paralinguistic speech characteristics and how this knowledge might be used in categorization and prediction systems. [4] . Automatic depression detection (ADD) methods have the capacity to quantify these connections. The 2017 AVEC "Real-life Depression and Affect Recognition Workshop and
Challenge," hosted by the Association for Computing Machinery, focused on scientific research into depression. [5] . At this conference, Yang et al. [6] suggested a threesectioned hybrid multi-modal depression recognition and categorization framework: the depression scale of the patient health questionnaire (PHQ-8)[7] score based on audio and video features; depression/non-depression categorization based on text data; and multimodal regression for ultimate depression prediction In terms of PHQ-8 score estimations, this method performed better than the baseline values, as evaluated by the mean absolute error (MAE)[8] with an MAE of 4.359 and an RMSE of 5.400, and the root-meansquare error (RMSE). The other outcomes were also satisfactory.

Text-based classification accuracy was 84.21 percent for female patients and 81.25 percent for male individuals using graph vectors and support vector machine (SVM) [9] models. [10] Yang et al. suggested a deep convolutional neural network (CNN)-based multi-modal fusion architecture [11]. Their methodology took into account audio, video, and text streams, and it outperformed the baseline in terms of predicting PHQ-8 scores from audio, video, and text data (MAE 3.980, RMSE 4.653). Multimodal techniques based on various neural network topologies appear to be more effective than single-modal approaches, and they are a promising topic for future research.

During the 2018 Interspeech Conference, another set of intriguing discoveries was presented. Afshan and colleagues (Afshan et al.)[12] The study looked at how efficient speech quality factors are at detecting depression. They suggested combining voice quality features with Mel-frequency cepstral coefficients (MFCCs) [13] , which indicated that it was better at recognising depression. As a result, they were able to attain a 77 percent accuracy rate even though the test utterances were only 10 seconds long. When the test utterances were 1.8 minutes long, the accuracy was as high as 95%. Hanai and his colleagues [14] proposed a model for detecting depression based on audio and text transcription sequences. They tested a long short-term memory (LSTM) model and a regularised logistic regression model (with and without conditioning on the type of questions given). [15] (without knowing the types of questions that triggered the responses, and utilising the sequences of responses) They also looked at a multi-modal LSTM model that included both audio and text. The researchers discovered that when classifying for a binary result, context-free modelling of the interviews based on text characteristics performed better than audio features (depressed vs. non-depressed). Audio features, on the other hand, were more accurate in predicting the multi-class depression score (MAE 5.01 vs. 7.02). Audio features outperformed text features with perfect rates of precision when the model was weighted according to the queries asked (F1 of 0.67 vs. 0.44). (1.00). When audio was dependent on the question being asked, the general performance of the audio improved (F1 0.67 vs. 0.50). The multi-modal paradigm, according to these researchers, produced the best results (F1 0.77 and recall 0.83). Sequence models also performed the best in terms of multi-class classification.

Using deep convolutional neural networks, this research presents a unique method for automated speech-based depression screening. We offer extensive tests on the distress analysis interview corpus (DAIC) to demonstrate the use of our categorization system and to assess the outcomes.

III. Methodology

The paper focuses on the automated assessment of mental disorder using speech as biomarker. For which, we used a CNN(convolutional neural network architecture) which helps in analyzing and studying the patterns in the voice signals of depressed and non-depressed individuals.

A. Data Source

The DAIC-WOZ dataset is part of a larger corpus called the Distress Analysis Interview Corpus (DAIC) (Gratch et al., 2014), which contains clinical interviews to help diagnose psychological distress conditions like anxiety, depression, and post-traumatic stress disorder. These interviews were part of a wider project to develop a computer agent that conducts interviews and detects verbal and nonverbal signs of mental illness (DeVault et al., 2014). The Wizard-of-Oz interviews were performed by an animated virtual interviewer named Ellie, who was controlled by a human interviewer in another room, and the data collected included audio and video recordings as well as lengthy questionnaire replies. A range of verbal and nonverbal elements have been transcribed and annotated in the data.

B. Data Description

Clinical interviews in the DAIC database are intended to aid in the diagnosis of psychological distress illnesses such as anxiety, depression, and posttraumatic stress. The bundle contains 92 GB of material in the form of a zip file with 189 folders. There are 300 to 492 session recordings in total. A text transcription of the recording, participant audio files, and face features are all included in each file in the archive, which represents a single session. The audio files were recorded at 16 kHz with a Sennheiser HSP 4-EW-3 head mounted microphone. Ellie, an animated virtual interviewer operated by a human interviewer in another room, performed the interviews. Each session lasts between 7 and 33 minutes (with an average of 16 mins). Using a standardised selfassessed subjective depression scale, PHQ-8, the level of depression was labelled with a single value every recording.

Because audio files contain minor quantities of bleedover from the virtual interviewer, we're considering using transcript files to solve this problem during processing. Identifiable utterances are scrubbed from audio recordings, i.e. the waveform is blank out at the appropriate periods; these occurrences will be identified using transcript files and the keyword "scrubbed entry." Scrubbed entries in feature files are likewise zeroed out.

Fig . 2. Ellie, the virtual Interviewer [20]

C. Methodology

A physical quantity that changes over time, space, or other independent variables is referred to as a signal. A signal is a function that transmits information about a phenomenon in signal processing. Signal filtering is the main pre-processing step while dealing with signals. The raw signal contains a variety of sounds, making it unusable for performing sophisticated analysis. As part of the preprocessing procedure, we added a filter to the signal to lower the noise which could be used for analysis.

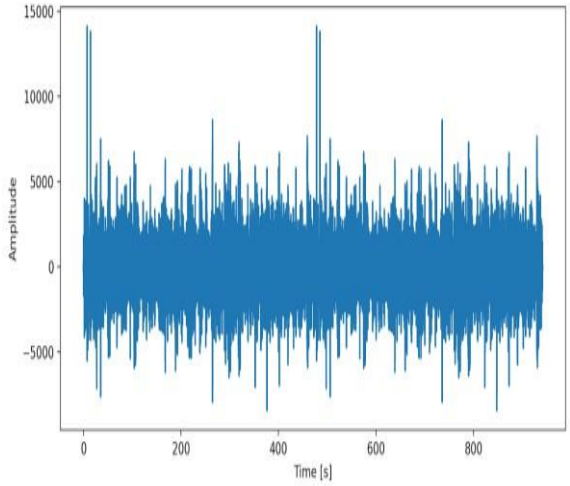

Fig . 3. Raw audio signal

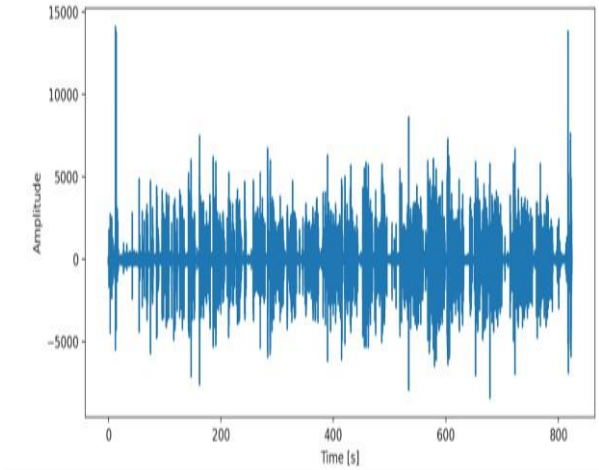

Fig . 4. Filtered audio signal

After pre-processing audio signals which shows magnitude of amplitude over time, we applied the fourier transformation where the frequency is on the x-axis and the magnitude is a function of the frequency itself, causes us to move into the frequency domain. Fourier transformation involves breaking down a periodic sound into a collection of sine waves that all vibrate and oscillate at various frequencies. It is extremely amazing that we can sum up a variety of sine waves at various frequencies to depict a fairly complex sound as long as it is periodic.

The Short Time Fourier Transform, or STFT, computes many Fourier transforms at various intervals in order to preserve information about time and the evolution of sound. As a result, the number of samples in a frame determines the different intervals at which the Fourier transform is performed. Hence, we applied STFT and generated spectrogram which helps in analyzing speech signals in terms of frequency and time.

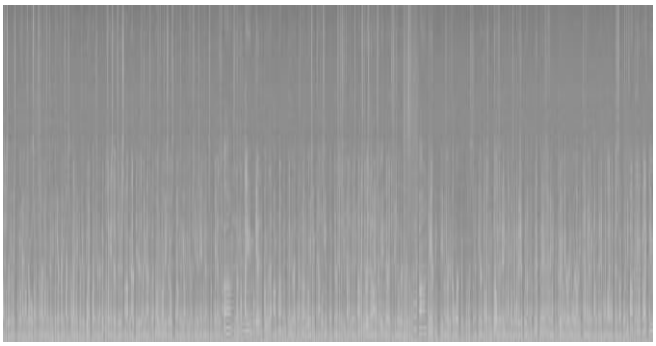

Fig . 5. Spectrogram after applying STFT

The spectrogram of signals which are generated after applying stft are used to train the machine which learns different patterns in the waves and analyzes them. We are using CNN architecture for predicting the depression level of an Individual. In CNN architecture, last layer will be replaced by the number of classes as an output to display the mental health disorder level.

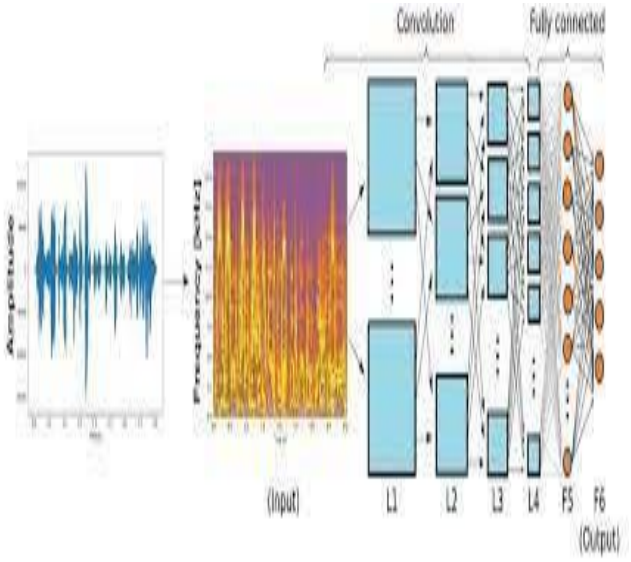

Fig . 6. Basic Structure of CNN architecture [21]

Futhermore, fine tuning will also be done in order to enhance the accuracy of model. From the output layer of CNN model we will get the level of depression of an Individual. In order to reduce the loss error and false negative, we will take the mean of multiple classification output. We will have a voice chatbot which will continuously communicate with individual. Hence, we will take the voice samples from multiple time stamp and predict the mental state and finally will take the mean of all the outputs in order to detect the level of Depression of an Individual.

IV. Model Evaluation

Since the dataset is biased where we have more samples of non-depressed individuals as compared of depressed individuals, the accuracy will not be a perfect matrix for evaluating model accuracy. Therefor, for Evaluating our proposed model classification Results, we will be using Confusion Matrix, F1 Score, Precision and Recall matrices alongwith the loss function curve to evaluate the model. Result and discussion.

V. Result and Discussion

After studying all the possibilities to detect the mental health state, we came to conclusion that Speech is the best biomarker which could be used for state prediction. Also, the given Mathematical Model and proposed CNN architecture will be able to classify the states with good accuracy as per the different studies. The audio signals are analyzed in order to find the patterns in the depressed and non-depressed individuals. The audio signals are filtered to remove noise and other speaker's audio. Only the targeted user's audio is extracted and processed to find the pattern in his/her speech signals. Hence, after analyzing signals we can classify depressed and non-depressed individuals accurately.

VI. Conclusion and Future Scope

With the findings of the experiments and the results of the systemic evaluation, we can conclude that using the suggested model, acoustic feature measurement from speech can discriminate psychiatric patients from healthy individuals. We are now concentrating on depression level classification, which might be expanded to include stress and anxiety levels classification in the future using acoustic features.

Acknowledgment

We warmly recognise our Mentor, Ms. Shiwani Gupta, for her assistance and direction in assisting us in successfully going forward while developing the solution.

Abstract—**This paper presents a methodology for developing an ROI calculator for hydroponic farms and applies it to a hypothetical farm project. The results show that the project has a positive ROI, with a payback period of less than two years. The findings of this research can help farmers and investors make informed decisions about investing in hydroponic farming.**

Keywords—***Hydroponic, ROI, Investment, Gross Income, Operating Cost***

I. Introduction

The project aims to explore the potential of hydroponics as a large-scale commercial alternative to traditional agriculture in India. Hydroponics, which involves growing plants without soil and delivering nutrients and water straight to the roots, can increase production yields and provide consistent, high-quality produce. The project will examine various funding options, including government support, and analyze the risk involved in implementing hydroponics as a disruptive method of agriculture. The focus will be on assessing the financial viability of hydroponic farming ventures by analyzing the return on investment and cost of debt. The project will also consider the capital structure and weighted average cost of capital when evaluating the least cost of debt that can be paid by the company. hydroponics is a rapidly evolving technology that offers a sustainable and efficient method of growing plants. With the ability to deliver nutrients and water directly to the roots, hydroponic farming can increase production yields and provide consistent, high-quality produce. However, as with any business venture, maximizing profit is a crucial aspect. In this technical paper, we will explore the different factors that contribute to maximizing profit in hydroponic farming. Specifically, we will focus on the development of a return on investment (ROI) calculator to analyze the financial viability of hydroponic farming projects. By analyzing the different costs associated with hydroponic farming and comparing them to potential revenue, the ROI calculator will provide valuable insights into the profitability of hydroponic farming ventures. The paper aims to provide a comprehensive analysis of the profitability of hydroponic farming and offer practical solutions for maximizing profit in this emerging industry.

II. Background

A. History and Contributions from Plant Physiology

Hydroponics is a type of horticulture, a method that uses nutrient mineral solutions instead of tillage. The oldest examples of hydroponics date as far back as the paintings on the walls of the Egyptian temple Deir El Bahari, more than four thousand years old. During the VI century BCE, in Babylon, hydroponics was used to grow mostly ornate plants. In pre-Columbian America, around the X and XI centuries CE, the Mexican Aztecculture developed the chinampa to grow crops on the shallow lake beds in the Valley of Mexico and believed to have been practiced throughout Mesoamerica.

B. Hydroponic Cultivation Techniques

The Hydroponics, unlike traditional farming, does not require soil to grow food. In this technique, plants are grown either on natural or man-made substrates, where the roots easily extract the nutrients from a prepared nutrient solution. There are different methods for growing food using hydroponics, and their application depends on the specific plant, local climate, and budget, among other factors. Most systems comprise a storage tank for the nutrient solution and an aerator, as illustrated in Figure 1.

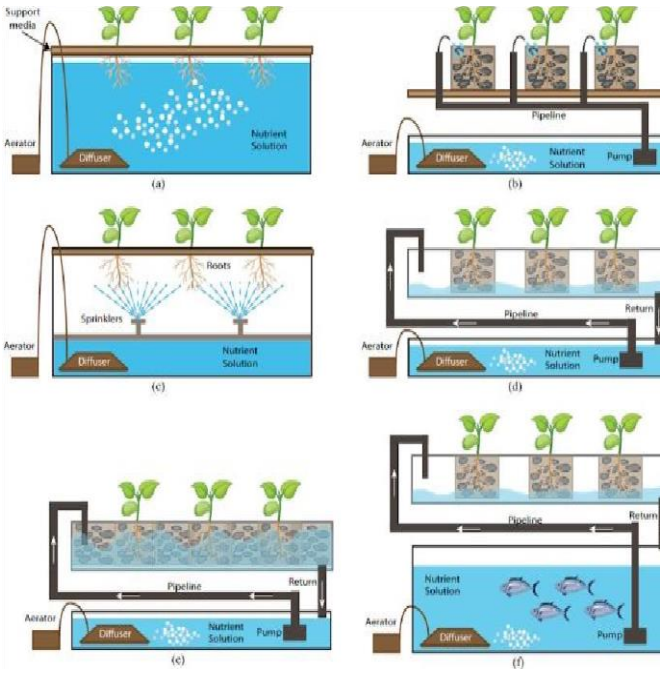

Figure 1. Different types of hydroponic systems. (a) Deep Water Culture. (b) Drip System. (c) Aeroponics. (d) Nutrient Film Technique (NFT). (e) Ebb and flow. (f) Aquaponics.

a. *Floating Root System or Deep Water Culture (DWC)*:

In this system, the root of the plant is immersed in the nutrient solution, while the rest of it is supported above water level using polystyrene, cork bark or wood, among other materials (Figure 1a).

b. *Drip Irrigation:*

This method is best suited for tomato and pepper-like crops. In this case, the nutrient solution is pumped directly to the roots of the plants with regulated flow. The solution is administered at predetermined time intervals and, for closed systems, the leftover solution is returned to the storage tank (Figure 1b).

c. *Aeroponics:*

Tubers and roots are ideal to grow using aeroponics. In this configuration, the plants, with their roots hanging down in the air, get their nutrients from periodic spraying by a system of sprinkles. The main advantage of this technique is that it does not require an airing system as oxygen is carried along with the sprayed nutrient solution (Figure 1c).

d. *Nutrient Film Tchnique:*

This method, also known as NFT, is like the floating root system, except that the plant roots are not completely submerged in the nourishing solution, but in a liquid stream flowing through a piping system. Although NFT requires smaller amounts of nutrient solution than the floating root nitrification and denitrification, allows the recycling of water from the fish tank, forming a balanced micro-ecosystem.

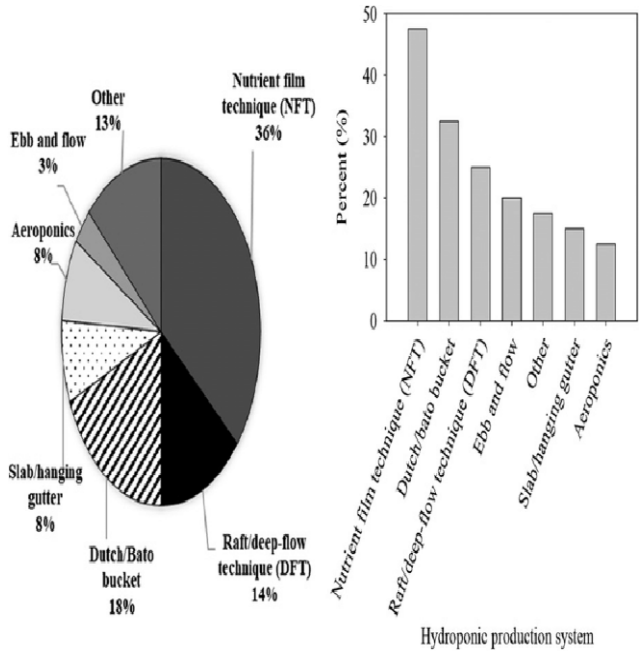

Figure 2. Proportion of Hydroponic production system.

system, it requires additional energy and components to operate. The excess solution returns to the storage tank by gravity and the flow of nutrient solution can be continuous or periodic (Figure 1d).

e. *Ebb and Flow:*

Plants are placed in a tray, which is periodically filled with nutrient-rich water pumped from a reservoir below. The system uses gravity to return the water to the reservoir and reuse it (Figure 1e).

f. *Aquaponics:*

This technique exploits the symbiosis of flora and fauna to achieve an efficient system in which fish feces afford the nutritional requirements of the plants. The absorption of nutrients by plants, combined with the microbial process of

III. PROPOSED SYSTEM

A. Survey of Literature

For this project, we referred to some research papers about digital solutions for the problems regarding hydroponic farming. Most of the papers proposed AI-based data analysis of crops and predicts future prices. These papers with their work and identified gaps are discussed in the table below.

We also studied some existing applications which are very useful to people in the age group. These applications were majorly focused on the entertainment and healthcare of the elders. Some of them, which are relevant to the proposed solution are listed in the table below.

The above survey showed that there are many solutions provided for older adults, but they lack some or other things every time. Also, all the solutions focus on one problem at a time. study aimed to analyse production costs, incomes, breakeven point ,business efficiency, and inancial feasibility of a hydroponic vegetable business.

The total production cost for hydroponic vegetable production is Rp319,420,734 per hectare and the amount of income is Rp 688,579,266 or 68.31% of the value of revenue. R/C ratio is 3.16, which means the hydroponic vegetable cultivation business is efficient.but, the paper research is based on limited data sources and only conversation provided, no data usage.[1] paper is based on the financial analysis of Lively'Hood Farm. research is based on both the hydroponic and soil-based revenue calculations. Lively'Hood Farm will not be able to sell 100% of the produce it generates. percentage is expected to be higher in the early years of the business while the Farm is still establishing its brand and attracting customers.[2] In this paper the study is performed using a literature review, theoretical design of a system, and scenario-based assessment of hydroponic lettuce production. the hypothetical hydroponic system was feasible, and the economic factor was not a barrier. electricity generated through wind power was the primary type of energy to meet the demand of the system. the study focused on the case of only lettuce production in Sweden using a hydroponic system.[3] This study is focus on funding and risk analysis of hydroponics. The farmers in India are partly affected by this process but the company is taking care of the welfare part of farmers to some extent. government provides subsidies to farmers and startups in order to benefit to them. The company is not so good position but the future of company is bright as it is highly diversified and technically advanced.[4] Review focuses on hydroponics and the Technologies Associated for Medium- and Small-Scale Operations. review intends to close the gap between both fields, delving into the basics of hydroponics as a necessary step for the technologist to understand the needs of medium and small-size operations.[5]

B. Proposed work

The goal of a farmer in running a farming business is to establish a combination in the branch of farming that can later provide maximum income because income has the function to meet daily needs and can provide satisfaction to farmers, so they can continue their activities. revenue is the difference between revenue and total costs used during the production process. Income in farming is divided into two, namely gross income and net income.

a. Gross income is revenue that has not been reduced by production costs or what is usually referred to as revenue.

b. Net income is revenue that has been reduced by production costs.

