3.1. Dance Data Collection. "Dance data acquisition" is the first step in the dance virtual visualization scene design of motion capture technology. Data acquisition is a prerequisite and foundation in the process of dance digitization. In the process of dance digitization, data acquisition is a prerequisite and foundation. Only after the data information has been collected, the data information can be presented through the subsequent virtual display platform [13]. At present, dance data collection mainly includes three parts: first, "collecting dance materials." There are many dance materials in our country, and there are many channels for collection, such as individual performances, stage performances, and folk visits. The relevant personnel should prepare the collection equipment in advance and choose more advanced digital cameras, digital cameras, etc. Second, "digitize the material." After the dance materials are collected, they should be systematically organized. During this process, the relevant personnel should actively listen to the suggestions of professional dancers, make reasonable use of the dance materials, and then perform dance demonstrations based on the dance materials finally sorted out. Through the motion capture system, capture those classic dance moments and realize the digitalization of dance. Third, "Building 3D Models." The threedimensional model is constructed in 3 ds Max. The reference is based on the general body proportions of most men and women, and the corresponding costume models are established in combination with dance characteristics. It should be noted that the models are mainly divided into two types: one is the "fine model," which is generally not displayed on the virtual platform and is mainly saved as a kind of data which saves 360-degree video flies; the other is the "fine model." One is the "simple model," which is mainly used for virtual platform display. There are many classifications of dance, and combined with the characteristics of different dances, it is also possible to carry out "key binding," that is, to systematically evaluate the bound skeletal model and set relevant weights.

3.2. Dance Animation. Dance animation can be understood as the combination of "3D animation" and "motion capture data." 3 ds Max, Motion Builder, and other software can well link 3D animation and motion capture data. At this point, the work of data acquisition and dance animation is basically completed. After that, export the model file, motion data, etc. through 3 ds Max, and save it in FBX format.

3.3. Display System. At present, the "display system" mainly uses the three-dimensional game engine UNITY 3D. Tis display system includes the following modules in the opening session, just like film and television dramas, basically every three-dimensional animation video will introduce some basic information, such as production unit, content introduction, system name, which has become a conventional general title module; dress-up module - In short, this module is mainly used to change clothes, according to different regions, different dance style, and switch between different clothing animation models; camera control module: - unity 3D is a very popular 3D game engine because it has a very powerful control ability, through the dance movements presented by the 3D model. The viewer can observe from various angles, and can basically achieve a 360-degree panorama. At this time, the viewer will feel very wonderful. The presentation of the dance and the change of perspective can be controlled by a small mouse in the hand. At present, the camera control module can be programmed independently, or the default control system can be used: the dance selection module—the classification of dance can be measured from different dimensions. The dance selection module is mainly used to select the type of dance. At present, the main types of dances are dances performed on a large scale and in a standardized manner on major holidays, some minority dances circulated in the folk, some collective dances created by people spontaneously, and some dances composed and performed by dancers with special talents, used for dances on some special occasions, with certain funny elements and commemorative meanings in Children's Day, weddings, and corporate annual meetings; gender selection module - the role of this module is well understood, which is to distinguish male dancers and female dancers. In the three-dimensional game engine U-NITY 3D display system, through the coordinated operation of these five modules, the effect of virtual demonstration is finally presented. This system can now be used not only on computers but also on mobile phones.

4. Method of Motion Visualization System

The idea of the method proposed in this paper is based on principle of slit camera. The slit camera is used for judgments of horse racing and track sports, the media art and so on. On another our research, principle of the slit camera is applied to video scene display compactly and to extract features of video scene. The best feature of the slit camera is to be able to display the local domain of the space of long time scene compactly and to extract characteristics of the scene by well-known image processing techniques on displayed images without original scene. So we need no

programs for extraction of some kind of characteristics other than using package software like Photoshop R. To show and extract the characteristics of motion, we transform position and/or angle data given by sensors at a moment to a color line which correspond to one slit of the slit camera, and place the lines in a row every moment. Now, we describe how to visualize motion of four limbs as a example of our method. Four limbs (Right arm, left arm, right leg and left leg) are corresponding to sensor number 7-9, 8-9, 3-9, and 4-9 respectively. We explain about the left arm movement. We are drawing red line from coordinate original point to left elbow and to back (Figure 4). In this case, difference vector between No.8 and No.9 represents direction of left arm and the angle θ is computed easily. Then corresponding to the angle information θ, color information on RGB is determined following way. Because range of value θ is $\theta = 2/\pi \geq 0 \geq -2/\pi$. So we
set the RGB value of line as follows.

R = 255, G = 0 and B = 0, when $\theta = 2/\pi$.
R = 0, G = 0 and B = 255, when $\theta = -2/\pi$

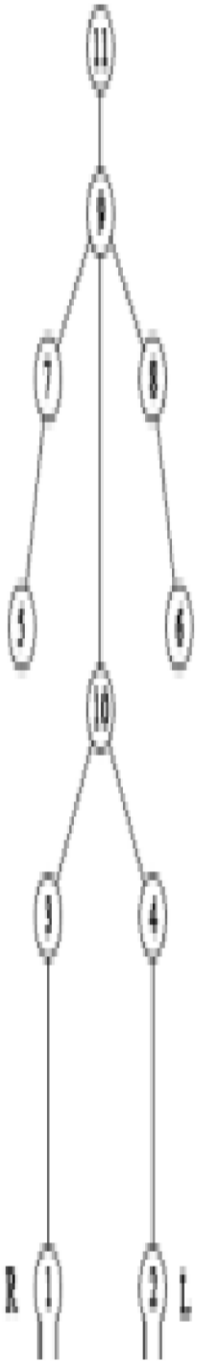

Figure 1: Human Model

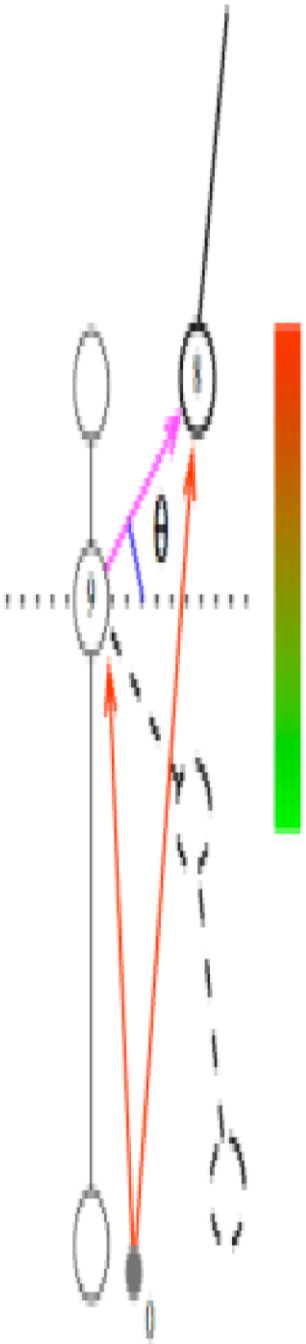

Figure 2: Vector & Degree

The color of intermediate angle is shown in Figure 2. Figure 3 shows the movement of right arm, left arm, right leg, and left leg as a color belt. A horizontal axis of the color belt shows time. As shown in Figure 3, we can understand intuitively a series of action of an actor especialy repetition of an action. This is data of a certain the radio gymnastics which is well known as a healthy physical exercise in Japanese. This exercise consists 13 phrase about three minutes (Figure 4).

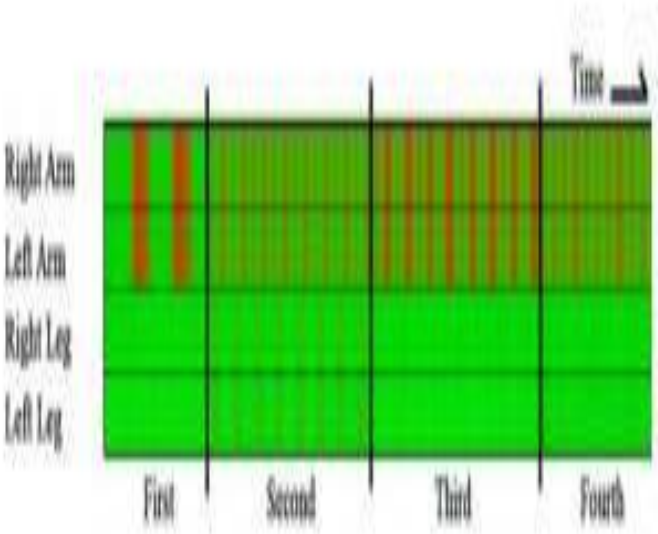

Figure 3: Color Belt

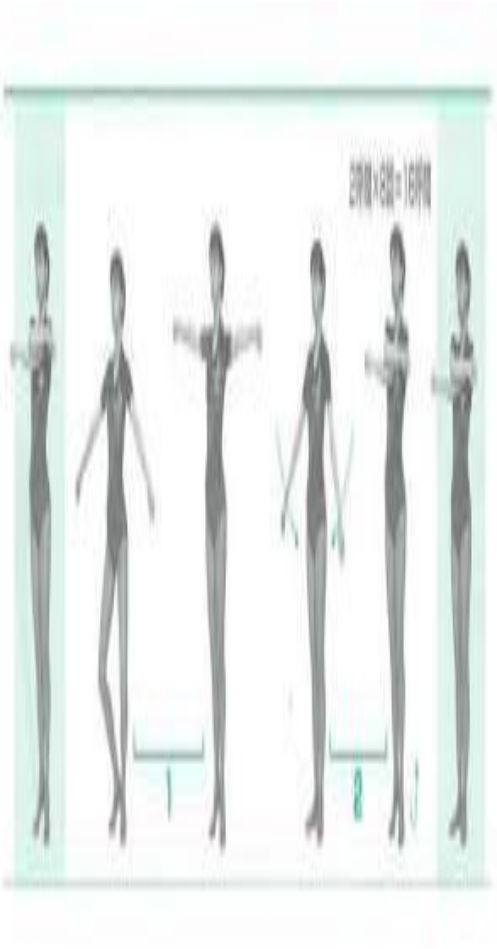

Figure 4: Sample of physical exercise

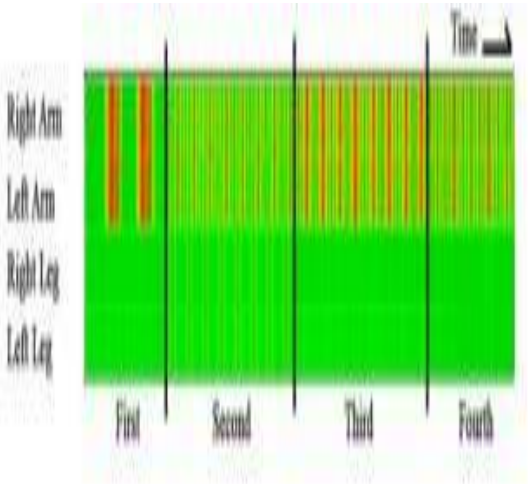

Figure 5: Color Belt2

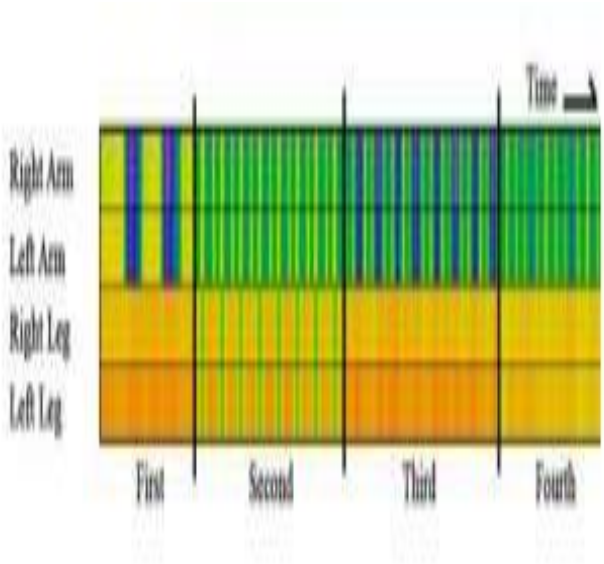

Figure 6: HSV Conversion

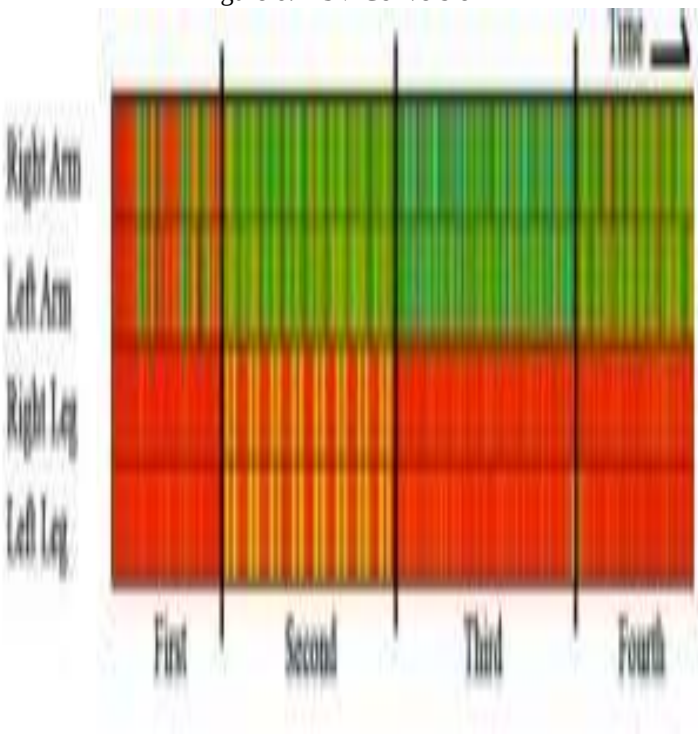

Figure 7: Prewitt Filter (Hue threshold value:0)

5. VISUALIZATION VARIATIONS

The user, whether this is the performer alone or the teacher, can make some initializations and choose among different options of visualizing the different parameters. These parameters mostly are particle systems and motion trails. Our particle systems consist of a large number of primitive 3D shapes. Their behavior replicates phenomena such as smoke, fire etc. and they are produced by an emitter. The emitter is an invisible spot which operates as the source of the particles that are being rendered. Our Motion trails are entities

that consist of large number of sprites that are too close to each other and replicate the effect of a light trail.

5.1 User Interface (UI) :Through this menu the User can change several settings during the session. For the time being we have implemented controls such as buttons for changing the camera view , morphing to another avatar ,taking screenshots, recording videos, restarting the scene and hiding the menu itself, switches for activating/deactivating particles and sliders for adjusting the shape of the motion trails and the duration that they remain rendered .However, there are corresponding hotkeys for quicker actions.(Figure 8) The user can decide on which joint of the avatar he/she will put the particle emitters, and therefore decide to bring the performer's focus and attention on a particular body part or joint. The switches and sliders allow the user to change the mode of emitting style. This can inspire different qualities of movement. In the following section we describe in detail what these different options and variations for the visualizations are.

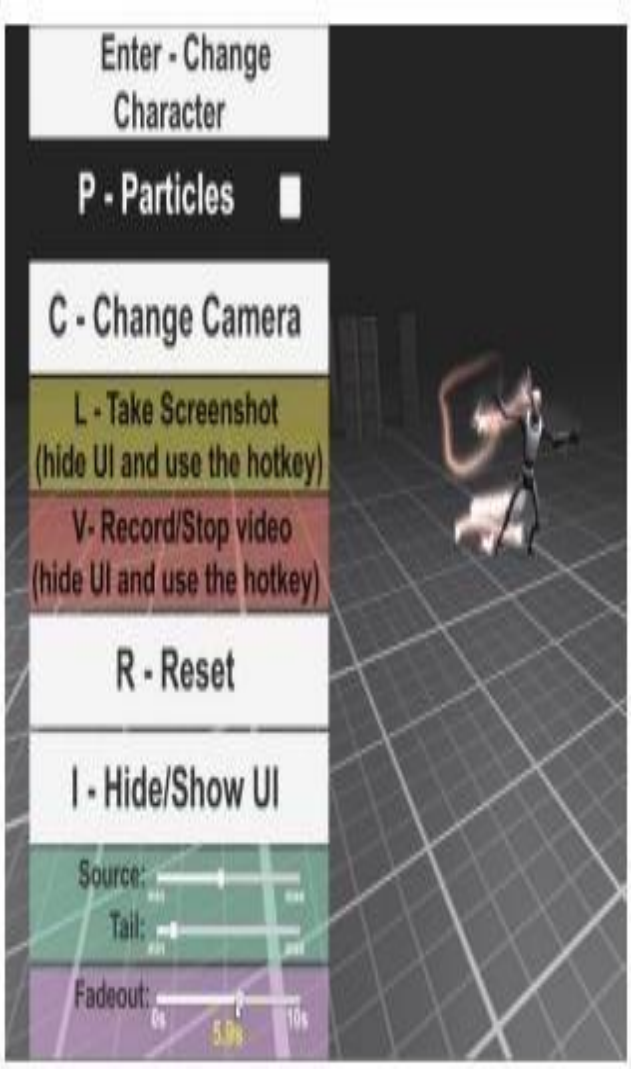

Figure 8: UI and avatar (a) with motion trails

5.2 Avatar variations One of the main questions when it comes to teaching dance through animation, is how the avatar looks like and how the characteristics of this avatar reflect the body image related with the dance practice or context . In this work, through the simple interface, the user can choose different avatars -predefined 3D models. In the following figures, four of the different anthropomorphic Unity avatars, which have been used in the experiments are shown. In addition, we have collaborated with a 3D artist, for creating additional customized 3D models depicting anthropomorphic but more abstract shapes. Figure 9 shows one of these anthropomorphic prototypes which depicts a "sharp" character with spikes on its back. It is true however, that all the examples shown in the Figures, reflect a variety of mainstream or archetypical characters and more abstract body representations. The different avatars allow the interactive experience to range from a gamified, creative experience, which can be addressed also to children, to an improvisation environment where the looks of the character can guide the performers' movement qualities into a "motion story".

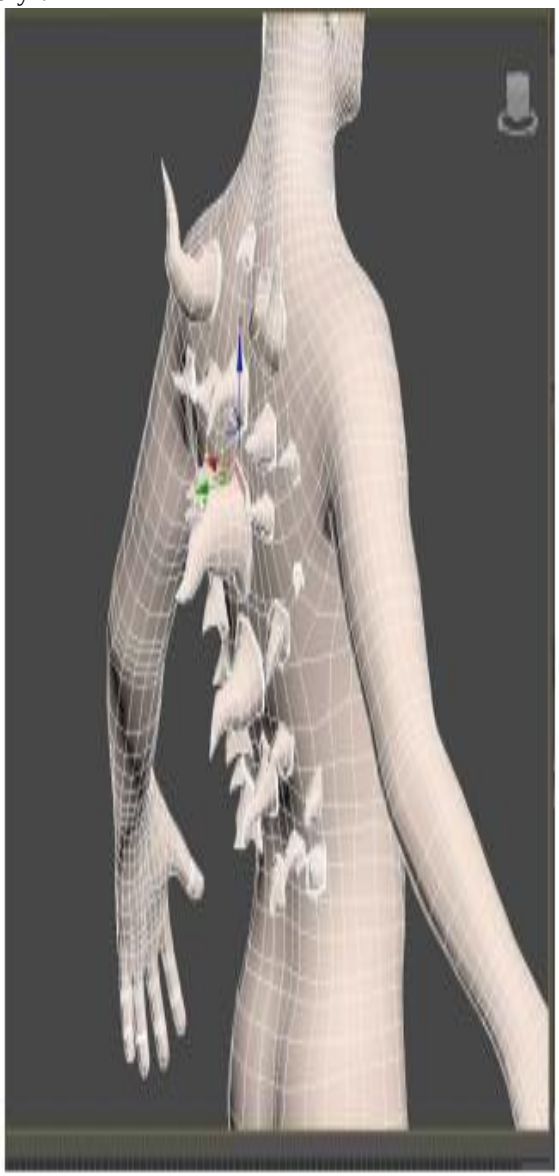

Figure 9: Initial prototype of 3D model with spikes Also, there are be three emitting modes:

Continuous Mode Particles are pre-emitted during the session and when the User changes the avatar, the flow of the particles doesn't start again from scratch. This mode is currently used for the particles.

Fade-in Mode Particles start to be emitted when the session starts. Also when the User changes avatar, the emitter starts again from scratch and a fade-in effect is created. This mode is currently used for the particles.

Trigger Mode Motion trails are rendered only when the Avatar moves the joint where the emitter is attached to. When a specific joint stops moving, its corresponding emitter stops rendering. The fade-in and fade-out effects apply here too. This mode is currently used for the motion trails.

5.3 Screenshot and Video recording. The system provides recording options for archiving and further analysis of the movement of each performer in relation to the different options of visualizations. The user (performer) can record her/his actions by recording the session as an image sequence (which can be edited to a video with a video editing software) in order to see how its avatar moves, how it interacts with the visual world and how the particles visualize his/her movement, after finishing the dance learning task, or improvisation. Also, a recording can be made in the Animate software, where it will be exported as a .bvh file which contains mocap data and will show the movement of the skeleton, which can be later edited in an 3D animation software.

6. Conclusion and Future Work

Using the visualizing method proposed in this paper, it is possible to display to be compressing time and space by color belt image and to extract of characteristics of motion by applying image processing method. The virtual visual scene design of dance based on motion capture technology is of great significance for the diversified presentation and inheritance of dance, especially for some relatively classic and small minority dances, because fewer people learn these dances, these dance forms are facing a crisis of inheritance. The virtual visual scene design of dance based on motion capture technology can better protect these minority ethnic dances, so that more people can see the charm of this dance and are willing to inherit and develop it.

For the future, we will look for a way to feature extraction and representation for a more comprehensible way

Abstract— **This research has explored the issue of insecure direct object references (IDOR) in web applications, which can allow attackers to gain access to sensitive resources and perform unauthorised actions. Also discuss various methods to prevent this vulnerability, including implementing proper authorization checks, using access control lists, and employing tokenization to securely reference objects. In this research, also propose an innovative solution that utilities machine learning algorithms and anomaly detection techniques to identify potential IDOR vulnerabilities before they can be exploited. This solution involves fuzz testing user input to discover potential IDOR issues and then leveraging machine learning algorithms to determine which input values are most likely to lead to unauthorized access. By proactively identifying and addressing IDOR vulnerabilities, this approach can help organizations enhance the security of their web applications and protect against attacks that could compromise sensitive data and systems.**

Keywords— IDOR, Security, Web Application, Network, Vulnerability1. Introduction

I. Introduction

Insecure Direct Object Reference (IDOR) http://www.hdfcbank.com/transaction.php? is a security vulnerability related to using id=113 identifiers to directly access internal

The term IDOR gained popularity after objects without additional authorization appearing in the OWASP (Open Web checks.

Application

Most websites repeatedly generate user

Security Project) 2007 Top 10. However,

IDs, cookie IDs, and other identifiers. For this is just one example of many access example, suppose one user's ID is 112 and control the next user's ID is 113. Database implementation errors that can lead to requirements are:

access control bypass. [5] IDOR http://www.hdfcbank.com/transaction.php? vulnerabilities are most commonly id=112

associated with horizontal privilege http://www.hdfcbank.com/transaction.php? escalation, but can also occur in id=112

conjunction with vertical privilege

The IDOR vulnerability allows hackers to escalation. access other users' data simply by changing the

Example

IDOR vulnerability with direct references to database objects Consider a website that uses the following URL to access the customer account page, which retrieves information from the backend database: [3] https://insecurewebsite.com/customer_account?customer_number=132355

Here, the customer number is used directly as a record index in queries made against the main database. If there are no other controls, an attacker can simply modify the customer_number value, bypassing the access controls to view the records of other customers. This is an example of an IDOR vulnerability that results in horizontal elevation of privileges.

An attacker can perform horizontal and vertical privilege escalation by changing the user to a user with additional privileges while bypassing access controls. Other possibilities include exploiting leaked passwords or changing settings when an attacker accesses a user's account page.

IDOR vulnerability with direct references to static files

IDOR vulnerabilities are common when sensitive resources reside in static files on the server-side file system. For example, a website may store transcripts of chat messages on disk with ascending filenames and allow users to retrieve them by visiting a URL such as:

https://insecurewebsite.com/static/12144.txt

In this situation, an attacker could simply rename the file to obtain a transcript created by another user, thus obtaining the user's credentials and other sensitive data.

II. BRIEF HISTORY

If the server doesn't check incoming HTTP requests to access objects, there is a vulnerability known as an Insecure Direct Object Reference. The application exposes the underlying object details to the attackers since it is unable to verify the legitimacy of the person attempting to access an object. Attackers then obtain access to the object without authorization and change the value of the object's ID parameter to carry out their malicious actions.

As a result, users can be unknowingly forwarded to dangerous pages. In the worst situation, users' private and confidential financial and personal information may potentially be compromised.

Three security flaws lead to the Insecure Direct Object References vulnerability:

- To adjust an object reference, a client can change user-supplied data such as form or URL parameter values.
- The web server makes an internal process or item directly accessible.
- For access to internal objects, the programme doesn't do enough authorization checks.

The effects of the attack may be disastrous because object references reveal information about the core implementation details of the application.

A successful IDOR attack can have different impacts, such as:

Unauthorised access to sensitive data: – Object references often include database IDs, which attackers can access to expose sensitive information about the application/users. The unauthorised user can also use database entries to prepare malicious SQL payloads for further attacks.

Object manipulation: – Attackers who have access to internal references have direct access to the application's data and state. Attackers can then edit the exposed items to change data, gain access to secret features, or gain more power.

Direct file access: – In order to influence the host's file system, malicious users can combine IDOR attacks with directory transversal attack strategies. This enables individuals to freely upload and download files and alter content that other users access.

Priority levels of IDOR vulnerability based on their severity:

P1 - Account takeover, access to highly sensitive data (credit cards, etc.)

P2 - Modifying/deleting other users' public data, private/public sensitive data (tickets, invoices, payment information, etc.) P3 - Access / Delete / Modify Personal Data (limited personal information: name, address, etc.) P4 - Access to unrelated data IDOR Vulnerability At the discretion of the program manager.

III. IMPLEMENTATION OF SECURE CODING TO AVOID IDOR

The IDOR vulnerability primarily causes unauthorised access to user account information on the backend of the web application using unauthenticated support in SQL.

With the code below, an attacker can change the information_schema parameter of the web application and enter multiple account numbers to retrieve information.

```
String query = "SELECT * FROM
information_schema WHERE account = ?";
PreparedStatement test =
connection.prepareStatement(query, ... ); pstmt.setString(1,
request.getParameter("information_schema")
);
ResultSet results = test.executeQuery( );
```

General Remediation

The disclosure of private object references like keys or file names should be avoided by developers. Parameter validation must be implemented correctly. All of the Referred objects should be verified. Tokens ought to be created in a way that only the user may map them to them; they shouldn't be made available to the general public.

Query Component : id=23

Here, we can see that the /profile page is being requested, and the query component includes the parameter id with the value of 23. This page might be displaying private user information to us, and by altering the value of the id parameter, we could view information about other users.