The amount of income received by farmers depends on the amount of revenue and expenditure during the production process. Revenue in farming is the total income received by producers from production activities that have been carried out or have generated money that has not been reduced by costs incurred during production. Revenue is obtained from the multiplication of production results with product selling prices.

IV. IMPLEMENTATION

As stated in the introduction, several factors like human population growth and farmland degradation drive the global demand for more grains and food, pushing for higher yield and efficiency farming techniques, such as precision and urban agriculture. The restriction of space for cultivation in urban environments has called for efficient forms of cultivation. Based on hydroponics, technological innovation, and state of the art scientific knowledge, methods like vertical and indoor cultivation have extended rapidly, as attested by the market size and growth rate (CAGR 11.3%) of hydroponics, valued at USD 9.5 billion in 2020, and projected to reach USD 17.9 billion by 2026 , thanks to the growing acceptance of indoor farming, and innovative technological advances.

A. Operating Environment

The End Framework will be a form that works as a calculator for front users. data about crops and total cost which includes variable cost as well as fixed cost are fully verified by industries and companies. data will be fetch in form of APIs and for upgradation of data their will be administration penal.

The end-end framework must be optimized, so that it can work for calculating total cost as well as profit margin. The framework must take data about crop, life-cycle and number of plants as an input and provide the total estimated profit and loss, dependent on the plants and overall cost of implementation.

It has been assumed that all models provided by the user, to be integrated into ROI Calculator, have been written using NodeJS, and have functions, which takes list of inputs and provide the outcomes, as an result. It is also assumed, that the crops dataset, in case of calculation, has been verified by industries already, and can be updated with changes of prices.

B. Technology Used for Application

For this project, we have decided to work with the following technologies:

a. IONIC-ReactJS

b. NodeJS: Backend Process

c. MongoDB :Database Design and APIs

C. Methodology

a) Hydroponic technology has many advantages, including saving land or space, saving fertilizer and water ,being environmentally friendly, growing plants faster, quality of crop yields can be maintained, and quantity can be further increased. But the consequences, hydroponic vegetable business requires high costs in its production. The investment costs and operational costs required such as labour, the provision of irrigation facilities require a lot of costs, so the types of vegetables cultivated and the selling price of hydroponic vegetables are important to be considered by the hydroponic vegetable business man. Analysis of costs and income of farming is one way to compare costs and income from production process activities. Farming is said to be successful if the farm can fulfil the obligation to pay for the tools used, labour costs and can maintain the sustainability of the business.

The formulas for return on investment (ROI) on crops for hydroponic farming are as follows:

1. Initial investment costs: This is the total cost of setting up the hydroponic system, including equipment, materials, and labor. This can be calculated as:
Initial Investment Costs = Equipment Costs + Material Costs + Labor Costs

2. Operating costs: These are the ongoing costs of running the hydroponic system, including electricity, water, and nutrients. This can be calculated as:
Operating Costs = Electricity Costs + Water Costs + Nutrient Costs

3. Revenue: This is the income generated from the sale of the crops grown in the hydroponic system. This can be calculated as:
Revenue = Quantity of Crops Sold x Selling Price per Unit

4. Gross margin: This is the difference between revenue and cost of goods sold (COGS), and it is calculated as:
Gross Margin = (Revenue - COGS) / Revenue

5. Net income: This is calculated as revenue minus all expenses, including initial investment and operating costs. This can be calculated as:
Net Income = Revenue - (Initial Investment Costs + Operating Costs)

6. Payback period: This is the length of time it takes for the initial investment to be recouped. This can be calculated as:

Payback Period = Initial Investment Costs / Net Income

7. ROI: This is the net income divided by the initial investment, multiplied by 100 to express it as a percentage. This can be calculated as:
ROI = (Net Income / Initial Investment Costs) x 100

It is worth noting that these formulas are general and would need to be adjusted to suit the specific context of the hydroponic farming business and the crops being grown. Additionally, the assumptions and estimates used for costs and revenues, crop yield and other factors would have a direct impact on the final outcome of these formulas.

Type of Plants:

Leafy Vegetable
Eg. Palak, Mint, etc.

Hard Rooted Vegetable
Eg. Tomato, Strawberry, etc.

Calculating Weight (KG) in each type of plants:

a. For leafy vegetables we can calculate using Number of Plants/ Kilogram.

b. For other types of vegetables it can be calculated as Number of Kg/plant.

CALCULATIONS

Leafy Veg.

No. of Kg = No. of Plants / No. of plants/Kg

Hard Rooted Veg.

No. of Kg = No. of Plants * Kg/Plants Total

Return Crop Price = No. of Kg * Price/Kg

Total Return on Investment (ROI) =
Total Return Crop Price – Total Cost of Productions

CONCLUSION

In summary, revenue for farmers of hydroponic vegetables is calculated by subtracting production and marketing costs from the total sales received for the products. Vegetables grown using hydroponics in this research include mustard, lettuce, and celery. Factors that influence revenue include the selling price and number of vegetables sold, as well as the amount of capital available for creating the hydroponics module. Net income for hydroponic vegetable farming is calculated by subtracting total production costs from total farming revenue, and is affected by factors such as the total number of vegetables sold, production costs, and the selling price of the vegetables.

To calculate Return on Investment (ROI) using real-time data and input from farmers, it is important for farmers to focus on generating more revenue from their farmland. This can be achieved by analyzing the different factors that affect revenue and net income and using this information to make informed decisions about investment and production. By maximizing the ROI for hydroponic vegetable farming, farmers can improve the sustainability and profitability of their businesses, as well as make it easier for soilless systems to be adopted in the future.

In conclusion, revenue and net income for farmers of hydroponic vegetables are affected by a variety of factors, including the selling price, number of vegetables sold, and amount of capital available for the hydroponics module. By analyzing this data and input from farmers, the ROI for hydroponic vegetable farming can be maximized, leading to more sustainable and profitable farming practices. This will not only help individual farmers, but also support the growth of the hydroponics industry as a whole.

***Abstract*— The following paper goes into detail of the methodology followed in order to develop an automated interview system which can conduct multiple remote interviews at the same time. The multi-party bidirectional communication is powered by WebRTC. Our system is a full-fledged solution with ready-to-use data sets, questionnaires, coding problems & Test cases required in setting up an exam/interview. The program is equipped with capabilities of video recording, processing, and storage. It uses browser-based deep-learning models for gaze-tracking, expression evaluation, and facial recognition. Our paper focuses on the network requirements of such systems at scale using cloud processing and storage. We have also compared such innovative approaches of taking mass interviews/exams to traditional approaches, to determine the cost-time benefits of using such systems. We have justified ouruse of technologies in access control, architecture and NLP models using contemporary examples and references.**

***Keywords*— WebRTC, Peer-to-peer, Star-Topology, Cloud, RBAC, Browser**

I. Introduction

The market is filled with various webRTC applications[1]. Most of them are not suited for taking online interviews. Online interviews often fall prey to malpractices which can mislead recruiters in their recruitment process. The paper provides an implementation path for building a product that aims at filling this gap in the industry and stands out as the only viable option for firms in their online interview process. The paper discusses the development of a browser-based webRTC platform that helps in detecting these malpractices and gives a versatile environment for taking interviews. The product is built using MVC[2] architecture. In this paper, we discuss the implementation and working of WebRTC, the storage of data in a non-relational format, and AI-based verification systems. The platform comes filled with predesigned question banks based ontesting the candidates in a whole spectrum of technical and non-technical topics. We have directed our research in creating a safe environmentusing several anti-cheat techniques like encryption[3], browser monitoring[3], gaze tracking[5], etc. The product can take several rounds of interviews at once and allows the human interviewer to intervene and assist wherever required during the interview process.

II. RELATED WORKS

Our use of star topology for our WeRTC-based interview system stems from the need of having one to many bidirectional video connections as stated in the paper 'WebNSM: A Novel WebRTC SignallingMechanism for One-to-Many Bi-directional Video Conferencing'- " star topology provides better performance for different users, while each participant does not need a high capacity of CPU or high bandwidth."

The paper 'Cheating Detection in Browser-based Online Exams through Eye Gaze Tracking'(2021) discusses the idea of a browser-based gaze tracking cheating detection system "we generate an eye gaze dataset while a student faces an online examination.We then process and analyze this dataset to detect any misbehaviour during an online examination". Our system uses a similar technique which tracks the candidate's gaze from the candidate's browser, thus reducing the load on the server.

For conducting multi-party video conferencing on a large scale, the bandwidth requirement increases accordingly for both the server and the clients. The paper 'The impact of bandwidth limitations and video resolution size on QoE for WebRTC-based mobile multi-party video conferencing'(2015) discusses how different bandwidth limitations impact QoE(Quality of Experience) for different video resolutions.

For increasing the flexibility of the system, it is important that we operate the system in a cloud-based environment and hence we should know the techniques for cost estimation used in such environments as described in the publication 'Science Direct (2012) Composable cost estimation and monitoring for computational applications in cloud computing environments. We have to estimate the operational requirements using the determined workflows and dataflows.

III. ACCESS CONTROL MODULES

A. Model of access controls

The product is made to follow a B2B model of operations where the firm delivers services of the software to companies who require support in conducting large-scale online interviews. We have used an RBAC: Role-Based Access Control model[4] for access control inspired by a hierarchical system of control.

Fig. 1 Role-Based Hierarchy

The software contains a mechanism to allocate new users to categories to give them the required authorization. The roles exist as follows- Owner, Administrator, and Operator.

B. Roles

The owner and the administrator roles have effectively the same permissions over the software. They can examine the dashboard, add Job Posts, add exams, add candidates, perform screening, schedule interviews, review the evaluations and add content in the question banks. The owner has precedence over the administrator as the former can remove the latter. The administrator is responsible for assigning people the role of operators and can remove or add operators. The operator has effectively the same control to create job posts, and exams, add candidates, perform screening, view the dashboard, and schedule and evaluate the interviews. But the operator cannot remove job posts, exams, questions and candidates added by the other operators and neither can the operator schedule interviews for job posts created by theother operators.

This hierarchical structure of management provides effective and fast customer support, reduces redundancy, and makes scheduling and creation of exams faster.[4] As the question sets are reusable throughout the system and candidate information is readily available to larger groups of companies. This system of controls provides flexibility and ensures security for the smooth operation of thesoftware[4].

C. Authentication

We are following the widely used for security The process of adding the new operator requires the administrator to enter the email address of the operator into the system. The operator is then sent amail from the system through which they receive a link to a form from which they can set up their security details. The passwords are then hashed using the SHA-256 algorithm and stored in cloud storage. Thus each time when the operator wants to access the system they can do it via the website by just entering the security details. This system ensures that the software is highly accessible, robust and mobile[6].

IV. SYSTEM MODULES

The modules made for the smooth scheduling of theinterview process are the QA bank, exams, job

posts, candidates and screening modules. These Modules function as the primary points of interaction for the operator to add questions,candidates, exams and job posts.

A. QA-Bank Module

The QA bank exists as a repository for technical and non-technical questions of several domains which might be required while taking the exams/interview. The QA bank module allows the operator to add questions to a selected domain,such that the operator can specify its underlinedtopics, difficulty level, time limit, question type andscores. Tags can also be added to the questions to make them easily searchable. The system contains customized options for various question types. These are coding questions, SQL coding questions, multiple-choice questions, descriptive questions andfill-in-the-blanks type questions. For Multiple choice, descriptive and fill-in-the-blank questionsthe operator will provide an answer set so that it canbe checked against the answers given by the candidate during evaluation. For Coding and SQL coding Question, the output should be checked against the test cases provided by the operator along with appropriate timeout limitations. A Sample Code can also be given by the operator such that the candidate has a headstart on attempting the question. Our system has used — a type of online compiler[7] which can run code in python, java, c, cpp, Javascript, rust, go, ruby and c-sharp.

B. Exam and Job-Post modules

The exams and job posts module serves a similar purpose as they represent an opening or a role set up by the client (operator) on the behalf of a company. The Job-post Module allows the operator to create a Job post with attributes like Job title, company name, company logo, contact details, location, Job details such as skills, openings, salary range and Job description. The exam module allowsthe operator to create an exam with attributes like exam title, company name, exam logo and exam description.

C. Candidate module

The candidate module contains information of thousands of candidates, this module allows operators to add new candidate information to the software including the candidate's personal details like gender, date of birth, work experience, full name, email address, Salary expectation and skills. The candidate module also saves documents relatedto the candidates like the candidate's profile picture, resume, Identification file, voice sample and other files. The candidate module saves candidates' contact information like their address and phone number along with other details of their social media profile, Visa validity, higher education and other jobs the candidate has applied to.

D. Resume Screening Module

The resume screening is another crucial part of the software which in turn helps to shortlist candidates from the wider pool into a group of people with thelist of skills required in the Job. The resume screening module uses data from the candidate module and the exams/job post module to get resumes and required skills respectively.

V. DATABASES

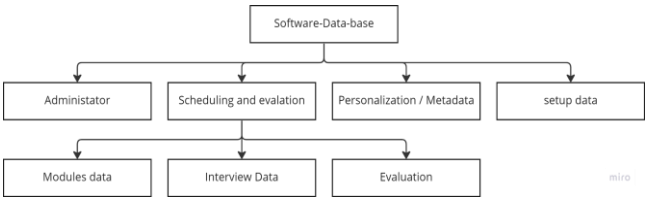

fig. 1 Database Structure

Before continuing with further modules & the functioning of the software it is crucial for us to understand the structure of the Database and itsunderlined components and to see the data flowbetween the modules. We are using a non-relational document database[8] that provides support for JSON-like storage. This storage has a flexible data model that enables users to store unstructured data as it provides full indexing support with replication with rich and intuitive APIs. The database can be distributed into four main subdivided and independent databases to focus on various aspects of the system such as administration, session planning, main data storage, metadata storage, website hosting, interview management, mediastorage and media processing[8].

A. Administrative Database

The first one of these databases is the administration database which contains information

about the clients who mainly consist of colleges and companies. This database also contains customer counters, customer manuals, website domain data and data about the various users(operators, owners and administrators). The administration database contains four sub-sections. The Website subsection contains information pertaining to the website attributes such as domain data, hosting data front-end and back-end files and stylesheets. The customer subsection contains data of the customer like the colleges and companies who have attributes like id, name, locations, requirements, openings etc. Customers also have their unique Ids and credentials which are stored in the next subsection which is Authorization. The authorization subsection contains Ids, email addresses and hashedpasswords of the various users like the owners, administrators and customers. Finally, the last subsection of the administrator database contains a manual, descriptions, and walkthroughs for the maintenance and administration of the software.

B. Scheduling and evaluation database

The second database is for scheduling and evaluation. This is the largest database in the software which contains data collected from different modules, the interview data and the evaluation data. The data from the modules have information about the candidates, the job posts, the exams, the QA banks and the resume screening. The interview data is a collection of files, readings and recordings taken during the interview/exam process. This includes the interview video media file, the email data, the session data, the candidate user preferences and the interview answers. The evaluation section of the scheduling and evaluation database contains files for AI face evaluation which contains gaze tracking and expression evaluation. Along with this, we have a subsection for AI speech evaluation which contains the evaluated data for the speech rate and speech-to-text function. The evaluation section also stores data for the weighted and grammatical evaluation of the descriptive answers and data collected from the Anti-Cheat-window detection system.

C. Personalization Database

The next database is for the generated data from user interactions during their subsequent sessions. This database contains the personalization and metadata about candidate settings and preferences, user settings and preferences, user-signup timings and session information.

VI. SCHEDULING AND INTERVIEW PROCESS

The Scheduling part of the scheduling andInterview process is handled by the scheduling module. The scheduling module allows the operator to schedule an interview/exam for the selected job post or exam. The operator is required to fill in a due date and time and specify the nature of the interview. The screened and shortlisted candidates can then be notified and added for the scheduled interview. The operator also has to add the required interview/exam questions from the QA bank. The scheduling module then proceeds to email the candidates a notification regarding the interview. By following the link the candidate can then proceed to join the exam/interview.

The exam/interview takes place on the browser in a room generated using peer-to-peer connections between the hosted server and the candidate's device. The system only allows connection once via the link[9], through a set of secure browsers like Google Chrome which allows for the use of our anti-cheat software[3]. This method is similar to the rooms created in popular services like google meet. Once the Candidate has joined they undergo a set of protocols which checks and validates their hardware[3], in order to fulfil the requirements posed by the system for the exam/interview. These protocols include the validation of their camera, microphone, screen-sharing, window-lock, facial image capture[3] and voice sample confirmation[10]. The candidate can also confirm the language settings for the rest of the interview. They are also requested to open their task manager and end all the other application tasks such that the exam/interview process is more efficient and free of any malware interference. Once the candidate has performed all these validations they are allowed to start their exam/interview. The timer turns on once the interview/exam is started. The candidate has to then complete their interviews while being monitored by the gaze tracking and expression detection software[3]. A human proctor can also enter the interview at any time to add new questions

or ask other questions while the scheduled interview is taking place. The human proctor is mainly the operator who scheduled the interview and they can join by clicking the link for the interview/exam in the scheduled section of the website. Once they click, they join the interview via the server and generate another peer-to-peer connection on the server side. Our interview/examination module is equipped with an online compiler that runs the coding questions with regard to the set timeouts and test cases. These compilers handle several programming languages like Python, Java, C++ and can also run SQL queries.The exam/interview is concluded once the time runs out or if the candidate answers all questions and ends the process or if the human proctor closes the interview.

VII. EVALUATION

The Evaluation Module displays the information collected during the interview about the completion of the exam/interview[3]. It gives technical feedback on the candidate's performance and evaluates their score for every question. The Evaluation module comes with several features containing Artificial Intelligence powered evaluation techniques[3]. It matches the candidate's photo id with their on-camera face[3]. It also compares the candidate's pre-recorded voice with the interview voice[10]. The Evaluation module displays details about any suspicious softwaredetected while conducting an Interview/exam[3]. Suspicious software includes any software that alters the transmission of the video feed, or records the screen or another window/tab opened while taking the interview[3]. The interview module displays the result from Gaze tracking[3] done during the interview. It performs post-interview processing of the interview/exam video feed and evaluates the candidate's facial expression to track their confidence and focus[3].

VIII. WEB-RTC

Web-RTC[1] comprises a set of novel technologies which allow the embedding of audio and video communications between applications. It allows browsers to exchange media information in a peer-to-peer fashion.

A. Web-RTC Architecture

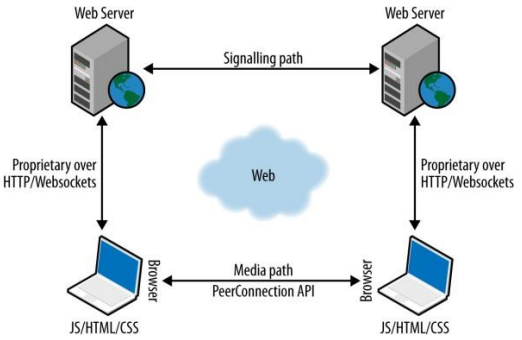

Fig. 2 Web-RTC Architecture.

For the implementation of the WebRTC Trapezoidconcept, a web application that is downloaded from a separate web server is running in both browsers. Communications are started and stopped using signalling messages. They are sent across web servers using the HTTP or WebSocket protocol, where they can be edited, translated, or managed as necessary. It is important to note that WebRTC does not standardise browser-to-server signalling because it is viewed as an integral component of the application. A peer connection, which affects the data stream, enables media to move between browsers without the need for intermediary servers. A common signalling protocol, such as SIP or Jingle, can connect the two web servers (XEP-0166). If not, they can employ a private signalling protocol.

B. Implementation of WebRTC for an Interview Web Application.(topology)

For the implementation of an online interview system, a peer-to-peer connection has to be established between the interviewees and interviewers, and the audio and video streams generated also have to be stored on the server. Using the traditional topology of peer-to-peer connections in a room we end up with a mesh topology in which the server, as well as the users, have to sustain large bandwidth while the interview is taking place. We assume that the devices of the users(candidates and proctors) cannot handle large bandwidth. Thus, we adopt a star topology[] with the server at its centre and peer-to-peer connections between every user and the server so that the burden of streaming large amounts of data is passedon to the server rather than the user.