Post Variables: Reading through a website's forms may occasionally disclose fields that are open to IDOR abuse. Consider the HTML code below for a form that refreshes a user's password as an illustration.

```
<form method=”POST” action=”/updatepassword”>
<input type=”hidden” name”user_id”
value=”123″> <div>New Password:</div>
<div><input type=”password”
name=”new_password”></div> <div><input
type=”submit” value=”Change
Password”>
</form>
```

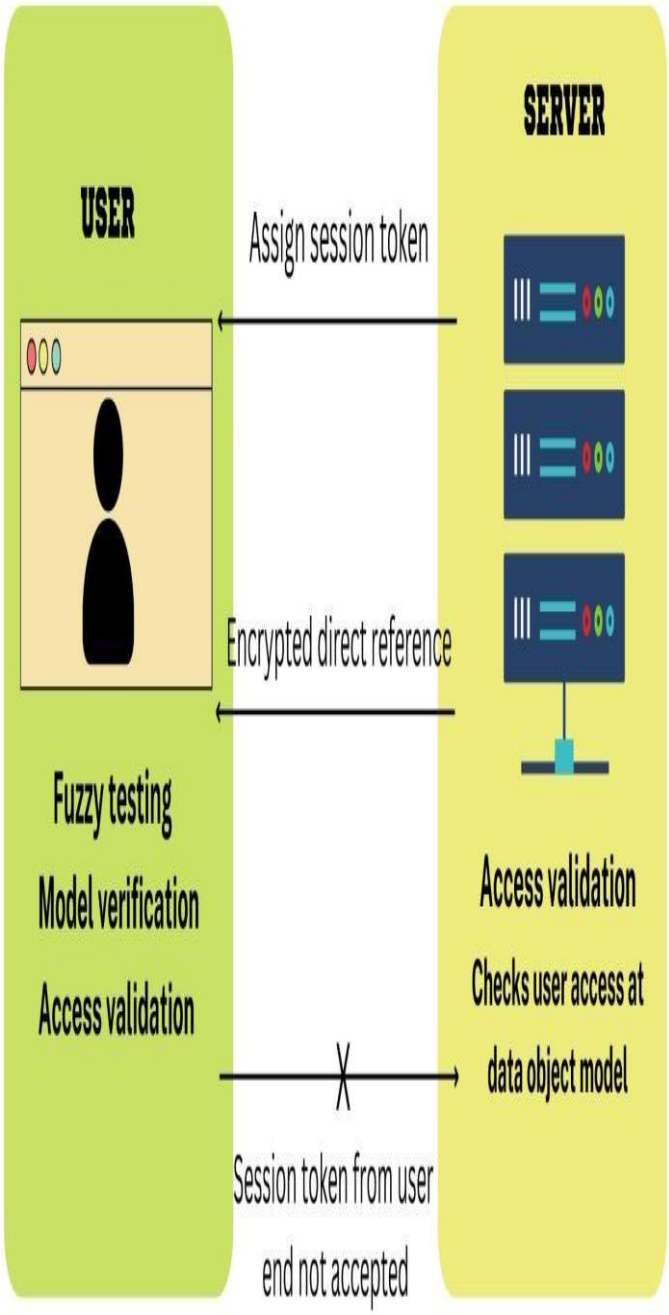
Here, above the code user_id is passed to a webserver in a hidden field. Changing the value of this field from 123 to another user id may result in the password of another user's account being changed.

Session cookies for enhancing website security

Cookies are used to remember your session when you visit a website like this one. Typically, this will entail delivering a session id, which is a large string of random, difficult-to-guesstext, such as 5db28452c4161cf88c6f33e57b62a357 the web server will use the session cookies to securely validate and retrieve user's data. Examplehttps://pass.com/messages?user_key=5db28 452c4161cf88c6f33e57b62a357

The website would be more secure, and the attacker would have a far more difficult time guessing the key. However, the majority of websites use unsafe, direct, object, and reference.

These types of "Direct Object References" expose IDOR vulnerabilities, allowing anyone to obtain information that is not associated with his identity.



Why and when to use cookies ?

Cookies enable us to keep track of the status of the programme using tiny files stored on the user's computer because the HTTP protocol is stateless. Where the cookies are kept is up to the browser.

Internet Explorer frequently stores them in the Temporary Internet Files folder. The user experience can be customised by giving customers the freedom to choose their preferences. The subsequently requested page is customised in accordance with the preferences stored in the cookies.

Cookie example code <?php setcookie(cookie_name, cookie_value, [expiry_time], [cookie_path], [domain],
[secure], [httponly]);

?>

A simple software that enables us to save the user name in a cookie with a 10-second expiration time. The implementation of the "cookies.php" example from above is displayed in the code below..

<?php setcookie("user_name", "Guru99", time()+ 60,'/'); // expires after 60 seconds
echo 'the cookie has been set for 60 seconds';?> Output : the cookie has been set for 60 seconds

Retrieving cookie value:

Create another file named "cookies_read.php" with the following code.

<?php print_r($_COOKIE); //output the contents of the cookie array variable ?>

Output:

IV. PROPOSED SYSTEM

Proposed system to prevent IDOR protection: There can be various ways to prevent from IDOR some of the ways are stated below:

1.Fuzzy Testing – Before submitting the code to the server, the developer must fix all of the mistakes. For instance, logging onto any social networking website takes an email address and password. To minimise input, the password and email must both follow a specified format.

2.Model Verification – In order to concentrate on model verification, numerous fields are associated with the post parameter in this model verification module, thus the developers need to safeguard the website against parameter tampering. You might also refer to it as parameter verification. Verifying that a string is within the appropriate minimum and maximum lengths is a form of verification. Also, make sure that the system is free of any undesirable characters, such as some special characters like ->. plus a lot more.

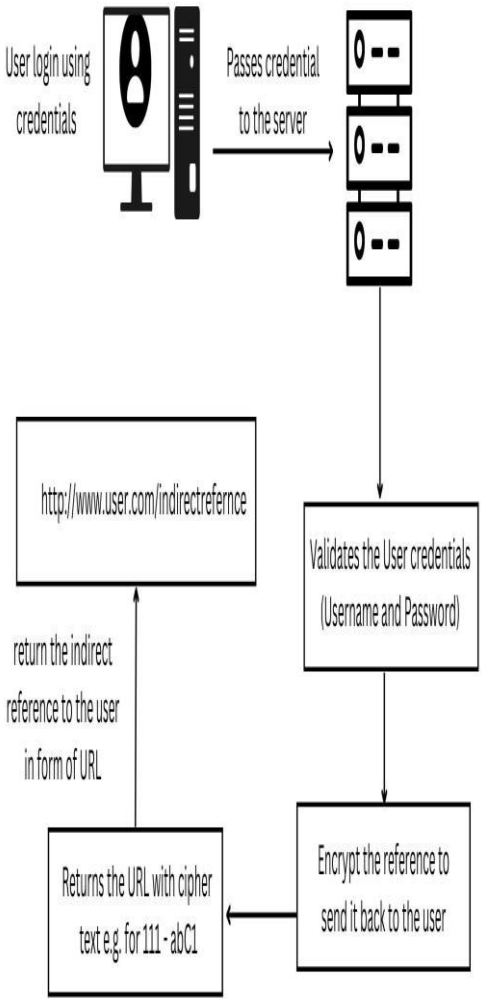
3.Access validation – The best strategy to stop an IDOR attack is to carry out user access validation. The system/application should stop the request if an attacker tries to tamper with the database or any application code after confirming the user's access. 4.Avoid Exposing Direct Object References - Use the data already existing in the user's session on the server to find the resources to serve rather than relying on the references in the URL. If users are only permitted to access their profile, like in the www.example.com/profile/3032 route solution we just reviewed, we may utilise the logged-in user's ID in the session to retrieve it, negating the need to send id as a URL parameter.

5.Use an Indirect References Map- We can utilise the indirect reference map technique if the developer is unable to prevent revealing the references to objects in the URL. The fundamental concept is to replace the sensitive direct reference in the URL with an unpredictable random value (such as GUID)

6.Check User Access at the Data-Object Level - This defence method deals with the vulnerability's main cause, an inadequate or absent access check. First, you should never limit access control to client-side checks because an attacker can quickly get around these. It is rather simple to include permission checks at the functionality or route level while implementing the serverside access controls.

We have discovered that encryption algorithms like RSA, AES, and Base 64

V. CONCLUSION



approaches can be used to prevent Insecure Direct Object Reference.

Abstract—**This case study focuses on estimating position of User Equipment in a radio network using neural networks. Both Convolutional Neural Network and Dense Neural Network were used based on the available features. The model's performance was validated using K-Fold cross-validation.**

Keywords—***channel impulse response, user equipment, convolutional neural network, dense neural network, K-fold cross validation.***

I. INTRODUCTION

In positioning scenarios, multipath, non-line-of-site (NLOS), indoor coverage and non-ideal synchronization may create obstacles that can be challenging to solve using conventional techniques. As a result, an AI-based positioning strategy is employed.

The aim of performing this study is to estimate the position of a user experiment (x, y) in a given area using features of a radio network gathered by eighteen base stations. Following are the features incorporated in training the neural network.

1. Channel Impulse Response (CIR): The technique of channel sounding involves figuring out a transmission channel's impulse response, particularly a cellular radio channel. The idea was inspired by traditional acoustic distance-measuring techniques, such as using an echo sounder to gauge water depth. The channel impulse response (CIR), which includes the magnitude and phase of the signal, gives intricate, thorough information on the effect of the channel of interest on a radio signal. As a result, it is perfect for describing the channel. The radio channel is negatively impacted by reflection-induced signal echoes, diffraction and scattering-induced distortions, building and tree induced shadow effects, and even weather-related impacts like rain and snow.
2. Reference Signal Received Power (RSRP): In order to always connect to the cell tower with the best signal, user equipment continuously scans the signals emitted by all neighboring cell towers. A modem uses a value known as RSRP to decide which tower to connect to. Reference Signal Received Power (RSRP) is the linear average of the power contributions made by the resource elements that transmit cell-specific reference signals within the bandwidth of the measurement under consideration (in [W]). The antenna connector on the user equipment (UE) is to be used as the RSRP's reference point. With the restriction that relevant measurement accuracy standards must be met, the
3. UE implementation is left to decide how many resource elements within the considered measurement frequency spectrum and within the measurement time are employed by the UE to estimate RSRP.
4. Time of Arrival (TOA): The time of arrival (TOA) is the length of time it takes for a signal to travel from the source to the receiver. In order to measure the TOA information, the source and all of the receivers must be precisely synchronized. If a two-way or round-trip TOA is computed, a similar system is not required. The measured distance between the source and the receivers is obtained by multiplying the computed TOA by a specified propagation speed, typically represented by the letter c. The source must be located on the circumference of the circle that the measured TOA represents having its center as the receiver in a two-dimensional (2D) space

   A distinct intersection point between three or more of these circles produced by the noise-free TOAs corresponds to the source position. To estimate a two- dimensional position of a source, a minimum of three sensors are needed, and these can be represented as a collection of circular equations. By using the optimization criterion and the known sensor array geometry, the source position can be calculated.[8]
5. Time Delay of Arrival (TDOA): TDOA is a positioning method that is calculated by finding the difference between the TOA of radio signals. In a

real-time location system (RTLS), TDOA is used to precisely determine the location of tracked entities in real-time, such as tracking tags attached to personnel or important assets. It requires three or more remote receivers (probes) that can pick up the desired signal. Each probe is time-synchronized to record the appropriate I/Q data blocks. To determine the difference in arrival times at each probe, software modifies the time signature of each I/Q data set. This reveals the variation in the source's separation from each pair of probes. A collection of curving lines indicating answers to the distance equations are produced by using many probes.

6. Position (Pos): Determines the x and y co-ordinates of a User Equipment in a given area on the basis of features such as fingerprinting, received signal strength (RSS), angle of arrival (AOA), time of arrival (TOA), time difference of arrival (TDOA), etc. One can directly

change the TOA and RSS to reflect the range measurement.

An ensemble model composed of Convolutional Neural Networks and Deep Neural Networks were used for the final prediction where all four features were given as input attributes. A K-Fold cross validation method was used to validate the neural network's performance.

II. BACKGROUND

Wireless technology enables communication between users or the movement of data between locations without the use of cables or wires. Radio frequency and infrared waves are used for a lot of the communication.

The two types of wireless networks that are most frequently encountered in real-world situations are:

1. Local Area Network (LAN): Used in places such as your office's internal network or your home's network of devices (computers, game consoles, mobile phones and tablets connected to the same router in one location form a local area network). In the past, establishing a local area network required a wired connection using what is known as an "ethernet cable." WiFi is currently widely utilized for local networking, even if wired networks are still extremely popular for a variety of factors, including superior protection from interference and security when compared to wireless.
2. Wide Area Network (WAN): The Internet could be seen as a wide area network (WAN), a sort of network that spans a greater area. Because they are typically faster, more dependable, and less prone to interference, wires are utilized to move the majority of the data moving through the network in the case of the Internet. But still, more and more people are using cellular data to access to the Internet wirelessly since the introduction of the contemporary smartphone and other portable devices like tablets.

The advent of Industry 4.0 and the development of mobile wireless technology, from 3G/4G to 5G, have led to an increase in the complexity of wireless system design. Due to demands for effective resource sharing among growing user bases, wireless networks have also grown more challenging to operate. Since traditional rule-based engineering approaches are no longer sufficient to address these problems, many engineers are turning to artificial intelligence (AI) as a solution.

Artificial intelligence (AI) has introduced the sophistication required for contemporary wireless applications, from coordinating communications between autonomous vehicles to optimizing resource allocation in cellphone conversations.

The fifth-generation (5G) mobile network era has made it possible to integrate edge computing, big data, Internet of Things (IoT), artificial intelligence (AI) and other technologies. Big data analytics, accurate parameter estimation, interactive decision making, and compelling applications of wireless networks (e.g., heterogeneous networks (HetNets), cognitive radio (CR), Internet of Things (IoT), and machine to machine (M2M) networks) have all been successfully supported by AI algorithms. Future wireless network architecture integration of AI has emerged as a technology trend for investigation and research. The architecture for wireless network transmission in the future will benefit greatly from AI. In addition, more study is required on how AI is applied to modelling communication network channels, network operation and maintenance, network security audits, and other areas.[7]

The function of AI in wireless technology will grow along with the variety and volume of devices linked to networks. Engineers need to be ready to integrate it into evermore complicated systems. Future success of the technology will depend on understanding the advantages and existing uses of AI in wireless networks, as well as the best practices required for effective implementation.

III. METHODOLOGIES IMPLEMENTED IN THE MODEL

Machine learning lifecycle is a systematic iterative process of developing an optimal model ready for incorporation into a production system and consumption by the targeted end-users. It involves training, testing, and deployment of the model. Following are the methodologies incorporated in this model: -

1. Dense Neural Network: A node layer of an artificial neural network (ANN) consists of input layer, one or more hidden layers, and an output layer. Each node, or artificial neuron, is connected to other nodes and has a weight and threshold that is associated with it. Any node whose output exceeds a defined threshold value is activated and begins supplying data to the network's topmost layer. In this instance the activation function used prominently was Rectified Linear Unit (ReLU).

2.Convolutional Neural Network: Convolutional neural networks outperform other neural networks when given inputs such as images, voice, or audio. There are three main categories of layers:

a. Convolutional layer

b. Pooling layer

c. FC (fully-connected) layer

A convolutional network's primary layer is the convolutional layer. The fully-connected layer is the last layer and convolutional layers or pooling layers, come after it. The CNN[1][2] becomes more complicated with each layer, detecting larger areas of the image. Initial layers specify basic elements like colors and borders. The prominent features or shapes of an object are first recognized when the visual data moves through the CNN layers, and eventually the intended object is recognized.

3. K-Fold Cross Validation: A resampling technique called cross-validation is used to assess machine learning models on a small data sample. The process contains a single parameter, k, that determines how many groups should be created from a given data sample. Thus, the process is frequently referred to as k-fold cross-validation. In applied machine learning, cross-validation is usually used to measure how well a machine learning model performs on untrained data. That is, to use a small sample to assess how the model will generally perform when generating predictions on data that was not utilized during the model's training.

IV. METRICS FOR EVALUATION OF MODEL

To evaluate performance of the model, following metrics were used: -

1. Mean Squared Error (MSE): MSE measures the amount of error in a statistical model. It is defined as the mean or average of square of difference between the actual values and the predicted or estimated values. It is represented mathematically as follows: -

$$MSE = n^{-1}\sum ni=1(yi - ypred)2 \quad (1)$$

Closer the value of MSE is to zero, more accurate the model is.

2. Position error at 0.9 cdf: A cumulative density function (cdf) is used to describe the probability distribution of the variables. In this case the cumulative density function was plotted against position error in model and the error at 90% cdf was observed. Lower the error value, more accurate the model is.

V. IMPLEMENTATION OF MODELS

The dataset is a labelled set of wireless communication data which contains large amounts of channel samples in different forms which can be used for AI-based wireless communication research.[12]

The implementation of the model took place in four stages. In the first stage, channel impulse response was provided as input to the neural network model. In the second stage, RSRP, TDOA and TOA were used as input features. In the third, all four inputs were given to the neural network. Results of all three stages were compared to see which approach was more optimal and accurate and validated using K-Fold Cross Validation Method.

A. Stage 1: Channel Impulse Response

In the initial stage, Channel Impulse Response was used to predict the position of User Equipment. The dimensions of the input are as follows: -

(80,000, 18, 256, 2)

Since the input is 4 dimensional, a convolutional neural network[5] approach was used. Following is the model of neural network that was implemented.

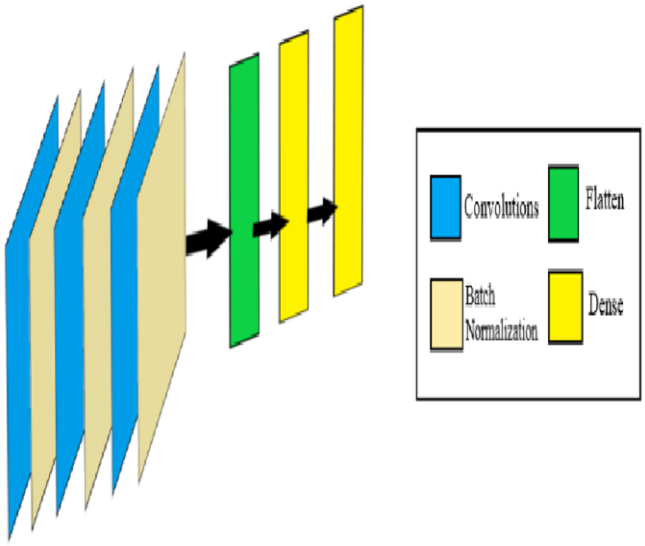

Fig. 1. This figure shows the flow of Convolutional Neural Network executed for stage 1 i.e., predicting position of User Equipment using Channel Impulse Response.

B. Stage 2: RSRP, TDOA and TOA

In the second stage the input data given was RSRP, TDOA and TOA. Each of them had a dimension of: -

(80,000, 18)

Since the data provided was two dimensional, all three inputs were merged to form a three-dimensional data of the form: -

(80,000, 18, 3)

This input was fed into a model containing Dense layers. An illustration of the model incorporated is shown below: -

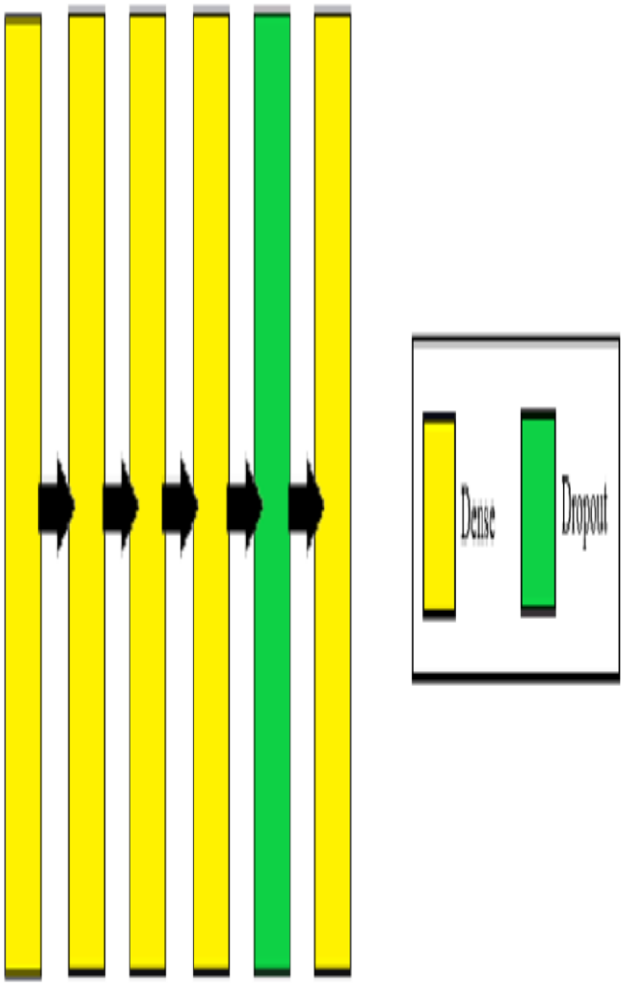

Fig. 2. The figure shows the execution of a simple Artificial Neural Network, taking inputs rsrp, tdoa and toa, comprising only of Dense Layers along with one dropout layer.

C. Stage 3: Ensemble Model

This penultimate stage used all four inputs for prediction. Considering the fact that inputs were of different dimensions, an ensemble approach was used. Here the models were defined functionally. In the first part of the ensemble

convolutions were declared to predict position on getting CIR as input. In the second part dense layers were used so as to predict using RSRP, TDOA and TOA. Outputs from the final layer of both the models were then concatenated and a Dense layer was mentioned to predict the final position of User Equipment. The ensemble approach is illustrated diagrammatically below: -

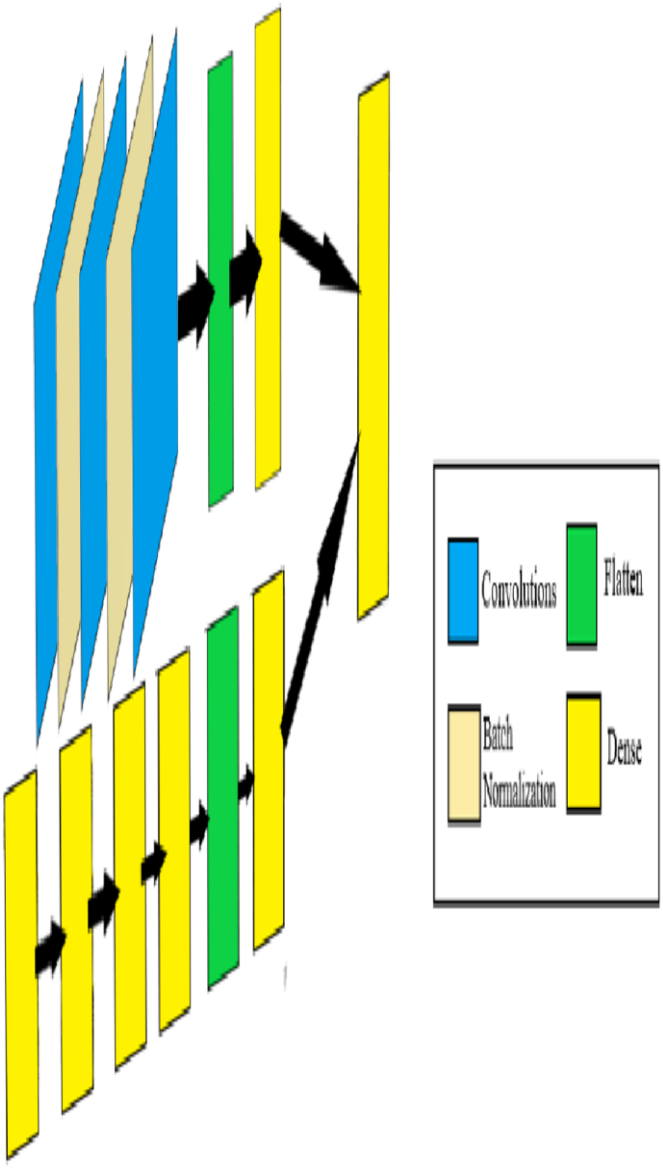

Fig. 3. Figure shows flow of neural network model in two stages. The first one being a Convolutional model and the second one being a dense neural network model, both outputs merging into one dense layer which provides position of User Equipment as output.

D. Stage 4: Validation using K-Fold Cross Validation

The final stage consisted of validating the above ensemble model using K-Fold Cross Validation[13]. 5 folds were used and after the conclusion of execution of each fold, the MSE and position error at 0.9 cdf was noted. The above folds were iterated over both 30 and 50 epochs.

VI. RESULTS DISCUSSION

Upon execution of all the above stages, following were the results: -

Model	**No. of Epochs**	**MSE**	**Position Error at 0.9 cdf**
Stage 1: CNN	25	1.0143	2.141
Stage 2: ANN	300	0.5967	1.288
Stage 3: Ensemble Model	50	0.0676	0.519

a. The above table displays MSE values and position error after execution of each model.

During analysis it was found that the ensemble model provided the most accurate result with very low position error. To further prove this statement the cdf plot and a frequency plot which shows the distribution of error are shown below:

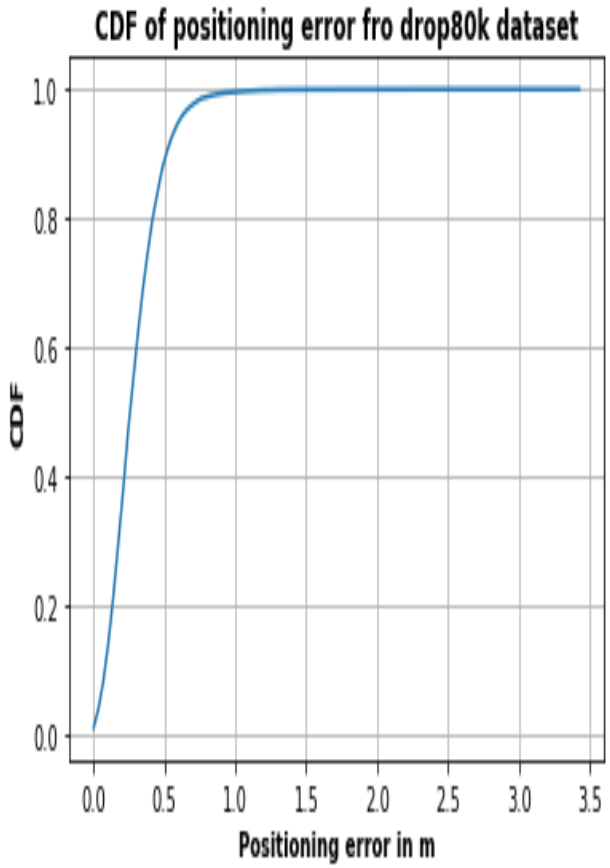

Fig. 4. Cumulative Density plot for ensemble method.

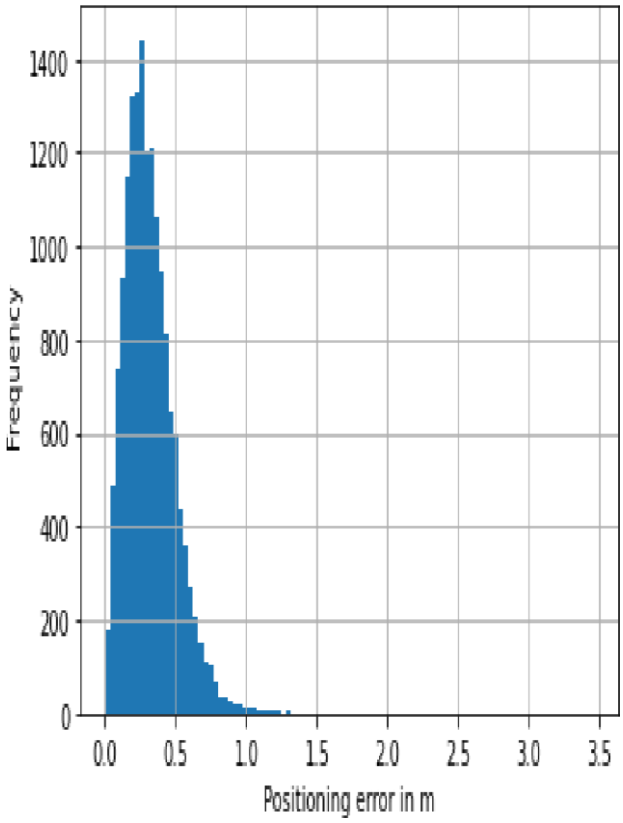

Fig. 5. Frequency plot for ensemble method.

As observed in the frequency plot, majority of the position error is approximately distributed between 0.0 and 0.55 making the model most accurate amongst the three.

K-Fold Cross Validation was performed on the Ensemble model iterating over both 30 epochs and 50 epochs to observe how results change with changes in input values. MSE values and position error at 0.9 cdf after execution of each fold is tabulated below: -

Epochs: 30			
Indices of samples inputted	**K-Fold Value**	**MSE**	**Position Error at 0.9 cdf**
0-16000	1	0.1257	0.7448
16000-32000	2	0.098	0.6516
32000-48000	3	0.1131	0.7219
48000-64000	4	0.1261	0.7307
64000-80000	5	0.13	0.7458
Epochs: 50			
Indices of samples inputted	**K-Fold Value**	**MSE**	**Position Error at 0.9 cdf**
0-16000	1	0.1135	0.6482
16000-32000	2	0.1277	0.7447
32000-48000	3	0.0659	0.537
48000-64000	4	0.0947	0.6346
64000-80000	5	0.0676	0.5236

b. The above table displays MSE values and position error at 0.9 cdf after execution of K-Fold Cross-validation over 30 and 50 epochs.

The MSE values and position error values changed with changes in input values and better results were observed while iterating the folds on 50 epochs. This goes on to validate the accuracy of predictions of position produced by the ensemble model and how these results could be improved by increasing the number of iterations.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to Mr. Keerthi Srinivas, direct guide, Mr. Venkatesh Muralidhara and Mr. Hari Swaroop Kanzal Venkatesh (Director L1 Development) of Altiostar Networks India Pvt. Ltd. without whose guidance and support this project would not have been possible.

It would be unfair to not acknowledge the help and support given by the Professors, students, friends etc.

Particularly, my sincere thanks to the faculty guide Mrs. Jagruthi Jadhav for her guidance and constant support. Immese gratitude is offered to the HOD, Dr. Megharani Patil, the Principal, Dr. B. K. Mishra and the college management for their support.

FUTURE SCOPE

While the above method provided a good result, there is further scope to improve the model in following aspects: -

1. The above model can be run on increased number of epochs to achieve better accuracy.
2. The model should be robust to different types of input features and be able to predict with the given data.
3. While being robust to varied types of features, it must also be able to compute the position of user equipment's without taking up too much memory.
4. The model must also be able to compute data in real time.

CONCLUSION

In this paper a deep learning-based approach for estimating position of User Equipment in a radio network is proposed. The results show that an ensemble model taking all four inputs would outperform other models implemented in this study. The same has been validated by the use of K-Fold Cross-Validation. This goes on to provide a promising direction for future research in the field of wireless networks.

Abstract- **Artificial Intelligence (AI) has been making remarkable advancements in recent years and has the potential to revolutionize many aspects of our lives. From self-driving cars to healthcare systems, AI has the ability to make tasks easier, faster, and more accurate. However, the increasing reliance on AI has raised concerns about its transparency, accountability, and interpretability. eXplainable AI (XAI) is a field that focuses on explaining the predictions made by AI systems. This has become increasingly important as AI is being used in sensitive and critical applications such as medical diagnoses, financial risk assessments, and criminal justice decisions. It is essential to ensure that the decisions made by AI systems are transparent, trustworthy, and can be justified to stakeholders. The paper explores the challenges associated with creating explainable AI systems and the different techniques that are being developed to overcome these challenges. Further it presents a summary of the strengths and weaknesses of various XAI techniques. The paper will provide an overview of the state-of-the-art in XAI and highlight the need for further research in this field.**

Index Terms **– *eXplainable AI (XAI), Machine Learning***

I. INTRODUCTION

Artificial Intelligence (AI) has become an increasingly ubiquitous technology, permeating various domains such as healthcare, finance, and transportation [1]. While AI systems have demonstrated remarkable performance, there are growing concerns over their lack of transparency, accountability, and interpretability [2]. This lack of transparency is often referred to as the "black box" problem and is a major hindrance to the widespread adoption of AI systems. The need for more transparent AI systems has led to the development of a new field called eXplainable AI (XAI) [3]. XAI aims to design and develop AI systems that can provide humanunderstandable explanations for their predictions, decisions, and internal workings.

XAI has gained significant attention in recent years, and researchers have developed various techniques for improving the interpretability of AI systems. These techniques range from model-agnostic methods, such as saliency maps and feature importance analysis, to modelspecific methods such as decision trees and rulebased models

The motivation behind the research in the field of XAI aims to overcome the challenges of gaining transparency and trust in the decisions made by the AI/ML models, compliance with regulations, improved decisions and model selection for solving a specific problem.

1. Transparency and Trust: The black-box nature of AI systems has led to a lack of trust and accountability among stakeholders. XAI aims to address this issue by providing explanations for the predictions and decisions made by AI systems. This increased transparency can lead to improved trust and confidence in AI systems.
2. Compliance with Regulations: There are various regulations and ethical guidelines that mandate the need for explainable AI systems, such as the European Union's General Data Protection Regulation (GDPR) and the US's Algorithmic Accountability Act.
3. Improved Decisions: Explainable AI can help decision-makers understand the reasoning behind AI predictions and decisions, allowing them to make better-informed decisions. This is especially relevant in high-stakes domains such as healthcare and finance.
4. Model Selection: XAI can help practitioners compare and evaluate different AI models, making it easier to choose the most appropriate model for a given task.

There are different challenges associated with Explainable AI as stated by authors of [4]. One of the primary challenges in XAI is developing methods for making AI models transparent and interpretable, without sacrificing performance. A black-box model is one in which the decision-making process is not clearly understood, making it difficult to trust the output of the system. This lack of transparency can be especially problematic in critical applications, such as medical diagnosis or autonomous driving, where the consequences of incorrect decisions can be severe. XAI aims to address this issue by developing methods for making AI models more interpretable and transparent so that the decision-making process is better understood and trusted.

Another challenge in XAI is developing methods for interpreting the output of AI models in a way that is meaningful to humans [4]. This is particularly important in applications where the model makes decisions that significantly impact people's lives. For example, in a medical diagnosis application, it is important to be able

to understand why a model made a particular diagnosis so that healthcare professionals can verify the accuracy of the decision. Similarly, in autonomous driving, it is important to be able to understand why a model made a particular driving decision so that the safety of the system can be assessed.To address these challenges, XAI research has focused on developing new methods for making AI models more interpretable, such as using local explanations, feature importance methods, and model distillation. Another approach is to develop new AI models that are inherently interpretable, such as decision trees and rulebased systems. XAI research has also focused on developing new methods for visualizing the output of AI models, such as using heat maps, saliency maps, and activation maps.

In addition to these general challenges, XAI also faces several specific challenges based on the different phases of the machine learning life cycle: design, development, and deployment [4]. During the design phase, XAI researchers must consider the interpretability and transparency requirements of the system, and choose the most appropriate AI models and methods. During the development phase, XAI researchers must implement these models and methods, and ensure that they are validated and tested. During the deployment phase, XAI researchers must ensure that the system is deployed in a way that is secure and trustworthy, and that the decision-making process is transparent and understandable.

This paper provides a comprehensive review of stateof-the-art XAI techniques. We categorize XAI techniques into two broad categories: Inherently Interpreting methods and post-hoc methods. We also highlight the open research challenges in XAI and suggest directions for future research. This paper provides a comprehensive overview of the XAI field and serves as a useful reference for researchers, practitioners, and decision-makers interested in developing more transparent and interpretable AI systems.

II. RELATED WORK

The Machine Learning models that exist in the literature can be distinguished into two types, Inherently Interpretable Models, and Post-hoc Explainable Models. The inherently interpretable models are selfexplanatory or interpretable by design whereas post-hoc explainable models are prebuilt models that are explained by external XAI techniques. [5]

A. Inherently Interpretable Models

In general, the models which are understandable by themselves fall under the category of Inherently Interpretable Models, they are also known as transparent models. Examples of such models are as follows:

A.1. Linear Regression/Logistic Regression-

Linear Regression is a machine-learning model used to predict a value of the dependent variable y, given the value of the independent variable x. This model assumes the linear dependence between the input (Predictor) and output (Predicted) variables, inhibiting an adaptable fit to the data. This nature of the model fits it under the category of inherently interpretable models. The models' explainability can be correlated with different users depending on the application. Although Linear Regression/Logistic Regression possesses the properties of an inherently interpretable model, depending on the context, it may fall under both categories. For example, for ML experts the model is self-explanatory but in the case of the users who are not ML experts, post-hoc explainability techniques (like visualization) can be used to interpret the behavior of the model. This model is used in practice by many researchers. The authors of [6],[7], [8] and [9] agree that the overall model evaluation gives an improvement over a baseline.

A.2. Decision Trees-

Decision trees are a popular tool in Explainable AI (XAI) because they provide a clear and interpretable representation of the decision-making process used by the model. A decision tree is a tree-like model that makes predictions by recursively partitioning the data into smaller subsets based on the values of the predictor variables until each subset consists of instances with similar values for the response variable. The tree structure of a decision tree can be visualized, and the decisions made by the model can be traced from the root to the leaves, making it easy for humans to understand how the model is making its predictions [10], [11]. The internal nodes of the tree represent the questions being asked about the data, and the leaves represent the final predictions. In XAI, decision trees can be used to generate explanations for the predictions made by the model. For instance, the tree structure can be used to identify the most important features used by the model to make its predictions, and the decisions made at each node can be used to highlight the reasoning behind the prediction. This makes decision trees a useful tool for applications where interpretability is important, such as medical diagnosis, fraud detection, and customer segmentation. However, it is important to note that decision trees can have limitations when dealing with complex and non-linear relationships between the predictor variables and the response variable. In these cases, decision trees can easily overfit the data, leading to poor generalization performance on new data. To address this issue, ensemble methods, such as Random Forests and Gradient Boosting, are often used to improve the robustness and accuracy of decision tree models.

A.3. K-Nearest Neighbours-

K-Nearest Neighbours (KNN) is a simple and intuitive machine learning algorithm that is used for classification and regression tasks. In KNN, the prediction for a new instance is based on the majority vote or average of the k-nearest neighbours in the training data. In KNN, the distance metric used to determine the nearest neighbours can be customized, such as Euclidean distance, Manhattan distance, or Cosine similarity. The value of k, the number of nearest neighbours used for prediction, is a tunable parameter that can be optimized through cross-validation or other model selection methods [12], [13]. In Explainable AI (XAI), KNN is used as a baseline model for comparison with more complex models, such as deep learning networks, to assess their performance and interpretability. KNN provides a simple and interpretable representation of the decision-making process used by the model, making it easy for humans to understand how the model is making its predictions. However, KNN can have limitations when dealing with large and high-dimensional datasets, as the computation time and memory requirements can become prohibitive. In these cases, other machine learning models, such as decision trees or support vector machines, may be more appropriate.

A. 4. Rule-Based Models-

Rule Based Models use rules to represent the knowledge coded in the systems. They are widely used in expert systems for knowledge representation [14]. The first approach discussed here is The Bayesian Rule Lists. This was first introduced by Ben Letham and Cynthia Rudin in 2015 [15]. They proposed a rule list classifier for stroke prediction in which the rules are represented as a sequence of conditional if-else-if constructs. The classifier predicts the stroke risk in advance, considering the different factors leading to a stroke condition in patients. The interpretability of decision statements is simplified by the high dimensional and multivariate feature space by the discretization of if-then conditions. The decision list has posterior distribution yielded by the Bayesian rule list. Healthcare experts or doctors want to make certain decisions, so they want simple models which are easily understandable by themselves rather than complex models. Although the model is simple, another criterion is that the predictions made by the model should be accurate. In this paper, the researchers designed a generative model to produce if/else-if lists that strike a balance between accuracy, interpretability, and computation. Another approach that can be linked to rule-based models is Fuzzy rules/ systems. Fuzzy rules are a kind of if-then statements specifying some conditions and generating truth to a specific degree instead of complete true or false results. A deep rulebased fuzzy system is used to predict patients' mortality in the ICU. It consists of a diverse dataset combining categorical and numeric attributes in a hierarchical manner [16].

Rule-based models are useful in various fields in terms of interpretability. The main problem with the approach is the amount and the length of the rules generated. The main objective of the rule-based approach is that the user can analyze, interpret, and understand the model. The number of rules in a model will improve the performance of the model, but at the same time, it may compromise the interpretability. It may become difficult to interpret if there are many antecedents.

A.5.Risk Scores-

Risk scores refer to the predictions or assessments generated by AI models in terms of risk levels. These scores are used to identify the level of risk associated with a particular decision or event [17]. In XAI, the risk scores are accompanied by an explanation of the reasoning behind the score, which helps humans understand and interpret the results of the AI model. The goal of XAI is to provide transparent and interpretable models that can be trusted by humans, especially in sensitive and high-stakes applications, such as credit risk assessments, fraud detection, or medical diagnosis.

A.6. Generalized Additive Models-

Generalized Additive Models (GAMs) are a class of non-parametric statistical models used in Explainable AI (XAI) to make predictions based on a linear combination of smooth, non-linear functions. GAMs are a flexible alternative to traditional linear models and can capture complex relationships between the predictor variables and the response variable. In XAI, GAMs are used to generate explanations for the predictions made by the model. For instance, the smooth functions in a GAM can be interpreted as the contribution of each predictor variable to the prediction, providing insights into the model's decision-making process. This makes GAMs well-suited for applications where interpretability is important, such as medical diagnosis [18], financial forecasting [19], and risk management. However, while GAMs provide a more transparent view of the model's decision-making process compared to black-box models, the interpretability of the smooth functions can still be limited, particularly when dealing with high-dimensional data or complex interactions between predictor variables.

A.7.Prototype-Based Models-

Prototype-based models are a class of machine learning models that are used for classification and clustering tasks. They work by representing each class or cluster as a prototype or representative feature vector. The prototypes are learned from the data and can be thought of as the central or average feature representation of the

data points belonging to a particular class or cluster. During the classification or clustering process, new data points are compared to the prototypes and assigned to the closest class or cluster based on a distance metric, such as Euclidean distance or cosine similarity. The decision boundary between the classes or clusters is defined by the prototypes [20]. Prototype-based models are often used in Explainable AI (XAI) because they are simple and intuitive to understand and can provide straightforward explanations for the predictions made by the model. For instance, in a classification task, the prototypes can be used to represent the decision rules used by the model, making it easy for humans to understand how the model is making its decisions.

However, prototype-based models can have limitations when dealing with complex and non-linear data distributions, as the prototypes may not accurately represent the underlying relationships between the features and classes. In these cases, other machine learning models, such as deep learning networks, may be more appropriate.

B. Post-hoc Explainable Models

Posthoc Explainable Models refer to machine learning models that have been trained to make predictions, but the explanations for the predictions are generated after the fact, rather than being built into the model itself. Posthoc explanation methods are used to generate explanations for the predictions made by black-box models, such as neural networks and gradient-boosting machines, which can be difficult to interpret. These methods can provide a local or global explanation for the predictions, either by highlighting the features used by the model to make the prediction or by approximating the decision boundary used by the model.

B.1.Local Explanation:

It refers to the process of understanding the behavior of an AI model by examining the contributions of individual input features to the model's prediction. The goal of local explanation is to understand why the model made a particular prediction for a specific instance, rather than trying to understand the behavior of the model in general. There are several methods used for generating local explanations, including Feature Importance, Rule-Based, Saliency Maps, Attention Mechanisms, Prototypes/Example Based, and counterfactuals. Some popular Local Post-hoc explainable models include:

*B.1.1 LIME, or Local Interpretable Model-Agnostic Explanat*ions is a method for generating local explanations for complex machine learning models. The goal of LIME is to provide a simple and interpretable explanation for the predictions of any machine learning model, regardless of the underlying architecture.[21] and all its variations [22, 23].

LIME works by approximating the complex machine learning model with a simpler, interpretable model in the vicinity of a specific prediction. It does this by perturbing the input features of a specific instance and measuring the impact on the model's prediction. The resulting relationship between the input features and the model's prediction is then used to generate an interpretable explanation for the prediction.

LIME has several advantages over other local explanation methods. First, it is model-agnostic, meaning that it can be used with any machine learning model, regardless of the underlying architecture. Second, it provides explanations that are simple and interpretable, making it easier for humans to understand the reasoning behind a model's prediction. Third, it is computationally efficient, making it possible to generate explanations for large numbers of predictions in a reasonable amount of time.

B.1.2. SHAP (SHapley Additive exPlanations): The method is based on the concept of Shapley values from cooperative game theory and provides a fair and consistent way to distribute the contribution of each feature to a prediction. The main idea behind SHAP is to attribute the prediction of a machine-learning model to each of the input features. The method computes the expected value of the prediction when a feature is included in the input and when it is not and uses this information to calculate the contribution of each feature to the prediction.[24]

SHAP has several advantages over other explanation methods. It is model agnostic; thus it can be used with any machine learning model, regardless of the underlying architecture. It provides consistent and fair explanations, meaning that the contributions of each feature to the prediction are based on a well-defined mathematical framework. Also, it can generate both global and local explanations, allowing for a complete understanding of the behavior of the model.

Another approach to tackle the contribution of each feature to predictions has been coalitional Game Theory [25] and local gradients [26]. Similarly, by means of local gradients [27] test the changes needed in each feature to produce a change in the output of the model.

B.1.3. Rule-Based Approach-Anchors: The goal of anchors is to provide a simple, interpretable explanation for the predictions of a machine learning model by identifying the input features that are most important for the prediction. Anchors work by generating a small set of rules, called anchors, that are used to explain the prediction of a model. These anchors are based on the relationships between the input features and the model's

prediction, and they are designed to be both simple and interpretable [28].

The main advantage of anchors is their simplicity and interpretability. By using a small set of rules to explain a prediction, anchors provide a straightforward way to understand the reasoning behind a model's decision.

B.1.4. Saliency Maps: The goal of saliency maps is to highlight the input features that have the greatest impact on the prediction of a machine learning model [29].

A saliency map is a visual representation of the model's decision, where the most important input features are highlighted. The map is generated by computing the gradient of the model's prediction with respect to the input features and visualizing the resulting information as a heatmap, where the color encodes the magnitude of the gradient.

Saliency maps have several advantages over other explanation methods. They provide a visual representation of the model's decision, making it easier for humans to understand the reasoning behind a prediction. They can be generated for any machine learning model, regardless of the underlying architecture. Also, they provide a global explanation of the model's behavior, which can be useful in identifying potential biases in the model's decision-making process.

B.1.5. Prototype/Example-Based Approach: The goal of prototype-based explanations is to provide a humanunderstandable explanation of a machine learning model's prediction by comparing the input to a set of prototypes or examples. Prototype-based explanations work by identifying a small set of prototypes or examples that are representative of the data and are used to explain the prediction of a machine-learning model [30]. The model's prediction is explained by comparing the input features to the prototypes and identifying which prototypes are most like the input. The main advantage of prototype-based explanations is their simplicity and interpretability. By comparing the input features to a small set of prototypes, prototypebased explanations provide a straightforward way to understand the reasoning behind a model's decision.

B.1.6. Counterfactuals: The goal of counterfactual explanations is to provide an explanation of a machine learning model's prediction by showing how the prediction would change if a certain input feature were different. Counterfactual explanations work by generating alternative inputs that are like the original input except for one or more features. The model's prediction for these alternative inputs is then compared to the original prediction to determine how the prediction would change if the input features were different [31, 32].

The main advantage of counterfactual explanations is their ability to show how a model's prediction would change if certain input features were different. This can be particularly useful in understanding the decisionmaking process of a model and identifying any biases that may be present.

The local explanation is important in XAI because it provides a way to understand the behavior of complex AI models and makes the decision-making process more transparent. This is particularly important in applications where the model makes decisions that significantly impact people's lives, such as medical diagnosis or autonomous driving. By providing a way to understand the reasoning behind a model's prediction, local explanation helps to build trust in the model and increase its overall effectiveness. *B.2. Global Explanation*:

It refers to methods that provide an understanding of the behavior of a machine learning model across the entire data distribution. The goal of global explanations is to provide a comprehensive and holistic understanding of a model's behavior, beyond just a single input or prediction.

Global explanations can be achieved through various methods, such as feature importance measures, modelagnostic interpretability techniques, and model-specific techniques. Feature importance measures provide a ranking of the most important features in a model, helping to identify which features drive the predictions the most. Model-agnostic interpretability techniques, such as partial dependence plots and individual conditional expectation plots, provide a way to understand the relationship between the model's predictions and the input features. Model-specific techniques, such as decision trees and rule-based models, provide an explicit representation of the model's decision-making process and allow for a stepby-step explanation of the model's predictions.

B.2.1 Feature importance measures: These methods provide a ranking of the most important features in a model, helping to identify which features drive the predictions the most. The most used methods include permutation importance, mean decrease impurity, and mean decrease accuracy [33].

B.2.2 Model-agnostic interpretability techniques: These methods provide a way to understand the relationship between the model's predictions and the input features, without relying on any specific model architecture. Partial dependence plots and individual conditional expectation plots are examples of model-agnostic interpretability techniques.

B.2.3 Model-specific techniques: These methods provide an explicit representation of the model's decision-making process and allow for a step-by-step explanation of the

model's predictions. Examples of model-specific techniques include decision trees and rule-based models.

B.2.4 Model-level explanations: These methods provide an overall explanation of the model's behavior, regardless of the specific input or prediction. Modellevel explanations can be provided through various methods, such as decision surface visualization, model predictions on synthetic data, and model predictions on an artificial validation set.

B.2.5 Model Distillation: Model distillation provides a way to understand the behavior of a complex machine learning model by training a smaller, simpler model to mimic the behavior of the complex model. By looking at the predictions and decision-making process of the student model, it is possible to obtain a global explanation of the behavior of the complex model.

Model distillation provides a holistic view of the model's behavior, as opposed to local explanations, which focus on the behavior of the model for specific input instances. The student model provides a distilled version of the complex model's behavior, which can help provide a better understanding of how the complex model makes its predictions and can be used to detect and address any biases or limitations in the model's behavior.

B.2.6 Representation-Based Approach:
Representationbased explanations refer to methods that explain the decisions of a machine learning model by focusing on the representations learned by the model. These representations are typically intermediate representations in the model, such as activations in a neural network, and can provide insight into how the model is processing the input data.

In representation-based XAI, the focus is on understanding the internal workings of the model by examining the learned representations. This can help to identify what features of the input data are being used by the model to make its decisions and how these features are being combined to produce the final prediction. Additionally, representation-based explanations can help to identify any limitations or biases in the model's behavior and to understand the general structure of the model's representations.

There are several methods for generating representation-based explanations, including activation maximization, occlusion, and gradient-based methods. These methods can be used to generate visualizations of the model's representations, such as saliency maps or activation maps, which can provide insight into the model's behavior. Additionally, representation-based explanations can be used to understand the performance of the model, debug the model, and improve its accuracy.

The methods that fall under global explanation in XAI cover a wide range of techniques and provide different perspectives on the behavior of a machine learning model. By combining these methods, a comprehensive understanding of the model's behavior can be obtained, increasing the overall transparency and interpretability of the model.

III. COMPARATIVE ANALYSIS

Comparative analysis of inherently interpretable and post-hoc techniques can be done based on various factors, such as the level of interpretability, the ease of implementation, the accuracy of the explanation provided, and the flexibility of the technique.

1. Level of Interpretability: Inherently interpretable techniques generally provide a higher level of interpretability than post-hoc techniques. Inherently interpretable models are designed to provide an explanation of the decision-making process at each step. In contrast, post-hoc techniques provide an explanation after the model has already been trained, and the level of interpretability may depend on the type of post-hoc technique used.

2. Ease of Implementation: Post-hoc techniques are generally easier to implement than inherently interpretable techniques. Inherently interpretable techniques require the model to be designed from scratch with interpretability in mind, which may not always be possible or practical. Post-hoc techniques can be applied to any trained machine learning model, regardless of the technique used to create it.

3. Accuracy of Explanation: Inherently interpretable techniques generally provide a more accurate explanation than post-hoc techniques. This is because the inherently interpretable models are specifically designed to provide an explanation of the decision-making process. In contrast, post-hoc techniques may rely on approximations or simplifications of the original model, which may not provide an accurate explanation.

4. Flexibility: Post-hoc techniques are generally more flexible than inherently interpretable techniques. This is because post-hoc techniques can be applied to any machine learning model, regardless of the technique used to create it. In contrast, inherently interpretable models are designed to work with specific types of data and may not be as flexible.

Both inherently interpretable techniques and post-hoc techniques have their advantages and disadvantages. Inherently interpretable techniques provide a higher level of interpretability and accuracy but may be more difficult to implement and less flexible. Post-hoc techniques, on the other hand, are easier to implement and more flexible but may provide less accurate explanations.

IV. TRADEOFF BETWEEN MODEL COMPLEXITY AND PERFORMANCE

The trade-off between model complexity, performance, and interpretability refers to the balance between these three factors in machine learning models. In general, more complex models tend to have higher performance, but lower interpretability. Conversely, models with simpler structures tend to be more interpretable but have lower performance.

For example, deep neural networks are complex models that are capable of achieving state-of-the-art performance on many tasks, but they are considered black-box models that lack interpretability. On the other hand, linear regression models are simple models that are easily interpretable, but they have lower performance compared to more complex models in many applications.

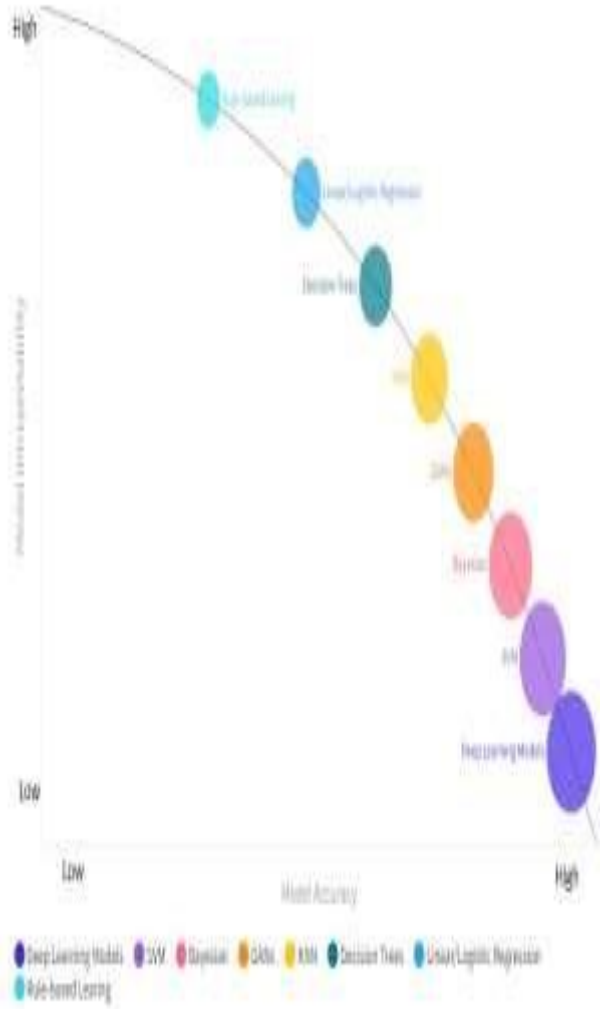

Fig. 1. Tradeoff Between Model Complexity And Performance

This trade-off poses a challenge in the field of Explainable AI (XAI), where the goal is to develop accurate and interpretable models. One approach to address this trade-off is to use post-hoc explainability methods that can be applied to complex models to make them more interpretable. Another approach is to use inherently interpretable models that balance model complexity and interpretability.

Eventually, the choice of model will depend on the specific requirements of the problem at hand and the trade-off between model complexity, performance, and interpretability that is acceptable.

V. CHALLENGES AND FUTURE SCOPE

Challenges associated with Explainable AI:

1. Trade-off between Explanation Quality and Model Performance: There is often a trade-off between the quality of explanations provided by XAI techniques and the performance of the underlying AI model.
2. Difficulty in Defining Explanations: There is no clear consensus on what constitutes a good explanation. Different stakeholders may have different criteria for what constitutes a satisfactory explanation.
3. Scalability: XAI techniques can be computationally expensive and may not be feasible for large, complex AI models.
4. Human Interpretability: The explanations provided by XAI techniques may not be easily understandable by human stakeholders, particularly if they are not experts in AI and machine learning.
5. Generalizability: XAI techniques that work well for one AI model or task may not work well for others. This makes it challenging to develop generalizable XAI techniques that can be applied across a wide range of AI models and tasks.

The field of Explainable AI (XAI) is a rapidly growing area of research that seeks to make artificial intelligence systems more transparent, understandable, and trustworthy. XAI is an interdisciplinary field that draws on knowledge from computer science, statistics, mathematics, psychology, philosophy, and other domains.

There are many exciting research opportunities in XAI that will help advance the field and make AI systems more accessible and usable. Some of the most promising areas of research in XAI include:

1. Improving explainability and interpretability methods: As AI models become more complex, it becomes increasingly difficult to understand how they make decisions. This lack of transparency can create challenges for the deployment of AI in critical domains and hinder its widespread adoption. Further research work is needed to develop new and improved methods for explaining the behavior of AI systems. This includes developing strategies that

provide explanations at different levels of abstraction and developing methods that are more intuitive and accessible to users.