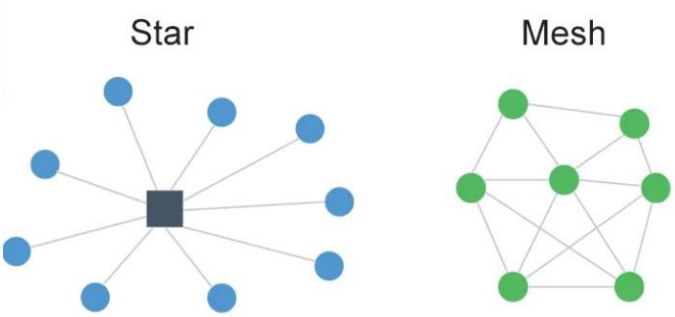

Fig. 3 Star Topology and Mesh Topology

For the system, mesh topology[] proves to be difficult to scale. This is because of the increased load on candidates and proctors. Each user must constantly be active to relay messages across the mesh and the large relay of traffic on one node of the mesh. This will quickly drain the capacity of the node. Thus, to solve this problem we use star topology which makes it easy to add new nodes as it is easier for installation and reconfiguration of the streams and it is more reliable as nodes are independent of each other. Failure of one will not affect the functioning of the overall network.

C. Bandwidth requirement for the video stream.

Thus, we get a UDP[11] transfer network in which a large amount of data is transferred to and from the server. This data usually consists of two video streams, one from the webcam of the candidate/proctor and one from the shared screen of the user. For our software, we have assumed that these streams have a video quality of 720p and a refresh rate of 30fps. For two such streams this results in a bandwidth requirement of 5.36Mbps and 7.0 Mbps for uploads.

D. Maximum Scenario

Depending on the number of connections between the users and the likelihood of the proctors sharing their screen and video we obtain 3 possible scenarios. A maximum scenario in which each of the proctors is sharing their screens and webcam feed with each of the other proctors and the candidate.

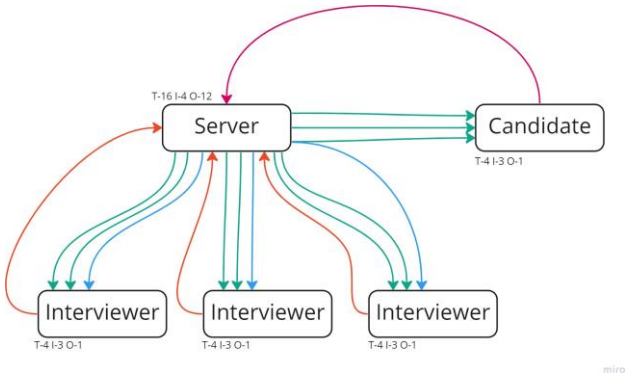

Fig. 4 Maximum Scenario with all proctors sharing their screens.

As we can see in fig.3, the magenta arrows indicate the UDP streams coming from the candidate to the server, the orange streams coming from the proctors to the server and the green, and blue arrows indicate the output streams relaying the video streams to the users from the proctors and candidates respectively.

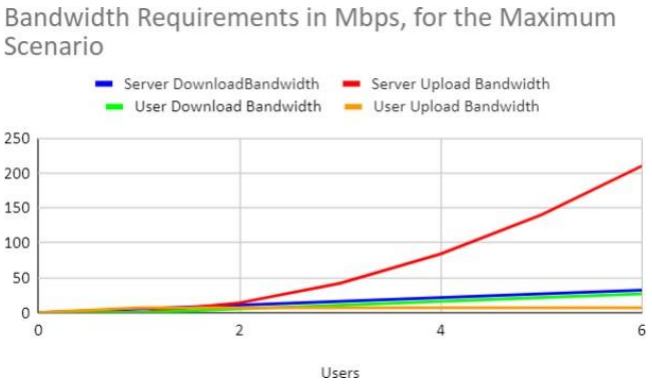

Fig. 5 Graph showing the Number of users vs Bandwidth requirement for the maximum scenario.

As you can follow from this chart, the server uploadbandwidth increases at the rate given by the formula

$$2 \times UPBW \times (N^2 - N)$$

N: Number of users

UPBW: Upload bandwidth (3.5 Mbps||for a stream of 720p 30fps)

Similarly, the server download bandwidth can beshown using this formula

$$2 \times DLBW \times N$$

DLBw: Download bandwidth(2.69 Mbps||for a stream of 720p 30fps)

The user upload bandwidth remains constant, at thevalue equivalent to

$$2 \times UPBW$$

as each user only uploads two video streams each but the user download bandwidth increases with a rate of

$$\text{DLBW} \times 2 \times (N - 1)$$

as each user will download the stream of everyother user.

E. Minimum Scenario

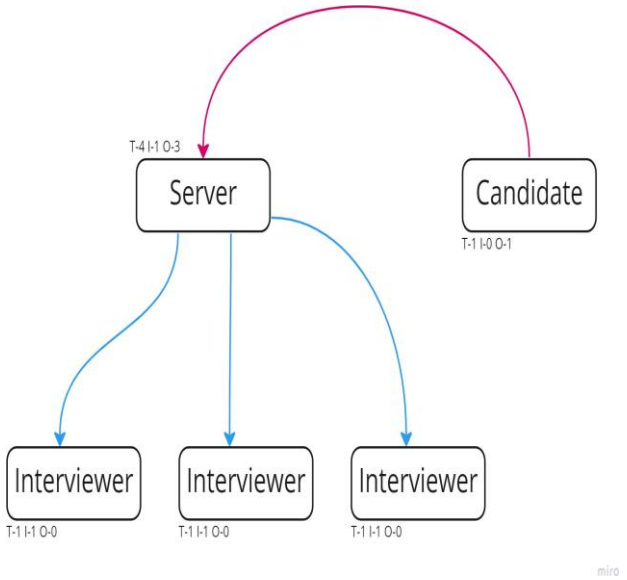

Fig. 6 Minimum Scenario with only candidate sharing video stream.

Fig. 5 shows the minimum scenario in which only the candidate is sharing their screen and webcam feed while the proctors only receive the stream.

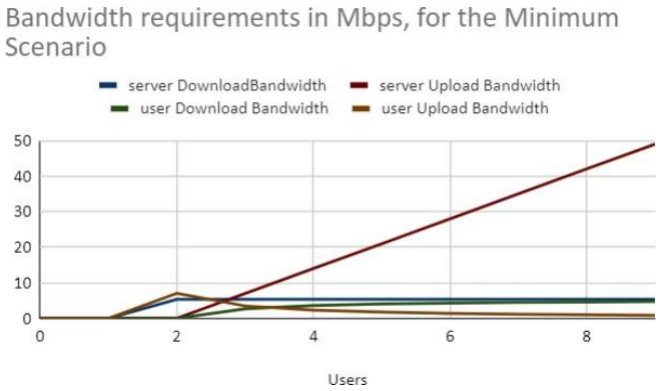

Fig. 7 Graph showing the Number of users vs Bandwidth requirement for minimum scenario

In this scenario, the number of input streams of the server remains constant and thus the bandwidth download bandwidth requirement for the server
also remains constant at 2 × DLBW. The number of upload streams from the server increases linearly with the increase in the number of proctors at the rate of

$$2 \times \text{UPBW} \times (N - 1)$$

The total user(proctor and candidate included) upload bandwidth per user decreases as each new user joins as only the candidate is sharing the stream. While the total download bandwidth peruser remains mostly the same.

F. Average Scenario

Both of these scenarios are extreme cases and extreme examples of user behaviour. In reality, the proctors would sometimes share their webcam feed and screens. Thus, the mean or average of both of these extreme scenarios is used to stimulate the average behaviour during the interview/exam process. The figure below represents one such case for an average scenario interview with three proctors.

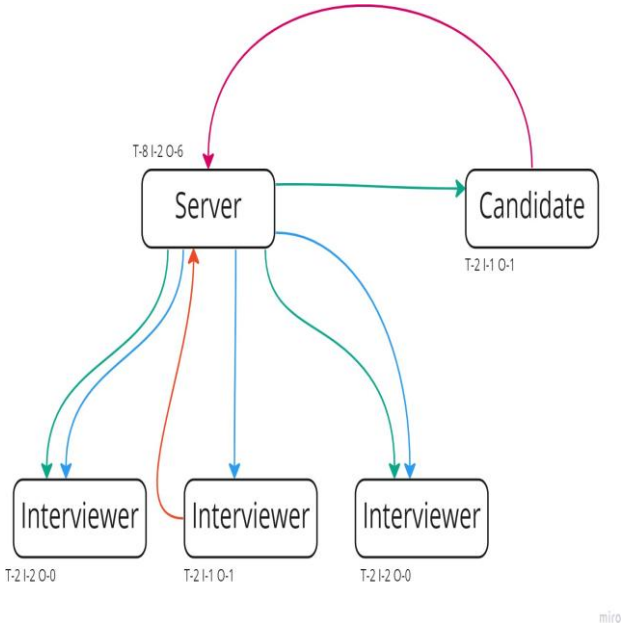

Fig. 8 Average Scenario with some interviewers sharing their video streams.

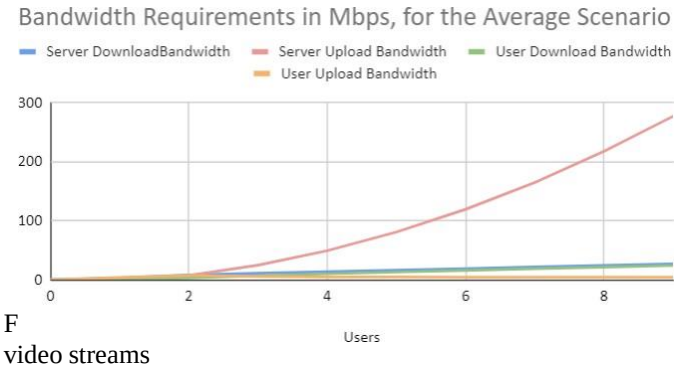
fig.7 is the graphical representation of the bandwidth requirement in Mbps in the assumed median scenario for varying numbers of users givenby the common formula of

$$(\text{MaxBW} + \text{MinBW})/2$$

MaxBW: Maximum bandwidth
MinBW: Minimum bandwidth



F
video streams

IX. RATE OF MONITORING

In the real world, the system should be capable of conducting multiple interviews and exams simultaneously. Each one of those interviews/exams would have one candidate and their connection to the server. The number of interviewers/proctors joining the interviews may vary according to the organisation's requirements. Our system is built as such to allow for a single proctor to join any interview as needed. There can also be multiple proctors joining a single interview to monitor the candidate's conduct. Therefore, to calculate bandwidth requirements for an average interview in the system, we must know the number of proctors joining each interview. This can be done by simply calculating the rate of monitoring. The rate of monitoring(Rm) is the number of proctors over the number of ongoing interviews. It is important because it directly affects the server download and upload speeds. The effect of the rate of monitoring on the bandwidth requirement can be directly seen using this chart.

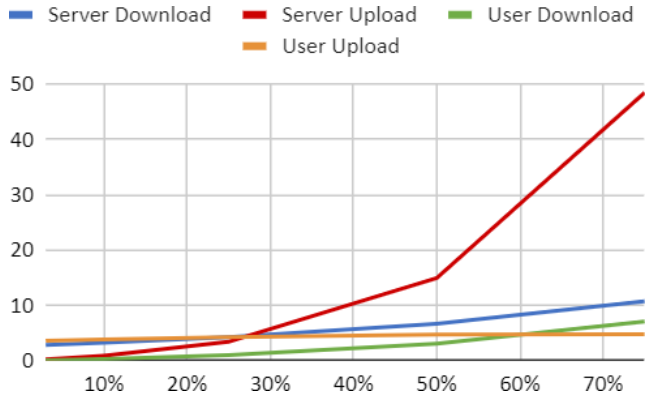


Fig. 10 Graph showing the Rate of monitoring vs Average Bandwidth Requirement.

Here, the x-axis is the rate of monitoring and the y-axis is the average bandwidth requirement per interview(maximum of 8 proctors) in Mbps. The average bandwidth requirement per interview for a maximum of 8 proctors is calculated using this formula,

$$\sum_{n=0}^{n} R_n \times Bn / \sum_{n=0}^{n} (Rm_n)$$

n: Number of proctors
Rm: Rate of monitoring
Bn: Bandwidth required for 'n' number of proctors.

as the server upload bandwidth increases at the rate of $x \times (x - 1)$ and is not convergent for higher rate of monitoring. One can adjust the values of the rate of monitoring and the number of users to find the optimum mix. For our calculations, we have taken the value of a 5% rate of monitoring and a maximum limit of 8 proctors[12]. The system can still work fairly well up to a 25% rate of monitoring. Beyond that, the bandwidth requirement rises exponentially.

X. MEMORY REQUIREMENT AND COSTING

Our system is designed to store designated data of the interviews/exams in cloud storage. We have used the model of S3 storage given by Amazon AWS[13] to determine the memory costs of runningthis system at scale. In the previous passage, we used the monitoring rate to calculate the average bandwidth requirement of the interviews. Using this, we can estimate the total memory required to store the video footage for the interviews in our system. Our system uses three types of storage, the first is Amazon S3 Standard infrequent access- For long-lived but infrequently accessed data that needs millisecond access which has a per month cost of $0.0125/GB. The second one, Amazon's S3 Glacier Flexible Retrieval (Formerly S3 Glacier)***- For long-term backups and archives with a retrieval option from 1 minute to 12 hours which has a per month cost of $0.0036/GB Finally, the last type of storage used is Amazon's S3 Glacier Deep Archive*** - For long-term data archiving that is accessed once or twice in a year and can be restored within 12 hours with a cost of $0.00099/GB. Forthe 720p 30fps footage of webcam and screen recording, for an average of 5% rate of monitoring with a maximum of 8 proctors per interview, we get the per hour memory collection of 10.388GB using this formula.

AvgIHR = Average DLBW × 60 × 60 / 1024 .

where the *Average DLBW* for the server is equal to 2.95Mbps and the *Average UPBW* for the server is equal to 0.397 Mbps. We are using the standard infrequent access memory to store the data of the interview for one day during which it will be processed to check for expressions tracking, facial recognition, gaze tracking and screen monitoring. Then the data would be transferred to the Glacier flexible retrieval storage so that the user can access it within the set period of 1 month. This would result in a cost of $0.04172 per hour of an interview using the formula,

$$\text{Memory Cost} = \text{AvgIHR} \times ((\text{SIAM}/30) + \text{GFRM}) 10.388 \times ((0.0125/30) + 0.0036)$$

AvgIHR: The net data consumption for an average interview for a specific rate of monitoring. (here 5%)
SIAM: Standard Infrequent access per GB per month
GFRM: Glacial Flexible Retrieval per GB per month

We can also store data in the Glacier Deep Archive for each additional month at a cost of $0.010284 per hour of interview.

XI. DATA TRANSFER AND PROCESSING COST:

While the data incoming from the internet to EC2is free, we sustain a $0.05 per GB cost for sending data out from Amazon EC2 to the internet. This totals up to $0.0697 per interview hour for our system. Along with this, we must also account for the cost of running the instances. Each instance of m6in.32xlarge in Amazon EC2 provides the user with 128 core vCPU, 512 GB of RAM, a bandwidth of 200GBps and instance storage of elastic capacity with a bandwidth of 80GBps. For each interview, we estimate to require up to 0.008 of such instances when we account for the processing requirements ofthe various AI tools, Video Streams and other processing tasks. The cost of one of these instances is equal to $8.91072 per hour. This amount totals
$0.00718 per hour of interview.

XII. RESULTS AND DISCUSSION

The above discussion focused on the various costs involved with taking these online interviews at scale using our interview system. The total cumulative technical running costs of taking these interviews through our system amounts to a sum total of $0.11856 per interview hour at a 5% rate of monitoring using the formula:

$$\text{Total Cost} = \text{Memory cost} + \text{Data-transfer cost} + \text{Instance cost}.$$

To understand how this might be beneficial to a company transitioning to our AI-based interview system, we need to focus on finding if this switch would result in a more efficient hiring process. To measure success, the company would be using ‘the number of hours saved’ as the main indicator. Thus a cost-benefit analysis could be used to prove that our system is better than the traditional method.
To do this, we will use the example of company X wishing to interview 5000 applicants for an opening of 50 posts. Our AI-based resume screening system could first help them shortlist about 4000 out of those 5000 candidates to be taken in for the interview. Out of these 4000 candidates, 100 could be shortlisted after the first round of technical(online) interviews to fill in for the final round of in-person interviews lasting about 1hr. Let us suppose that the company has a team of 20 staff members to conduct the interviews. If each primary interview takes 4 hours of time. Then based on this calculation, while using our system at a 5% rate of monitoring it would take about 10 batches to complete the interview process and about 16000 hours of total interview time. If we multiply it by the system’s cumulative operational costs of $ 0.11856 we get a total cost of $1896.973 for the interviews plus $164.55 cost of each additional month of storage. While this might seem expensive we should also take into consideration the total amount of working hours saved by the recruitment team.
Using our system with a 5% Rate of monitoring, it will take the interview team 10 batches(4000*0.05/20) of 4hr interviews in the primary round and use face-to-face interviews for the next 5 batches(100/20) of the 1hr of final round interviews, it would take the interview team of 20 people a total of 45 working hours to complete the interviews, which is approximately 5.625 working days.
While using the traditional method of only taking one on one interviews. would take the same team,

200 batches(4000/20) of 4 hrs to take the primary round and 5 batches(100/20) of 1 hr final round, resulting in a total of 805 working hours or 100.625Working days to complete the task. Thus in this given example, the total resultant time saved is equal to 15200 working hours which is equal to 760 hours for each member of the 20-member recruitment team, which is about 95working days(each of 8 hrs) saved per teammember.

Thus even while considering the additional operating costs, support costs and maintenance costs and time required for scheduling the interviews(maximum 5 hrs) we should be able to at least see 93%+ time-saving in the whole interview process for the recruitment teams for a maximum cost of approx $0.45per interview(4hr each) in the given hypothetical example.

XIII. CONCLUSIONS

From this research we have not only provided the reader with a complete description of our software along with its modules and databases but we have also given a detailed summary of the mechanism, topologies and technologies used in building this system. We have done a comprehensive study of thecosts that go into operating these mechanisms on a per-interview/exam basis and we have compared it with the traditional methods to obtain meaningful insights about the effectiveness of using our system.The descriptions included in this paper covers Browser based gaze tracking and facial recognition, Memory calculations for big data models, Star topology-based study of UDP peer-to-peer connection bandwidth requirements, calculations related to the rate of monitoring etc. We have also uncovered the mechanisms around one of the most crucial technologies that is Web-RTC and have provided a summary of a hypothetical example of how such a technology can provide a cost and time-efficient mechanism for conducting interviews and exams in the real world while reducing the risk and cheating discrepancies associated with web browser based online interviews and exams.

XIV. ACKNOWLEDGMENT

This paper would not have been possible without the unwavering support from Hiringtek.inc and Thakur College of Engineering and Technology's Computer Engineering Department. We would like to give special thanks to our guide and mentor Dr Megharani Patil(Associate Professor - Computer Engineering Dpt and I/C HOD of AI & ML) and Director of Development and Quality Assurance at HiringTek Pvt. Ltd Mr S.P. Laxman.