2. Exploring the psychological and social aspects of XAI: AI models can encode biases and make unfair decisions, which can have serious consequences for individuals and society. Further research is needed to develop XAI methods that can help identify and address biases in AI systems. Researchers are interested in understanding how people perceive and understand explanations from AI systems, and how these explanations can be made more useful and usable.

3. Developing XAI for safety-critical applications: In critical domains such as healthcare, finance, and criminal justice, it is important to ensure that AI systems are transparent and trustworthy. Researchers are working to develop XAI methods that can provide safe and reliable explanations for these applications.

4. Integrating XAI with inference: Researchers are interested in exploring how XAI methods can be integrated with causal inference methods to provide more robust explanations for AI systems.

5. Developing XAI methods for autonomous systems: Autonomous systems, such as self-driving cars, require transparent and understandable explanations to ensure their safety and reliability. Researchers are exploring new XAI methods that can be used to explain the behavior of autonomous systems.

6. Combining XAI with active learning: Active learning is a machine learning technique that involves actively seeking information to improve the performance of a model. Researchers are exploring how XAI methods can be integrated with active learning to improve the transparency and reliability of AI systems.

7. Developing XAI for deep learning models: Deep learning models are highly complex and can be difficult to explain. Researchers are working to develop XAI methods that can provide meaningful explanations for these models.

8. Exploring the ethical and legal implications of XAI: As AI systems become increasingly widespread, it is important to understand the ethical and legal implications of their use. Researchers are exploring the ethical and legal considerations of XAI and developing guidelines for the responsible development and deployment of AI systems.

9. Improving the integration of XAI with other AI technologies: Researchers are exploring how XAI can be integrated with other AI technologies, such as reinforcement learning, to provide more comprehensive explanations for AI systems.

These are just a few of the many exciting research opportunities in XAI. As the field continues to grow, researchers will likely identify new challenges and opportunities for advancing the field of Explainable AI.

Abstract – **The banking sector is an important subset of our economy and plays a very crucial and significant part in its growth and development. The expansion and credibility of the banking sector are attributed to the fact that it caters to their financial needs and accordingly provides products and services to the customers. The innovation. Technology has brought about aparadigm shift in all aspects of banking like routine operations, transactions, products and processes, delivery ofservices in terms of various e- channels, credit administrationand credit management, audit and compliance and Fin Techspartnership. The study attempts to highlight the role of technology in banking and how technology-led innovations and initiatives will determine the business of banking as a whole. The significance of these technology- driven innovations and transformations is that they put both bankers and customers in a win-win situation. The objective of this study is to investigate the digital innovations adoptedby the Public Sector Banks and Private Sector Banks for e-commerce Practices in India. This study draws on existing literature in the form of scholarly articles annual reports of various Banks, Newsletters and various websites related to digital banking.**

Keywords: Digital Innovations (DI), Indian Banking System (IBS), Block Chain (BC), Artificial Intelligence (AI), FinTech.

I. INTRODUCTION

At Present, everyone desires a healthy, robust and sustainable banking system is critical for the growth and development of our economy. The banking system is the mainstay of our economy and Technology has become thebackbone of modern-day banking. The banking industry has witnessed a tremendous shift since 1969 after the nationalization of commercial banks. In 1997 ICICI bankwas the first bank to offer internet banking services. Since then, to survive in this competitive market almost every bank has shifted from paper-based banking to paperless banking, i.e., towards digital banking. The services provided by the banks to their customers create a huge impact on them. The success of the banks depends on thecustomer's attitude and perception, and satisfaction with theservices rendered by the banks. At present, there are 22 private sector banks and 12 public sector banks. Almost all banks are providing online service facilities. Nowpeople can do banking from anywhere at any time with very minimal cost. The development of electronic home banking has significantly necessitated the reorganization of banking services and operations. Digital modes have replaced the brick-mortar model of branches.

II. RESEARCH OBJECTIVES

a)To understand the changing digital scenario in the Banks in India
b)To examine the Digital Banking new trends and Innovations in Indian Banks.
c)To analyse the various Digital Banking Products and Services, Digital Banking Channels offered by Indian Banks.
d)To analyse the role of FinTech in Indian bankstowards digital transformation

Problem Formulation

Problem-1:-Use of various digital apps for providing digital innovation services to the customer in an efficient way core banking with secure and service

Problem: 2:-Providing various digital modes of service for better and safe digital banking which is innovative and preventive for money transfer and distribution

Hypothesis Development:

The researchers have taken two types of hypotheses for enhancing the digital innovation banking service in IndianBanking such as;
Ho: Null hypothesis has taken that, the digital Innovation mode of banking is not providing safe and secure banking service to their esteemed customer
H1: There is a need for use of a digital innovation mode of the banking system for a better banking service in Fin Tech areas of banking service.

III. RESEARCH METHODOLOGY

The Present study is exploratory, descriptive and based on secondary data. Secondary data and information havebeen collected from scholarly articles, annual reports of the selected banks, "RBI Report on Trend and Progress of Banking in India', 'RBI Working Group Reports, 'RBIBulletin, RBI Annual Reports, Reports published by various Sites of Government of India and various other Websites. For the present research work, various bankingjournals and other financial newspapers have also been referred to various studies on this area by several research agencies have also been considered.

IV. REVIEW OF LITERATURE

In the literature Review section, the researcher has to

trytheir level best for proving the authenticity of theresearch work reliably as related to the aforesaid research title "Role of Digital Marketing and Innovations on E-Commerce Practices - An Exploratory Study" henceforth, they have taken some of previous Authors research paper as a reference and trying to further extend the research work in a better way of study concerning the paper of Dr. Rajeshwari, M.Shettar (2019) [1]in his article entitled "Digital Banking an Indianperspective", focused on the benefits of digital banking. He also stated that the use of digital banking will reduce theoperating cost of the bank.

Ipsita Paria and Arunangshu Giri (2018) [2] in the article "A Literature Review on Impact of Digitalization on Indian Rural Banking System and Rural Economy" describe that digital banking has immense capacity to accelerate financial inclusion apart from offering the benefits of ease of operations and low-cost factor. K. Suma Vally and K. Hema Divya (2018) [3] in their article "A Study on Digital Payments in India with Perspective of Consumer's Adoption", highlighted that digital technology for payments system has resulted in the improvement of the quality of banking service leading to the achievement of the objective of cash-less society. According to S.V. Mohana Sujana, "Digitalization in the banking sector" (2018) [5] The paper focused on the role of digital banking, and the advantages and disadvantages of the online banking sector. Innovation is a crucial component for entities to generate value and offer competitive benefits (Tellis et al., 2009). Organizations adopt innovative models to reengineer their operations and increase their competitive strengths. Competitive advantage can be maintained by embracing innovation (Aydin and Dube, 2018). Innovation envisages the introduction of novel methods, new techniques, and reengineered processes to produce extraordinary results in the form of superior services and products (Oliva and Kotabe, 2019). So far as the word digital banking is concerned, 'Digital Banking' can be defined as the digitalization of various traditional banking operations and performance and processes that were earlier available to the customers by a visit to the bank's branch or ATM only. Digital Payments have been defined by the Payment and Settlement Act, 2007 as "electronic funds transfer means any transfer of funds which is initiated by a person by way of customers' mandate, authorization or instruction to their bank to initiate banking transactions by debit or credit to the bank account through electronic, online, internet, mobile apps and includes ATM, Point of sale, Card Payments, Direct deposits, transfers and withdrawal of funds." Digital Banking activities include online account/ fixed deposit opening, funds transfer, credit card payments, requests for cheque book, change/block pin numbers, Loan applications,bill payments and investments. Artificial intelligence is having a positive impact on the banking sector. The advanced presentations of AI and automation undoubtedly give useful skills. Language translation, chatbots, and virtual reality are just a few of the well-established claims, but many more are demonstrating a significant influence and effectiveness when used across industries [13]. (R. Goel, T. Singh, S. K. Baral,S. L. Sahdev & S. Gupta, 2022).

The history and evolution of Digital Banking are traced back to the 1960s with the launch of cards and ATMs. Developments of the World Wide Web and Internet Bankinghave also seen the simultaneous evolution of Digital Banking. Online Banking emerged in the 1990s. At that time, it was an idea, taking into consideration the securityand safety of customer financial data. The USA was the first country in the world to start online banking in October 1994.

Table-1: Digitalization in Banking

1980	• The mechanisation of Payment System Processes,Computerization • Standardisation of Cheques, Encoders, MICR Implementation and Minimal use of Bank Drafts and Cheques
1990	• Computerization of Branches, Expansion of Products and Services, Connectivity with other branches • Core Banking Systems, ATMs and ElectronicFunds Transfer, Online Banking
2010	• Internet Banking, Mobile Banking, Real Time Gross Settlement, National Electronic Funds • Transfer (NEFT) and National Electronic ClearingServices (NECS)
2011	• Emerging Financial Technology (FinTech), E-Collaborations with Fin Tech and Adoption of • New Technology, Biometrics and ChequeTruncation Systems
2012	• Rupay and National Automated Clearing House (NACH) Introduced by NPCI. Rupay-An Alternative to Visa and Master
2013	• Aadhar Enabled Payment System (AEPS)
2014	• *99# USSD Unstructured Supplementary Service Data
2016	• Unified Payment Interface (UPI), Bharat Bill Payment System (BBPS), National Electronic Toll • Collection System, Bharat Interface for Money(BHIM)
2017	• Bharat QR developed by NPCI, Master Card, Visa • Integrated Payment System - Money is transferred directly to the user's linked account
2018	• Release of RBI Report of the Working Group on FinTech and Digital Banking and Draft Enabling Framework for Regulatory Sand Box
2019	• RBI Payment System Vision 2019-2021 released
2020	• Availability of NEFT on a 24x7x365 Basis i.e., 16.12.2019

The Banking System in India has witnessed a radical transformation from the conventionalbanking system to the electronic banking system of convenience. Payment Systems in India keep on evolving from manual to electronic to digital banking with new emerging technologies and Innovations. It started in the 1980s with the need for Computerization, Electronic Payment Systems in 2010 and move on to Digital and Fin-Tech E-collaboration. Figure 2 reflects the timelines of the evolution and achievements of Payment Systems from the 1980s till date. RBI Payment System Vision 2018 was Infinity. India started adopting digital innovations in linewith innovations adopted by its global peers. ICICI Bank was the first bank to initiate the Internet banking revolution in India in 1997 under the brand name based on the four important strategic pillars ofrobust infrastructure, responsive regulation, customer centricity and effective supervision. The major achievements during this period, Customer focus started to shift from paper-basedclearing instruments like cheques, demand drafts

and pay orders which have a longer cycle of settlement of 3-4 days due to physical movement ofthe cheques from a place of deposit to clearing centre and then to the drawee bank for payment. Various Initiatives were taken by RBI, NPCI, Government of India and Banks in promoting different types of electronic and digital banking products such as:

- Real Time Gross Settlement (RTGS): An electronic and continuous transfer of funds on a real-time gross basis without netting. This payment system is used for high-value transactions above Rs2 lakh and the beneficiary receives the funds instantly
- Electronic Clearing Service (ECS): A retail electronic payment funds transfer system for transactions of bulk collection and payments which are repetitive. An ECS Debit andCredit transaction facilitates fund transfer from one bank to many bank accounts and many banksto one bank account.
- National Electronic Funds Transfer (NEFT): One-to-one nationwide electronic payment System where individuals, corporate, and firms can transfer funds to others having a bank account throughout India.
- Immediate Payment Service (IMPS): It is an arrangement which envisages instantaneous electronic funds transfer systems 24x7 between all the banks in India through ATM, Mobile and Internet
- Mobile Banking Mobile: Banking Services are offered 24x7x365 by banks to their customers through Mobile Applications via internetbanking or mobile data connection
- Card Payment System: Indian Customers are increasingly using Cards for shopping at point of sale, online shopping through the internet and mobile banking as compared to cash withdrawals at ATMs.
- Bharat Interface for Money (BHIM): An application for funds transfer on a Unified Payment Interface (UPI) for quick transactions of payments simply and easily. Customers can send and receive money through BHIM Application by using Virtual Payment Address i.e. UPI ID and Mobile number. BHIM transactions from NPCI Platform show that BHIM volume for the year FY2019-2020.
- ATMs and Point of Sales (POS): Numbers are also increasing. No. of ATMs and POS as of March 2020 is 210760 and 5137822 respectively. The amount of ATM transactions is 26769158 lakhs and POS transactions are 4764615 lakhs in 2019-20.
- Aadhaar Based Retail Payment Systems consist of Aadhar Enabled Payment Systems (Inter Bank) through Micro ATMs (e.g., Cash Deposit /Cash withdrawal) and APBS Credit (UIDAI number-driven Disbursement).

Clearing, Settlement & Payments	Lending, Capital raising & Deposits	Market Provisioning	Management of Investment	Risk Management &Data Analytics
Digital currencies Mobile and web-based payments Distributed ledger	Peer-to-peer lending Crowdfunding Digital currencies Distributed Ledger	Cloud computing Smart contracts e- Aggregators	Smart contracts Robo advice e- Trading	Artificial Intelligence, Robotics & Big data

Table-2: Significant Innovation in Fintech

Gomber et al. (2018) stated that Fin-Tech or digital innovations have played a pivotal role in transforming. The Indian Banking and Payment System is witnessing various new emerging technologies like Blockchain, Artificial Intelligence (AI), Robotic Process Automation (RPA), Biometrics, Chatbots, Machine Learning, and the use of Big Data and Predictive Analysis offered by FinTech Companies. Odinet, (2018) defined Artificial Intelligence as "AI is best understood as the overarching field that seeks to create complex machines that can exhibit all characteristics of real human intelligence". AI facilitates increased revenue, reduced costs, better compliance and higher profits. A Report by Accenture (2018) has pointed out that AI has the potential to add USD 957 billion by 2035 (1.3%of GDP) to the Indian economy. Thus, an illustrative use of AI by banks operating in India is presented in the table below

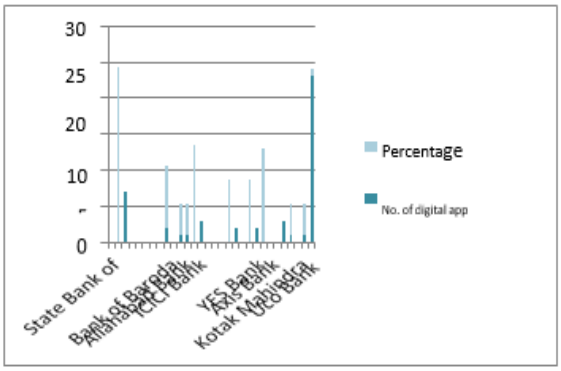

Figure 1: Application Usage in Banks

Table-3: Digital Apps in Banks

Name of Banks	No. of Digital apps using	Use of AI	Percentage
State Bank of India	07	➢ Partnered with Pay jo to launch SBI Intelligent Assistant (SIA) an AI-powered chat assistant designed to address customer enquiries ➢ Partnered with Hitachi for payment servicesthat will use the AI technology of Hitachifor SBI PaymentServices ➢ Utilizing IBM Watson to perform a variety of jobs ➢ AI-based solution presently in use developed by Chapdex. ➢ The chat assistant,known as SBI Intelligent Assistant, orSIA, will help customers witheveryday ➢ Deploying artificial intelligence (AI) in a big way to improveefficiency, detect human behaviour and reduce operational costs. ➢ Using AI and Robotic Process Automation(RPA) can help in making internal banking processes more efficient.	24.28
Bank of Baroda	02	➢ Using AI-empoweredrobot 'Baroda Brainy' ➢ Using AI solution by Quadratyx	8.70
Allahabad Bank	01	➢ Using AI-enabled app 'emPower' for e-commerce payments	4.35
Canara Bank	01	➢ Using humanoid robotMitra and Candi	4.35
ICICI Bank	03	➢ Using iPal, an AI-basedChatbot ➢ AI features such as facial and voicerecognition, bots etc are being leveraged. ➢ Deployed robotics ➢ software to ease over200 of its processes.	13.58
HDFC Bank	02	➢ Launched IRA 2.0, aninteractive humanoid ➢ 'Eva' is an AI-based Chatbot, developed by Sense forth AIResearch	8.70
YES Bank	02	➢ Using YES TAG ➢ Using AI solution byQuadratyx	8.70
Axis Bank	03	➢ Launched an AI-enabled app developed by Active AI ➢ "Thought Factory"- an Innovation Lab based on innovative AItechnology ➢ Solutions for the banking sector.	13.58
Kotak Mahindra Bank	01	➢ Using AI solution byQuadratyx	4.35
UCO Bank	01	➢ Using AI solution by Quadratyx	4.35
Total Bank-10	23		100%

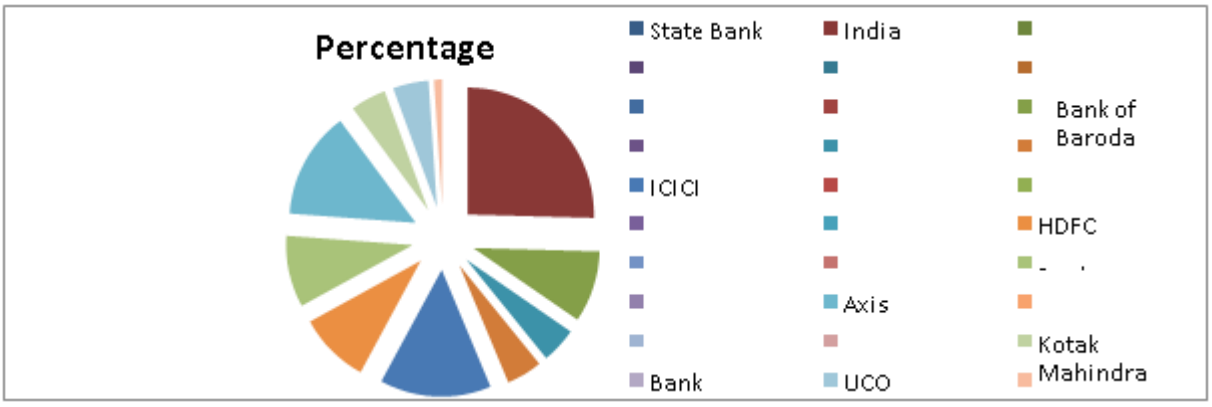

Figure 2: Semiotic models of Pie Chart for using apps by various banks and their percentage

a)

Data analytics – Data analytics techniques assist us totake raw data and uncover patterns to derive valuable insights from it. Several Indian banks like HDFC Bank, SBI, ICICI, Bank of Baroda, and Kotak Mahindra Bank have already initiated data analytics initiatives.

b) Cryptocurrency: It is a peer-to-peer (private) digitalsystem of payment with the transactions recorded in a public ledger using its unit of account.

c) Chatbots: It facilitates quicker resolution of customer-related issues. It is more effective than traditional methodslike email, phone etc.

d) Big Data: Big data technology aids in the analysis and processing of various transactions and data for extracting crucial information for sustaining competitive advantage.It helps in recognizing recent market movements andreorganizing operational issues and processes to manage risks.

e) Blockchain Technology: It holds the potential to influence various banking transactions like Trade Finance,Cross Border Payments, Digital Identities etc.Operational efficiency, simplicity, transparency and the customer experience in banking can be improved by the use of Black chain technology.

f) Cyber Security: Sometimes online transactions are susceptible to the risk of a data breach. Hence, banks need to strengthen cyber security in banking processes. Cyber security in banking transactions helps in protecting customer assets.

g) Robotic Process Automation (RPA): Robotic processautomation has streamlined back-office processes which used to be performed by Bank employees. With the shift from man to machine, banks have witnessed improvementin efficiency, cost reduction and manpower-related issues.

h) Cloud Computing: Rapid development of products and services is possible due to the adoption of Cloud Computing Technology. With the usage of Cloud Computing, services like Core banking, Net Banking,Mobile Banking, wallets and Card Management are handled properly. Productivity, performance and profitability can be improved by Cloud Computing. NASSCOM reports that the cloud market in India is also expanding and is expected to grow to $7.1 billion by 2022. State Bank of India has collaborated with Oracle and the Bank of Baroda has collaborated with IBM for an acceleration of Cloud Innovation in their respective Banks.

i) Distributed Ledger Technology (DLT): A distributed ledger is a database allowing the recording of the transaction of assets and their details in multiple places simultaneously. There is no central data store or administration functionality in Distributed Ledger Technology which is available in traditional databases.

j) Predictive analytics is used as a decision-making toolin several industries and disciplines, such as insurance, banking and marketing. Predictive analytics can provide a holistic view of the customer's journey with the bank and further help strengthen the relationship. Banks need to embrace the capabilities of data and analytics to improve risk modelling and fraud detection.

k) Machine Learning: Machine learning models can also predict which banking tools individual members might use and recommend them so that customers can make better financial decisions. These solutions can be used by banks for risk prediction, risk prevention, fraud detection, investments, investment modelling customer services, customer modelling, etc.

Artificial Intelligence (AI) Application is adopted in Machine Learning.

The emergence of New Emerging Financial Technology (Fin-Tech) & E-Collaborations a New Paradigm in the Indian Banking Industry:

According to the Financial Stability Board (FSB), of the Bankfor International Settlements (BIS), “FinTech is technologically enabled financial innovation that could result in new business models, applications, processes, or products with an associated material effect on financial markets and institutions and the provision of financial services”. All these products are having their existence in global finance, which with or without the intervention of a nodal intermediation agency, create an association between thelenders and borrowers, and share information between seekersand

Artificial Intelligence (AI) Application is adopted in Machine Learning.

The emergence of New Emerging Financial Technology (Fin-Tech) & E-Collaborations a New Paradigm in the Indian Banking Industry:

According to the Financial Stability Board (FSB), of the Bankfor International Settlements (BIS), “FinTech is technologically enabled financial innovation that could result in new business models, applications, processes, or products with an associated material effect on financial markets and institutions and the provision of financial services”. All these products are having their existence in global finance, which with or without the intervention of a nodal intermediation agency, create an association between thelenders and borrowers, and share information between seekersand

c) Digital Native, Intelligent, Social, connected (DISC)Approach - needs to be adopted by the banks today to understand customer context and provide fresh, agile and relevant digital solutions to consolidate their digital leadership. Merchant Acceptance and Infrastructure needto be increased both in rural and urban spaces.

d) Skilled Resources: Automation in the banking process through Digitalization, Artificial Intelligence (AI) andRobotic Process Automation (RPA) has brought about sociological challenges. Banks need to understand the impact on jobs and train the workforce with new IT skills,

e) Cyber Security Risks: The Centre for Software and IT Management (CSITM) in their study conducted at

IIM Bangalore has pointed out that one of the most important challenges in building trust among customers is cyber security risks. In their study, they have identified the potential risks in Digital wallets, specific bank apps for account holders, direct links with user’s banks, and basic USSD services. Other types of security risks are phishing,vishing, hacking, credit card fraud, cloning etc.

f) Lack of Technological Infrastructure: A countryrequires an adequate level of infrastructure to

adopt the appropriate technology and provide the necessary support for its growth and usage. However, theinfrastructures in India need to develop

V. OPPORTUNITIES:

a) New Innovative Product Design: Due to various initiatives taken by RBI, the Government of India and Banks in promoting digital innovations, there has been increasing adoption and usage of digital banking by customers. The new-age customers are aware of the benefits and ready for new digital solutions. Banks need to focus more on product design, service delivery, and customer support. Bharat Bill Payment, an Interbank Web-based Platform, an E-mandate part of NACH and a Digital platform for high-value electronic transactions are the proposed new launches by NPCI.

b) Better Regulatory Environment: Data Connectivity and the Spread of Smartphones have improved the digitalecosystem by providing an efficient and effective regulatory environment.

c) Leveraging the power of social media: Social MediaTechnology, Digital Assistants and third- party channels like Facebook, and Twitter for leveraging internal capabilitiesare likely to become the primary channels by 2022 apart from online and internet banking.

VI. HYPOTHESIS TESTING:

In the section of Hypothesis Testing, the researcher has taken several response models for justifying the hypothesis, therefore, they have taken 10 Banks of different branches with taken 500 Customers
from Bhubaneswar smart city, Odisha (India) (*Each having 50 respondents) with gender discrimination and different profession, Business, Cultivator, Govt, Service, Private service, Company Service etc. After obtaining the data will be presented in the appropriate data table and then classified thedata for its accurate analysis and interpretation thereon. Here, various response models are given for the reader's kind perusal and perception:
As per the aforesaid data table and mean value for female customers is 42.0 and for the male customer is 58.0 and the Meandifference between them is 16. 0, and the number of banks is10 d.f is (N-1=09).it is proved that more customers are preferred use of a Digital innovation banking system. Hence, the table contains critical values of the student's t distribution computed using the cumulative distribution function. The t distribution is symmetric so that $t_{1-\alpha,\nu} = -t_{\alpha,\nu}$.

Thus, the t table can be used for both one-sided (lower and upper) and two-sided tests using the appropriate value of α.

The significance level, α, is demonstrated in the graph below, which displays a t distribution with 10 degrees of freedom. The most commonly used significance level is $\alpha = 0.05$. For a two-sided test, we compute $1 - \alpha/2$, or $1 - 0.05/2 = 0.975$ when $\alpha = 0.05$. If the absolute value of thetest statistic is greater than the critical value (0.975), then we reject the null hypothesis. Due to the symmetry of the t distribution, we only tabulate the positive critical valuesin the table Thus the significance level at 0.1 level is 0.8186 and the 0.5 level is 0.8289, the obtained data is more than the table value, therefore the use of AI in Digital innovation in the banking sector is justified and the null hypothesis has been rejected and the alternative hypothesis is accepted due to its high significance and justified in both the levels of the significance level of 0.01 and 0.05 alpha level.

SUGGESTIONS & RECOMMENDATION

- Loss of data can be avoided by employing well-trend IT experts.
- Tough laws should be enacted for the cyber-attack.
- Workshops and seminars related to digital payments should be organized so that the common people and rural people can get the maximum benefits of bank facilities. Hence, Digital Banking Literacy programs should be runin rural and backward areas.
- Technology should be developed and expandedso that people from remote areas can also take advantage of it.

FINDINGS

- Digital innovations help in reducing operating costs and widening the customer base.
- Reports can be generated and analysed for various purposes at different points in time.
- It is the safer way to handle financial transactions and to prevent misuse of DBT under Digital Banking.
- The Indian Banking and Payment System is witnessing various new emerging technologies like Blockchain, Distributed Ledger Technology (DLT), Artificial Intelligence (AI) Machine Learning, Robotic Process Automation (RPA), Biometrics, Chatbots and the use of Big Data and Predictive.

LIMITATIONS

- The banking in India has been transforming itselfat a rapid pace, especially with the entry of FinTechcompanies and Payment Banks we can expect further changes.
- The public sector banks have been merging to create stronger entities than other Non-Banking Financial Companies (NBFCs) are also making forays into banking.
- One needs to keep an eye out by continuously examining the changing scenario over the next
few years.
- Digital Innovative banking has limited current players in banking so it will be prudent to include others also in the research.

CONCLUSION

In conclusion, we may conclude that the vision of the Digital India programme is to transform India into a digitally empowered society and knowledge economy. The above statistics and discussion show the rising trends in the adoption of digital innovations and new Fin Techemerging products. While there will always be challenges, opportunities also exist for those banks and

financial Institutions who are ready to innovate and offer more digital financial products to the customer. The Digital Payment Ecosystem with Fin Tech collaboration and global technology giants are acting as aggregators for retail transactions. Measurement of Digital Payments should be carried out at regular intervals to study and monitor the progress. The new emerging financial technologies in Indian Payment System will continue to be evolving, reaching global heights with regulatory compliance and risk management to achieve the vision ofDigital India. B y digital India Programme for ensuring better customer service thereby attaining the goal of a cashless economy. Both the Public Sector Banks and Private Sector Banks are moving towards technology-intensive customer services. With digital technology opportunities andchallenges, the banking industry is rising along with digital innovation. Digital banking has become more popular during the pandemic period of lockdown as related to the COVID- 19 effect.

Abstract – **The research seeks to identify the elements of consumer purchase behavior to shop through digital or E pharmacy through social media influence in India: based on theoretical models such as Technology Acceptance Model. The persistent of this research is to determine the impact and relationship among the independent variables trust, perceived usefulness and perceived intention on online purchase of medicines through social media influence (dependent variables) . A structured questionnaire covered descriptive inquiries and qualitative questions to collect data from the 100 respondents from the different age groups pertaining to Indian context especially millennial using a structured, self-administered and internet mediated survey. The study is cross sectional which studies the relationship between variables and influence of the social media on the purchase of online medicines. The findings shows that there is positive relationship amongst the independent variables trust, perceived usefulness and perceived intention on the online purchase of medicines through social media influence but perceived intention comes out to be more important constructfor buying medicines online along with the trust.**

Keywords: ***Consumer, Buying, Technology,Government, Pandemic*.**

I. INTRODUCTION

After the outbreak of the unpredictable and ferocious pandemic in 2019 various verticals of ecommerce have seen an outrageous demand out of them is one excellently demanding and forthcoming online pharmacy market also known as digital or E pharmacy. Over the past decade internet has emerged as favorite market place for the consumers, distributors and retailers due to convince it provides along with it also helps incost cutting. From the perspective of an average consumer, they saw some products are suitable to sold online and some don't (Poop & Joseph; 2000) similarly it is evitable to study the consumer behavior and attitude regarding the online purchase of goods and services what motivates them, right type of advertisements etc. Researchers have focus on all type of patterns of behavior but there is a little emphasis given to the online selling of medications Rajama and Pelton (2009). Although it is due to the law which restricts and regulate the selling and purchase of medications online. Only fully legal OTC drugs, supplements and vitamins could be sold over the internet. But we saw some emerging e pharmacies like 1mg in India which is doing potentially well and have their greatest selling during the pandemic Digital marketing is the convergence of the digital revolution with pharmacy. It uses digital tools and technologies to improve business, practice andpatient care. We also use E pharmacy or online pharmacy as its synonyms. It is a platform which provides drugs in both lawful and unlawful manner. India's digital market is booming at a rapid speed with increasing number of Internet users , the total time invested by Indians is more than 17 hours in 7 days AK Jain (2020). Social media have catered a greater demand in the business market with huge number of consumers available on it. Social media marketing or SMM is a public entertaining platform which also works as great marketing tool. Social media marketing emphasis on the promotion and selling of the goods and services through various social media platforms, butit can be a time-consuming activity for businesses as one has to be consistent but it is a great place to understand consumer behavior. Advanced features like demographic of the user can helps the advertisers to segment their population and ads accordingly. Similarly social media marketing or influence could be great opportunity for the online pharmacy owners to sell drugs and reach out the potential customers with certain lawful regulations. SMM for e pharmacy helps in generating suggestions through paid promotions, as people visits moreon social media sites ads on it can increase the visibility of one's brand. It also helps in increasing customer loyalty. The best way of using the SMM is to run pilot testing where you can know about your consumer preferences at low costs. Despite the advantages of using Social Media Marketing for selling drugs online there are many rules and legal regulations which control the usage of e pharmacy. Asper the 2019 report there were approximately 8,50,000 pharmacy retailers or offline brick and mortar stores which counts for 99 % sales of drugs whereas online pharmacy contributes only 1% sale of drugs in India Sinha's (2019) . But after the outbreak of pandemic, increasing digital usage and awareness there is a potential increase seen the acceptance of online pharmacy among the government, investors as well as consumers. Unlike any e commerce store the concept of online pharmacy is very different due to the rigid rules and regulation. Healthcare is a serious concern not only in India but also globally. Moreover, the government cannot address the healthcare sector alone. Corporations should take the initiative and indulge in health-related sectors like blood donation camps, health camps, health activities, and policy implementation (Yadav, M., Singh, P., & Baral SK. (2022). In year 20005 the online pharmacy startups came together to make an IPA – Indian Pharmacy association which promises an ethical trade of medicines through online platform in India, there are other multiple laws by the government of India which regulates the online selling of drugs like Drug and Cosmetic Act 1940, Information Technology Act

2009 and the Indian Medical Act 1950. We can observe a positive shift towards online pharmacy due to the increasing chronic diseases and busy lifestyle of people. But due to the security and other reasons consumers are very slow to adopt to new online drugs but steady and slowly there will a major boost in the digital pharmacy. The preceding researcher's emphases on thevariables like trust, risk, and usefulness (Jan Savorc 2019) to study the consumer buying behavior directly on theonline purchase of medicines but with the ongoing pandemic and advancement of technology befits to study the influence of social media on digital pharmacy as increasing social media users as well as growth of social media marketing which conditionally helps to understand the consumer buying behavior.

OBJECTIVES OF THE STUDY

The study envisaged on the following objectives;

•To find the relationship and impact of trust on online purchase of medicines through social media influence

•To find the relationship and impact of perceived usefulness on online purchase of medicines through social media influence

•To find the relationship and impact of perceived intention on online purchase of medicines through social media influence

•To find the relationship and impact of social media influence on online purchase of medicines

LITERATURE REVIEW

As a consumer, all people are different from each other. One person may like a product or services which others may not like. Identification of consumer behavior and buying pattern of a product or service is an important tool to identify different factors affecting a consumer buying decision.

Researcher also confirms the connection between social media and consumer buying behaviour to purchase particular products. Ahmad Juwaini (2021) the research focused on the online transportation services through social media influence. The study aimed at finding the relationship between trust and intention to purchase services through social media marketing. Research showed the positive relationship between intention to purchase and social media influence, whereas there is no significant relationship between trust and intention to purchase online services. Dan-Cristian Dabija & Mónika-Anetta Alt (2021) Researchers shows the positive relationship between social media influencers and consumer decision making process.NASIDI, QARIBU YAHAYA and Hassan, Isyaku andFazil Ahmad, Muhamad (2021) the researchers showed the framework on meditating effect of social media with relationship between perceived usefulness, reliability on online shopping behavior. Mohamed Ibrahim, Osama & Ibrahim,Rana & Al-Tandem, Noor & RILEY, KAREN. (2020). Advanced usage of social media positively impacts the life of the pharmacists as they agreed that social media, text messages-mails used by them effectively improves patient communication, WhatsApp is the most used platform for communicating with the customers. Irshad, Madeeha & Ahmad, Muhammad Shakil & Malik, Omer. (2020). Remuneration as well as the social motivation impacts the consumer buying behavior positively and have a direct impacton their purchase decisions and indirectly mediated through trust Mekala, Rajanikanth. (2019) The study shows key factors for the success of e-commerce and social networking includes trust generated from the peers in the form of reviews and recommendations and perceived usefulness of the product andthe social networking sites. Radhakrishnan, Venkateswaran & Ugalde, Bernard & T., Rogelio. (2019) The use of social media and its tools helps the organizations in increased branding of their products and reach out the more segments of customers also increases the brand awareness. A. Chakraborty, Prabal & Satsangi lok. (2019) E pharmacy adds to the convenience for the elderly people by improving consumers experience suffering from chronic conditions who aren't able to reach the offline pharmacy or their children lives away from them. Ebrahim, Reham. (2019) SMM activities comprise only three dimensions; trendiness, customization and word-of- mouth. These attributes of social media marketing directly influence brand loyalty and indirectly influence brand equity mediated by brand trust. The study emphasis the role of trust and provide guidance toward measuring the effectiveness of social media marketing. Raina, Madhur; Srivastava, Mallika (2019) The researcher used technology acceptance model (TAM) and Self Determination theory (SDT) to study the intention of the consumers towards electronic healthcare. The research shows the poster relationship between intention to use internet and e healthcare. M. Rakibul Hoque, Yukun Bao & Golam Sorwar (2017) The researchers used the technology acceptance model, the study determined that perceived ease ofuse and perceived usefulness and trust ($p < 0.05$) were significant factors influencing the intention to adopt e-Health in developing countries. Kumar, Davinder & Kumar, Virender & Savarna,. (2016). Online pharmacy leads to minor financial losses with considerable legal and health hazards which changes consumers behavior towards purchase of medications online. Lack of personal touch, quality check and illegal traders also marks up to the dangerous and contaminated online pharmacy. Crilly, Philip & Kayyali, Reem. (2016). Pharmacists uses social media platforms especially Facebook to interact with the patience by providing them links to various health resources and giving compliance with tips of using the drugs and other products which promotes the meaningful health and consumer behavior changes Hoong Fong, Ng & Yazdanifard, Assc. Prof. Dr. Rashad. (2014) With the advancement oftechnology it is inevitable to separate the online World from social media and consumer behavior; there is no escape route from social media these days for both the individuals and the companies. In the digital stores where the consumers couldn't sense the products they purchase, due the lack of face-to-face communication and personal touch consumers usually develops low trust and perceived highlyelevated risk. Bell M, Douglas J, Cutts C (2014) It

isapparent that most of the social media users falls into the younger age bracket whereas the people with long term health conditions typically doesn't active on social media which is major drawback for the online health platforms. Bell, Maria & Douglas, Janet & Cutts, Chris. (2014)Disciplines like medicine information

,safer usage, usage in chronic diseases , evidence based guidelines in area there is an uptake and use of social media platforms used by the health care industry for increasing and improving thepatience outcomes Jeff Cain (2010) The familiarity of social media to public and its economical nature along withthe ability to distribute information rapidly creates an opportunity for the pharmacists who wanted to provide innovative heath care facilities both at individual and publiclevel.

RESEARCH METHODOLOGY

A structured questionnaire covered descriptive inquiries and qualitative questions to collect data from the 100 respondents from the different age groups pertaining to Indian context especially millennial using a structured, self- administered and internet mediated survey. The study is cross sectional which studies the relationship between variables and influence of the social media on the purchase of online medicines. Sample was selected

based on convenience sampling, sampling the frame was difficult dueto time and financial constraints. Internet is used to distribute the survey seems to be sensible for the research during the pandemic. The research potentially covers the social media users who are online consumers, reduces the uninformed occurrence of responses. There are defined hypothesis prominent to 4 variables which are defined under the table-1. The hypothesis is framed based on technology acceptance model (Figure-1). It aims to examine the relationship between independent variables online trust, perceived usefulness and perceived intention on the online purchase behavior of buying medicines online through social media influence (dependent variables). These variables are defined based on TAM and existing theories applied to the specific situations. (TAM; Davis, 1989) known as technology acceptance model is considered to be themost influential model of technology acceptance despite of the criticism it faces, it focuses on two factors which influences the individual's intention to use new technology: perceived ease of use and perceived usefulness. TAM forecasts individual adoption of technology and its voluntary use (Rupak Rauniar,2012). It focuses on the technology users and how theycan adopt to the new technology.

The main objective of this model is to emphasis on the potential of the users. The two major constructs use in the model are perceived usefulness and perceived ease of use. The TAM has been continuously studied and also has been expanded and upgraded (Venkatesh & Davis2000) it has also been used in the ecommerce context with inclusion of trust and perceived risk. (Venkatesh & Bala 2008). Reliability is checked by Cronbach's Alpha using Microsoft Excel 2010 further regression analysis is used to determine the relationship between variables.

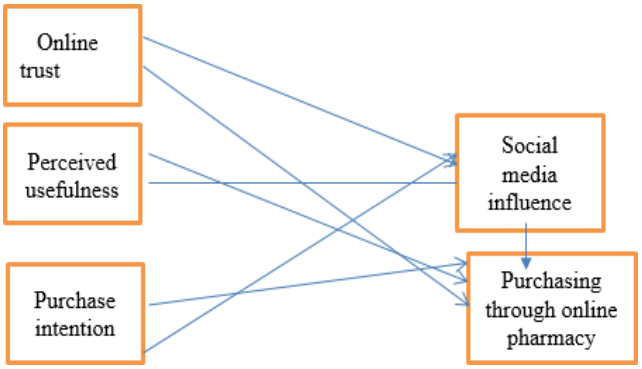

Fig.1. Technology Acceptance Model

Table 1: About the Key Constructs

CONSTRUCTS	DEFINATIONS	REFERENCES
Online Trust (TRUST)	A significant factor determining successful online interaction predicting the behavior of an entity and selection of anentity	(Mark Perry ,2010)
Perceived Usefulness (PU)	Consumer behavior is determined by their attitudes towards the Adoption of technology i.e., perceived usefulness andperceived ease of use while interacting during the online transactions	(Barki, 2007 Renko, 2015) (Eagly and Chaiken
Purchase intention(INT)	Aperson's commitment, decisionsandplans to carry out	

Hypothesis Development

Rajković 2021 shows that social media can help in building trust among consumers and towards the business. The researcher showed the positive relationship between trust and an intention to purchase. Researcher also confirmsthe connection between social media and consumer buyingbehaviour to purchase particular products.

H1 There is a positive effect of trust on social media influence

H1A There is positive relationship between trust and online purchase of medicines

Nasidi, Qaribu Yahaya and Hassan, Isyaku and Fazil Ahmad, Muhamad (2021) the researchers showed the framework on meditating effect of social media with

relationship between perceived usefulness, reliability on online shopping behaviour. M. Rakibul Hoque, Yukun Bao& Golam Sorwar (2017) The researchers used the technology acceptance model, the study determined that perceived ease of use and perceived usefulness and trust($p < 0.05$) were significant factors influencing the intentionto adopt e-Health in developing countries.

H2 There is positive effect of perceived usefulness on social media influence

H2B There is positive relationship between perceivedusefulness and online purchase of medicines

Irshad, Madeeha & Ahmad, Muhammad Shakil & Malik, Omer. (2020). Remuneration as well as the social motivation impacts the consumer buying behavior postiviley and have a direct impact on their purchase decisions and indirectly mediated through trust

H3 There is a positive effect of purchase intention on social media influence

H3C There is a positive relationship between purchase intention and online purchase of medicines

Crilly, Philip & Kayyali, Reem. (2016). Pharmacists uses social media platforms especially Facebook to interact with the patience by providing them links to various health resources and giving compliance with tips of using the drugs and other products which promotes the meaningful health andconsumer behavior changes Hoong Fong, Ng & Yazdanifard.

H4 There is positive effect of social media influence ononline purchase of medicines

More than one item is defined for some variable. All the variables are opinion variables measured on 5-point likert scale(1 strongly disagree to 5 strongly agree). Demographic information like age and income has multiple choice options to categorize from whereas gender category follows simple scale(dichotomous male/female). The ethical issues are taken care of at all stages of research by keeping anonymity and confidentiality with the volunteering nature. Due to social media influence the more emphasis is given to the social media users and millennial with no information.

RESULT & ANALYSIS

More than one item is defined for some variable. All the variables are opinion variables measured on 5-point likert scale (1 strongly disagree to 5 strongly agree). Demographic information like age and income has multiple choice options to categorize from whereas gender category follows simple scale (dichotomous male/female). The ethical issues are taken care of at all stages of research by keeping anonymity and confidentiality with the volunteering nature. Due to social media influence the more emphasis is given to the social media users and millennial with no information harmful is asked to fill in the questionnaire, there was no financial reward given tothe respondents. Since the Cronbach's alpha value of the whole questionnaire comes out to be 0.879 i.e., 88% which comes outto be very good and the data stands reliable because the benchmark is 0.70 i.e., 70%. Therefore, we can move forward with our data collected from 100 respondents. The resultsbelow were derived from reliably test or Cronbach's Alpha testwhich was applied on the data using Microsoft Excel 2010. Thevalue of alpha in each case was reliable as it was above 0.70 0r70% and can be further used for the study

Male respondents are higher than the female respondents, more respondents are between the age 18-24 and are

active social media users. The income is distributed evenly and 23% of the respondents prefer not to disclose their income. correlation of single determination shows 0.681293 which is 69% of variation in trust on the social media influence can be explained by the regression similarly 40% of variation in perceived usefulness on social media influence and 52% of variation in perceived intention on social media influence can be explained the simple regression analysis. Whereas social media has direct and positive relationship or impact on trust ($p<0.05$), perceived usefulness ($p<0.05$) and perceived intention ($p<0.05$) thus H1, H2 and H3 are supported. Due to less variation the data doesn't shows much higher correlation between the variables. Similarly, there 85% of variation in trust on the online purchase of medicines can be explained by the regression analysis, 79% of variation in perceived usefulness, 88% of variation in perceived intention and 76% of variation social media influence on online purchase of medicines can be explained by the regression analysis. Online purchase of medicines has direct and positive impact on trust ($p<0.05$), perceived usefulness ($0.05>p$), perceived intention ($p<0.05$) and social media influence ($p<0.05$) thus H1A, H2B, H3C and H4 stands supported.

CONCLUSION AND RECOMMENDATIONS

Correlation analysis shows the relationship between all the variables and hence found the six-hypothesis supported. Regression analysis also supported and found out all the constructs statistically significant predictors to know the impact of social media influence on purchase of medicines online or the use of digital pharmacy. Purchase intentions of the consumers towards online pharmacy has a larger effect along with the trust. But it is significantly true that with widespread of social media users SMM have great impact and opportunity for the digital pharmacy to study their consumer behavior, needs and wants. The research also contributes to the existing studies as it uses the researchers' patterns through internet toolsto know the consumer behavior towards the smaller segmentation of pharmaceutical products. The research applied Technology Acceptance Model a theoretical model with general validation. The research is unique under the online shopping of medicines through social media influence can be knowledgeable and resourceful for the existing literature contributing to study different constructs towards the digital pharmacy and consumer behavior. Our discoveries give a few important experiences to the buyers to acknowledge thee- drug store by utilizing online media impact. E-retailers and administrators completely comprehend the significance of web-based media impact during the time spent

presentinge-drug store; such firms ought to promote their meds and grandstand the utilization of meds on various online media which can fulfill the buyers' requirements. Findings of the research suggests that more people are becoming aware of the social media and Millennial are the active users of different social media platforms and Trust is one of the importance factors impacting the online purchase of medicines along with the intention to purchase due to the pandemic. Most importantly it is recommended to the e- sellers to focus on the factors which authentically shapes and attracts online consumers like the type of advertising, benefits, loyalty programs etc. Trust can become one of the major factors which hinders the online purchase process, e-pharmacy should focus on the authenticity of the consumer data and also following all the norms, rules and regulations provided by the Government and medical authorities. Perceived usefulness and socioeconomics are the progression forward towards internet purchasing conduct through online media impact, so the perceived usefulness and socioeconomics are impacted by the web-based media input posted across various societies which sway internet purchasing conduct of medication (e-drug store). The impact of perceived usefulness on goal in past investigations have been differed, either with huge (Chen and Tan, 2004; Pavlou, 2003) or immaterial (Chen et al., 2002; Shan et al., 2005) effects on purchasing behavior.

LIMITATIONS OF THE STUDY AND FUTURE SCOPE

The findings of the research should be taken with some limitations. First of all, only Indian residents were surveyed,which means that the results can be applied in India, but care must be taken in application anywhere else due to the cultural background. Other issue is that respondents came mostly from Delhi, capital and Delhi NCR, which is more cosmopolitan that the rest of the state. This may affect the obtained responses as city residents tend to adopt more quickly new trends. The study doesn't cover the true rural population, which may bias the results.

There are several recommendations for the future researchers to study the consumer behavior and pattern towards purchase of medicines online not only by the social media influence but other influences like EWOM and more. Researchers can study different variables or constructs to determine the consumer behavior towards digital pharmacy. Also, other variables like perceived ease of use, innovations, shopping attitude of the consumers along with the risk should also be studied as proposed by different theoretical models. Last but not the least population outside Delhi should be studied with the probability sampling covering the rural population also.

Mobile Security Operation Centre (mSOC)

Sudhir Walia, Qazi Mustafa Kaleem , Shinu Abhi
REVA Academy for Corporate Excellence, REVA University, Bengaluru, India

Abstract – **Attacks on the internet are becoming increasingly threatening. For naïve home users, who are poorly protected, there is always an imminent danger of getting cyber attacked.**

This paper is aimed to design and build an IoT-based Network Security device that would run as an access point for users to connect to the Internet in a home setting. The paper discusses a standalone perimeter security solution with Incident Response (IR) life cycle management and controls through an IoT device – Raspberry PI. Enterprise-level features such as Next Generation Firewall (NGFW), Network Intrusion Detection System (NIDS), Domain Control for Ad/Spam blocking, Security Information and Event Management (SIEM) for Log Co-ran System on Chip (SoC), which can be installed anywhere and carried for mobile operations. Hence, the name, Mobile Security Operation Centre (mSOC).

This solution intends to protect the user when browsing the internet and blocking or providing visibility to the malicious connections being made to or from users. The mSOC can perform domain filtering based on whitelist/blacklist and Regex Pattern. It can also identify the domains that are blocked or allowed. It also provides visibility to traffic, application statistics, and IP reputation. IP reputation and Malicious Domains then can act as input to the iptables for L3/L4 blocking. A Software User Interface is developed to integrate and manage multiple Open-Sourced applications like dnsmasq/ elk/ graylog/ SQlite3/ Iptables/ adminlte as a single product that could serve as a complete security solution for a home or Small Medium Business (SMB). Thus the proposed solution secures naïve users from security exploitations.

*Keywords**: Internet, NIDS, IoT, NGFW, Raspberry Pi, SIEM.***

I. INTRODUCTION

The number of Internet users worldwide had increased to 5.95 billion in 2022, with the internet penetration rate reaching to 62.5% of the world's total population [1]. The num- bers provide a valuable context for digital adoption and growth. With this digital growth, new cybersecurity issues are constantly emerging, with new viruses and mal- ware being discovered daily. To prevent future attacks, it is important to know the most common types of attacks and their causes.

While organizations have the budget and resources to protect users from cyber threats, individual users lack the resources and skills to protect themselves. Among the top at- tacks on home internet users, 9% of malware were emails and more than 80% of re- ported security incidents were phishing attacks. Spam accounts for 14.5 billion mes- sages globally per day. In other words, spam/phishing makes up for 45% of all emails, of which at least 20% of home users fall victim to [2]. The most common attacks are phishing, whaling, malware, social engineering, ransomware, and Distributed Denial of Service (DDoS) attacks

Most of the technology deployment involves the protection of assets in an organisation. However, the studies show that it is not just the organisations that are prone to cyber- attacks, but everyone connected to the internet is vulnerable.

There is limited literature available on the implementation of IoT-based security solu- tions for Small Offices/Home offices (SOHOs) and Small and Medium Enterprises (SMEs). Feasibility studies of implementing Raspberry Pi-based Domain Filtering, SIEM, and IP reputation for SOHOs and SMEs are hardly available in the extant liter- ature.

The need for security is at the forefront today for all. Constructing a smart home brings convenience yet it comes with the demands of securing sensitive areas that contain a wide range of IoT devices. With the increase in cybercrimes, network security is a must-have for businesses and SOHOs. For users to work from home, employees must constantly be linked to the home network to work. As a result, home network security must be updated, vulnerabilities minimised, and additional security implemented. The number of IoT devices that may connect to the home network is also considered to boost security since the network is the primary entrance point for hacking IoT. In a study done for RPi as a packet analyzer and honeypots [3], RPi has been utilised as a low-cost, power-efficient, and practical home network security system, including IDS Suricata, several honeypots, and a tshark packet analyzer. When the system is running, the device performance is also measured. The ELK stack is used to display log data from the four sensors.

RPi-based security solutions can take on the event of a data breach [4]. It is the hard- ware that supports Debian based OS which provides utility features like Vulnerability Analysis, Network Analysis, Security Policy measures, Firewall, DNS and DHCP Server, and a proxy to route and filter the traffic. The main priority of small companies is to protect the data. However, making a one-touch security solution is extremely dif- ficult with a restricted budget. The company's credibility and reputation are in danger if they disregard security. This cannot be solved with a mostly one-touch i.e., an expen- sive system that is costly for a small business. The intended solution considers the needs of such an organization. This cost-effective solution can be viable for a small organism- tion.

RPi-based Invasion Detection Systems use open-source code to detect intrusions on SOHO networks [5]. Some of the malware looks for fields such as port numbers and packets that are encoded especially, but snort IDS can detect files that contain Malware embedded codes. Small Office Home Office (SOHO) networks, use some Intrusion Detection Systems (IDS) that can be activated to monitor possible attacks. Intrusion Detection Methods (IDM) are a convenient, in-home, inexpensive form of network se- curity. Visible IDMs use software and hardware implementations to packet filter, sig- nature-based detection programs, to detect cyber-attacks in real-time, or to record in- formation and then send it to 24 hours online reporting service.

Senior management must always be aware that the security specialist at the company is useful in implementing a virtual security stack; however, the basic premise of their se- curity service must be economically developed since the budget is limited and RPi can be used as a low-cost option [6].

There is an ever-increasing need to make our networks more secure and to ensure against breaches, leaks, and risks from bad Internet actors. Adding security features to homes connected to the cloud can make it more stable, with minimal downtime. Mod- ern-day insecurity has many risks; cybercrime, hacking, network attacks, and Distrib- uted Denial of Service (DDoS) [7]. Therefore, the authors have produced this guide for a secure home network. It provides an overview of using an Intrusion Detection System IDS, network security system, network intrusion prevention system, or IT security de- vice. The hand-held device is used by a guardian to check an area and to keep an eye.

Another study tested the performance of Raspberry Pi in context to network perfor- mance, latency, throughput, and CPU and memory usage. The study presents a design for a Snort-based IDS device that was implemented on the RPi 3. Sniffer Protocol is also utilised to examine network traffic, and the SHA3 technique is employed to gen- erate the hash value regularly [8]. There are five types of assaults implemented in this paper: RDP Brute Force, ICMP flooding, SMTP Brute Force, SYN Flood, and Web Phishing. 'htop' utility was used to do performance testing, and 'sha-sum' program was used to run the test vector method. The Raspberry Pi detected 100 per cent of threats with less than 50 per cent CPU and 10 per cent RAM. As a result, the system may be used on home networks as a viable and low-cost alternative for implementing cyber-crime security.

A novel solution like mSOC – Mobile Security Operation Center based on IoT devices like Raspberry Pi can provide a Web-based user interface to configure domain filtering, IP reputation, traffic filtering, and Data Visualization.

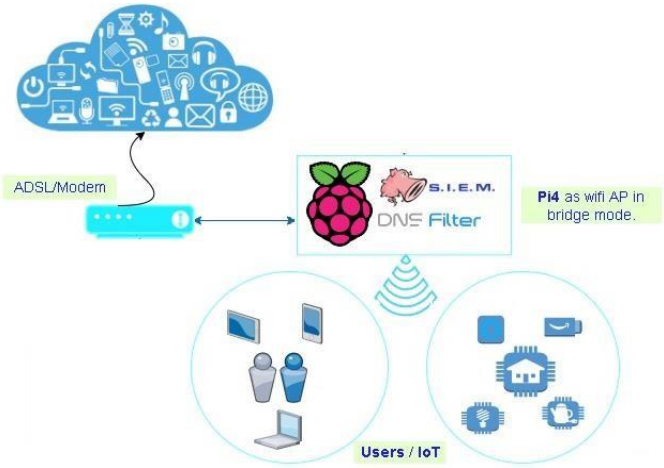
1 Solution Phases

The objective of the study is to secure home users with IoT devices like a Raspberry Pi, customised to provide a security solution. This study mimics the basic SOC – Security Operational Centre functionalities at the home level and controls at the fingertips of the user.

At its core, mSOC will be a small, portable device, pre-packaged with the functionality of mSOC. The device could be seamlessly deployed anywhere (called as Plug & Protect): As shown in Fig. 1users in a smart home could use it to protect their smart objects. It is effectively a portable, on-demand, device that protects users from attacks or suspicious activities.

Fig. 1. mSOC Solution

This solution involves developing a complex system with the following requirements in mind:



a. Portability: It is small enough to be able to carry the device and secure them wherever required.

b. Minimum configuration: The device should require limited configuration and default protection enabled.

c. Frontend Software Application Development: Develop a user interface to manage and control SOC functionalities.

d. UX and Data Analytics.

2.1 MSOC – Tools Integration

In the primary stage, open-source applications were selected and scoped for mSOC solutions. The scoped application modules are studied to be supported on the ARM CPU architecture and compatible with Raspberry PI Hardware limitations. Based on the research and tests, Open-Source modules in Fig. 2, SNORT- as NIDS, dnsmasq – as Domina Filter, Graylog – as ELK for SIEM, Linux IP Tables – as Unified FW con- trols, SQLite – as DB, were concluded.