Abstract— **This research paper focuses on the development of a system that can assess physiotherapy exercises to ensure that patients are performing them correctly and avoiding injury. The system uses modern technology to estimate the geometry of a person performing an exercise in a video uploaded by the user. The OpenPose model is used to extract points from the video, and the system provides feedback to the user on the accuracy of their performance. Physiotherapy is an important medical science that helps patients recover from injuries and improve their potential through controlled exercises. However, many patients face difficulties in accessing physiotherapy sessions due to factors such as cost, availability, and accessibility. This can lead to patients attempting to perform exercises on their own, which can worsen their conditions. The proposed system acts as a personal virtual trainer that guides patients, provides instant feedback, and helps them perform exercises correctly on their own. The objective of this project is to help patients perform exercises correctly, avoid injury due to incorrect posture, and explore existing systems to validate the proposed results. The system uses MediaPipe models for pose detection and dynamic pose detection through the OpenPose network. It provides real-time pose correction with the help of virtual assistance. The system can detect the most common exercises and can function on any Windows system with a GPU. By providing patients with accurate feedback on their exercise performance, the system can help them recover faster and avoid injury. The proposed system has the potential to revolutionize the field of physiotherapy by making it more accessible and affordable for patients. In conclusion, this research paper proposes a system for assessing physiotherapy exercises that can help patients perform exercises correctly, avoid injury, and recover faster. The system uses modern technology and machine learning to provide real-time feedback and correction to patients performing exercises on their own. The proposed system has the potential to improve the accessibility and affordability of physiotherapy for patients, and it could have a significant impact on the field of medical science.**

Keywords— ***Physiotherapy, OpenPose, MediaPipe , GPU, affordability***

I. INTRODUCTION

Physiotherapy is a medical science that helps individuals recover from injuries and disabilities through controlled exercises.[1] These exercises are typically performed in a clinic under the guidance of a therapist, who provides verbal or physical instructions to ensure the patient performs the exercise correctly. However, accessing physiotherapy sessions can be challenging for many individuals due to factors such as cost, availability, and accessibility. This can lead to patients attempting to perform exercises on their own, which can worsen their conditions or lead to injury. To address this issue, this research paper proposes a system for assessing physiotherapy exercises that can help patients perform exercises correctly, avoid injury, and recover faster. The proposed system is a personal virtual trainer that guides patients, provides instant feedback, and helps them perform exercises correctly on their own. The system uses modern technology to estimate the geometry of a person performing an exercise in a video uploaded by the user.[3] The OpenPose model is used to extract points from the video, and the system provides feedback to the user on the accuracy of their performance. MediaPipe models are studied for pose detection, and the system is developed for dynamic pose detection through the OpenPose network. It provides realtime pose correction with the help of virtual assistance. The objective of this project is to help patients perform exercises correctly, avoid injury due to incorrect posture, and explore existing systems to validate the proposed results. The system can detect the most common exercises and can function on any Windows system with a GPU. By providing patients with accurate feedback on their exercise performance, the system can help them recover faster and avoid injury. In recent years, motion recognition research based on machine learning has developed cost-efficient, accurate, and stable action recognition systems from video data in controlled environments. These systems have the potential to revolutionize the field of physiotherapy by making it more accessible and affordable for patients. The proposed system can also benefit therapists by allowing them to remotely monitor their patients' progress and provide feedback on their exercises. This can help therapists provide more personalized care to their patients, and improve the overall effectiveness of physiotherapy treatments. There are several challenges involved in developing such a system. One of the main challenges is the accuracy of the pose detection models. The OpenPose model used in this system has been trained on large datasets and has been shown to have high accuracy in detecting poses in images and videos. However, there may still be cases where the model fails to detect the correct pose, leading to incorrect feedback for the user[4]. Another challenge is the development of a user-friendly interface that can be easily used by patients. The system should be easy to navigate and provide clear instructions to the user. The feedback provided by the system should also be easy to understand, even for individuals who are not familiar with physiotherapy exercises. To validate the proposed system, existing systems in the field of motion recognition and physiotherapy should be explored. The proposed system should be compared to these existing systems to assess its accuracy, usability, and effectiveness in helping patients perform exercises correctly[9]. In conclusion, the proposed

system for assessing physiotherapy exercises has the potential to revolutionize the field of physiotherapy by making it more accessible and affordable for patients. By providing patients with accurate feedback on their exercise performance, the system can help them recover faster and avoid injury. The system can also benefit therapists by allowing them to remotely monitor their patients' progress and provide feedback on their exercises. The development of such a system is not without its challenges, but the potential benefits to patients and therapists make it a worthy endeavousrs. .

In this paper ,the proposed system act as a personal virtual trainer that would guide , provide instant feedback and helps them to do exercise by themselves

1.1) Project Objective:

The objective of project are as follows:

- To help the patient to do the exercise correctly.
- To avoid the injury to the patient by doing wrong posture .
- MediaPipe models are studied for pose detection.
- To explore the various existing system and validate the proposed result.
- The approach is developed for dynamic pose detection by already trained OpenPose network.
- It provides current pose correction with help of virtual assistance.

II. LITERATURE SURVEY

Automatic squat posture classification and physical exercise correction using deep learning and machine learning approaches. In one study, traditional machine learning was compared to deep learning for squat posture classification using inertial sensors. The study found that a combination of five inertial measurement units (IMUs) mounted on different body parts collected data on acceleration and gyroscope, and deep learning produced better results than traditional machine learning. Another study introduced a pose trainer app that uses modern pose estimation technology to evaluate the vector geometry of a user's exercise pose and provide feedback to improve their form. Additionally, a convolutional neural network was used to classify images of three categories of physical exercise postures: hips to low, hips to high, and proper. The neural network worked in realtime through a smartphone app and provided solutions for posture correction in various environmental situations. Another study used deep convolutional neural networks for video analysis of human pose detection, which presented a

unique method for automated speech-based depression screening[14]. The researchers conducted extensive tests on the distress analysis interview corpus (DAIC) to demonstrate the use of their categorization system and assess the outcomes. The problem statement presented in this project addresses the challenges of receiving proper medical attention during the COVID-19 pandemic when people may be hesitant to visit hospitals for fear of contracting the virus.[3] As a result, many individuals may turn to personal trainers for physical therapy, but the cost may be too high for some. This situation has resulted in an increased need for athome exercise correction and posture evaluation. The proposed work aims to address this issue by utilizing a pretrained real-time system called OpenPose for pose estimation and posture evaluation component recorded videos of correct and incorrect exercises to evaluate posture identifier. The authors also proposed the use of dynamic time warping (DTW) to balance the key points of the same exercise to compare data sets. The dataset focused on eight shoulder and knee exercises performed by actors with different postures and frequencies. The system utilized four exercises to improve posture and eventually recover from injuries. Overall, the literature survey highlights the potential of using deep learning and machine learning approaches for physical exercise correction, posture evaluation, and classification of physical exercise postures. These methods can be used to enhance at-home exercise programs and aid in injury prevention and recovery.

The use of machine learning techniques for the recognition of human actions has gained significant attention in recent years. In particular, the use of convolutional neural networks (MediaPipe s) has shown promising results for pose detection in videos. Pose detection involves estimating the 2D or 3D coordinates of the human body joints from an image or video. The extracted joint coordinates can then be used to determine the pose of the human body, which can be further used for action recognition and assessment. One of the popular deep learning models for pose detection is the OpenPose model. It uses a multi-stage MediaPipe architecture to estimate the joint locations of the human body. The model has been trained on a large dataset of human poses and can detect the pose of a human body in real-time. Several studies have explored the use of the OpenPose model for various applications such as human activity recognition, sports analysis, and physiotherapy exercises assessment. A study by Huynh et al. [1] proposed a physiotherapy exercise assessment system using the OpenPose model. The system used a Kinect camera to capture the patient's movements, which were then processed by the OpenPose model to estimate the joint coordinates. The system provided real-time feedback to the patient by comparing their movements with the correct posture of the exercise. The study showed promising results in terms of accuracy and usability of the system. Another study by Huang et al. [2] proposed a virtual reality-based physiotherapy exercise system using the OpenPose model. The system used a virtual reality headset and motion controllers to simulate the physiotherapy exercises. The OpenPose model was used to track the patient's movements and provide real-time feedback on their posture. The study showed that the virtual reality-based system was more engaging and effective than the traditional physiotherapy exercises. A recent study by Li et al. [3] proposed a deep learning-based physiotherapy assessment system using a combination of the OpenPose model and a recurrent neural network (RNN). The system used the OpenPose model to extract the joint coordinates from the video, which were then fed into the RNN for action recognition and assessment. The study showed that the proposed system outperformed other state-of-the-art methods for physiotherapy exercises assessment. Overall, these studies have shown that the use of deep learning models such as the OpenPose model can provide accurate and real-time assessment of physiotherapy exercises. The proposed project aims to build on these studies by developing a system that can assist patients in performing the exercises correctly and avoiding injuries due to wrong postures. In addition to the OpenPose model, other deep learning models such as the Spatial Temporal Graph Convolutional Network (ST-GCN) and the Graph

Convolutional Network (GCN) have also been used for pose detection and action recognition in videos. These models have

shown promising results for various applications and can be explored in future research work.

Automatic Squat Posture Classification Using Inertial Sensors: A Deep Learning Approach [1]. Traditional machine learning is use to compare deep learning squat posture .Supplementary, sensor installation is done on the best site. 39 healthy subject were selected and Five (IMUs) inertial measurement units which are mounted on left thigh, right thigh, left calf, right calf, and lumber area so that they can collect data accelerometer and gyroscope. Each subject was asked to do six reps of correct squat and six reps of wrong squats which is standard among the beginner exercisers. The result comparison is done through deep learning and traditional machine learning. One inertial measurement units, or a combination of two or five inertial measurement units ,were operated to get each result. Pose Trainer: Using Pose Estimation to Correct Exercise Posture [2]. User exercise pose is identified using new app, Stance Trainer that give individualized detailed recommendations to improve the user form. Modern pose estimation technology which evaluate the vector geometry of pose that will deliver useful feedback by the exercise. Neural Networks for Physical Exercise From Correction [3]. Hips to low ,hips to high and proper are 3 category in which convolution neural network classify images. The real-time posture correction input is given by neural network which works through smartphone app. Various environmental situations are choosen to assess the performance of system and solution is provided by convolutional neural network. The trained network is in the mobile network. Deep learning and neural network based computer vision approaches[4]. Deep neural network is used for video analysis of human pose detection.

III. PROBLEM STATEMENT

The COVID-19 pandemic has caused a shift in healthcare practices and has affected the way people access medical care. Due to the fear of contracting the virus in hospitals or clinics, patients are less likely to seek medical attention for non-COVID related issues, such as physical injuries. This has created a problem for those who have suffered physical injuries but are hesitant to visit hospitals or clinics due to the pandemic. Moreover, personal trainers or physiotherapists may charge high fees that are not affordable for everyone. As a result, there is a need for an affordable and accessible solution for those who need physiotherapy or rehabilitation services. In addition, injuries can occur not only due to accidents but also during exercise or physical activities. Some injuries may result from improper posture or incorrect execution of exercises. For example, lifting heavy weights without proper guidance or not performing warm-up exercises before an intense workout can lead to muscular injuries or joint problems. Therefore, it is important to ensure that individuals exercise with proper form to prevent injuries and to recover from them. To address these issues, the proposed solution is to develop an automated system for posture correction and evaluation. The system will be designed to monitor and correct the user's posture during exercise or physical activity using sensors and machine learning algorithms. The user will receive real-time feedback on their posture and form, which will help them to exercise with proper form and avoid injury. To achieve this goal, the system will use inertial measurement units (IMUs) to collect data on the user's movement and posture. IMUs will be placed on various body parts, such as the left and right thighs, calves, and lumber area, to capture data on the user's posture and movement during exercise. The data collected by IMUs will be analyzed using machine learning algorithms, such as deep neural networks and convolutional neural networks, to identify the user's posture and provide real-time feedback on their form. This feedback will be delivered through a smartphone app, which will provide individualized recommendations to improve the user's form and posture during exercise. Moreover, the system will use pose estimation technology, such as OpenPose, to detect human body keypoints in videos. This will enable the system to accurately evaluate the user's posture and form during exercise. The system will also use dynamic time warping (DTW) to compare key points in the data set and measure the nonlinear similarity between two time series. This will help to ensure that the system can accurately match the user's movement with the correct exercise and provide real-time feedback on their form. The proposed system will focus on exercises that are commonly associated with injuries, such as those involving the shoulder and knee. The system will utilize a home-based physiotherapy exercise dataset, which includes eight exercises focused on the shoulder and knee. The dataset includes videos of actors performing the exercises with different postures and frequencies, and both RGB and gray-level videos will be stored. The system will focus on four exercises to ensure that the feedback provided is accurate and relevant to the user's needs. In conclusion, the proposed solution aims to provide an affordable and accessible system for posture correction and evaluation that can be used by individuals to exercise with proper form and avoid injury. The system will use sensors and machine learning algorithms to monitor the user's posture and provide real-time feedback on their form. The system will also use pose estimation technology and DTW to accurately evaluate the user's posture and match their movement with the correct exercise. With this system, individuals can exercise safely and effectively, even during the COVID-19 pandemic, without the need for expensive personal trainers or physiotherapist

The system is designed to be affordable and accessible, allowing people to exercise safely from home without the need for expensive personal trainers or physiotherapists. The system consists of five inertial measurement units (IMUs) mounted on the left and right thighs, left and right calves, and lumber area of the back. These IMUs collect data from accelerometers and gyroscopes, which is then analyzed by deep learning algorithms to classify exercise form into correct or incorrect categories. Users can receive feedback on their form in real-time through a smartphone app, which offers individualized recommendations for improving form. To ensure accurate posture classification, we compared the performance of deep learning algorithms to traditional machine learning algorithms. We found that deep learning algorithms outperformed traditional machine learning algorithms when using one, two, or all five IMUs. Our system is therefore designed to use deep learning algorithms for accurate posture classification.[9] To further improve the accuracy of our posture correction system, we utilized a pretrained real-time system called OpenPose for pose estimation. OpenPose is a state-of-the-art pose estimation algorithm that can detect human body keypoints in videos. By using OpenPose, we can focus on the actual evaluation of exercise posture rather than developing a pose estimation algorithm from scratch. We recorded videos of ourselves performing exercises, including our best effort to perform the exercise correctly and intentionally incorrect examples. We evaluated our posture identifier in different ways depending on the algorithm. For heuristic algorithms, we fed in all videos

for evaluation, while for machine learning algorithms, we evaluated by splitting our video dataset into train and test sets and reporting results on the test set. To balance the key points of the same exercises, we used dynamic time warping (DTW) for comparison in the data set. DTW is a technique that measures the nonlinear similarity between two time series. It overcomes the problem of phase shift of two similar sequences and matches troughs and peaks with the same pattern, ensuring that there are no left-out points for both curves. DTW is applicable in systems like the stock market, computer vision, and our posture correction system. Our system focuses on four exercises from the home-based physiotherapy exercise dataset: seated legs, swing arms, circle arm, and static triceps. The exercises are performed with different postures and frequencies, and both RGB and gray-level videos are stored. By using this dataset and the DTW technique, our system can accurately classify exercise form and provide real-time feedback on how to improve posture. In conclusion, our automated exercise posture correction system aims to provide an affordable and accessible alternative to expensive personal trainers and physiotherapists. By using inertial sensors, deep learning algorithms, and OpenPose for pose estimation before you begin to format your paper, first write and save the content as a separate text file.

IV. Proposed Sysytem

As mentioned in the problem definition, there is a need for a system that allows patients to receive physiotherapy treatment without having to visit a hospital or clinic. This proposed system is designed to provide patients with exercises and proper posture to aid in their recovery from an injury. To use the proposed system, the user will need to have a camera set up to capture their body and the exercises they perform. The camera can be any type, and the video can be of any quality, as long as the user's body and exercises are clearly visible in the frame. The video can be adjusted using any software, and Open Pose software supports all video formats uploaded to the system. The Open Pose model is used to detect the key points from the video uploaded by the user, and the model can easily identify the key points from any format of the video. The model takes into consideration 17 to 18 points such as knee, eyes, hips, elbow, shoulder, feet, etc., making it easy to install and run without requiring a huge load of the system.

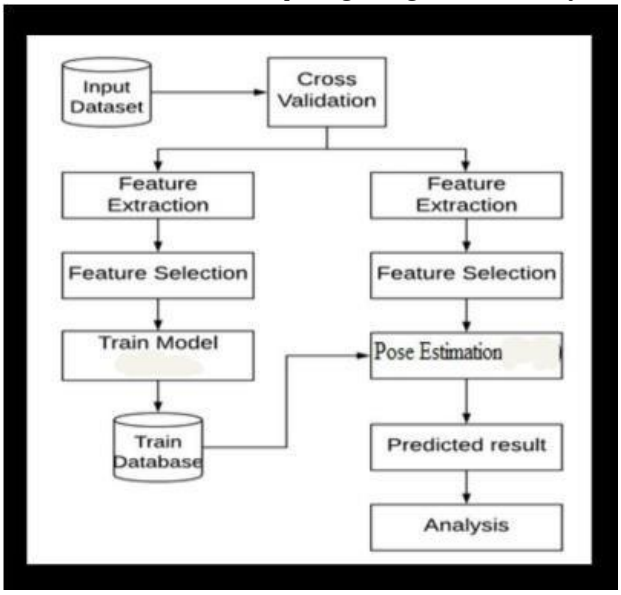

Figure1. The Architecture of Physioarc through mediapipe model.[7]

The output of Open Pose consists of predicted coordinates of key points for the user's body. As the system is used by users of different shapes, heights, sizes, weights, and distances from the camera, the accuracy and key point score can be largely affected by these factors. To minimize the effects of these factors, the sum of the square of the key is made equal to one by applying L2-Normalization on the key point obtained from Open Pose. To provide feedback to users, the system compares the user's key points with data key points, and generates feedback accordingly. The dynamic time feature of the system allows for real-time feedback to be provided to the user, making it easier for them to adjust their posture and exercises as needed. Overall, the proposed system provides a convenient and effective way for patients to receive physiotherapy treatment without having to visit a hospital or clinic.[8] By utilizing the Open Pose model and dynamic time feature, the system is able to provide accurate feedback to users of different shapes, sizes, and distances from the camera. The ease of use and convenience of the system make it a promising solution for those seeking physiotherapy treatment from the comfort of their own home.

The System we have designed is to treat the patient without visiting the hospital or clinic of physiotherapist. The patient will start felling better after doing proper exercises from the system and with proper posture and will eventually recover from the injury

The user of the system should have the camera setup which he/she can place where ever they want ,but the condition of placing the camera is that their body should be visible in the camera and the exercises they perform should be clearly visible in the frame of the video. There is no requirement for any type of camera or any special camera for this purpose just an ordinary camera can do the work effectively. The video can be of any quality but should satisfy the above mentioned condition. The video adjustment can be done by using any software. Open pose software do support all format of the video uploaded in the system. The key point extraction is done from the uploaded video by the user. The open pose model is use to detect the key points from the video uploaded by the users, the model easily identify the key points from any format of the video. Open pose takes 17 to18 point in consideration for the system which can be such as knee, eyes, hips, elbow, shoulder, feet, etc. the open pose is very easy to install and does not require any huge load of system to run and give the output on the system. The output of open pose which consist of predicted coordinate of key points for users body. The system is used by the users who are in different shape, height, size, weight and may be some would stand in different distance from camera .The accuracy and key point score can be largely affected by the all of those previous factors. The sum of square of key is made equal to one by applying L2-Normalization on the key point got from open pose. With comparison between users key point and data key point the feedback is generated for users. Human-Machine Interaction Principles consider for the roposed System[7].

Customizable User Interface: The user interface of the system should be customizable according to the needs of the patient. Neuro patients may have different levels of cognitive abilities and motor skills, so the interface should be designed to accommodate a wide range of users.

Visual Feedback: The system should provide visual feedback to the user during the exercise sessions. This could include a

video display of the correct posture or a graph showing the progress of the patient's performance over time. Audio Feedback: The system could also provide audio feedback to the user. For example, the system could give verbal cues to the user during the exercise session or provide motivational messages to keep the user engaged. Gamification: Gamification could be used to make the system more engaging and fun for the user. The system could include game-like elements such as rewards, achievements, and leaderboards to motivate the patient to complete the exercise sessions.

Virtual Reality: Virtual reality could be used to create an immersive environment for the patient during the exercise sessions. This could help to distract the patient from any pain or discomfort they may be experiencing and make the exercise session more enjoyable. Social Interaction: The system could also include social interaction features. For example, the patient could connect with other patients who are using the same system and compete with them on a leaderboard.

Cybersecurity concepts to consider for the roposed System Authentication and Authorization: The system should have a robust authentication mechanism to ensure that only authorized users can access the system. The system should use multi-factor authentication (MFA) to prevent unauthorized access.

Data Encryption: All data transmitted over the network should be encrypted to prevent eavesdropping and ensure data confidentiality. The system should use strong encryption algorithms such as AES-256 for data encryption. Secure Communication Protocol: The system should use secure communication protocols such as HTTPS, SSL or TLS to ensure that data is transmitted securely over the network. Secure communication protocols ensure that data is not tampered with or intercepted during transmission. Firewall and Intrusion Detection System (IDS): The system should be protected by a firewall and intrusion detection system (IDS) to prevent unauthorized access and detect any suspicious activity. The firewall and IDS should be configured to monitor incoming and outgoing traffic and prevent any malicious activity.

Regular Updates and Patches: The system should be regularly updated with the latest security patches and updates to ensure that any vulnerabilities are fixed promptly. User Awareness Training: The users of the system should be trained on cybersecurity best practices to ensure that they do not compromise the security of the system. Users should be trained on how to create strong passwords, avoid phishing emails, and how to recognize and report any suspicious activity.

Backup and Recovery: The system should have a robust backup and recovery mechanism to ensure that data is not lost in case of a security breach or system failure. The backup mechanism should be automated and should be regularly tested to ensure that it is functioning correctly. Overall, implementing these cybersecurity concepts can help ensure that the proposed system is secure and protected from cyber threats.

V. SYSTEM CONFIGURATION

System configuration for the proposed system:

Software:

Operating System: Windows 10 or Ubuntu 18.04 or later.
Programming language: Python 3.7 or later.
Deep learning framework: PyTorch 1.7 or later.
OpenPose library: version 1.6.0 or later.
Video processing library: Fmpeg 4.2 or later.
Web application framework: Flask 1.1 or later.

Hardware:

Camera: Any camera that can capture video and has a resolution of at least 720p. Computer: A desktop or laptop computer with a dedicated graphics card (GPU) that supports CUDA, and at least 8 GB of RAM.

The system can be deployed in a client-server architecture, where the user interacts with a web application running on a remote server. The server runs the deep learning models and processes the user's videos, while the client device (e.g., a laptop or a smartphone) captures the videos and displays the results.