Fig. 2. Modular Stages

mSOC is developed with the following features:

a.Domain Filtering: Filter domains based on a blacklist, and whitelist. Support Regex-based filtering

b.NIDS: Snort IDS for traffic visibility, app identification, and IP Reputation check.

c.SIEM: Analytics and Data Visualization of Domain/IDS logs. Geo-Location information of CPE

d.IPtables: To block traffic based on L3 and L4 filters.

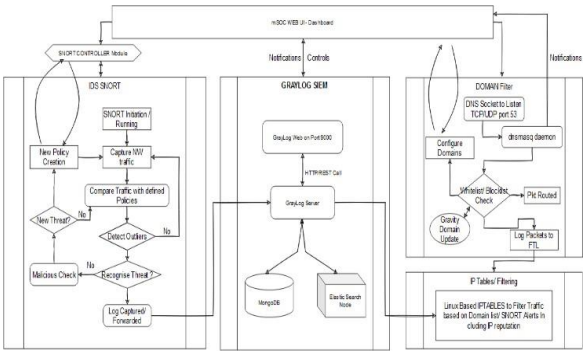


Fig. 3. Software Architecture

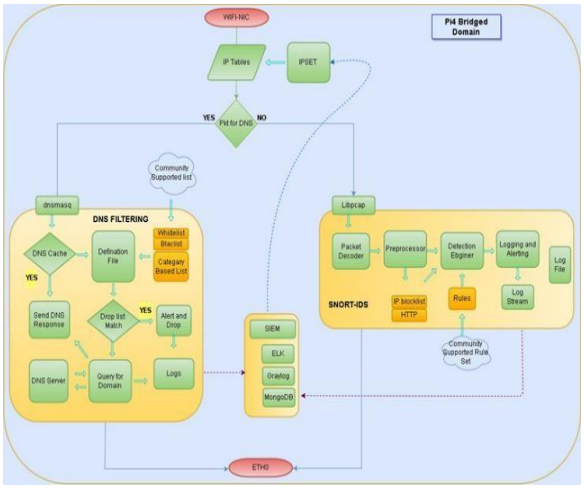

Fig. 4. Modules and Packet Flow

2.2 MSOC – Control

The second stage was a development of a Web-based Graphical User-interface that co-relates all the available data and showcases these raw data into useful information on a single dashboard – Operation view, as shown in Fig. 3. Web UI also helps integrate and manage all modules as one entity.

a. Domain Filtering Configuration and Management

b. SNORT rules management

c. Domain Filtering log correlation and Analytics

d. System Management and Monitoring

Each module in Table 1 is developed on a PHP framework to edit and manage individual applications.

Module Name	Module Function
Message.php	Manage Notifications
Adlist.php/ domains.php	Manage ad list & domains to filter.
Networks.php	Showcase real-time network mapping ofclients
Debug.php	Helps to display debugs logs on web UI
snort_rule_manager.php	To manage snort rules and controls.

3.3 Iptables & Ipset: Stateful Firewall.

The Linux kernel has a packet filtering capability to control inbound/outbound and transit traffic using the iptables utility. Iptables provide L3 and L4 firewall filtering solutions that can be easily managed and configured.

Iptables is particularly well-suited for Linux-based firewalls. It can filter traffic based on L3 and L4 information, it can also check if there is an existing connection bypass for further filtering to reduce the processing overhead. We can use IOC feeds to apply to iptables, but the feed can have thousands of IPs, which can affect system per- formance. In combination with iptables, we can use an ipset list that can have thousands of IP or port combinations, and this single ipset list is called in iptables. Lockup with ipset is very fast as IP address and port pairs as saved in the hash. This provides the ability to block thousands of IPs with one iptables rules without much impact on per- formance. Iptables rules are saved in /etc/iptables/rules.v4. There are four ipset lists are created, which are further mapped to the main ipset list called in the iptables drop rule.

3.4 Web UI /Dashboard

Front-End web page design and structure were developed to enhance the users' experience. Striking a balance between functional and aesthetic design with seamless smartphone capability.

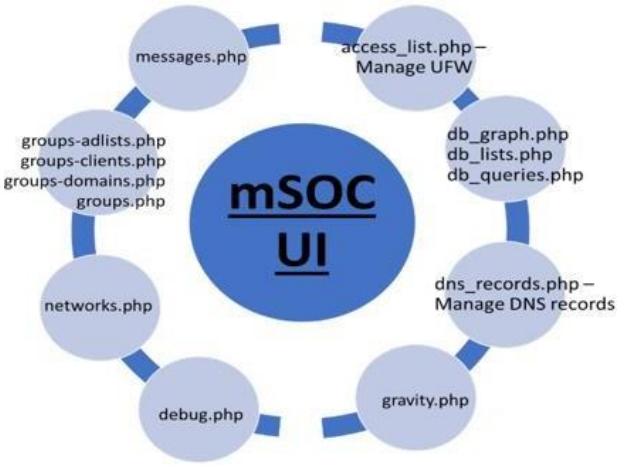

Fig. 6. UI Interactions

Open-Source Code Adminlte [10] was re-used to achieve a better user experience in the dashboard showcasing Timeline, Pie charts and Bar charts etc., Web pages are opti- mised for best speed and scalability by employing a diverse selection of markup languages to design web pages including HTML, CSS, JavaScript, and jQuery.

Back-End development is done on PHP; all the web pages are directly called on click this helps us to reduce overhead by eliminating pre-defined frameworks. For Web Hosting lighttpd daemon is used to handle HTTP requests. All the associated PHP files are shown in Fig. 6.

access_list.php, auditlog.php, cname_records.php,

db_graph.php, db_lists.php, db_queries.php, debug.php, dns_records.php, groups.php, network.php, queries.php, queryads.php, settings.php, taillog-FTL.php, taillog.php

Lighttpd (pronounced /lighty/) is a secure, fast, compliant, and very flexible web server that has been optimized for high-performance environments. lighttpd uses memory and CPU efficiently and has lower resource use than other popular web servers. Its advanced feature set (FastCGI, CGI, Auth, Output-Compression, URL-Rewriting and much more) make lighttpd the perfect web server for all systems, small and large. lighttpd is released under the Open Source revised BSD license

AdminLTE is a fully responsive administration template based on the Bootstrap 4.6 framework and also the JS/jQuery plugin. This is a highly customisable and easy-to- use template and fits many screen resolutions from small mobile devices to large desktops. Table II captures all the possible plugins that are being used to develop the frontend web application.

Table 2. Open-Source Plugin

Used For	Plugins
Charts	ChartJS, Flot, Sparkline, uPlot
Editors	Summernote, CodeMirror
Form Elements	Bootstrap Colorpicker, Bootstrap Slider, Boot- strap Switch, Date Range Picker, Dropzone JS, iCheck Bootstrap
Icon Packs	FontAwesome 5, flag-icon-css
Table Grids	DataTables, jsGrid

4. Conclusion and Recommendations for Future Work

At the core of our proposal stands a Raspberry Pi equipped with DNS filtering, Snort IDS, IP-Filtering, Data Analytics, and a Single pane of glass to manage the solution. This study argues, that our architecture, based on a commodity device such as the Raspberry Pi, can perform as a security operation centre, dashboard, single window control management, and integration of multiple open-source applications.

To support our claims, we carried out tests involving Raspberry Pi acting as an Access Point, analysing and filtering different types of network traffic from connected devices and users. Additionally, this study experimented with a different configuration, namely an App Detection engine, DNS filtering-based opensource database, and the number of rules loaded.

Our experiments' results show that the Raspberry Pi is capable of hosting all modules of mSOC, making RPiDS a feasible solution. Surprisingly, RPi4 can handle the demanding resource requirements of the mSOC module without overwhelming CPU and RAM. In the further scenario of testing, a family of 4 with multiple IoT devices connected to mSOC with high data rates, and memory never reached 100% utilisation. Still, experiments with networks bigger than a smart home are needed to better grasp the true limits of the Pi4+mSOC, for application in SME use cases.

In the future, this study plans to evolve User Interface, Data Correlation, and Data Analytics and move them to the cloud. RPi4 will run as an edge device managed centrally from the cloud or mobile app.

Additionally, this study intends to add features like Zero Touch Provisioning, IoT devices detection & Segmentation, and URL filtering.

5. Acknowledgment

This study would not have been possible without Dr. Shinu A, Mr. Sandeep Vijaya Raghavan, and Dr. Rashmi Agarwal, whose guidance from the initial step of research enabled us to develop an understanding of the subject. I am thankful for the extraordinary

experiences she arranged for me and for providing opportunities for me to grow professionally. It is an honour to learn from Mr. Sandeep Vijaya Raghavan and Dr. Shinu Abhi.

I am extremely thankful to all my faculties Associated with REVA University for their noble guidance, support with full encouragement and enthusiasm.

Abstract – Recently the topic of 'mental health' has gained high awareness, especially among younger generations. The age group that mostly gets affected by mental disorders is between 15-49 years of age. Research conducted on different social media data has found that a person with mental disorders (such as depres- sion, anxiety, etc) tends to use social media more as compared to a mentally healthy person. Most users convey their emotional states through posting on public platforms, tweeting and accordingly watching related videos on YouTube that best describes their current mental state. It is also found that there is a difference in users' social media activities (on Facebook, Twitter, and YouTube) with a healthy mind and one with an unhealthy mind. A study conducted in 2018 found that 45% of teenagers worldwide are constantly using the internet. According to research, teenagers use the internet on average for about nine hours each day. The internet can prove to be the easiest medium to monitor a person's online activities (such as posting on social media, writing emails, watching or liking YouTube videos, commenting on YouTube videos, etc). The aforementioned activities and the internet usage time of a person can help to understand his/her mental state. The user's social media activity can be analysed for finding potential patterns in his emotions/mood. These patterns can be helpful in uncovering underlying mental health issues such as depression, stress disorders, PTSD, schizophrenia etc. These findings can be reported to the user's therapist for their monitoring record. To predict the mental state of the user by analysing their social media activities, an initiative was taken to develop an application with the objective to forewarn its users of any negative patterns regarding the state of mind that they exhibit. This application makes use of the Bidirectional LSTM algorithm, a deep learning method to identify a user's emotions (one among the 6 defined emotions) and stores it for further usage. This application feeds the user's data retrieved by the Chrome extension from 4 sources i.e. Twitter, YouTube, Gmail and Journal, to the trained model and stored the output. This output is displayed in a graphical format as well as in detail to the user. This application can become a personal companion to users by keeping track of their emotions and identifying any decline in their mental state and hence improving their emotional well-being.

Keywords: **Index Terms—mood, mental health, social media, gmail, chrome extension, deep learning, lstm**

1. INTRODUCTION

The World Health Organization (WHO) reported in September 2021 [1] that 3.8 percent of the world's population experiences depression, with 5.0 percent of adults and 5.7 percent of those over 60 years old being affected. Around the world, 280 million people suffer from depression. Apart from depression, there are many

more mental disorders such as anxiety disorders, personality disorders, panic disorders, bipolar disorders, eating disorders, Obsessive-compulsive disorder (OCD), schizophrenia, post-traumatic stress disorder (PTSD), and other conditions that have an impact on people's daily life. Since 2012, the rate of youth depression has increased from 5.9% to 8.2% [2]. The symptoms of depression can affect academic achievement and tamper with personal relationships.

Mental illness prevails among people of all age groups but teenagers form the most vulnerable crowd among all the groups. Mental illness affects or will affect 1 in 5 young individuals (ages 13 to 18) throughout their lifetime [3]. The majority of teenagers feel a level of discomfort in sharing or expressing their feelings in front of their family members. People who have jobs or run businesses often experience tremendous stress which if not managed properly may lead to serious emotional issues. Senior citizens tend to experience feelings of loneliness, anger, irritation, emptiness etc. which if not addressed can contribute to the aforementioned disorders. Even if people recognise the fact that they are struggling mentally, not all of them are financially sound to be able to afford professional medical help for the same. Folks often overlook any mental issue and give more attention and priority to their physical illnesses. Hence, looking at the concerns stated above, there is a need for a solution that is accessible to the public for free and at their fingertips.

Today's world is being ruled by technology and no human can avoid it. We, as people living in the internet era, have two worlds - the online world and the offline world. We spend a lot of time in our day on the internet. A person's online presence says a lot about them, particularly about their mental well-being. The kind of social media activities they engage in viz - posting updates on public platforms, tweeting, watching YouTube videos and commenting under them etc., can be helpful in getting to know the users' mood. An application that can keep track of these social media activities and gauge the user's mood can aid in the early identification of potential mental health issues. Early detection of such issues can be very useful for treating the disorder at an early stage for faster recovery. This can only be possible if there is any medium through which a person's mental state can be known daily. This can be achieved by developing an application that will monitor its users' social media engagement and will predict their moods on a day-to-day basis. If a person is experiencing a negative range of moods (for eg. sadness, anger, irritation, emptiness etc) very frequently then that can alarm for a potential mental disorder.

The structure of this paper is as follows: The literature review that was done to research the current products and strategies on the market is described in Section 2. The proposed system design is discussed in Section 3. The produced application's tech stack, dataset, and implementation are all described in Section 4, which

illustrates how the application functions in its entirety. Section 5 consists of the results that were obtained on the development of the application. The paper is concluded in Section 6, which also includes the future scope, acknowledgements, and references.

II. LITERATURE SURVEY

Our emotional, psychological, and social well being — which impacts how we feel, think, and behave — is referred to as mental health. Our mental health influences how we respond to stress in various contexts and how we make decisions in life. Mental and physical health are equally important for our well being and overall health. Taking care of or mental well being is very necessary in every parts of our life including adolescence, adulthood and old age. Considering the changing lifestyles of people, mental health is being compromised and many people find it difficult to cope up with it. The massive use of social media during these decades has made this worse. A survey found out that around 95% of teens have access to a mobile phone and over 45% of them indulge in social media almost constantly [4]. In the data proposed by WHO [1], around 75% of people belonging to low- and middle-income countries do not obtain therapy due to a lack of finances, qualified specialists, and associated stigma.While neglecting the notion that depression may explain increased social media use, several academics have previously blamed social media for rising rates of depression. According to academics, experimental techniques that allow us to investigate temporality and causality show less evidence that social media precipitates depression symptoms and more evidence that baseline levels of depressive-related symptoms forecast future social media use [5]. The University of Pennsylvania performed study on 143 students' use of social media. The study found that individuals' feelings of loneliness and unhappiness decreased as they used social media less and less. For the first time in scientific research, the study showed a causal association between these traits, according to the researchers. It also stated that limited access to social media might result in lower feelings of loneliness and melancholy than unlimited access [6]. A study on people with an without psychosis observed that when people vent on social media or indulge in emotional posting, these signs are predictive of low mood, low self-esteem and excessive paranoia. Despite the fact that the effect of social media use as a whole was not moderated by psychosis, but the drops in mood that follow social media use are probably more harmful to those who already suffer from psychosis because they initially reported lower levels of mood [7]. For those who are depressed, prompt identification and treatment of unpleasant feelings are essential. The use of mobile phones and concurrent emotional states have been linked. Technological advancements have introduced the possibility of predictions through Machine Learning and AI. A combined assessment of 48 studies was proposed in a research. The study of people's mental health was discussed by examining their social media usage. It gives an overview of most recent developments in ML Models for mental health prediction [8]. In one of these studies [9], it is discussed how to alter machine learning methods to look at such patterns for the prediction of bad moods. The research looked at data from 68 participants. The overall rate of negative emotion prediction accuracy was 86.17%. Based on mobile phone usage trends, the created system was capable of forecasting unfavourable feelings. By automatically identifying negative feelings and offering individuals preventative therapies before they progress to clinical depression, this technology has the potential to provide ecological momentary intervention (EMI) for depressive illnesses.

YouTube is a largely used social media mostly among youngsters. A study [10] was conducted about users YouTube watching patterns. Sentiment analysis model was executed over keywords and titles to predict negative emotions in the text for the user. One such set of Authors [11] carried out analysis of the comments under personal vlogs on YouTube about living with BPD (Borderline Personality Disorder) and found out the different themes in these comments. An individual's negative mood polarity is typically characterised by emotions of sorrow and insignificance. Major signs of depression include a pessimistic outlook and gloomy emotions [12]. The initial symptoms are more of a mood's negative polarity. It has been discovered that people between the ages of 15 and 49 are the most affected. This age group uses social media the most and expresses their opinions there. According to a study's findings, people who are unhappy often linger and watch depressing videos in an effort to feel validated or find companionship [13]. The mental condition of a spectator can be inferred from this behavioural pattern. Another study

[14] conducted on data from Twitter and Weibo for mental disorders stress and depression highlights an analysis of online behaviour of users for people suffering from these mental health disorders. Observations stated that stressed and depressed users use more negative words from categories like death, biology, anger and anxiety while posting on Twitter, showing that are more emotional online. Depressed users tend to use more first-person singular pronouns indicating more self-awareness and their posting behaviour shows they are more likely to post between 23:00 and 6:00 indicating possible symptoms of insomnia. Depressed users also show a lack of social engagement with others.

Researchers now have access to a wealth of Web-based social and health-related data thanks to the widely used social media platform Twitter. Emotional research often makes use of sentiment analysis of social media text. A study [15] was conducted to see whether self-reported moods and Twitter data were related. The observations pointed towards the success of using Twitter data for prediction emotions for a user. A research [16] extracted 9300 tweets to find out if tweets can be categorised into depression related just by using keywords. It was observed that to categorise whether a tweet relates to depression or stress or none of those, Natural Language Processing is necessary. Recent splurge was seen in Tweets regarding Mental health, Depression and other such mental disorders when a strong influence or celebrity provokes the topics or when deaths of such huge influences comes into limelight [17]. In one such Twitter study [18], the authors sought to understand why people

tweet about their mental health. A sense of community and promoting mental health awareness and eradicating stigma were two of the factors identified. According to a research [19], people with mental health disorders are increasingly using social media to share their experiences with their illnesses or seek guidance. Making the decision to interact with like-minded others online when one is mentally ill marks a turning point in their sickness. This era is the start of a time where stigma against mental health and illnesses is challenged, seeking help and support is increased, physical and mental well-being is promoted. There are challenges involving finding appropriate methods for analysing social media data. It was found that people suffering with mental illnesses are more likely to move towards social media for information and support from their peer network because they feel a sense of belongingness. Hence, social media is a ripe platform for analysing a users mental health issues and for retrieving such data.

Despite many studies focusing on the direction that increased social media use can lead to depression, only a few studies have looked at the possibility that depression may really explain greater social media usage [5]. Exploration in this directions can open up many possibilities in Mental health treatments. Even though research has established that a person's mental health can be predicted by analysing his activity and interaction on social media, there are not many products in the market that helps one achieve that.

[8] Furthermore, no study has suggested a possibility for a solution that simultaneously analyses data from several social media platforms, including Twitter and YouTube, to forecast a user's emotions. Research has not been conducted in detecting mood and later on analysing the trends for detecting various mental illnesses beforehand. There are no methods that provide necessary interventions and remedies or care along with detection to affected users, in an personalised way [14].

III. PROPOSED SYSTEM DESIGN

The proposed system achieves the data collection of the user's social media data through a chrome extension. The data is gathered by doing web-scraping of the websites of Gmail, YouTube and Twitter. For Gmail, the body of the email is collected. For Twitter, the tweet is collected and for YouTube, the title of the video is gathered. For the people who are not active on any of these three platforms, a separate functionality of "Diary Writing" is inculcated, where the user will briefly describe his/her day. This collected data will be the input to the machine learning model and will predict the sentiment attached to the text. The six emotions that can be predicted by the system are joy, love, surprise, fear, anger and sadness. The predicted emotions are stored in the database and are analysed further. A person's mood must be observed for a minimum of 7 to 12 days to be able to detect any potential mental concern. After this analysis is done the results of the week are summarised and are displayed to the user. The diagram of the proposed system is given below along with the detailed description of its individual modules.

Fig. 1. Proposed System Design

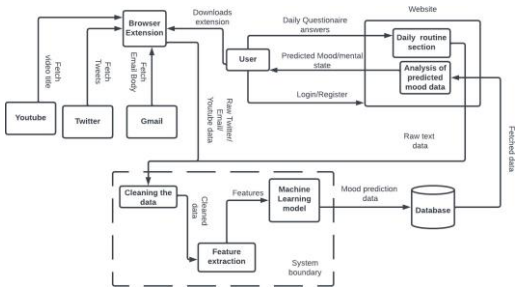

Figure 1 depicts the working of the proposed system. The system diagram for our proposed system here shows the input/output for the system, the flow of data and other processes taking place in various parts the system.

A. User

The end user is a person who is interacting or initiating the interaction with the system. The user directly interacts with the browser extension by downloading it and accepting its terms and conditions. Then the user interacts with the website by logging in /registering with the system.

B.Database

The Database is a collection of entries which can be created, retrieved, updated and/or deleted. The proposed system uses a Database to store different entries for the user. This Database will store the authorisation information for various users. For each user, it will store retrieved data for analysis, the source of the data and its corresponding predicted emotion.

C. Sentiment Analysis Machine Learning model

The Machine Learning model for Sentiment analysis forms the main system. The model takes users sentences as raw input for prediction. This raw data is of String datatype. This model is trained only once initially using a train data set. Before the result can be predicted, some pre-processing must be done on the data.

1) Data cleaning: The raw data received is then passed to the data cleaning module where the sentences are cleaned to remove any punctuation, symbols, emojis and other un-necessary characters. This helps to keep only the necessary parts in a sentence i.e. words. Then stop-words are removed to eliminate any unnecessary words and keep only those which are necessary for the algorithm.

2) Feature extraction: Then this cleaned data is passed to the Natural language processing module where the cleaned data is further processed into tokens and vectors. These vectors act as features for the algorithm.

3) Machine Learning model: The processed data then passes to the actual ML algorithm where the algorithm per- forms Multiple class prediction on it based on 6 distinct emotions - Joy, Love, Surprise, Anger, Sadness, Fear. The ML algorithm proposed here is Bidirectional Long-Short-Term Memory (BiLSTM) algorithm used in Deep Learning. This algorithm gives one among the 6 emotions as output. This output is then stored in the Database for the corresponding user along with the output

emotion.

D. Browser Extension The browser extension is a software that interacts with certain contents on your web browser. This extension, along with the consent of the user, targets 3 websites - Gmail, YouTube and Twitter. The browser extension receives data from these 3 websites when the user prompts it to and feeds the data to the Machine Learning model in the form of raw data. The Ml model then uses this data to gain predictions for its associated emotion. This data is then stored in the Database along with predicted output.

E. Website User send the Login/registration data to the Database via the Website for authorisation. The Website for the system acts as a platform for the end user to view the data and its analysis such as the trend in emotion for the past 7 days. The data is retrieved from the Database for the corresponding user and displayed on the website for the logged in user. The Website also uses this retrieved data for analysis of the user's history of emotions and displays it on the website for useful insights. Another module where the user can interact is the Journal input. The user's input in the Journal is passed though the ML model for analysis and is stored in the Database along with its predicted emotion.

IV. IMPLEMENTATION

The application's actual implementation is presented in this section. This web application is built using the python framework Django and MYSQL database. This application uses a machine learning model to detect users' emotions. This model is trained using Bi-direction LSTM (Long Short- Term Memory) algorithm. To train this model, the dataset was used from Kaggle. The dataset has 2 columns- text and emotion. The text column contains the input text and the emotion column contains the actual emotion associated with the text. Based on the proposed system flow diagram, we have implemented and created a web desktop application.

A.Home Page

Fig 2 represents the 'Home' page of the application. This is the website's landing page, consisting of a navigation bar with 'About us' and 'Contact us' pages. This page also contains the register and login options for users.

Fig. 2. Home Page

B. About Us page

Fig. 3 represents the 'About Us' page which gives detailed information about how this application works in simple terms and what are the offerings of application.

C. Contact Us Page

Fig 4 shows the 'Contact Us' page of the application. Anyone can get in touch with the owners and get their queries clear.

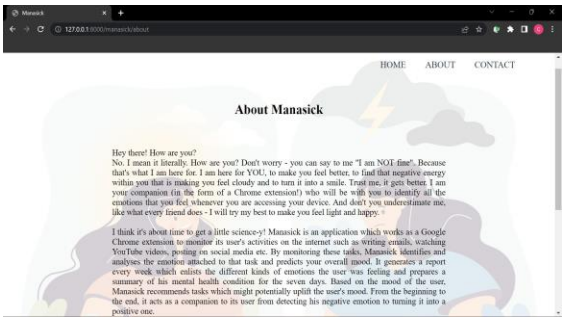

Fig. 3. About Page

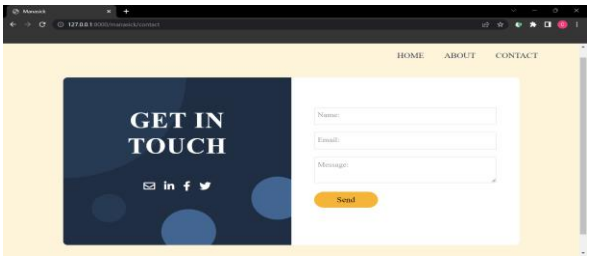

Fig. 4. Contact Page

A. *Terms and Conditions*

Fig 5 represents the 'Terms and Conditions' page. This page informs users that the application will be collecting their social media data through Twitter and YouTube and emails from the Gmail platform. Initially, the 'Confirm' button is disabled as user has not yet agreed with the terms and conditions. Fig 5 shows the same case.

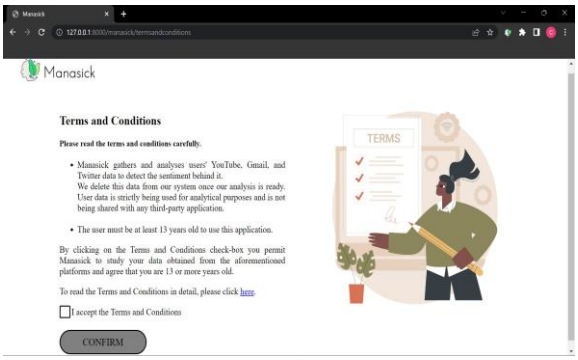

Fig. 5. Terms and Conditions Unchecked

Fig 6 represents the case when the user agrees with all terms and conditions. Once the user accepts the terms, the 'Confirm' button enables and the user can proceed with creating a new account.

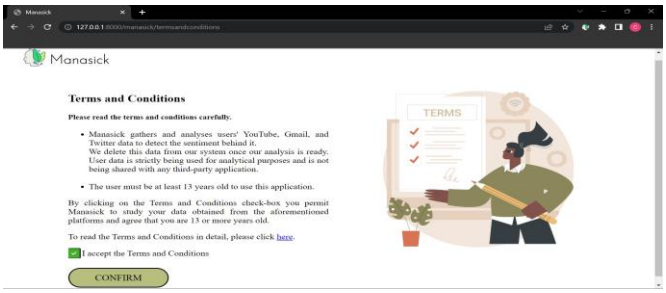

Fig. 6. Terms and Conditions Checked

E. Register Page

Fig 7 represents the 'Register' page of the application. The new user has to create an account before starting to use the features provided by the application. The user will create a unique username, enter the first name, and last name and create a password. On clicking the 'Register' button, the user gets registered to the system.

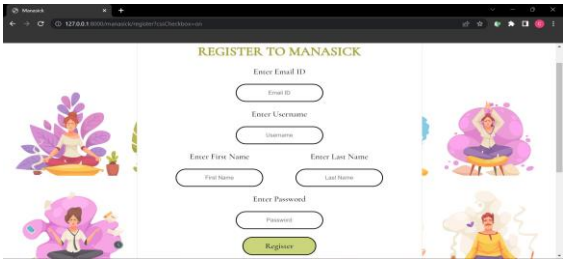

Fig. 7. Register Page

F. Login Page

Fig 8 represents the 'Login' page of the application where the user can get logged in to the system using the uniquely created username and password during registration.

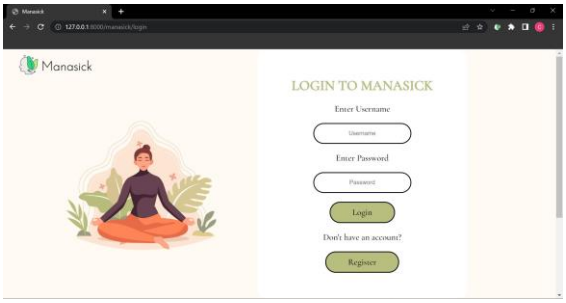

Fig. 8. Login Page

G. User Dashboard

Fig 9, represents the 'User Dashboard' page of the applica- tion. This page is only visible to users who are logged into the system. This page consists of two options: 1. Describe your day, 2. View your analysis.

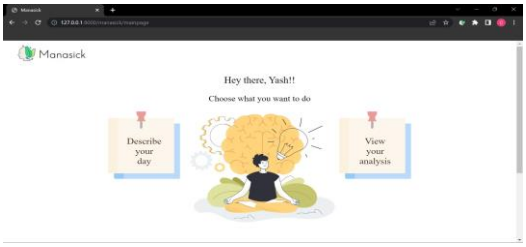

Fig. 9. User Dashboard Page

H. Daily Journal Writing

On clicking on 'Describe your day' on the 'Dashboard' page (fig. 9), the 'Daily Journal Writing' page opens, and fig 10 represents the same. This page describes what actually journal writing means and what is the motivation of this section. It contains a 'Start Writing' button which redirects users to a page where user can describe their day (fig 11).

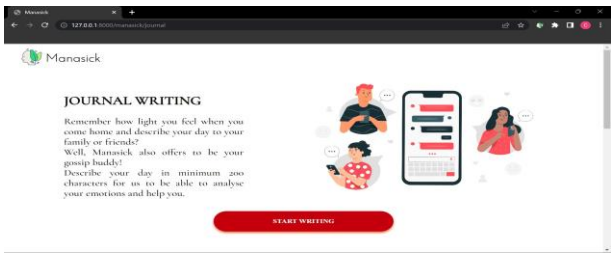

Fig. 10. 'Start Writing' button for the diary

Fig 11 represents the page where user can describe their day in at least 200 words. Users can write anything about 'how was their day?', 'how are they feeling right now?', 'is anything bothering them?', etc. This text is then analyzed and sentimental analysis is performed on the input given by the user to predict their mood.

Fig. 11. Diary for the user input

I. Extension

This application uses the chrome extension 'Manasick' to collect users' social media data from YouTube and Twitter and through the Gmail platform. The extension scraps the data whenever user is watching any youtube video, writing emails, or posting something on Twitter. This scrapped data is then sent to the application and sentimental analysis is performed on it to predict their mood.

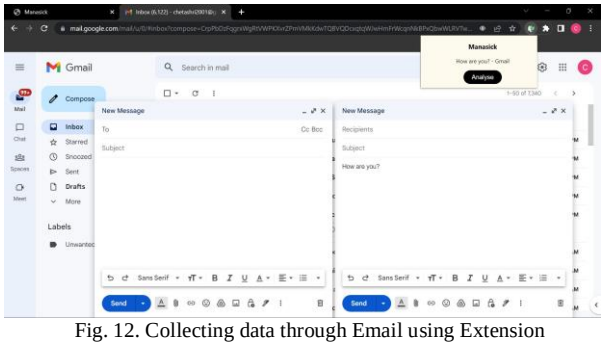

Fig. 12. Collecting data through Email using Extension

Fig 12 represents the case where the chrome extension identifies the mail written by the user. The written mail can also be seen when clicking on the extension icon.

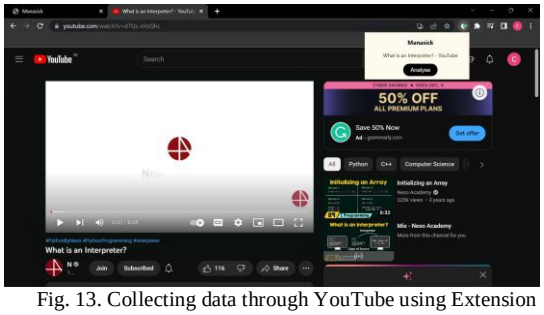

Fig. 13. Collecting data through YouTube using Extension

Fig 13 represents the case where the chrome extension collects the title of the YouTube video that the user watches. This title can also be seen when clicking on the extension icon.

Fig 14 represents the case where the chrome extension collects the text of the Twitter post that the user posts. This text can also be seen when clicking on the extension icon.

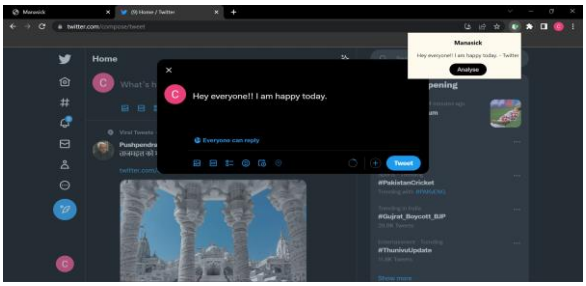

Fig. 14. Collecting data through Twitter using Extension

J. Analysis

On clicking on 'View your analysis' on the 'Dashboard' page (fig.9), the user gets directed to the analysis page, fig. 15 and fig 16 represents the same.

Fig. 15 represents the summarized mood analysis of the user for latest 7 days in graphical order. The maximum emotion of the day is considered the overall mood of the day.

Fig. 15. Summarized Mood Analysis

Fig. 16 represents the user's analysis overtime the period. Users can see their complete analysis done by the application for the entire period the user was active, for the last 3 days, for the last 7 days, and for the last 14 days. According to the suggestion, received from the counselor, it has been noted that the person needs to take more care of their mental state if negative emotions last for more than 12 to 15 days. If the user experiences negative emotions for more than 14 days then an alert is sent to the user about the same.

Fig. 16. Analysis Page

K. Detail Analysis

Fig 17 and fig 18 represents the detailed analysis of both daily journal writing and analysis of social media activities.

Fig. 17. Detailed Analysis Page

Users can see the inputted data and social media activities along with predicted emotions and timestamps. For analysis of social media activities, every entry also displays the source of the data.

User can also filter the data based on timestamp (such as 7 days, 14 days, and 21 days). and platform (Gmail, Twitter, YouTube). Fig. 18 represents the same. By default, all data is displayed on the page

Fig. 18. Detailed Analysis Page with Filter

V. RESULTS

After the development of the application, it was tested across 18 users and a total of 187 entries were collected from them over the time span of 7 days. 47.49% of the data gathered comprised of diary entries, 2.67% of the data consisted of emails, 42.24% of data consisted of YouTube videos and 7.48% of data comprised of tweets. For the collected data, we were able to predict the emotion associated with the input text with accuracy of 93%.

The table I summarizes the results achieved by the ap- plication in terms of the accuracy obtained by successfully predicting the accurate sentiment behind each text input

Sr. No.	Source	No. of Entries	Accuracy
1	Diary Writing	89	91%
2	Gmail	5	95%
3	YouTube	79	87%
4	Twitter	14	92%

TABLE

ABLE SHOWING THE ACCURACY OBTAINED FROM EACH SOURCE OF DATA

The table II presents a comparison of the developed application with a few other applications already available in the market considering a number of features. The table compares the proposed system features and also specifies what alterna- tive features are present in rest of the applications mentioned in the table.

Features	MoodSmart (Depression detection app)	Mind Alcoe (Jour-naling app)	MindDoc (Mental health trackig app)	Manasick (our proposed application)
Input for user's mood	Text	Emoji selection	Emoji selection	Text
Data collection From Social media	Twitter	No	No	YouTube, Twitter
Data collection from Gmail	No	No	No	Yes
Journal writing For mood prediction	No	Yes	Yes	Yes
Method for data Extraction and display	Mobile appli ca-tion	Website	Website	Website and Chrome extension
Mental state analysis from mood history	Analysis (7 days)	Graph	Graph	Analysis (7 to 12 days)

TABLE II

TABLE SHOWING A COMPARISON BETWEEN THE PROPOSED APPLICATION AND 3 APPLICATIONS AVAILABLE IN THE MARKET

In the table II, the first feature for comparison is the way in which the input is taken through the applications for finding out user's mood. For two of the considered applications, the user's mood is directly input as an emoji selection i.e. selecting one among the 6 given emotions. but for our developed application, the user does not need to select his/her mood, it will be predicted using a text input itself. The second feature is the social media used in data collection for predicting user's mood. Our developed application uses data from both YouTube as well as Twitter whereas the rest of the applications don't use a social media application or use only Twitter for this purpose. The third feature is whether data is being collected from the user's Gmail or not. Except our developed application,

no other application is using Gmail for data gathering. The fourth feature is the use of Journal writing for taking input for user's mood prediction. Along with our developed application, other two applications employ a journal writing feature. The fifth feature is the mode used for extracting and displaying the user's mood data and associated analysis. Our developed application makes use of a Google chrome extension as well as a Website for this purpose while other applications use common modes like Websites and Mobile applications. The sixth feature is whether the mood history of a user is used for further analysis of mental state or not. Two of the considered applications don't provide a particular analysis as such, but just display the trend in user's mood in a graphical format on the Website/application. Whereas our developed application and one other application analyse user's mood history and present an analysis from than on the website/application. The other application presents an analysis for the data from past 7 days whereas our developed application not only presents an analysis for the past 7 days but also for for the past 14 days and the past 21 days.

VI. CONCLUSION

In this project, primarily we devised a method of analysing a user's social media data and predicting the emotion attached to it with the help of sentiment analysis. As stated earlier, there are many people to neglect their mental health and any concerning symptoms that might indicate mental illness. The proposed system gathers the data for the analysis in a very less intrusive way.

The application is successfully able to collect user's social media data from Twitter and YouTube as well as from the user's Gmail by web scraping through the chrome extension. It also takes the user input in the form of diary writing for those users who do not engage on any of the aforementioned platforms. The application is also successfully able to run the machine learning model on it to predict the associated emotion.

The system identifies 6 emotions namely - joy, love, surprise, fear anger and sadness. After monitoring the mood of the user for at least 7 days it produces a summary which tells the user whether or not he/she needs to pay more attention to his/her mental health. The application is also able produce an analysis of the stored user emotion data for the past 14 and 21 days. Hence, both the objectives of our project were achieved

i.e. Scrapping the user's data and training and implementing a Sentiment analysis model on the input data.

The future scope for the web application Manasick includes providing personalized interventions to users whose behaviour exhibits negative emotions.

VII. ACKNOWLEDGEMENT

Under the direction of Dr. Nataasha Raul and Prof. Meghana Naik, all authors have significantly contributed to the work described in the publication (e.g., developing the application, providing technical assistance, assisting with writing and edit- ing, general support).

,

Abstract – In this paper we study the concept of Advertising, we have developed a mobile application in which various companies and users can advertise their products in our mobile application. and the viewers can see those ads and go through a survey on those products and services related questions. In this application we have designed two interfaces for the viewer and the ads- publisher. As we know now a days online marketing plays a vital role in increasing sales and revenue, so we developed an application on that domain to users to advertise their products and services , as we said in start that there are two interfaces in the application ,the second interface and the most important interface where the viewer review the product and service of the advertiser by answering the survey about the ads image or video which they seen in the application, with this the viewer can ignite interest on the product and can try its service or buy those products ,for viewing those content in this application the viewer gets coins in return ,for viewing every ads in the application it increases the count of the views of the viewer and here one view is equal to one point and here viewer can see only few number of ads per-day , when the views reaches the prescribed number of views ,the views can be converted in to rupees and the viewer can withdraw those money from the wallet by adding bank account or purchase a coupon related to the product or service in the list provided.so It is an application where the viewer views the ads for gaining points and with those points they can either withdraw money or purchase coupons and gift-cards, with this application the advertisers gains popularity to their products and services,the viewer if the products more familiar to the interest of the viewer ,the viewer may purchase or try the service or product. In this way the application works, which mostly benefits both party's interests and can be mostly used to increase the sales of the products and services, which in turn leads to profits and betterment of the company or industry.

Keywords: Index Terms—print, direct mail, television, radio, mobile, social media.

1. INTRODUCTION

Nowadays, Advertising plays a major role in increasing in selling of products or services to the company, As these they are many products are coming to the market everyday but users doesn't have much awareness about the product quality or features and usage about it, In this case advertising plays an impact role of selling those products and gives a proper explanation about the product usage and verification of the selling company , It leaves a positive feedback to the customers towards company. Most companies prefer advertising their products and services and investing more money in adver- tisements. If suppose some new product came into market, which customers doesn't know about the product at that time advertisement paves a way to customers to identify the product which they may buy it according to their needs. As in today world, there are many products are coming to our daily life, as there is a huge competition among the sellers to increase their revenue but due to the less influence about the name of company and proper description the product popularity may decrease and may affect on the annual revenue on the product and cause company a huge loss in the selling of the product. To overcome the problem of how to attract customers to purchase the products, companies try to advertise their products in social media, articles, websites, videos which help them to gain the attraction of the customers and purchase them.

Advertising is classified in to among the following types like print, direct mail, television, radio, mobile. Print advertising, it is a type of advertising which is advertised using newspapers or templates, or other printed materials. It is mostly in the form of printed materials. Most of the companies advertise their products in magazines and journals which are mostly read by specific people, they always try to publish their ads or description about the products in mostly popular magazines which is read by many people. Direct mail advertising, it is a type of advertising in which companies advertise their products through mail to the customers. It involves sending mail to customers. In this advertising, it sends mail to the existing customers who were once purchased products from the company and to the customers who subscribed their mail for updates, they send to those people which increase the awareness in the customers about the products. Television advertising in this advertising the company tries to promote its product by making a 20- or 30- or 60-second video and telecasting it on TV. It costs more compared to the other advertisements. It is telecasted daily on the TV channels during some shows. Radio advertising It is a type of advertising in which a company promotes its product over the radio. They sponsor it through radio during breaks. It is also a form of advertising which may not be much effective over Television advertising. Mobile advertising is a type of advertising in which a company promotes their products in mobile devices with the internet. These advertisements appear in webpages, apps, or social media. It has an upper hand over other advertising forms as most people have mobile devices and have good internet connections, which they are more known about the products and services offered by the companies.

II. EXISTING METHODOLOGIES AND SYSTEMS.

As they are many existing sources are available for adver- tisement of products and services. Each model has its own functionality, In the sense they are specific for showcasing a particular company product and some are particular at promot- ing specific products and services. One of the existing model Google ads, which is quite popular in promoting services or products of the companies. Nowadays google ads pays a major role in advertising the details of products in the websites in the form of photos or videos or random description, the readers or viewers who view the site will get popped up

the ads of so on company and in the right or left side of website they will see the different types of ads on different products according previous feed of the particular reader or viewer.

As we know nowadays social media marketing is tremendously increased many companies hiring social influencers to promote their products over online by making video of the ads and they promote those ads in the social media applications like Instagram , Facebook , Snapchat and many more which helps companies to advertise the listing of products in online. Another application is ad-wallet which gathers ads from many companies in the form of videos or images and promote in there application where the viewer get rewards for the watching the ads, google survey which is also an application by google it instead of promoting content it asks questions to the user according to the recent search feed and collects feed back from them like asking the experience about the search and ask to give reviews on their personal experience.

III. PROPOSED METHOD

With the increasing of many products and services in the market which makes the low popular companies or newly established companies hard to sell their products or services to the customers, as customers are purchasing from the well settled companies, who has a good experience and are oldest in selling goods but due to this affect the new companies cannot able to resist or hold their position in the market which leads to huge losses and cannot able to attract the customers to purchase the goods, there is solution which can increase their sales that is advertising of their products so that in that advertisement they can say the total details of the product, price ,quality and the usage of the products in a proper description , so we created an application on the domain of advertisement to help the small scale industry and retailer to promote their products and services so that viewers of the application can able to look in to the product and may look interest in it and they can recommend or refer someone to purchase or go through the product, and viewers in the application may get rewards and coupons for viewing the ads and answering the survey ,which is related to the product ad which the viewer had viewed in this we have made an application which is used for promoting the products and services of the company in the form of picture and videos in the application.

IV.PROPOSED OBJECTIVES AND OUTCOMES

We have developed an application which overcomes the problem for companies to advertise their products and services, in this application they can publish there ads in form of videos or pictures which are viewed by the users of the application and answer the survey related to the product they viewed in the application, as in this application we have built two interfaces one is for the ads publisher and other is for the ads viewer here the publisher posts the ads and viewer who watches those ads for watching ads , the viewer get coupons or gift cards or coins for the views. The user can convert those coins in to currency and withdraw those amount by adding bank account in the profile , as we said there is a view count for the viewer so the viewer counts get increased for watching ads, in this application we are attracting users to view the ads to gain coin , so the user view the ads and after viewing the ads they need to answer the survey question related to the ads they have watched then only coins will upgraded in wallet, so by implementing this we are making the viewer to concentrate on the ads and understand the products what it is meant for , where to use and price of the product, this makes the user to go through the product , which can ignite interest to purchase them or suggest or recommend to others.

A. User Data Protection

The major thing here to remember before implementing the application is having an proper Authentication, which allows users to log in via an credentials. Let's see how a typical authentication system works

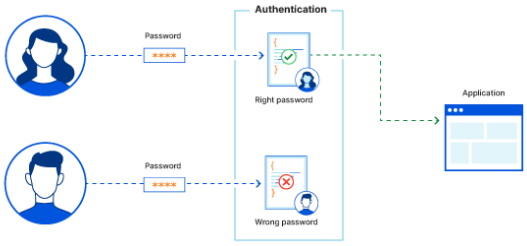

Fig. 1. Authentication

So, when the user open the application, him/her need to lo- gin with the credentials which are stored in the database while registering or creating the new account in the application. If the the user logged-in with the correct credentials the session time saved in the database and cache data stored in the local storage of the device for preventing to logging multiple times

,when user open the application it directly open the content rather again asking the login as the data of previous session stored in the local storage of the device.

V.DATA STORAGE AND COMPUTING

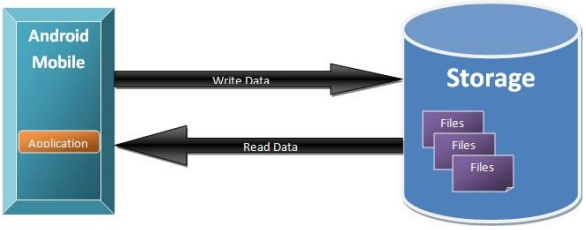

Fig. 2. Data Storage

While creating any application , the major concern arises here where the data of the application is stored , so we need a storage for the application as they are two types of the storage available their are physical storage and virtual storage.

A.Physical Storage

Fig. 3. Physical Storage

As the name represents ,it is storage unit which stores the data in the SD cards, USB drives and Hard disks, it is also present in the devices as a inbuilt storage like RAM and ROM, which in that RAM is used for accessing the data and ROM stores the data , more the RAM the data computing and accessing is fast and satisfies the user. Here physical storage plays a vital role as it stores the application data of the user in the device storage as their are two types RAM and ROM where one is used for accessing the cache data and the other is used for storing the the activities which are performed on the application by the user.

B.Virtual Storage

In this storage the data related to the application is stored in a data server which is managed by the database admins, it stores all the data of the users who are using the application and any updates related to the application is shared in the database server which reflects in the application which are used by the users, suppose if the user deletes the application and he wants to install it again but the user doesn't looses his data as the users data is stored in the database, when the user logins according to the credentials the application fetches the data of the user when last he/she used the application.

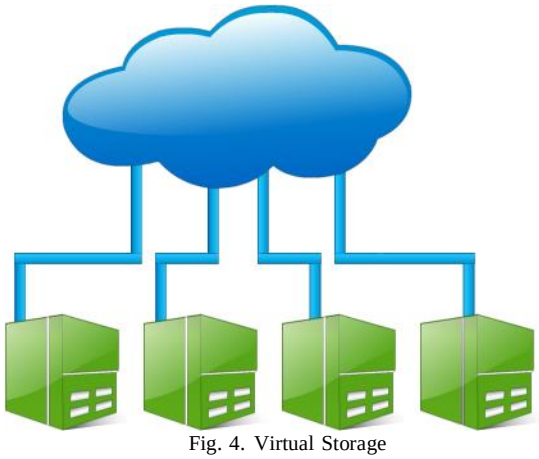

Fig. 4. Virtual Storage

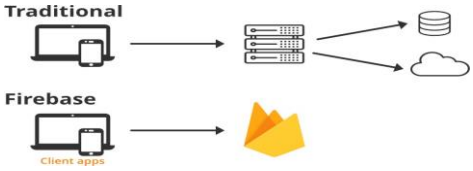
Here for the virtual storage, we used Firebase which is a cloud database maintained by the google, it is opensource cloud storage. we have used firebase as a database storage for our application , as all the details related to application are stored in the cloud storage, as we used cloud storage so we can upload all the data over internet and extract data over internet which can be accessible all over the world. The main advantage of using the firebase is we care least about the maintaining the data , as firebase is a built-in cloud storage which has many bulit-in functions which maintains the data automatically without any database admin as admin no need to worry about the security of the users data as it is stored in buckets each bucket has its own unique key which prevents collisions and other problems, it is a combination of cloud and database.



I. PROPOSED MODEL

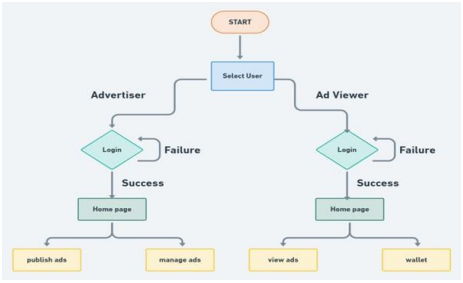


Fig. 5. Proposed Model

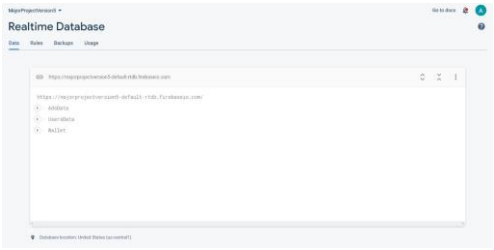

Fig. 6. Realtime Database

As the above model and the figure describes the working procedure of the application and number of objects involved in the application, we implemented three interfaces publishingads, viewing ads and wallet to check coins after logging in to the application.

VI RESULTS:-

A. Overview of the Application Process

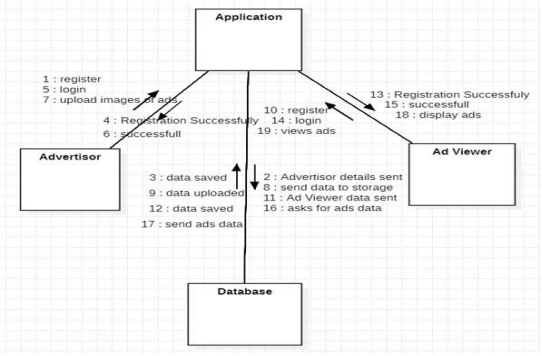

Fig. 7. The procedure of Application Work.

A. Security and Authentication:

To demonstrate the use of authentication we used a email account, in below figures show the clear procedure of how the process works. Starting from opening a registration page, then redirecting to the login page, auto-typing the credentials retrieved from the database, caching the session data.

Fig. 8. The Procedure To Register Account.

Fig. 9. The Procedure To Login Account.

The above pics shows the procedure of registration and login to the application. while during registration user registers with email id which is unique for each user and after registration is done successfully the user credentials stored in the firebase database and allocates a bucket for the user activities.after user login to application , if the credentials matches with the existing users in the database it gives permission to view the application data.

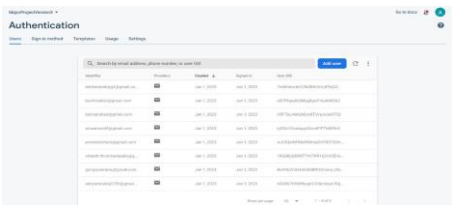

Fig. 10. Users Data In The Database

A. Proposed Application:

In this section we give the main working of the applica- tion, as we know the application is majorly focused on the advertising domain,we here focused on the publishing ads and viewing ads in our application.After registration and logintasks finished , we move to the next task where they are three tabs there are for publishing ads, viewing ads and wallet ofthe user.

Fig. 11. Home Page

1) Publishing Ads Tab: It is present bottom of the home page to the left corner. As the name represents it is used for publishing ads in the application and the ads published in the application are stored in the database along with the survey related to the ad which is published.

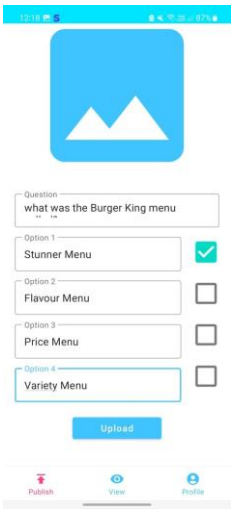

Fig. 12. Publish Tab

viewing Ads Tab: It is present bottom of the home page to the right of the publish tab. As the name representsit is used for viewing ads in the application and the ads published in the application are stored in the database which is published are displayed in this tab ,it contains all the ads which are associated with the application, when user clicks on the specific ads it opens a image of the ads and information regarding the

ads which are displayed and after 10secs and survey prompt appears which asks the question related to the previous ad viewed by the user and after correctly answering the survey question the response stored in the database.

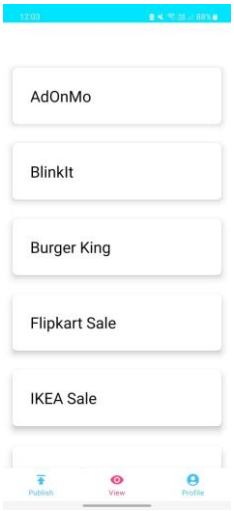

Fig. 13. Ads Tab

Fig. 14. Test Ad

2) Wallet Tab: After viewing the ads , a survey prompt appears which asks the question related to the previous ad viewed by the user and after correct answering the question , for every correct response user get rewarded with the wallet coins which can be used for buying the coupons or offerto the products and services of the ads associated with the application. As in the below pictures we have shown the work flow of the application.

Fig. 15. Survey-Prompt Page

Fig. 16. Wallet Tab

VII. Conclusion

The increase in the number of products and services launched every day has contributed to the increase in needfor marketing and promoting their services. But there isa lack of platforms for advertising products for small andmid-scale companies. For any company, marketing is very important because that's what influences the overall growth of a company. The proposed and developed android application will act as a medium for those companies which can attract new users by promoting their services. This app will allow companies to publish their ads and allow users to watch them and answer surveys about those ads, which may also lead to a user purchasing the product or service or it can also increase the popularity of the product among users. In future, the app could also allow its users to convert the coins into real cash and withdraw the money into bank accounts. In a way, it is useful for a publisher who wants to publish and an ad-viewer who wants to earn some rewards. This application could be the newest way of marketing products and services in the near future

Serverless Computing: Opportunities, Applicationsand Challenges

Karan Singhx, Siddhant Singh, Rahul Yadav,
Thakur College of Engineering and Technology Mumbai, India
karansingh.skd@gmail.com, siddhantsingh3210@gmail.com, rahul.yadav251@gmail.com

Abstract – **The emerging serverless computing paradigm has attracted attention from both academia and industry. This paradigm brings benefits such as less operational complexity, a pay-as-you-go pricing model, and an autoscaling feature. The paradigm opens up new opportunities and challenges for cloud application developers. In this paper, we present a comprehensive overview of the past development as well as the recent advances in research areas related to serverless computing. First, we survey serverless applications introduced in the literature and summarize the challenges they have faced. We categorize applications in eight domains and separately discuss the objectives and the viability of the serverless paradigm in each of those domains. We then classify those challenges into nine topics and survey the proposed solutions for each of them. Finally, we present the areas that need further attention from the research community and identify open problems.**

1. INTRODUCTION

Large technology companies such as Amazon, Google, and Microsoft offer serverless platforms under various brand names. Although the specifics of the services may differ the essential idea behind the offered services is almost the same

i.e. by rendering computation to the pay-as-you-go model, serverless computing tries to achieve auto-scaling while providing affordable computation services.

There are successful commercial implementations of this model. Amazon introduced Lambda in 2014 and later Google Cloud Functions, Microsoft Azure Functions and IBM Open Whisk were launched in 2016. Since then, many studies have focused on the challenges and open problems of this concept. Some of the previous studies are skeptical about the potentials of serverless computing due to the poor performance of their case studies. In contrast, others believe that serverless computing will become the face of cloud computing and the performance issues will be addressed eventually. The aim of the serverless services is threefold: (1) relieve the users of cloud services from dealing with the infrastructures or the platforms, (2) convert the billing model to the pay-as-you-go model, 3 auto-scale the service per customers' demand. As a result in a truly serverless application, the execution infrastructure is hidden from the customer and the customer only pays for the resources they actually use. The service is designed such that it can handle request surges rapidly by scaling automatically. The basic entities in serverless computing are functions. The customer registers their functions in the service provider. Then, those functions can be invoked either by an event or per users' request. The execution results are sent back to the customer. The invocation of the functions is delegated to one of the available computation nodes inside the service provider. Usually, these nodes are cloud containers such as Docker or an isolated runtime environment.