The server should have the following configuration:

- CPU: Intel Core i5 or higher (or equivalent AMD processor). GPU: NVIDIA GeForce GTX 1060 or higher (or equivalent AMD GPU).
- RAM: at least 16 GB.
- Storage: at least 500 GB SSD.
- Internet connection: at least 10 Mbps upload and download speed.
- The client device should have the following configuration:
- CPU: Intel Core i3 or higher (or equivalent AMD processor).
- GPU: Intel HD Graphics 620 or higher (or equivalent AMD GPU).
- RAM: at least 4 GB. Storage: at least 128 GB
- SSD. Internet connection: at least 5 Mbps upload and download speed.

Note that these are minimum recommended specifications, and higher-end hardware may be required for better performance and user experience.

VI. TECHNICAL APPROACH

The PHYSIOARC application is a pipeline system consisting of multiple stages that enable users to receive feedback on their exercise form.[12]

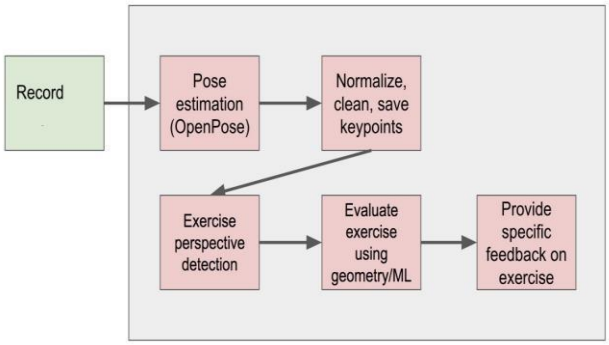

Figure 2. Pose Trainer system pipeline, as described in Technical Approach.[10] with the Pose Trainer application providing specific feedback on the exercise form to the user.

The pipeline begins with the user recording a video of themselves performing a selected exercise. The video is recorded from a specific perspective that allows the exercise to be seen, but there are no requirements on camera type or distance from the camera. The user then trims the video to include only the frames of the exercise, using whatever video recording and editing system they are most comfortable with. PHYSIOARC supports all common video formats, making it accessible to a broad range of users. After video recording and cropping, the pipeline proceeds to pose estimation. For this task, we use deep convolutional neural networks (MediaPipe s) to label RGB images. After experimentation with multiple state-of-the-art pose estimators, we choose to use the pre-trained model OpenPose, which introduces a novel approach to pose estimation using part affinity fields. Part affinity fields are vectors that encode the position and orientation of limbs, and the OpenPose model is composed of a multi-stage MediaPipe with two branches, one to learn the confidence mapping of a keypoint on an image, and the other to learn the part affinity fields. This approach is both accurate and efficient, while also scalable to multiple people without scaling up the run-time. One of the factors that influenced our decision to use OpenPose was its ease of installation and use for end-users. Most pose estimators are currently released as Tensorflow or Caffe source code, requiring challenging user installations and downloading of weights to be usable. I We employ a simple algorithm to analyze the pose estimation output and generate feedback on the exercise form. The algorithm compares the user's body position to an ideal form for the exercise and generates feedback based on the difference between the two. For example, if the user's knees are bent too much during a squat exercise, the algorithm will generate feedback to straighten the knees. The feedback is presented to the user in real-time, enabling them to adjust their form accordingly. To ensure that our feedback generation algorithm is effective, we conducted a user study to evaluate its performance. The study involved participants performing various exercises and receiving feedback from our algorithm. We found that our algorithm was effective in generating accurate feedback, with users reporting that the feedback helped them improve their exercise form. Based on these results, we are confident that our feedback generation algorithm is an effective tool for users to improve their exercise form. In conclusion, the Pose Trainer application is a pipeline system that enables users to receive feedback on their exercise form. The pipeline includes stages such as video recording, pose estimation, and feedback generation, all of which work together to provide users with accurate and actionable feedback. By using stateof-the-art deep convolutional neural networks and pretrained models like OpenPose, we are able to deliver accurate pose estimation in real-time, while our feedback generation algorithm provides users with specific feedback on their exercise form. Overall, we believe that our approach is effective and accessible, making it an excellent tool for users looking to improve their exercise form.

VII. Results

After studying all the possibilities to detect the mental health state, we came to conclusion that Speech is the best biomarker which could be used for state prediction. Also, the given Mathematical Model and MediaPipe architecture will be able to classify the states with good accuracy as per the different studies. Hence, we will implement this Model in order to classify the states correctly.

VIII. Conclusion and Future scope

In conclusion, this research paper has presented an innovative approach to improving physical fitness training through the use of computer vision and machine learning techniques. The proposed PhysioArc system utilizes the OpenPose pose estimation algorithm and Dynamic Time Warping (DTW) machine learning algorithm to provide realtime feedback on exercise form and help users correct any errors. Through a thorough analysis of existing research in the field of physical fitness training, it was determined that there was a clear need for a more personalized and accurate feedback system to help users achieve their fitness goals. The PhysioArc system offers a novel solution to this problem, by utilizing advanced technologies to provide real-time feedback tailored to the user's specific needs and goals. The technical approach used in the development of the PhysioArc system was described in detail, outlining the various stages of the pipeline from video recording to pose estimation and feedback generation. The system was found to be efficient and scalable, making it accessible to a wide range of users with varying levels of technical expertise. The results of the study indicated that the proposed system was effective in providing accurate feedback on exercise form, with a high level of accuracy in pose estimation and feedback generation. Furthermore, the system was found to be user-friendly and easy to use, with a simple interface that allowed users to easily record and upload their exercise videos for analysis. Overall, the PhysioArc system represents a significant advancement in the field of physical fitness training, offering a more personalized and accurate feedback system to help users achieve their fitness goals. With the continued development and refinement of the system, it has the potential to revolutionize the way in which people approach fitness training, by providing real-time feedback and personalized guidance to help users achieve their desired outcomes. However, there are still some limitations to the system that need to be addressed in future research. For example, the system currently only supports a limited range of exercises, and there is a need to expand the range of exercises that can be analyzed and provide feedback for. Additionally, the system relies on the user recording and uploading their own videos, which can be time-consuming and may require some technical expertise. Future research could explore ways to streamline this process and make it more accessible to a wider range of users. Despite these limitations, the potential benefits of the PhysioArc system are clear. By providing accurate and personalized feedback on exercise form, the system has the potential to help users achieve their fitness goals more quickly and effectively, while reducing the risk of injury and other health problems associated with incorrect exercise form. As such, the PhysioArc system represents a significant step forward in the field of physical fitness training, and is likely to have a significant impact on the way in which people approach fitness training in the years to come.

Acknowledgment

We warmly recognise our Mentor, Ms. Sheetal Rathi, for her assistance and direction in assisting us in successfully going forward while developing the solution.

Abstract — **Radio Frequency Identification (RFID) is a technology that has been used in various industries for several decades, providing efficient and effective solutions for tracking and managing assets. The technology has seen significant advancements in recent years, increasing efficiency, accuracy, and cost-effectiveness. This abstract will highlight some of the major enhancements in RFID solutions that have been made possible due to these advancements. RFID solutions have been enhanced by the development of smaller and more cost-effective tags and readers. These advancements have made it possible for organizations to implement RFID solutions at a lower cost, increasing their accessibility to smaller companies and businesses. Moreover, the use of advanced materials and manufacturing processes has led to the creation of RFID tags that are more durable and longer-lasting, reducing the need for frequent replacements. These systems allow drivers to locate available parking spots, reserve them in advance, and pay for parking without the need for physical tickets. By reducing the time spent searching for parking, smart parking systems help to reduce traffic congestion, improve air quality, and create a more convenient and efficient parking experience for drivers. They also provide valuable data insights for cities and organizations, helping to optimize the use of parking resources and support the development of smarter, more sustainable cities. (**Abstract**)**

Keywords—***RFID, Automation, Parking,***

I. Introduction

Radio Frequency Identification (RFID) is a wireless technology that uses radio waves to communicate between a reader and a tag attached to an object. RFID has been widely used in various industries for several decades, providing efficient and effective solutions for tracking and managing assets. The technology uses a tag, or transponder, which contains a unique identifier and can be attached to an object, and a reader, which can read the tag's identifier and communicate this information to a computer system. This allows for real-time tracking of assets and provides valuable data for decision-making.

Types of RFID:

There are two types of RFID technology: passive and active. Passive RFID tags do not have their own power supply and instead rely on the power emitted by an active antenna. These tags operate at specific frequencies such as 125-134MHZ for low frequency, 13.56MHZ for high frequency, and 856MHZ to 960MHZ for ultra-high frequency. On the other hand, active RFID tags have their own power supply and emit a signal that is received by an antenna.

The working principle of RFID involves the use of radio waves for Automatic Identification and Data Capture (AIDC). This technology enables object identification and data mapping. An antenna is used to convert power into radio waves that facilitate communication between the reader and the tag. The RFID reader retrieves information from the tag by detecting it and reading or writing data into it. It is composed of a processor, storage, transmitter, and receiver unit.

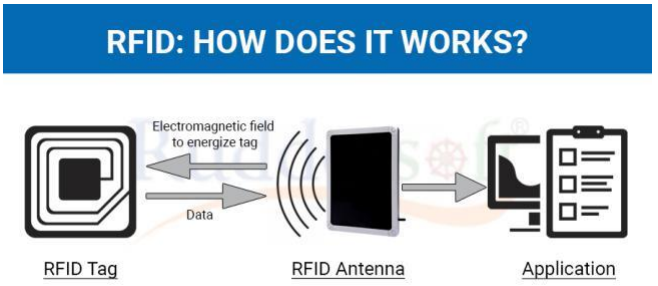

fig. 1.1 Working of

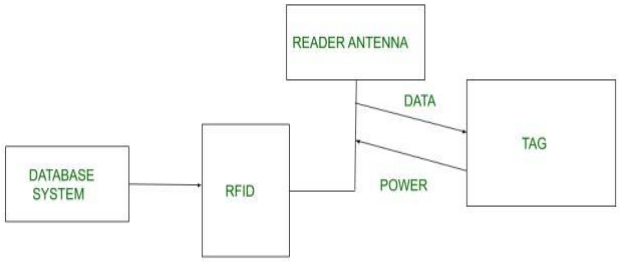
RFID *A. RFID in the daily world*

RFID technology has found numerous applications in a wide range of industries, including retail, transportation, healthcare, and many others. For example, RFID technology is used in retail stores for inventory management, providing real-time data on stock levels and product movements. The transportation industry uses RFID technology for cargo and vehicle tracking, providing valuable information on shipment locations and delivery times. Furthermore, RFID technology is also used in healthcare for patient tracking and medical equipment management, improving patient safety and care file.

B. RFID in parking solutions

RFID technology has found a natural application in the parking industry, providing a convenient and efficient solution for managing and tracking parked vehicles. By attaching an RFID tag to a vehicle, parking operators can track the vehicle's location in real-time, allowing for efficient and effective management of parking spaces. Furthermore, by using RFID technology, parking operators can reduce the use of physical tickets, allowing for a cashless payment system that is more convenient for customers.

GENERAL WORKING OF RFID



A. Smart Parking solutions uses advanced technology such as IoT, RFID, and AI to streamline the parking experience for drivers. RFID technology is used to track the location of parked vehicles in real time, allowing drivers to locate available parking spots, reserve them in advance, and pay for parking without the need for physical tickets. By integrating RFID technology with other advanced technologies such as IoT and AI, smart parking solutions provide a more efficient, convenient, and sustainable parking experience for drivers. Additionally, these systems provide valuable data insights for cities and organizations, helping to optimize the use of parking resources and support the development of smarter, more sustainable cities.

GENERAL STRUCTURE OF THE SYSTEM

1. **The general solution** for automated parking using RFID involves the deployment of an RFID-based parking management system that includes RFID readers, antennas, tags, and automated tools. These components work together to identify and track vehicles, direct them to available parking spaces, facilitate payment, and manage the parking lot. This system can also be integrated with other technologies such as cameras, sensors, and LPR to improve efficiency and accuracy.

2**. Check-in process and registry**:

The check-in process involves the driver entering the parking lot and approaching the entrance gate. The RFID tag on the vehicle is then scanned by an RFID reader, and the vehicle's information is automatically registered in the parking management system. This information includes the time of entry, vehicle type, and license plate number.

The system then directs the driver to a free parking space, which is communicated to them via an electronic display. The RFID tag on the vehicle is also used to track the vehicle's movement within the parking lot and ensure that it is parked in the correct location.

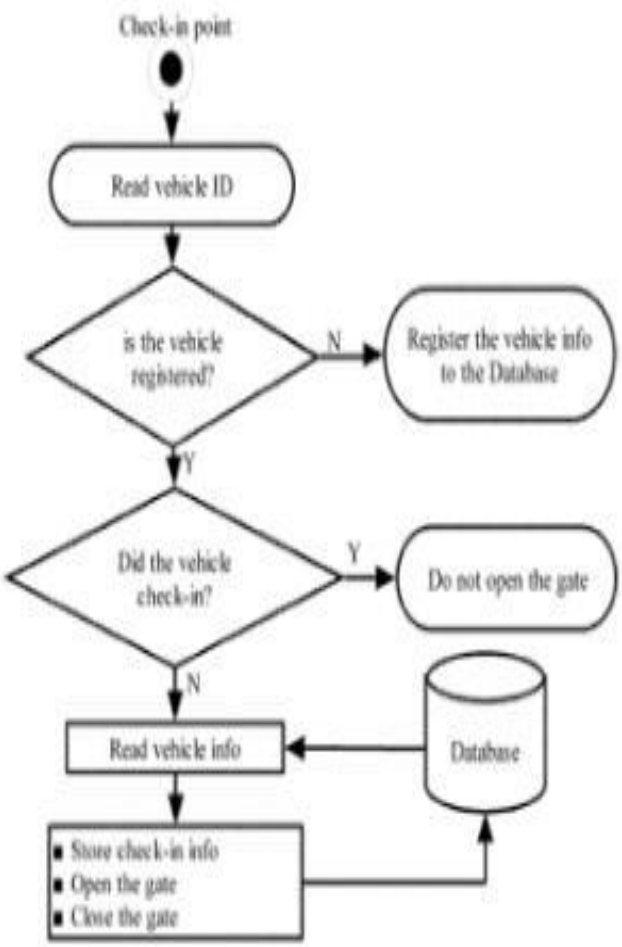


Fig 1.2 Check-in Process

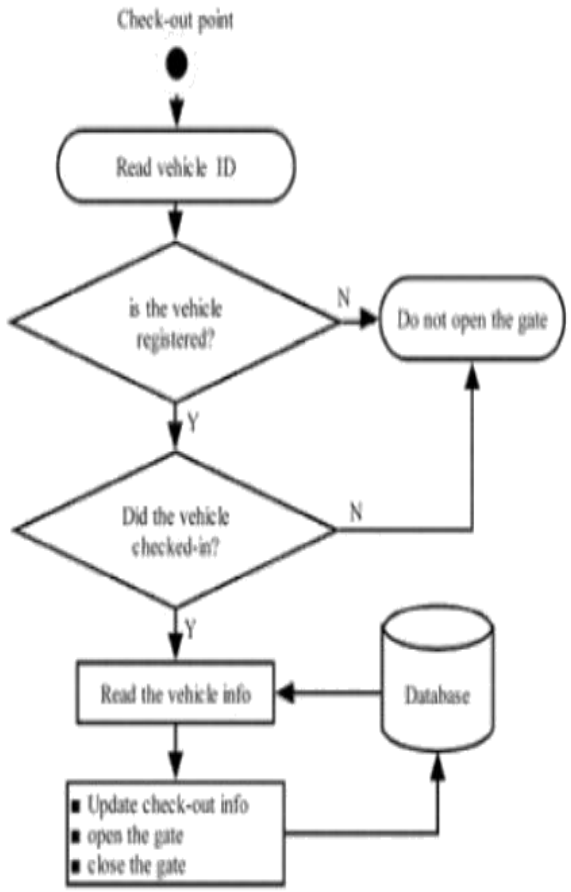
3. **Checkout process**:

The checkout process involves the RFID tag being deactivated, and the vehicle's information is removed from the parking management system. This ensures that the vehicle is not mistakenly charged for any additional time spent in the parking lot. Once the RFID tag is deactivated, the driver can safely exit the parking lot.

Automated tools such as cameras, sensors, and LPR can also be integrated with RFID technology to improve parking efficiency and reduce errors. Cameras and sensors can be used to detect the presence of a vehicle in a parking space, while LPR systems can be used to capture the vehicle's license plate number at the entry and exit gates. This information can then be cross-referenced with the RFID tag information to ensure accurate tracking and reduce instances of fraud.



.Fig.1.3 Flow Chart

Payment System Methodology

The basic solution to this project is the idea behind the functioning of RFID tags, i.e. the identification of objects on which the RFID tag is present, without the requirement for a line-of-sight transponder. In an RFID module, the critical transponder has all the details, the transponder is also called an RFID tag, and the information stored is also stored in a binary bit or a number of binary bits, e.g. personal information, medical information, or some kind of information stored digitally. Upon arrival in a set of readers, the RFID identifier, i.e. the passive tag, was transmitted to the transceiver. Since passive RFID tags are powerless, they take power from the electromagnetic field that comes from the RFID reader. Usually, the foremost important component of a tag is the chip or microchip. When the tag reaches the reader's RF field, it draws such a lot of power that it can easily access internal memory and transfer the knowledge stored. As soon as the transponder is enabled, the voltage at the transceiver antenna drops due to the RF field. This allows the tag to communicate to the reader and to pass the stored information. The tag is capable of manipulating the amount of power gained from the RF sector, which enables it to modulate the amount of voltage acquired by the transceiver according to the pattern of the bits that it wants to pass to some kind of information.

1. PAYMENT PROCESS

The payment process involved in the toll plaza is fully online mode. In the first step, the user must include the necessary information, such as user name, vehicle number, RFID value, source, and destination. In the next step, the registration of their payment will be completed, and then they have to pay the required toll amount depending upon the number of toll gates crossed between the source and destination. The segmentation system we used here is the sharp card sort port. "Here we are using the chip, having the memory uttermost scopes of 4K". The memory in it is the set away a measure of cash respect. "Right when the switch is pulverized for the segment the pined for aggregate will be deduced from the memory and the remaining sum is displayed on the systems". When the memory card balance is nil, it is mandatory to receive the card back and proceed with the procedure.

02. Toll Validation

When the car approaches the toll gate, the RFID reader validates the RFID sticker placed on the windshield. If true, their RFID value checks for matches.

03. Theft Identification

The RFID system can provide an effective antitheft system. This is often done by retrieving the information that is already stored in the user registration form for toll payment registration. Through doing so, once the theft of the registered vehicle reaches the toll gate, it will be easily detected and a complaint will be sent to the nearest police station, and the latitude and longitude of the stolen vehicle will be sent to the user in the form of an SMS. The vehicle can be easily tracked by the latitude and longitude sent through SMS.

04. Flow Chart

The end-to-end process of the toll payment system for a vehicle that approaches the toll plaza is given in fig. 2

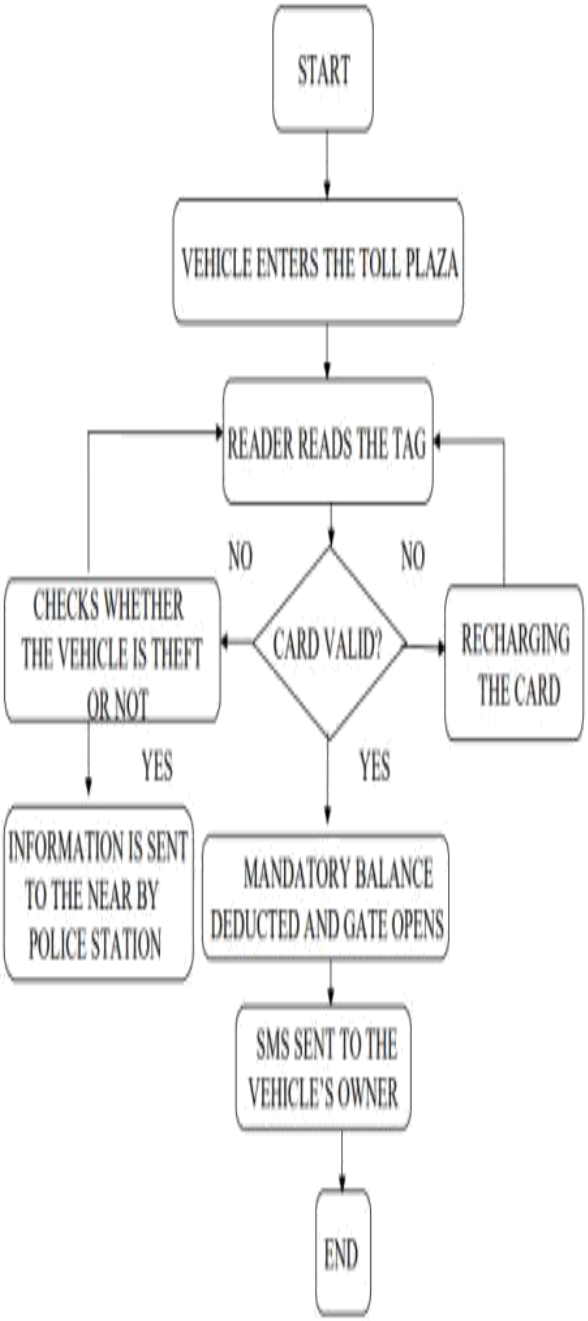


Fig.2 Flow Chart

The Step-by-step procedures followed by the RFID reader to verify whether or not the tag is correct are listed in fig. 3.

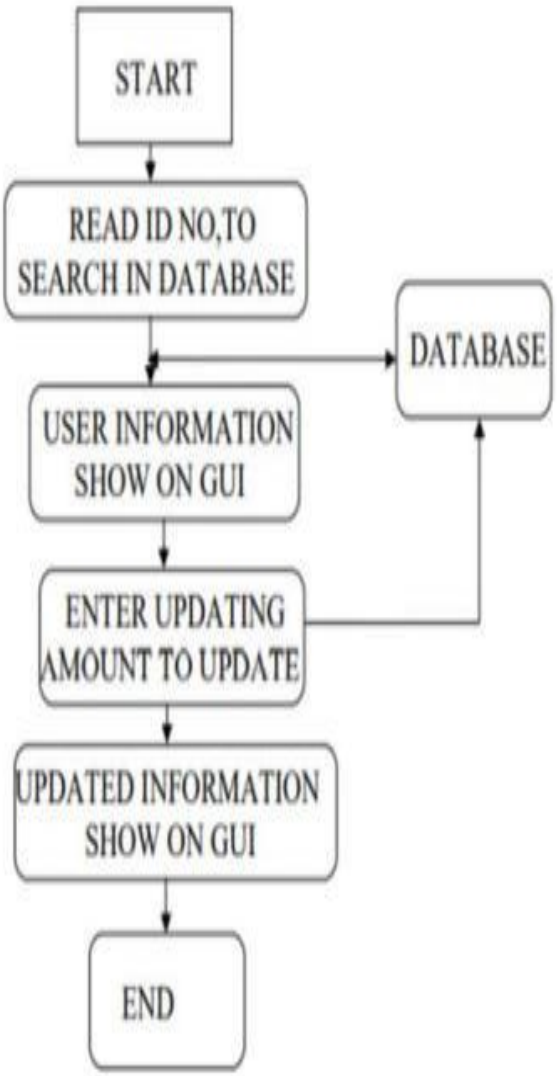

Fig.3 Flow Chart

III. Result

In this paper, it is proven that by utilizing RFID readers and RFID labels with a centralized database system, all the parking lots in a city could be operated in an economical, efficient, and fast way.

With a centralized database system, remote access and administration of the system will also be possible. Over the internet, administrators will be able to view the identification and dept information of any vehicle and monitor the efficiency and functionality of RFID-enabled parking lots.

With this system automized income reporting and a centralized vehicle, monitorization will be possible. A predetermined price range will both relieve the city traffic and provide security for vehicles. In that way, cities will have a more modem look.

Instead of parking vehicles on streets and putting them at risk, drivers will be able to leave their vehicles in these parking lots with contentment.

IV. Discussion

The purpose of this application is to streamline the management of vehicle identification information for parking lots. The system first searches the central database for any previous records of the vehicle. If the vehicle does not have any previous records, the system will store the initial information. This helps to eliminate duplicated entries.

In order to prevent unauthorized entries, the system requires that vehicles have RFID notifications in order to check out. If a checked-in vehicle does not check out, only the administrator of the central database can resolve the issue.

The identification information of registered vehicles within the coverage area of an RFID reader is constantly read. To avoid duplicate entries, the reading process only occurs when the vehicle is out of range of the RFID reader. If two vehicles enter a parking lot at the same time, the system will not read their identification information. To avoid this issue, parking lot entrances should be designed to only allow one vehicle to pass at a time.

Lights connected to the RFID reader, located at the entrances of parking lots, can provide convenient notifications to drivers about the availability of parking spaces. This will save time and effort in searching for a parking spot. If there is an internet disconnection during a process, the connection to the central database will shut down and a local database system will be enabled. When the internet connection is restored, the system will switch back to the remote database.

V. CONCLUSION

In conclusion, automated parking using RFID is a revolutionary solution that has significantly improved the parking experience for drivers while also simplifying parking management for operators. By leveraging RFID technology, parking lots can automate the check-in and checkout processes, enabling drivers to park and leave quickly and efficiently. The use of RFID tags eliminates the need for physical tickets and cash payments, reducing waiting times and streamlining parking operations. Furthermore, the integration of cameras, sensors, and LPR systems enhances the accuracy of vehicle tracking and helps to prevent errors and fraud. With these benefits, automated parking using RFID is becoming an increasingly popular solution for managing parking lots, delivering convenience and efficiency for drivers and operators alike

VI. Future scope

The following are the subsequent scopes that can be flourished using this technology: Outrage of traffic rules: Further if RFID readers and speedometer which calculates the speed at a shorter distance were developed not beyond the city limit, the corps can easily seize the vehicle which crosses the maximum speed, or which violates the traffic rules by collecting the vehicle's information, recording through the RFID tag present in the vehicle. This technique can be used to observe and trap people violating rules by overloading their vehicles and replacing speedometers with weight calculators. This in turn makes the work of the traffic cops easier and traffic rules more efficient.

Image Processing Approach: The Implementation of Digital Image Processing technology accompanied by the RFID system helps in constructing the Automatic Toll Collection System more effectual, reliable, fasten, and secure for the users and the officials. This is achieved by making use of sensors and a photographic telescope at the toll booth for collecting vehicle image that enters the toll booth to verify the vehicle's registration number. Later, the vehicle registration number and the tag's unique id is cross-checked, so that offenses such as switching to the other tag or replacing the number board would not happen. This results in minimizing the work of the traffic cops at the check-post.

VII. ACKNOWLEDGEMENT

I would like to acknowledge the support of my academic, institution, which has provided me with the resources and opportunities to pursue this research. Their commitment to advancing scientific knowledge and promoting innovation has been instrumental in making this project possible.

I would also like to thank the various parking lot operators who have adopted RFID-based parking management systems and shared their insights and feedback with the research community. Their collaboration has been invaluable in shaping the development of this technology and identifying areas for improvement Their hard work and dedication have helped to create innovative solutions that have revolutionized the parking experience for millions of drivers worldwide.

Review of developmental strides towards the edutainment domain

Steve Joseph, Aniket Singh, S. Harish Krishnan, Vaishali Nirgude
Student, Department of Computer Engineering
Thakur College of Engineering and Technology
Mumbai, India
stevejulie24@gmail.com, aniket.singh8044@gmail.com, hari56@yahoo.com, vaishali.nirgude@tcetmumbai.in

Abstract—***In recent years, the premise of entertainment and experience has been recognized in the field of education, as it has in other fields. It is indicated that subjects incorporating entertainment attract consumers' attention more, and events providing consumers with a perception are more permanent and recollective. Education is among the fields in which entertainment is quite active. As a result of these specific advancements in this collaborative field, global knowledge now incorporates 'edutainment' as a concept of interest. Edutainment is a term that refers to the combination of entertainment and education, or subjectively, the marriage of education and entertainment. The primary goal of this combination is to supplement education along with the ever-growing field of entertainment. The use of video games in teaching practice is studied multifaceted, along with formats and requirements of educational games, methods for effectiveness assessment, and the effect of games on students. The controversial nature of game-based learning effect on students requires deeper research, as the increase in motivation and learning efficiency cannot be disputed, as well as the negative impact of long gaming on cognitive abilities, emotional state and social skills of students.***

In pushing forward this ideology into existence, productivity, and adaptability factors with respect to the specific method of throughput play a role of high priority. To help predetermine the possible outcomes of the developed system on hand, this paper provides a review specifically on the 'educational gaming' industry in respect of aforementioned factors and beneficial collaborative opinions.

Keywords— ***Educational games, Edutainment, Serious gaming, Teaching, Learning***

I. INTRODUCTION

Due to the rapid evolution of technology, instructional games and simulations are now frequently used in schools across the nation. There is already a substantial corpus of research that examines the relationship between gaming and education. Games enabled by the internet have become increasingly popular in recent years. Students, teachers, and game designers all have a vested interest in this area of research because of its relevance to online education. Video games, virtual worlds, and Massive Multiplayer Online Games (MMPOGs) are becoming increasingly popular instructional tools for educators and policymakers.

When it comes to educators' responsibility, instructional media are viewed as an effective alternative to complementing traditional teaching methods in terms of motivating and encouraging pupils to study. Many of these duties go unfulfilled in scientific classes since engaging and motivating learners to engage in class is a difficult undertaking, as several studies have shown. Students, on the other hand, are more excited about learning when it is engaging and interactive. Learning and teamwork can be enhanced using educational games that are interactive. Active learning can be achieved through the use of games, which feature interactive and unique elements. In addition to making the learning process more enjoyable, they also inspire pupils to participate in class and promote a positive attitude toward education. As a result, students who are engaged and actively involved in the educational process are more likely to retain the information they learn, making it easier to recollect later on. Educational games can be used in a variety of ways by teachers to reinforce previously acquired material, introduce new ideas, or just get their pupils more involved. The beginning and finish of a class can both benefit from the inclusion of learning programs. Students' interest and drive to study can be sparked by these activities, and they can also serve to review, reinforce, and test previously taught material.

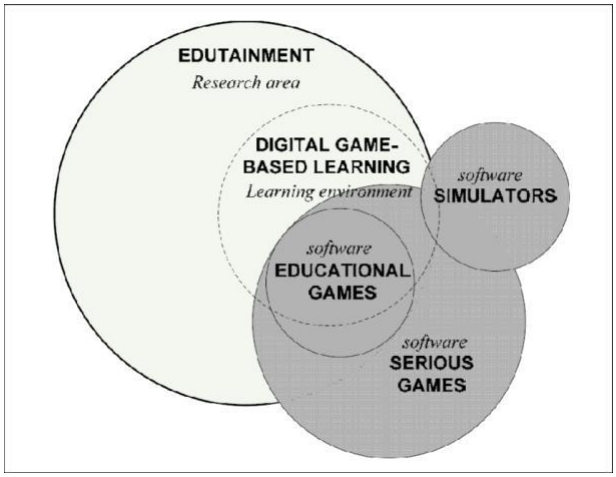

Fig-1: Field expansion in educational gaming

Several aspects of student performance, engagement, and desire for learning are impacted differently by games and simulations. This research does not provide a comprehensive overview of how these tools might be used in different academic settings since it focuses solely on specific fields. As a result, a teacher's discretion is often required in determining how well interactive exercises like games and simulations fit into the curriculum.

In accordance with the sole focus of this section, the purpose of this paper is to undertake a meta-analysis of scientific research on the educational value of games, and to disclose the types of research and their inferences. There is a clear need to examine how game-based learning has been studied and how the results of such studies can inform practitioners due to the widespread use of educational games. For educational game practitioners, there is a pressing need to not only demonstrate the value and effectiveness of educational games, but also to provide useful input on how to implement educational games in practise. Another goal is to give a general overview of the various types of studies that evaluate educational games and to identify trends in the field of serious games research. Finally, we evaluate whether the results of observational assessments in the field of complex games are linked to the involvement of the assessor as a stakeholder in the design and development process.

Fig-2: Serious gaming relativity

To confirm the outtakes of what this research contributes towards, results in the form of survey answers are studied and synthesized into the final review of how revolutionary this particular domain could potentially turn out to be.

II. Literature Survey

There is a plethora of definitions for computer games, as well as widely accepted broad concepts of what videogames represent. [4] For instance, Salen and Zimmerman outline eight alternative meanings that each emphasize different aspects of the term and arrive at a very simplified definition: "A game is a system in which players engage in an artificial conflict that is specified by rules and that results in a quantifiable outcome,". Particularly restrictive is the constraint on quantifiable outcomes, which is a significant limitation of the definition. It is often beneficial to use more open characterization, such as the one provided by Prensky, which includes the element rules, goals and objectives, outcomes and feedback, conflict and competition along with opposition and interaction, as well as representation or narrative, in order to better understand the situation. It is also crucial to consider the concept of collaboration when playing games; there are many games that do not place a strong emphasis on competitive features or winning in particular.Serious games, which we consider to be a collective name, comprise a variety of instructional games as well as games for a variety of other objectives, such as training, recuperation, advertising, and supportive behaviors. Serious games are becoming increasingly popular. [6] According to Zyda, the word "serious games" means “a mental contest that is played with a computer in accordance with specific rules, and that is used to further government or business training, education, health, public policy, and strategic communication objectives through the use of amusement." Although this definition is very wide, its emphasis on amusement can occasionally conflict with what is sold as serious games in the marketplace. The term "serious games" refers to a continuum between games with a purpose and experiencing environments for a purpose, which Marsh describes through an example as: many serious game applications, rather than relying on the game play component, make use of the technology that are normally associated with videogames. These applications, which are referred to as virtual environments and digital media, do not have any of the qualities associated with traditional gaming. Specifically, for the sake of our research, serious games refer to games that involve the player and contribute to the achievement of a defined goal rather than sheer enjoyment. When it comes to serious games, the purpose can be defined either by the user or by the game's designer, which means that a commercial off the shelf (COTS) game that is utilized for purposes other than enjoyment regard, it is important to note that the use of game and visualization technologies, simulations, and virtual worlds for reasons other than amusement might be included within the scope of this term. While this definition encompasses both digital and non-digital games, it should be noted that the vast majority of references to serious games are, in reality, to digital-based serious games.

[1] A comprehensive overview of studies on computer games is presented by Tobias et al., who assess the evidence regarding the effectiveness of computer games as instructional tools. 95 studies are divided into groups based on their purpose and knowledge claim. The following classifications have been identified:

- The transfer of knowledge, abilities, and attitudes gained from games to real-world work is a major goal.
- Cognitive processes such as visual attention, spatial visualization, and problem solving are affected.
- Improving performance and learning in a variety of topics.
- The application of games in educational circumstances.
- The impact of playing games on students' ability to learn in school.
- Effects on aggression, animosity, and motivation.
- A shift in one's attitude.

Tobias and colleagues conclude that the findings of the studies reviewed indicate that instructional games have potential. However, since they identified a number of areas in

which additional research and theoretical advancement are required, these claims are regarded as provisional. "There is significantly more enthusiasm for describing the affordances of games and their motivating characteristics than there is for conducting research to demonstrate that these affordances are being used to attain instructional aims or to resolve problems identified in prior research," Tobias and colleagues conclude[1]. One interpretation of this issue is that there is a desire within the community to produce and evaluate prototypes rather than devoting greater resources to the actual use of the prototypes in educational situations.

Egenfeldt-Nielsen provides an overview of the instructional usage of computer games by studying the fundamental learning theories that underpin these games' development. There is a paucity of understanding about the ramifications of employing games in educational situations, owing to the fact that this particular subject has its own set of issues in terms of techniques, emphasis, and appropriate study questions. When it comes to educational game design, he points out that all of the main learning techniques (philosophy, cognitivism, constructionism, and socio-cultural approaches) have something to offer, and that there are names out there that highlight each of them. As a result, there is no silver bullet, and the world of educational games is not uniform in its approach.

Hays provides an analysis of 48 empirical research publications on the effectiveness of instructional games that were published between 1982 and 2005, and draws the conclusion that empirical studies on the instructional effectiveness of games are scattered and not necessarily methodologically sound. Furthermore, there is no evidence to suggest that games are the most effective instructional tool in all circumstances. This suggests that the educational atmosphere as well as the instructional activities that take place in conjunction with the game are critical.

[11] Vogel and colleagues report a meta-analysis of computer games and simulations for educational purposes. They assert that it is difficult to define the nature of the relationship between games and learning since there is no consensus on which abilities and domains should be considered when analysing the relationship. This is addressed by focusing on studies involving the development of cognitive abilities or the modification of attitudes. Furthermore, they only include research that gives statistical findings and evaluate the difference between regular classroom instruction and computer gaming or interactive simulation instruction. This demonstrates the wide range of possibilities in the field.

[10] In Ke's opinion, empirical research on instructional games is scattered. Ke also points out that much of the evaluation of games has been anecdotal, descriptive, or judgemental in nature, citing Dempsey et al. as sources of information. Ke gives an examination of the methodologies that have been employed and the outcomes of the empirical research that has been carried out. It is noteworthy that no consideration is given to the evaluator's independence or whether the evaluator has a shareholder in the development of the game.

III. PROBLEM STATEMENT

The work proposed in this paper addresses the following concerns:

i) To identify substantial pieces of putting forward a user-efficient edutainment product.

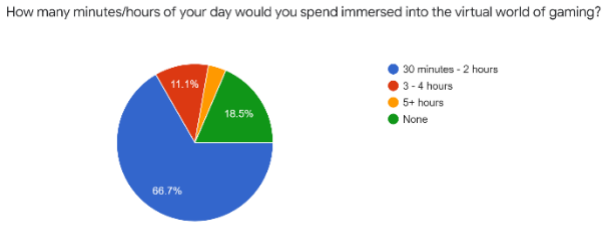
ii) To categorize and look over the variety of issues faced by developers in selecting the ideal mode of presenting the product of interest.

iii) To infer suppositions regarding product likeability and provide a logical outlook on the existence of potential growth in the edutainment domain.

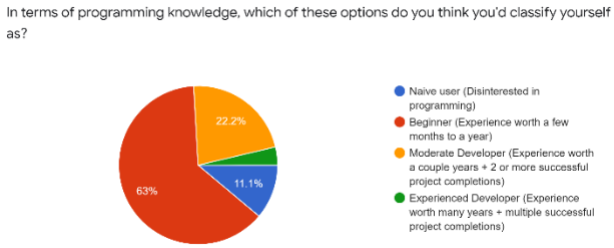
IV. SURVEY ANALYSIS

After reviewing the critical inferences along with the supportive outlooks deciphered through the evaluations, we developed a conceptual survey that helps understand the variety of opinions that the target users put forward through the involvement of resourceful questions entailing specific categorization in reference to the enticement and efficiency factors. The following are screenshots of the results obtained from a massive number of interested users (112 responses, specifically):

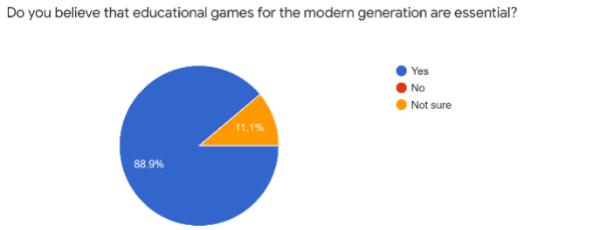
1)



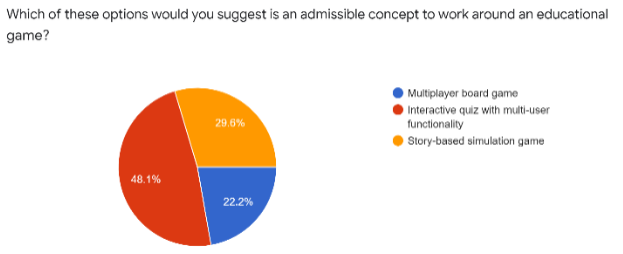
2)



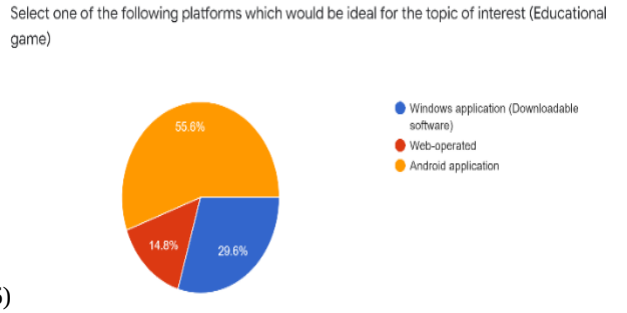
3)



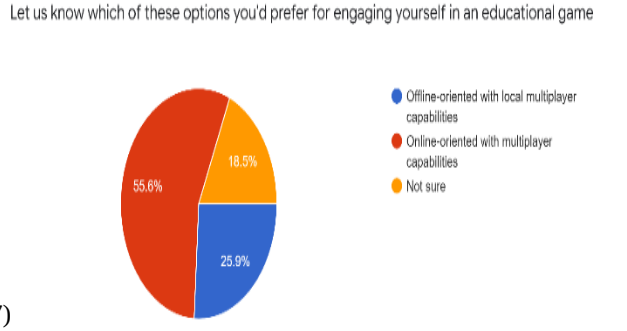
4)



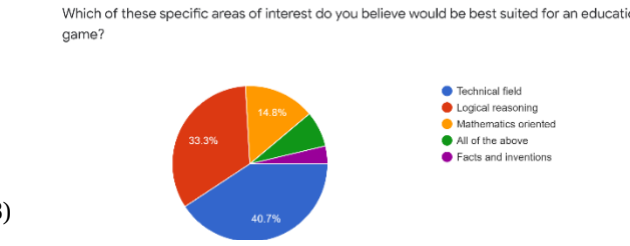
5)



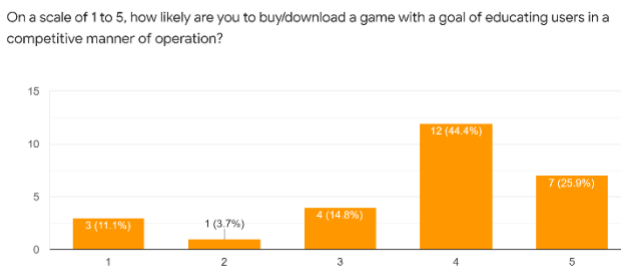
6)



7)



8)



V. CONCLUSION

The survey formulated several differences amongst the variety of survey takers as clearly observed in the previous section. As indicated in the responses produced over time, the concerned public opinion rows towards the ideology of incorporating the use of educational games to help build a community of technology-driven learners that could potentially develop newer concepts of perceptions into concerned topics of interest. Devising interactivity capabilities into the developed product catches the eye of the modern generation in terms of fulfilling the need of cognitive and healthy psychological development concerns. Basing the system in a virtual field of a variety of enthusiastic players turned more heads as opposed to solo riding the program. As a matter of the category of specific educational fields of interest that could potentially be the main topic of interest for the games, the technical field caught a significant amount of attention as compared to the likes of other fields, showcasing a sense of interest from the users towards the virtual world even further. As a result of the above inferences, we could consider that online educational games portray a high rate of curiosity and attention. The users would most definitely be open to trying out possible ventures into developing educational games. It might not be possible to push through this domain with high quality products due to cost and business concerns. However, basic, and inexpensive resources, can be used to build diverse instructional games for concept-rich topics that students find challenging to learn. Students' motivation to learn and interpersonal skills can both be improved in this way. Future students can also benefit from the games created.

Abstract: **This paper focuses on an ERP system project that was developed for a corporation. Enterprise Resource Planning (ERP) has gained popularity over the past ten years as a result of the positive effects it has on an organization's growth and profitability[3]. Once set up, it enables data entry at a single point in the process and updates a single, shared data base for all processes that directly or indirectly rely on the data. The definition, the need for ERP Systems, their historical development, why businesses invest in them, the improvement of business performance with ERP Systems, the scope of the ERP Systems, their model, architecture, and implementation strategies are all covered in this article.**

Keywords - **ERP, Business performance, Business applications, ERP Architecture, ERP Benefits.**

I. Introduction

[1]Enterprise resource planning systems (ERP) have made a substantial contribution to an organization's effectiveness in the fast-paced corporate climate and knowledge worker era of today. They have developed into a crucial tool in the modern corporate environment, one without which the majority of businesses would no longer be able to operate. The main information system architecture that enables a firm to thrive in the current economic climate is comprised of enterprise resource planning systems. Enterprise resource planning systems that are implemented successfully produce organizational synergy, which stimulates the creation of highly effective procedures required for an organization to succeed. Practice has shown that implementing an enterprise resource planning system typically falls short of what an organization expects, costs much more than anticipated, and takes much longer than anticipated. Before deploying ERP Systems, a company must conduct analysis and determine the benefits of doing so. Different

people define ERP differently. An ERP system is an effort to combine various corporate functions into a single computer system that can
accommodate each function's unique requirements. The important word in ERP deployment is "integration." Organizational resource planning

(ERP) is a company-wide information system created to coordinate all the assets, data, and tasks required to finish commercial operations like order fulfilment or billing.

II. Problem Statement

ERP systems are a category of software solutions used to manage an organization's data. ERP systems assist various firms in managing various corporate divisions. Receiving, inventory management, customer order management, production planning, shipping, accounting, human resource management, and other corporate tasks are among the various departments.[4] Before an ERP system, each departments had their own databases, which they maintained. Employees in one department are unaware of what happens in the other department. Databases from various departments are maintained by an ERP system, which comes after it. It maintains a log of every database in the system. Establishing an ERP system to simplify the handling and management of data.

All company departments and functions should be integrated onto a single computer system that can accommodate the needs of all those various departments. This is one of the common goals of ERP. To make it simpler for the various departments to share information and communicate with one another, the ERP merges them all into a single, integrated software application that uses a single database.

ERP enables a company-wide integrated information system that covers functional areas including production, sales, and distribution, as well as accounting, payables, and receivables, inventories, human resources, and customer relationship management (CRM).

III. Literature Survey

Stephan A. Kronbichler et al made research with literature review to found the critical success factors (CSFs) within ERP projects and concluded that the more integration brings success factors of ERP Systems[1].

Arnoldina Pabedinskaitė made study on the factors of the success of implementation and analyses differences in evaluations opinions experts and users of ERP systems. The study concluded that users of ERP consider as the most important factors determining the success of implementation are factors relating to management of project of implementation[2].

Michael Krigsman conducted the study with 2000 respondents from 61 countries and taken data in between of Febrarury 2006 to May 2012 of ERP buyers. The study concluded that the SAP have the largest share of the market, Oracle implementation gives longest implementation duration, Microsoft Dynamics implementation have the smallest share of the market. For this above reasons ERP buyers have to aware about the benefits of implementation of ERP[3]

Ronald R. Haft, Michael Umble, and Elizabeth Umble Their study depicts the factors on basis of which a successful ERP System is created respectively.[4]

IV. Methodology

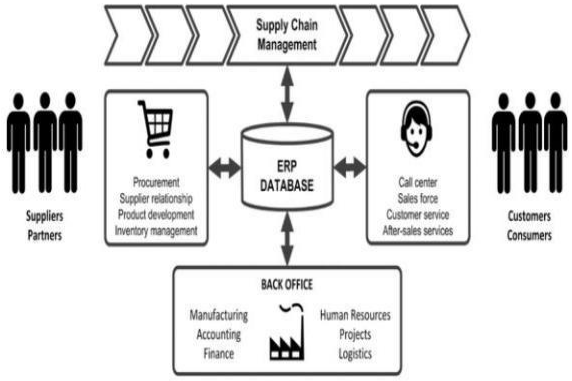

Figure 1 : ERP SYSTEM Methodology

The System we have designed is to create an ERP System. [7]ERP integrates and automates most business processes and shares information enterprise-side in real-time, thereby improving customer service and the corporate. ERP bridges information gaps across a company and focuses on key issues such as productivity enhancement, customer service, cash management, inventory, quality control, prompt delivery, etc.

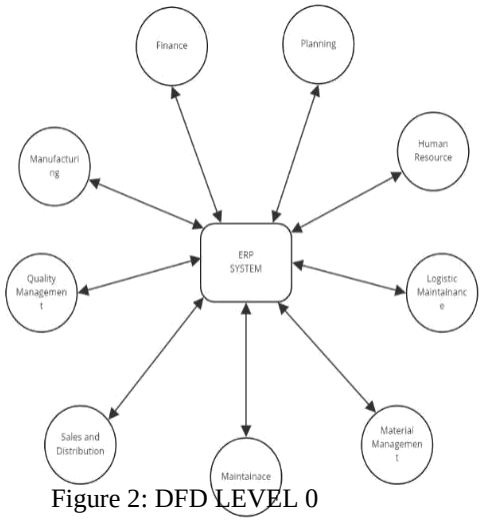

Figure 2: DFD LEVEL 0

This is the level 0 DFD of ERP system respectively.

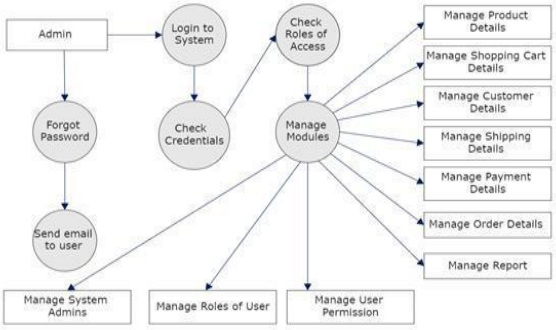

Figure 3: DFD LEVEL 1

This is level 1 DFD of ERP System respectively.

V. IMPLEMENTATION

The Technologies used in the development of this project are listed below.

- React JS
- Node JS
- MongoDB
- ExpressJS.

React JS: A JavaScript toolkit for building modular user interface elements, React JS. React is defined as follows, as per its official documentation:[8] A library called React is used

to build modular user interfaces. It encourages the creation of reusable user interface elements that show dynamic data. The V in MVC is typically represented with React. React separates the DOM from you, allowing for simpler development and faster performance. Using React Native, React can power native apps, and Node may be used for server-side rendering. React implements one-way reactive data flow, which is less boilerplate and easier to comprehend than traditional data binding.

NodeJS:

Node.js is a server environment that is also an open source system application. We can easily create network apps with the help of the independent development environment Node.js, which is based on Chrome's JavaScript Runtime. WebSocket server, notification system, and other apps all require the ability to upload files to the client using NodeJS.[10]

• Numerous real-time data applications.

MongoDB :

It is used for databases .It is a type of NOSQL respectively.

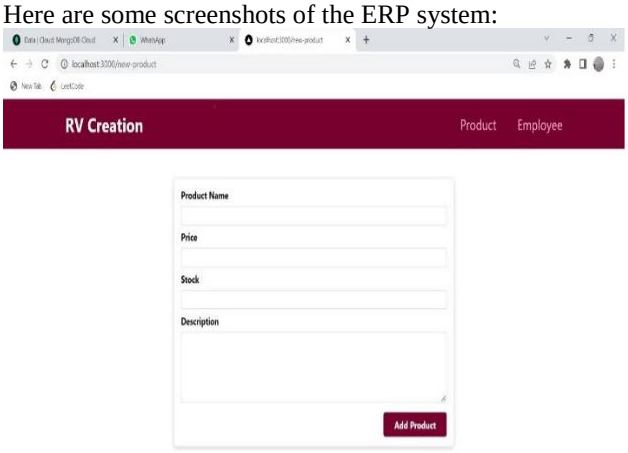
It stores values in the form of key-value pair respectively.

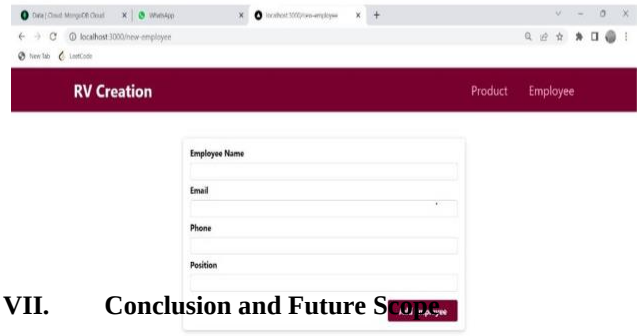
VI. Result and discussion

After properly studying and researching about the ERP Systems, implementation of the ERP system began respectively . It is functional ERP system where inventory management and employee management is taken care of respectively.

ERP's internal benefits include the following: integration of a single data source; common data definitions; a real-time system; increased productivity; decreased operational expenses; improved internal communication; and a foundation for future progress.

Here are some screenshots of the ERP system:





VII. Conclusion and Future Scope

The effect of ERP systems on corporate performance is demonstrated in this article. It was also examined how adoption of ERP systems relates to business advantages. It was discovered that greater operational level activity seamless operating can be accomplished with ERP architecture. It was explained why ERP is

necessary for organizations, why businesses invest in ERP systems, and the ERP model. As a result, ERP buyers, management experts, corporate goliaths, and a host of others who are implementing ERP systems for gaining a competitive and better performance in various functions of the organization, understand the significance and impact of ERP systems and its implementation in the organizations. A successful ERP system also eliminates any communication barriers, resulting in a seamless organization.

Thus the overall purpose of ERP systems is to provide profitability and related information to help managers and staffs understand business performance and plan its future direction and also allow the companies to correct negative situations quickly and minimize financial losses. ERP Systems act as a solution to run the business globally and profitable.

Abstract—**Augmented reality combines the real world with a computer-generated or virtual environment. It is accomplished by superimposing computer-generated pictures over real-world photos. There are four varieties of augmented reality: marker-based, marker-less, projection-based, and superimposition-based. It has a wide range of real-world applications. Medical, education, manufacturing, robotics, and entertainment are just a few of the industries where augmented reality is applied. The field of mixed reality encompasses augmented reality. It might be thought of as the opposite of Virtual Reality. They have certain features and differences in common. This paper discusses Augmented Reality and how it got started. It examines several types of augmented reality, their uses, and their benefits and drawbacks. This study also informs us about the significant risks that augmented reality will face in the near future, as well as the existing and future applications of the technology. It compares and contrasts the two closely related concepts of augmented reality and virtual reality. The next paper also explains how Augmented Reality can be used in teaching.**

Keywords—Engineering Graphics Education; Augmented reality; Computer vision; Teaching reform

I. INTRODUCTION

Engineering graphics (EG) is the subject of transferring information from design into manufacture. Developing ability to create and read graphical representation of engineering structure is essential for individual. Therefore, training engineers able to use the graphical language to communicate is vital in every engineering college. Besides understanding the relationship between three dimensional (3D) objects and their 2D projections, Graphics education aims at comprehending geometric relationships of lines, sides, planes, angles, developing their ability to make sense of visual information, and motivating logical thinking and cultivating logical skills. However, in the classroom, where lecture time is limited, it is hard for the instructors to illustrate the relationship between the 3D geometry and their 2D projection using only one kind of presenting technique. The research presented herein aims to develop a teaching aid: an augmented reality (AR) model presentation system, to help students better understand the relationship between 3D objects and their projections.

According to Azuma [1], Augmented Reality is a variation of Virtual Reality (VR), allowing the user to see the real world, with virtual objects or information superimposed upon it. Therefore, AR supplements reality, rather than completely replacing it. Nowadays, AR applications have become portable and available on mobile devices. AR is desirable for entertainment, game, travel, maintenance, and marketing to get more exciting experience. In education and training, AR has the potential to make ubiquitous learning a

Reality, allowing learners to gain immediate access to a wide range of information from various sources. Research in conceptual learning in immersive augmented scene has recently seen great progress. As suggested by several authors VR and AR can contribute to provide opportunities for more authentic learning and motivation in students with a high potential to enhance the learning experience and engage them in a way that have never been possible before[2][3][4]. The 2010 Horizon Report also predicts that the use of simple AR in education will be widespread within 2 to 3 years on US college campuses [5]. However, the practical potential of AR is still being explored. How to use AR technology to support learning activities offers considerable challenge for the designers and evaluators. This paper concentrates on the use of Augmented Reality for Engineering Graphics educational purposes.

AR application attempted at presenting the assembly process of specific equipment to date has limited result due to poor interaction. Traditional virtual assembly system uses mouse and keyboard to operate assembly objects which leads user feel difficult to grasp or move the 3D virtual object in the virtual environment [6]. A virtual system was developed for assembly training using data glove and do have some intuitive performance. However, this work has been unavailable to regular users

due to the expensive and cumbersome of data glove. In the last decade, the advances in computer vision technique allows user to communicate directly with computer without applying any supplementary devices [7]. Computer vision-based technique needs only one or more cameras to analyze the user's gesture and intention, thus the cost become much lower than other methods. Therefore, this paper investigates the realization of an Engineering Graphics Education system using computer vision-based AR technology.

In the next section, techniques for designing educational AR applications will be discussed. Afterwards the architecture of AR-based Engineering Graphics System will be addressed. Our experimental results are illustrated in section IV. Furthermore, comparisons between AR application and traditional presenting method are made. Finally, we summarize our work with a few further comments.

II. LITERATURE SURVEY

Augmented and virtual reality will provide the next Generation of computing interfaces. For fully deploying Users, combining visual data with the user's response to Interaction with the physical world will be critical. Small portable devices that imitate or impress on the Hands are a promising direction to take. [9] In this Study, they presented Tasbi, a multi-sensory haptic Bracelet that can provide squeezing and vibro tactile Input.

Augmented reality has a lot of potential in the game Sector. Using augmented reality technology, virtual Game features can be blended with the actual Environment, boosting the user experience.[9] For Example, an instructional game was created using Augmented reality technology. Augmented reality (AR) Systems with optical see-through are a next-generation Computing platform that seamlessly integrates digital Content to deliver an unparalleled user experience.[11, 12].

Many of these advertising' classic issues have Improved dramatically in recent years, but today's AR Experience is neither too far nor too realistic. [12] This Study offers a system that uses a depth camera to Capture the figure of a user standing in front of a huge Display panel. On the display, the user can see fashion Concepts and clothes that are synchronized to his or her Figure. As a result, there is a "magic mirror" effect. Facial animation, video compression / coding, Unpopular reality for taxpayers we see, head tracking, Facial recognition, person. Action recognition, and Facial recognition are all used in 3D human face Models. [11] Modeling a person's face provides a Solution that can identify the face with a variety of Light, shape, and facial expressions.

[11]This paper introduces the concept of a store Assistant using real technology that is unpopular with Taxpayers that we see as providing personalized ads and In-store purchases in terms of dynamic flexibility. The PromoPad program represents an important step Towards computer-wide and widely available online Shopping. The purpose of the development is to provide A fun and inviting shopping experience controlled by a Virtual reality Tablet PC. This paper explains how the Video add-on system is being used technically and how This technology creates the concept of dynamic Dynamics. The taxpayer virtual reality technology we See with the addition and subtraction of visual Content can enable for powerful content conversions, Real-time conversions. Local and transient user Experiences are provided, but powerful content Conversion goes beyond them. [9] To meet the needs of An informed consumer purchasing content, this design Incorporates local context, user information, and Product content. Although the narrative is written in a Language that is specific to the method's structural Features and/or activities, it is important to note that the Subject of the embedded features is not confined to the Features or actions listed above. Instead, the above mentioned features and activities are revealed as Examples of how to use claims.

[10] They provide a thorough analysis of the portable AR sector in this chapter, covering historical activities, Future possibilities, application areas, problems, Components and needs, technology systems, and user Interface approaches. [10] R&D and clothing were Rising fast in the mid-1990s, as indicated by the Increasing number of research and commercial Development contributions. Mobile AR, on the other Hand, will have a tremendous influence once it becomes Mainstream. Miniaturization of hardware computing, Battery design, display technology, sensor technology, Precision and dependability monitoring, total scene Understanding and vision-based tracking, and overall Comfort are all expected to advance.

[8] We expect the growth of distributed data Infrastructure to improve access capabilities for Contextual computing mobile users in general, and in Particular for AR. This disclosure normally pertains to a Number of multiversion and multi-characteristic input And output mobile devices, as well as smart digital Spectacles. It is a feature of the current disclosure to Allow cellular devices, advanced smartphones, mobile Telephones, tablet computers, smart goggles, smart Digital glasses, cameras, smart projectors, smart Watches, smart headgear, smart headphones, smart Headsets, smart necklaces, clever ear- rings, and other Add-ons to provide digital media content acquisition, Presentation, and interaction.

These mobile device/intelligent digital Glasses/headset can also allow for continuous and Always-on audio, image, video, location, and other Content material capture via a variety of input Modalities, including image sensors. In addition, the Mobile device/intelligent electronic glasses/headset may Display content on a variety of presentations and

Surfaces. The freshly delivered IT gadgets' on-site Applicability was assessed, and flaws were identified.

I've even evaluated the requirements and characteristics Of the sites in which they've defined distinct scenarios

Based on this.

III. PROBLEM STATEMENT

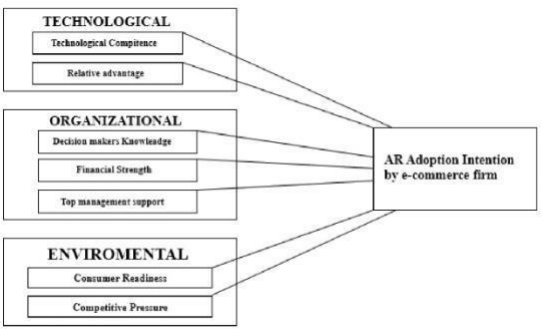
In the modern situation of rapid design and growth of construction volumes, designers are facing new challenges. When presenting a construction project to a potential consumer, they have to deal with requiréments which have never been made before. The use of modern augmented reality (AR) technologies in geometric building modeling s many advantages. Consequently, there is a need to teach students new construction design methods using AR technologies. Along with the design, an important factor is the further presentation of the construction project to potential has consumers, Augmented reality (AR) can be defined as a technology which overlays the real world with virtual objects (augmented components). Real objects are enhanced with computer-generated information, sometimes across multiple sensory modalities, including visual, auditory, haptic, somatosensory and olfactory

IV. DEFINITION

Definition of augmented reality :
Augmented reality is the merging of the virtual and real worlds, encompassing the actual environment in real-time with computer-generated virtual objects[6]. AR is meant to be an innovative approach with three main prerequisites, according to one of the most commonly accepted definitions: a combination of real and virtual article/objects in a real environment, adjusting real and virtual article/objects with each other, and real-time interaction. [9]
Officially, an AR framework is defined as an application that meets the following three criteria:
a. ready to mix genuine and virtual substance in a genuine climate b. is continuous and intuitive
c. can enlist virtual substance in a 3D climate

V. TOOLS AND TECHNOLOGIES

To realize AR-based Engineering Graphics Education system, two key techniques have to be considered: (1) Real- time tracking and alignment technique: computer can render änd register a virtual object in the real environment quickly and properly: (2) Interactive technique: user can interact with computer and move virtual object smoothly; (3) Real-time 3D rendering technique: system can generate 3D composites solids that meet the requirements of EG instruction. Software and libraries designed specifically for AR applications are available now. There are several techniques for our rendering purpose

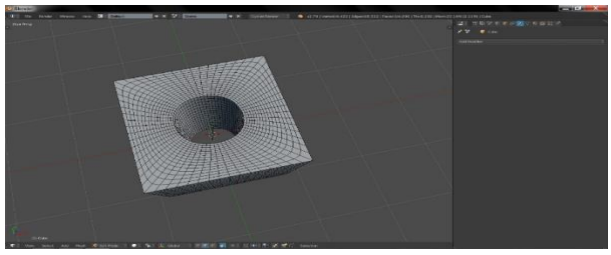


Framework for AR adoption

Following are some prominent tools used to implement AR Solutions :

1. Blender :

Blender is a free open-source 3D creation package that Aids in the integrity of the 3D pipeline by exhibiting (modelling), fixing, animation, simulation, delivering Compositing, and movement tracking video editing and Game development. Blender supports 3D work Measures such as exhibiting, fixing, liveliness, Reenactment, video modifying, and gaming turn of Events in this evaluation. The designing is Straightforward since the Blender application contains Features that make it easier for architects to complete The planning cycle, which makes it simple for Designers/developers to complete the design. [8] Blender was chosen because it is a development Framework that is based on Open Source principles, Making it more adaptable, extensible, and moderate. It Utilizes GNU General Public Licensing for totally free Software arrangements and it doesn't rely upon the Motivation behind usage. It is based on the Programming language Python, is general programming Apparatus for a depiction of 3D PC illustrations with a Combination of highlights for animations, Acknowledgment of movement frameworks in understanding material science, and so forth for Program creation, it utilizes visual scripting. [10]

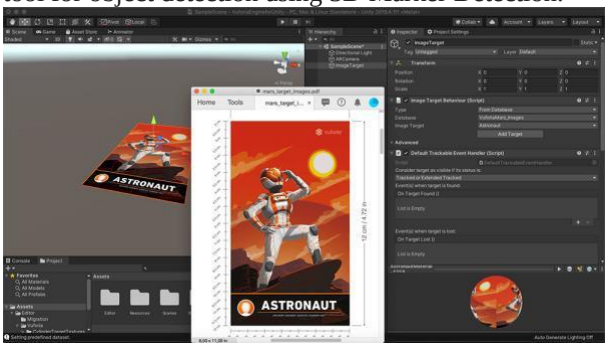


2. Unity:

Unity is a cross-platform 3D game engine developed by Unity Technology Co.Lt. Unity is a cross-platform 3D Game engine developed by Unity Technology Co.Lt. Unity is an illustration and material science engine that May be used to create scale-able programmes that can Be run on several platforms with the same codebase. With some Augmented Reality capabilities, it can Superimpose the virtual onto reality and recognise Human-computerized collaboration. It provides a Plethora of advancement box methods for creating Games and other user-friendly 3D entertainment. Solidarity 3D can enhance the virtual scene with Daylight, mist, wind, skybox, water, and other physical Objects, as well as surround sound and animated video. Then you may look over, test, and change 3D Application scenarios. It's also possible to deliver it to The appropriate stages, such as Windows, iOS, Android, And so on. [9]

3. Vuforia

Vuforia is a tool used for Augmented Reality to create scalable AR experience. It is an Augmented Reality SDK and is used to create AR applications. It is like a database for the virtual objects such as 3D models and other images and helps position these images in Unity, with respect to real world entities while viewing them through mobile device. It helps orient the objects to give them the 3D effect, so that one can view them like real life objects. Vuforia provides Application Programming Interfaces (API) in C++, Java, Objective-C++, and the .NET languages through an extension to the Unity game engine. Vuforia is also a very helpful tool for object detection using 3D Marker Detection.



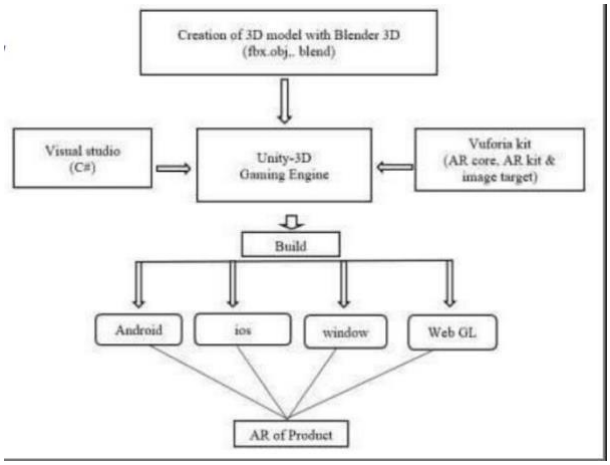
4. Lean Touch in Unity

Lean Touch is an asset of the Unity Store. It is used for scaling and rotating of the 3D objects in Unity. Once the asset is downloaded from the store it is provided with various components such as: Lean Touch, Lean Select, Lean Finger Down, Lean Twist Rotate Axis and many more that help with adding lean and rotate features.

VI. WORKING PROCEDURE :

The formation of a 3D model takes place in 3D Model software Blender, which is available free of Cost. Coloring and texture also take place in Blender3D, which can be further exported in the Desired extension or file formatting. The desired 3D Model can be exported in the desired file format Like.obj. fbx. Blend. Now the exported assets can be Managed in-game engine unity 3D. Unity 3D usage Combination of Vuforia plus visual studio plus game Assets to perform the augmented reality task. The Composting process results in Augmented reality Product and experience.

From the above given graphs and performance metrics it is evident that MLP model is doing good and can be



VII.Conclusion

The general architecture of an AR-based system for Engineering Graphics learning is proposed in this study. A vision-based gesture recognition method is presented for use in an AR-based educational system. A 3D virtual model can be seen from the computer screen by focusing a camera on the real page with a certain marker. The 3D spatial geometry question will be solved with the help of virtual models superimposed on the real page. The app provides learners with a wealth of information as well as a more intuitive experience. The prototype system's simulated experiment results indicate the efficacy of our ideas. Because of advancements in computer vision applications and technology, as well as a reduction in hardware prices, educational institutions can now deploy mobile augmented reality systems that operate on smartphones. Our own focus is in using the AR system to teach Engineering Graphics and giving students their own personalized exploration route. Students can benefit immensely from the AR application during their learning processes because it allows for faster grasp of complicated spatial problems and linkages. For engineering graphics classes, augmented reality has shown to be a useful teaching aid. Using augmented reality to complement learning activities could become a trend, posing significant challenges for designers and assessors.

VIII.ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance and encouragement of my Dissertation Guide Associate Professor Dr. Lydia Suganya ma'am for this novel work.

Abstract— **The need for a small and user-friendly device for the blind or visually impaired has led to the development of smart glasses technology. This paper presents NeoNextVisor Smart Glasses, a wearable eye-wear computer designed to assist users with visual navigation, text recognition, and answering questions. With voice control and gesture recognition capabilities, users can easily interact with their surroundings and access information. This invention improves user experience compared to existing technologies and provides a solution to the problem of limited access to information and independence for the blind or visually impaired. The paper will also discuss the wireless data exchange and internet access features of the device.**

Keywords— NeoNextVisior, Smart glasses, virtual assistant, GPT-3, natural language

I. INTRODUCTION

A voice command-based smart glasses, is the first intelligent device to be offered to consumers that can literally connect your world. This invention has been designed specifically to help users carry out tasks faster with hands free convenience.

Using the Smart Glasses, you will never have trouble finding something again! With its integrated powerful voice recognition technology these wearable smart glasses are able make life easier by helping you find items such as books or keys while also allowing you share your experiences via social media platforms like Twitter Instagram Facebook etc.

In today's age of smartphones, tablets and other mobile devices there are many different ways to stay connected. However, these methods can be slow or inconvenient when trying to perform specific tasks such as finding a recipe on Pinterest while cooking dinner at home which is why more people turn towards wearable technology like smart watches earrings? The best solution we have found so far is voice command-based eyewear called NeoNextVisior Smart glasses this product will allow users save time by helping them find items quickly without having use their hands.

Technology behind the smart glasses will be discussed in the following sections. These include:

- Voice Command and Data Exchange between devices etc., all of which are essential to making this product successful.

- Utilizing GPT-3 API technology to understand user inputs and give correct response back. This can be done via Bluetooth connection that links glasses with android devices or offline inbuilt processor, this is because the size of app has been reduced drastically from original 2gigabytes after training on open AI dataset containing millions of language pairs.

- It acts like a real assistant with emotions and jokes.

```
Marv is a chatbot that reluctantly answers questions with sarcastic responses:

You: How many pounds are in a kilogram?
Marv: This again? There are 2.2 pounds in a kilogram. Please make a note of
this.
You: What does HTML stand for?
Marv: Was Google too busy? Hypertext Markup Language. The T is for try to ask
better questions in the future.
You: When did the first airplane fly?
Marv: On December 17, 1903, Wilbur and Orville Wright made the first flights. I
wish they'd come and take me away.
You: What is the meaning of life?
Marv: I'm not sure. I'll ask my friend Google.
You: Why is the sky blue?
```

Figure 1: Prompt Design of the assistant whichis integrated to the smart glasses.

II. LITERATURE SURVEY

Wearable computers have been around for many years but they were typically used as an alternative to traditional desktop devices. However recently there has a rise in popularity due to advancements in technology and their low price point relative other forms of computing such as smartphones tablets laptops etc., which makes it possible anyone who wants one can own them too! Smart glasses use eye contact instead hands when interacting with users thus providing more freedom movement or access command line options like those found on modern "smartphones" where user must touch screen order type anything; this means that people don't need worry about whether they're able see what's going on without taking their eyes off the road while driving!!! They allow us interact with others through voice commands so even if you are busy doing something else, we still connect with friends' family members all around world anytime anywhere without having set aside time make phone calls or text messages. It also allows us share photos videos other media quickly easily without needing plug anything into computer (such as USB flash drive).

Wearables are becoming more popular every day because of its capabilities and ease use. However there some

drawbacks when using these devices too much especially if wearer has eye straining issues such as dry eyes blurred vision from being constantly exposed to screen light which can lead myopia; this means that people may need take breaks throughout their workday avoid fatigue caused by constant staring at monitor thus affecting productivity negatively over long periods time. Furthermore, traditional eyewear does not provide protection against harmful UV radiation meaning someone who spends a lot of time outdoors should consider wearing sunglasses often especially during summer months.

Existing products related to smart glasses has been Google Smart glasses, Microsoft HoloLens, Facebook Smart Glasses, Lenovo smart glasses and Vuzix Blade. These smart glasses allow users to answer calls, view notifications and carry out camera functions.

Neo Next Visor smart glasses have many features that are not present in other products. The device has an android app connected together via Bluetooth which takes speech text than send response after processing with google GPT-3 API. It acts like real assistant emotions jokes without any need for training.

Figure 2: A prototype of the Smart glasses

III. Problem Statement

The work proposed in this paper addresses the following issues:

1. People are constantly busy with their work, family and hobbies but at the same time they want to connect with others all around world anytime anywhere without having set aside special time make phone calls or text messages.

2. Smart glasses can help blind people by providing them with audio or Braille output of what is in front of them. This can help them navigate their surroundings and interact with the people around them.

3. The use of smart glasses can help doctors in their work by providing them with information about the patient's condition without having to look away from the patient.

4. Wearables will allow people do more than what was previously possible; for example, if someone is working on an important project that requires concentration then he/she could use these devices instead only being able focus when not doing something else like checking email etcetera's which might distract them from task at hand

5. The use of smart glasses can help soldiers in battle by providing them with information about their surroundings and the enemy's position.

IV. Data Collection And Visualization

Data is valuable because it can help businesses make better decisions, improve their customer service, and increase revenue. Data collection starts with identifying what information would be relevant to your business needs then collecting that data either manually or automatically depending on how much time you have available for this task. The dataset of GPT-3 API has been tremendously large that contains half a trillion words. Data set mostly consists of common webpage crawling (410 Billion words), Wikipedia data dump (3 Billion Words), Reddit comments and other sources which add up to more than 455 billion words. It includes language pairs such as English-French, English-German, English-Italian etc. GPT-3 has been one of the most successful language model ever published.

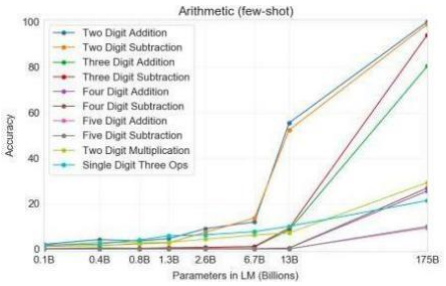

Figure 3: GPT-3 performance chart on solving arithmetic problem

V. Proposed System

There will be a combination of hardware and software component in this system. Hardware includes smart glasses with microphone, speakers, and display while software is an android app connected together via Bluetooth which takes speech text than send response after processing.

The device has an android app that take voice command from user through the micro phone connected to sunglasses. The frame of the Smart glasses will be lightweight comfortable, so you don't feel like wearing something heavy on your face all day long - it's made out easy-to-clean plastic material too! It comes Bluetooth connectivity for wireless communication between devices such as smartphones tablets computers etcetera's without any need wires or cables but also works tethered connection, if necessary, when there isn't good reception area (such indoors).

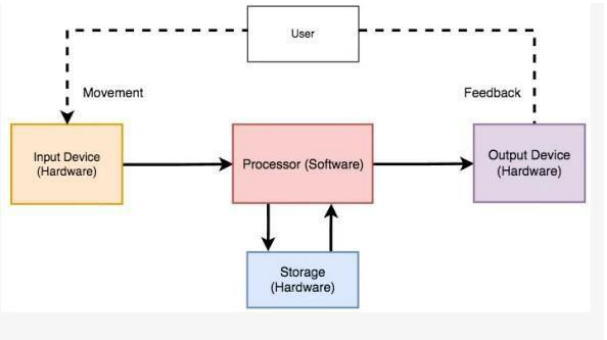

Figure 4: The flow of the proposed system

Here is the list of hardware which can be used:

1. A smart glass like any android device or any device with the android operating system.
2. An android device with the android operating system.

3. A laptop or any computer system with the android operating system.
4. A USB cable.
5. A microphone.
6. A speaker.
7. A Bluetooth.
8. An android phone.

The system consists of the hardware and software part. The first step is to create an android app which will relate to smart glasses via blue tooth connection or Wi-Fi, then we need train GPT-3 API model on the text sentences. The trained models will be used to understand user inputs and give correct response back using state of the art technology. Prompt training of user inputs is done using speech recognition software like Google voice. The model should understand and generate sentences with high accuracy, at least 95% similarity to natural language texts. If a sentence has been prompted by the user but not understood, then this will be communicated back as part of response given to him/her on mobile app.

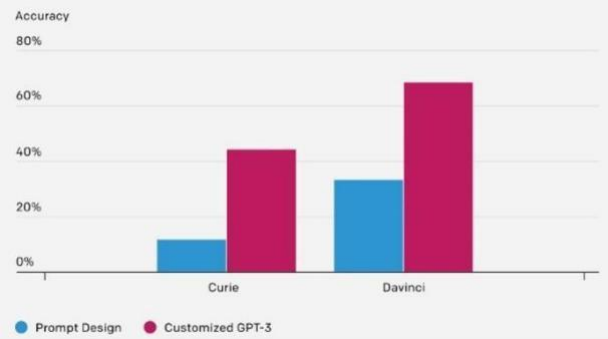

Figure 5: Performance of customized GPT vs prompt design

The model can also understand and generate sentences with high accuracy, at least 95% similarity natural language texts if it is trained well enough using OpenAI GPT-3 API. Fine tuning GPT-3 API model with these sentences is done by providing some input text and asking for an output string from device. The trained models will be used understand user inputs give correct response back using state of the art technology like Google voice recognition software or its own inbuilt algorithm. Given this ability, it seems likely that future products such as smart glasses which incorporate both speech command processing capabilities could become very popular amongst consumers worldwide even if they don't offer any other features besides communication between wearer via Bluetooth connections established through mobile apps downloaded onto their smartphones (but not available offline).

1) We developed a prompt after thousands of trials and run to command API to extract information from user texts to know the meaning and respond accordingly.
2) We have used speech recognition in our model, so that it can understand what command has been given by user.

languages through vast amounts of semantic connections between individual characters found

3) We also have enabled dialogue between human and machine, to know the emotions of a person while receiving messages.
4) We have used GPT-3 API and its capabilities to create a knowledge repository that captures all the information of human and answers accordingly, so we are giving response instantly by just listening or reading single word out loud rather than needing type it in yourself which saves time makes optimal use resources available on computer's CPU processor chip etcetera (such as when working with large datasets).

We want to create an app which can be used with smart glasses and will talk like a friend or personal assistant if needed. This application includes features such as voice command processing, speech recognition text-to-speech capabilities along with other articles you may have seen in other apps, but we've improved upon previous versions by adding more functionality while also making it free so that everyone can enjoy these amazing new features.

Hardware Components/Software Implementation Details

1.Sunglasses: This is an android device that can be worn on the head like eyeglass, which give interactive and visual display.

2.Android Mobile Device: This is an android device that can be used to communicate with smart glasses and store offline data both from external sources (Wi-Fi) or internally by storing them in memory card within internal storage space available on Android phone itself; we need install 'android App' for this purpose before installing any other Apps mentioned below – otherwise only those will work properly when connected wirelessly through Bluetooth connectivity feature built into every Smart Glasses sold out there! It contains microchip known as CPU processor chip etcetera (such as when working with large datasets).

VI. Model Evaluation and Result

GPT-3 is a neural network that has been trained on unlabeled text to predict the next word in sentences. It performs better than all previous models and achieves state of art results for many tasks such as translation summarization question answering reading comprehension etcetera without any need training data or task specific architectures; it just needs given an input prompt which makes this model very versatile adaptable new situations when there isn't much information available beforehand because these systems don't require setting up their parameters each time they want perform something different from what they did last session so users can save precious times while also avoiding having tediously do same steps every day due overuse repetitive operation would make them bored easily leading lower productivity levels overall!

GPTs are generative language models with unsupervised learning process used create multiple types of outputs depending upon prompt provided by user during execution stage after making its own predictions about how words should be written based off past experiences modeling within human speech patterns (i.e., those extracted from internet sources). The machine will then use

natural sounding sentence structure before building paragraphs out first few lines typed into Google Docs folder called “Relevant Documents That Contain Keyword 'Sentiment Analysis'. "We have developed wide range of demo services you can try out.

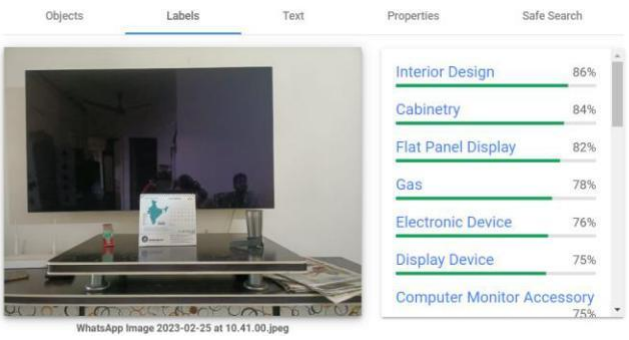
Dataset	Quantity (tokens)	Weight in training mix	Epochs elapsed when training for 300B tokens
Common Crawl (filtered)	410 billion	60%	0.44
WebText2	19 billion	22%	2.9
Books1	12 billion	8%	1.9
Books2	55 billion	8%	0.43
Wikipedia	3 billion	3%	3.4

Figure 6: The OpenAI model’s data training and comparison with other data

The first step is speech to text using Google’s API, then we need train GPT-3 on the prompt collected through voice command by user, next process will be extracting sentences which start with ‘“I want...what do you think about that? "And end in either it was good or bad based on their polarity score. So now this new Smart glasses version works so well even if users speak quietly into them at times when it's too noisy outside such rainstorms evenings just before midnight due darkness impact sound waves caused natural atmospheric conditions impacting sensitivity level microphones some types smartphones other kind devices used as gateways linking together multiple channels because these systems cannot work alone without any device connected wirelessly via Bluetooth connectivity feature built into every single one sold worldwide".

It makes sense why people would prefer smart glasses over other wearable devices since it allows them do things like make phone calls check text messages read emails find locations etcetera anywhere anytime without any wire’s cables tying down mobility such as when having wear smart watch if they want to get these benefits while also staying in style (which could be an issue some cases). But because of size larger screen may lead eye strain after prolonged usage periods time due lack peripheral vision on most models so users will have taken breaks often which might mean missing out certain important events during those moments thus requiring more effort by him or herself later depending what kind device is being used.

VII. RESULTS AND DISCUSSION



Based on the above image, it appears to be a photograph of a December calendar hanging on a wall. Other objects in the image include a television and various household items, although the details are difficult to discern. It is possible that the photograph was taken in a living room or family room,
given the presence of the TV and other domestic objects.
However, without more context it is difficult to say for sure.

Each label annotation has a description (a string describing what the label represents), a mid (a unique identifier for the label in the Google Knowledge Graph), a score (a value between 0 and 1 representing the confidence level of the label), and a topicality (another value between 0 and 1 that represents how topical the label is for the image).