In this paper, we also discuss the opportunities presented by serverless computing. We emphasize that serverless services are more customer-friendly as they relieve customers from the intricacies of deployment. They are also more affordable in some cloud computing scenarios that we will discuss later in this paper. We argue that new market places are emerging around these services, which implies new business opportunities

II. OPPORTUNITIES

In this section, we discuss the opportunities that serverless computing offers.

3.1No deployment and maintenance complexity: The very first and foremost opportunity that serverless computing offers is to relieve users from managing the infrastructure, which is now already accomplished in Infrastructure-as-a- Service (IaaS), however, users still have to manage their virtual resources i.e, installing and configuring related packages and libraries. Certainly, Platform-as-a-Service (PaaS) providers such as Herokuhave made the management slightly easier, although, users still have to configure the applicationto match the PaaS requirements which is not a trivial task. Serverless computing takes a big step inthis manner. Users only have to register their functions and then receive the credentials to invoke the functions.

3.2Affordable scalability: Another promise of the cloud computing is the ability for customers to deploy the functionalities of their applications without worrying about the scalability of the execution infrastructure or platform. The scalability is a direct result of the auto-scaling nature of these services i.e. per request the service invokes a copy of the requested function and there is virtually no bound for the number of concurrent requests. Each invocation is assigned to the most feasible and available resource for execution.

3.3New market places: With the advent of modern operating systems for mobile devices such as Android or iOS, various market places for applications, that are specifically designed for those operating systems, have emerged such as Google Play Store and Apple's App Store . Such a scenario is already appearing for serverless paradigm i.e. with the growth in the popularity of serverless computing, new market places for functions has emerged. In these types of markets, developers can sell their developed functions to others. Every generalized or domain-specific functionality can be bought or offered in those markets.

III.APPLICATIONS

Many real-world serverless applications have been proposed in the literature during the past few years. We categorize these applications into six domains., the main reason for migration stated in the papers, and assessments based on the arguments made by the authors, the obtained results, and the challenges they reported. In what follows, we survey these application domains, in detail.

4.1Real-time collaboration and analytics: The stateless nature of serverless services makes them an attractive platform for real-time collaboration tools such as instant messaging and chatbots. Yan et.al., proposed an architecture for chatbot on Open Whisk. An XMPP-based serverless approach for instant messaging is also introduced in . Real- time tracking is another example of collaboration tools that are very suitable for serverless services as these applications are not heavily dependant on the system's state. Anand et.al., proposed two real-time GPS tracking methods on low-power processors. Serverless services are also utilized for data analytics applications]. In these applications, various sources stream real-time data to a serverless service. The service gathers, analyses, and then represents the data analytics. The auto-scaling feature of serverless computing makes the handling of concurrent massive data streams, possible. Müller etc. proposed Lambada which is a serverless data analytics approach that is one order of magnitude faster and two orders of magnitude cheaper compared to commercial Query-as-a- Service systems.

4.2 Urban and industrial management systems: The pay-as-you-go model of serverless services paved the way for the introduction and implementation of various budget- restricted urban and industrial management systems. Al-Masri et.al., presented an urban smart waste management system. Hussain et.al., proposed a serverless service for oil and gas field management system. An implementation of a serverless GIS platform for land valuation is presented in . The distributed nature and auto-scaling feature of serverless services make it an apt choice for smart grids. Zhang et. al,] proposed event-driven serverless services to handle SCADA/EMS failure events. A distributed data aggregation and analytics approach for smart grids is proposed in . Serverless services have been also utilized for urban disaster recovery applications. Franz et.al., proposed a community formation method after disasters using serverless services. Another similar approach is also proposed in . The migration toward serverless paradigm seems a reasonable choice for this domain of applications, especially, for public sector services or for developing countries due to its lower deployment overheads and also its pay-as-you-go pricing model.

4.3 Scientific computing: It has been debated in that serverless computing is not an attractive alternative for scientific computing applications, albeit, many studies have focused their attention toward serverless services for those applications. We believe disagreement liesin the fact that the range ofscientific computing and its applications are vast and there are certainly some areas in this domain for which the utilization of serverless services is feasible. Scientific applications that require extensive finegrained communication are difficult to supportwith a serverless approach, whereas those that have limited or coarse-grained communication are good candidates. Also, note that scientific computations with time-varying resource demands will benefit from migrating to a serverless paradigm.

4.4 Artificial intelligence and machine learning: Machine learning in general and neural network-based learning, in particular, are currently one of the most attractive research trends. The suitability of the serverless paradigm for this domain has received mixed reactions both from research and industrial communities. For example, it has been argued that deep learning functions are tightly coupled (they require extensive communication between functions), and also these functions are usually compute and memory intensive, as such, the paradigm is not promising for these applications . Nevertheless, it has been discussed that deep neural networks can benefit from serverless paradigms as they allow users to decompose complex model training into several functions without managing virtual machines or servers. As such, various such approaches have been proposed in the literature. A case of serverless machine learning is discussed in. Ishakian et al., discussed various deep learning models for serverless platforms.

4.5 System and software security: The power of serverless computing has been leveraged for providing security for various software systems and infrastructures. A mechanism for securing Linux containers has been proposed in . Serverless services have also been utilized for intrusion detection. Stream Alert is a serverless ,real time intrusion detection engine built upon Amazon Lambda. Birman et al. presented a serverless malware detection approach using deep learning. Serverless approaches have been also used for ensuring data security. A method for automatically securing sensitive data in the public cloud using serverless architectures has been introduced in . Hong et al. presented six different serverless design patterns to build security services in the cloud.

IV.CHALLENGES

In this section, we summarize and discuss the challenges faced by the application domains. We categorize those challenges into nine topics and survey the existing solutions for each of them. We also present the areas that need further attention from the research community and identify open problems.

5.1Programming, modelling, testing, and debugging: As the topic of serverless computing is relatively new, its development tools, concepts, and models are not rich enough. This poses a great challenge for software developers. The lack of proper modelling paradigms leads to non-unified development approaches which will reduce the quality of the code and also complicate collaborations of developers in long term. To remedy this shortcoming, Perez propose a programming model and middleware for serverless computing applications. The focus of the paper is limited to file processing applications.

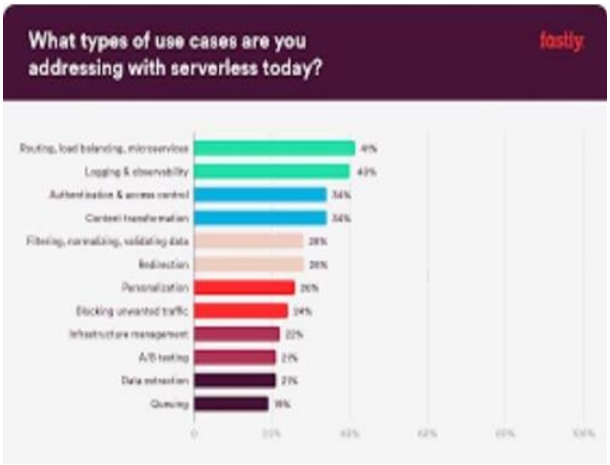
5.2 Pricing and cost prediction: Many big technology companies now offer serverless computing services with different specifications and prices. As the popularity of serverless services increases, the number of companies and their options for pricing will grow. Many factors affect the price offered by each company. These factors range from the company's revenue strategy to the platform it uses and the energy prices (based on the region or the time of day during which the function execution occurs). For example, a request that gets to a server at 2 a.m. in winter typically costs lower compared to that of the same request with the same resource consumption at 2 p.m. workday in the summer. Another factor is the load level that is imposed on the provider at that moment i.e. whether the provider nearing its peak power demand or not.

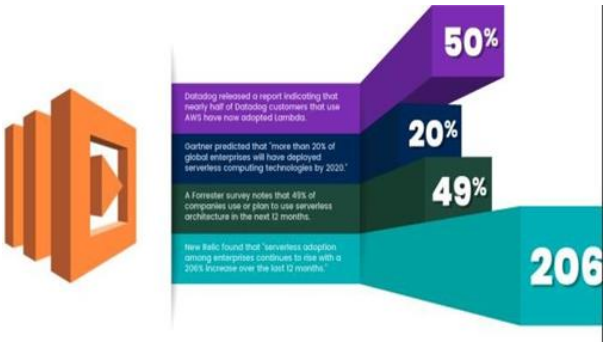
5.3 Networking, sharing and intra-communications: A serverless software is typically a composition of many functions that work together to provide the desired functionality. To attain this, the functions need to somehow communicate with each other and share their data or their state. In other cloud services, this is attained through network addressing. For example in IaaS, each virtual machine can send and receive data through point-to point networking using network addresses. Functions intra-communication and network-level function addressing in serverless platforms are challenging. Functions in serverless services have characteristics that must be considered to be able to introduce some kind of addressing scheme for them: Due to the auto- scaling nature of serverless computing, at any given time there may be several running invocations of the same function inside various computation nodes around the world. This rules out the possibility of addressing based on function name or location. The functions are often short-lived. The short life span of the functions means that any addressing scheme should be fast enough to track the rapid changes of the system's entire state.

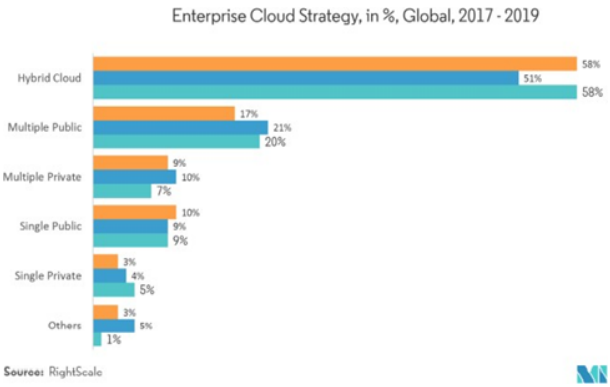
5.4 Serverless workflows: As discussed earlier in this paper, a serverless application is a composition of various functions working in coordination with each other to accomplish the desired tasks. Rarely, we have applications that are composed of a single function, instead, usually, there are many interdependent functions, processing and passing data to each other and send back the result to the application. For example, real-world implementation of an online social network (with functionalities similar to Facebook) on Amazon's Lambda infrastructure has around 170 functions. These small functions are orchestrated into high-level workflows to form serverless applications. In each application, functions are executed in various sequences. For example, users sign up in the application, view latest products, click on the add-to-cart button and check out. These 4 functions are executed in a sequence. Obviously, this is not the only execution sequence in the application since the user may have already signed up and just needs to sign in. There are many other possibilities for the sequences of functions. As we discuss in this paper, knowledge of these sequences (or chains) plays a key role in improving the performance of serverless services. Providers can use this knowledge to pre- fetch, prepare and optimize functions to reduce costs and serve customers with better performance.

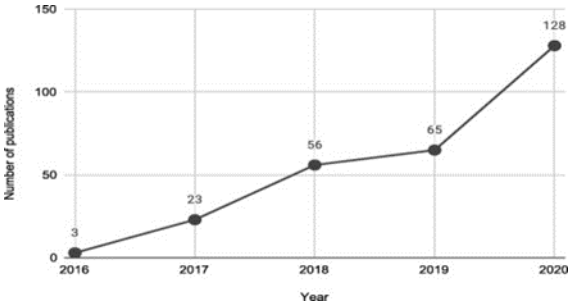
5.5 Security and Privacy: Security is an indispensable concern in any computation service, be it serverless or not. Various security challenges are common between serverless and other cloud services. Precht et al. reviewed some of those challenges. Here, we survey the security issues that specifically threaten the normal operation of serverless service. We also consider the privacy of users in such environments. Authentication and authorization. The foremost security challenge in any serverless scheme is how to authenticate applications so that only legitimate ones can use the available functions. Without authentication, a freeloader can use the available resources of the victims. A common approach to counter these attacks is the usage of authentication tokens in the header of requests. JWT is an example of such tokens.

SURVEY:









V.CONCLUSION

In this paper, we surveyed some of the new opportunities that the vast adoption of serverless computing model will present. Then, we surveyed and categorized various serverless application domains. For each domain, we summarized the objectives for migrating to serverless services and assessed the aptness of the paradigm. We listed challenges that those applications faced and discussed existing solutions for them. We presented the areas that need further research investigations and identified open problems.

Personalized Recommender for Social Media Advertisement

Aman Singh , Bhaskar Singh, Keval Surani, Mrs. Ashwini Patil
Thakur College of Engineering and Technology Mumbai, India
r.amansingh241201@gmail.com, rougesocket@gmail.com, kevalsurani15@gmail.com, ashwini.patil@thakureducation.org

Abstract— Many of the world's major e-commerce websites already use recommender systems to assist their customers in finding things to buy. The products can be recommended based on the site's best sellers, the customer's demographics, and a review of the customer's previous purchasing activity. The suggested system will employ mined knowledge gleaned from consumer behaviour and relevant persons to help consumers through the often-difficult chore of finding things they will enjoy. The project aims to build a machine learning model to predict the Click-through-rate of an advertisement displayed on social media. The system will be used by the advertiser to determine the probability of the user clicking the advertisement and then make a decision of whether publishing the advertisement on social media. Furthermore, the project will recommend the demographics of users whose predicted click rate is higher than one certain threshold to the advertiser. This operation not only can let the advertiser get the profit maximization but also make optimal investment on marketing and advertising.

Key words : **Social Media Advertisement, Click-through Rate, Customer Purchase Pattern**

I. .INTRODUCTION

Digital advertising that reaches your target audience through social media sites like Facebook, Twitter, Instagram, LinkedIn, and Pinterest is known as social media advertising. Popular social media platforms may be used by marketers and advertisers to advertise their products and drive sales. In essence, social media is a platform for communication and sharing that is supported by tools like those stated above. Social media is used to interact with friends and family that are spread out around the globe, but it is also a platform for businesses to connect with clients, investors, and staff. This is where social media marketing, a massive and rapidly expanding sector, comes into play.

Recommender systems are a powerful new technology that allows businesses to extract more value from their customer datasets. Customers can use these systems to locate things they wish to buy from a company. Customers gain from recommender systems since they can locate things they like. They, on the other hand, benefit the company by increasing sales. Recommender systems are quickly becoming a critical element in online E-commerce. The massive number of consumer data in existing corporate databases puts recommender systems under strain, and the rising volume of customer data available on the Web will put them even more under strain. New technologies are required to enhance the scalability of recommender systems considerably.

Here are some of the potential benefits of using personalization technology in social media marketing.

- Generate more leads and try to convert more users into customers.
- Improve customer engagement. Encourage
- promotions.
- Increase Facebook relevance score and ad spend.
- Increase brand loyalty.
- Increase brand awareness.

Figure 2: Users engaged in Social Media

A consumer engagement application for social media, the recommender system solution. It connects to a variety of social media data sources electronically, processes large amounts of unstructured social media communications, rates each message for brand relevance, and offers topic-specific messages for engaging customers on social media. A web-based dashboard offers the following features:

1.Visibility to relevant social media communications,

2.The option to filter suggestions by brand and hotwords (key words in the product catalog), and

3.The ability to message potential consumers and track customer reactions.

Figure 3: Importance of Social Media Marketing

II. LITERATURE SURVEY

The first step in developing a digital presence for any company is reaching potential audiences. Advertising has altered as the world moves towards more digitalization in all spheres of society. In order to reach their target customers based on keywords, advertisers invest a considerable amount of money. However, not every keyword performs as well as the others do.

Every advertiser wants to spend their cash on the most effective keywords possible, and machine learning may be used to analyze each phrase from among the many that are accessible. [1] Industry leaders have declared that organizations must use social media, such as Facebook, Twitter, Instagram, and others, in order to flourish in online settings due to social media's significantly higher level of efficiency compared to other traditional communication methods. As a result, more industries attempt to gain from social media because it may be used to develop strategy, accept management responsibilities in the plan of others, or follow instructions. [2]

In today's business environment, where customer loyalty can disappear at the slightest misstep and can also have online propagation of their unfortunate encounter with a particular product, service, or brand, social media websites offer businesses the chance to engage and interact with potential and current consumers, to encourage an increased sense of intimacy of the customer relationship, and to build all-important meaningful relationships with consumers. [3]

We have limited our options to the following techniques to estimate that:

(a)Linear regression (b)Random Forest (c)Gradient boosting

The outcome of each of the methods is the percentage of the amount that has optimal CTR and CPC. A statistical technique for determining links between dependent and independent variables is linear regression. In Predictive Analysis, Linear regression has also been found to perform better. [4] In our proposed solution it will be used for estimating CTR(Click Through Rate).

III. PROBLEM STATEMENT

The following difficulties are addressed by the work suggested in this paper:

1)To enable businesses to get a road map building brand loyalty through cost effective means of advertising which in turn will help them to expand their footholds in the world of globalization.

2)To help businesses to expand their footholds in globalization.

3)To maximize the sales with optimal investment on advertisement

IV.PROPOSED SYSTEM

The entire process of the proposed system has been classified into phases for ease of operations.

A) Social Media Data Analysis

B) Model for mapping Social Media with business requirements

C) Future Predictions (Analytics)

IV.PROPOSED SYSTEM

The entire process of the proposed system has been classified into phases for ease of operations.

A)Social Media Data Analysis

B)Model for mapping Social Media with business requirements

C)Future Predictions (Analytics)

The Proposed solution starts with a comprehensive analysis of social media data for various platforms like Facebook, Instagram, Twitter, Snapchat and Twitter. Datasets for the analysis purpose will be referred from trusted sources of Kaggle, or UCI Repository. Kaggle is a subsidiary of Google which is a popular platform for searching datasets. The machine learning community uses the UCI Machine Learning Repository, a collection of datasets, domain theories, and data generators, to empirically examine machine learning algorithms. David Aha and other graduate students from the University of California, Irvine started the archive in 1987 as an ftp archive. Since then, students, teachers, and researchers from all around the world have utilised it extensively as a key source for machine learning datasets. One of the top 100 "publications" in all of computer science, it has received over 1,000 citations as a measure of the archive's influence.

Numerous Features will be examined to determine whether they are correlated with the intended variable. This will benefit to narrow down the unwanted features and select only the important ones. These features will be

preprocessed with scaling, or performing feature engineering to increase their effectiveness with the target variable. One of the target variables is click-through rate which categorizes whether the customer has clicked on the advertisement or not. The category of customers who have clicked on the advertisement will be broken down into demographic details like Age, Gender, Time spent on social media, geographic area and pattern will be observed on social media platforms.

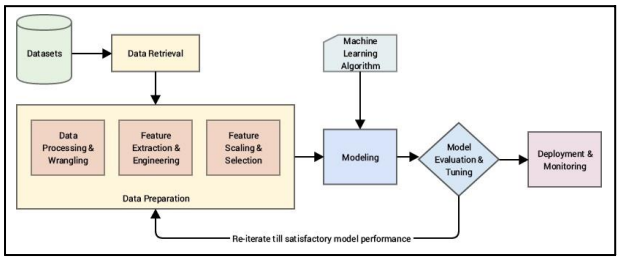

Figure 4: Feature Engineering

The Machine Learning Model will consider all the above parameters for studying and learning the dataset. Then, it will be feeded with a Test dataset and predict the optimal results for the given set of inputs. The model evaluation metrics like Accuracy, Recall, True Positive Rate, False Negative Rate, ROC Curve will be examined. Then, the best suitable model with the most effective evaluation metric will be considered and taken for hyperparameter tuning. The hyperparameters of the models will be tuned using GRID Search Technique to further enhance the efficiency of the model. Then, the model will be saved using the Pickle library.

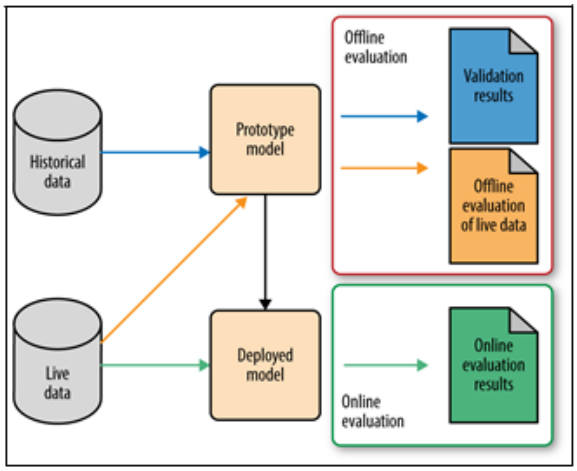

Figure 5: Architecture Diagram for the proposed model

Serialization is a way to write Python objects to disk so they can be moved anywhere and deserialized (read) using a Python script. Then, we converted the model which is in the form of a python object into a character stream using pickling.The idea is that this stream of characters contains all the information needed to restore the object from another Python script. This pickle file will be uploaded in the Flask environment.

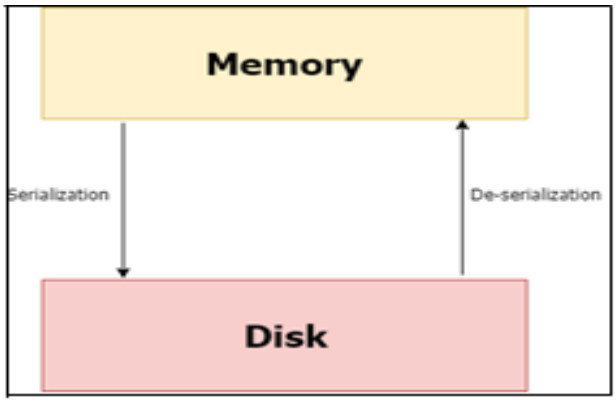

Figure 6: Pickle Module in Python

In the last phase of the project, a web-application will be built to make the software services easily available and accessible for the end-users. The user can just enter the project url and access the services. They need to provide their business details and target audience characteristics. The input will be fed to the Machine Learning Model and the output will be displayed.

Figure 7: Prototype of Prediction Web Page

Figure 8: Prototype of Report Web Page.

V.RESULT AND DISCUSSION

We begin with data cleaning of massive data files to highlight and identify the crucial features. The whole raw data contains advertising information, user profile information, user behaviour logs and advertising clicking information. Before we use them as the input data of the training model, we analyze the data in details and perform a lot of clean work for them The features of the social media data is used to record the attributes of the platform, such as domain name, device type, device connection, location, date and time, user demographics such as age, gender, interests. Similarly, we keep some main features for the advertisement, including the advertiser name, category and brand and pricing of the product.

Most of the features are categorical in nature, therefore we can perform column standardization as the 1st model is Logistic regression which assumes that features in the dataset follow gaussian distribution. The binary log-loss obtained for Logistic Regression with hyper-parameter tuning is 0.40037. The model is incorrectly projecting a lot of class 1 data points as class 0 data points, but this is predicted given the problem's class imbalance, as shown by the precision and recall matrices. The binary log-loss for Gradient Boosted Decision trees with hyper-parameter tuning is 0.39475 which is a very good improvement from the previous loss. So this implies that non-linear models work well when compared to linear models for the given data. Then, we apply the XGBoost Algorithm to the trained data, and evaluate the model performance metrics. The binary log-loss for the XGBoost model is 0.39065.

Table : Model Comparison

Model	Log Loss
Logistic Regression	0.40037
Gradient Boosted Decision Tree	0.39475
XGBoost Classifier	0.39065

To enable the stakeholders for ease-of-usage of the project, a front-end will be deployed through which users can generate predictions without installation of any softwares. They can simply navigate to the website and enter the advertisement and company data. The prediction results will be displayed on the webpage and recommendation graphs will be presented.

VI. CONCLUSION

In this Paper, various recommendation approaches are proposed to achieve maximum accuracy in user interests. The project successfully achieved the objective of an advertisement CTR prediction and recommendation system with a relatively decent accuracy. The system is beneficial to companies, brands, advertisers and also to the advertising platform as they can decrease their advertisement pollution on social media. We will see many marketing spaces and new methods being used to spread brand awareness. We think the future scope of digital marketing is very bright because people are using the digital platform at a large scale to interact with each other and pursue other activities. This means that the audience range will increase in the near future, helping several companies find potential customers.

VII. ACKNOWLEDGMENT

We express our profound sense of gratitude to the mentor, Mrs. Ashwini Patil, Assistant Professor, Computer Engineering Department, for systematic guidance and valuable advice. We would also like to thank TCET, for including this course in the curriculum. We take this opportunity to thank all my friends who helped me through their discussions and suggestions and for their help at various stages in the completion of this work.

Abstract – **: In today's day and age where amount of dataflow is astronomical. we receive many**
copies of the same multimedia, which leads to inefficient use of storage, low performance of CPU, RAM, and increasing consumption of battery. Duplicate file deduction is incredibly necessary to cut back consumption at runtime, to boost storage capability with larger accuracy and to provide a lag free/clutter free experience to the user.

Keywords: Detecting multimedia, storage management, optimization, performance.

I. INTRODUCTION

The planet is being full of varied types of transmission data within the previous couple of years. We've practiced the explosion of video content over the net in recent years as billions of videos on hold on and changed within the cloud, a large portion of that consists of near- duplicate video copies. Rapid advances in transmission technologies fuelled this growth. So, deduplication is required to eliminate the occupied cupboard space that would be used with efficiency for some other purpose. Deduplication has been usually used in backup and deposit systems to considerably increase storage use. There are differing types of deduplication techniques like data deduplication, image deduplication, and video deduplication. There are several strategies to manage file deduplication out of the higher than forms. however, removing image and video duplicates may be a troublesome task. that's as a result of the data is precisely replicated just in case of file deduplication. But just in case of a picture or video, one ought to conjointly deem

different formats within which an equivalent image or video may be stored. So, handling pictures and videos may be a quite difficult task

1.1 Image Deduplication

Image deduplication acknowledges duplicate pictures, removes all pictures however maintains one copy to form native references to the knowledge that users will access while not any drawback. the most construct within the deduplication of images is to delete duplicate pictures by 5 stages [1]comprising feature extraction, high-dimensional categorization(scaling, dynamical storage format), accuracy optimisation by extracting image edge info, centre of mass choice mistreatment cluster formation, and fixing the centre of mass image and deduplication analysis followed by comparison. When a new image comes in, the shopper 1st extracts the finger printer and sends the fingerprint to the perimeters of the storage. once the storage

aspect cannot find the corresponding finger printer in index tables, consequent image will be processed and therefore the image finger printer enraptured to index tables. as an alternative, the aspect of the storage can maintain the higher image perception-quality because the centre of mass image, and create some extent inform to the centre of mass image.

1.2 Video Deduplication

Video knowledge is a vital a part of the today's web data and it creates tons of flexibility in storage and distribution. Video deduplication is that the repetition of scenes or frames inside the video and conjointly among different videos. Consider 2 similar videos, for instance, wherever the action performed within the 1st frame of the primary video is replicated in the last frame of the second video. Then the last frame of the second video is redundant and may get replaced with a pointer. This not solely saves cupboard space effectively, but also greatly will increase the accuracy of duplicate pictures to be retrieved. the first videos got to be chunked into frames for additional process to perform video deduplication. within the case of variable-sized frames the frames are of an equivalent fastened size (in fixed-sized frames) or different sizes. almost like the technique of image deduplication, fingerprints are created for every frame and compared with the opposite ones of same or totally different videos. It can be indexed mistreatment knowledge structures like inverted index, B+ tree etc to keep up the order of the frames. so, the videos can be recovered in order and viewed by the users without any inconvenience.

II. Literature Review

Researchers are projected sure applications for image and video deduplication in real time. allow us to discuss a few of these applications' mistreatment differing types of strategies that would deliver an improved lead to day-after- day activities. Ashish Kumar Laitek al [2] projected a completely unique methodology for distinguishing and grouping near- duplicates from image streams announce on on-line social media. This is viewed because the drawback of clump the pictures

within the stream, such that every cluster consists of a series of near-duplicate images. [3] The projected technique could be a ranked one consisting of 2 levels – a worldwide feature descriptor-based similarity check at the highest level to attenuate search house, followed by neighbourhood Sensitive Hashing (LSH)-based similarity checking at ensuing level to discover similarity with solely many images, so maximising each exactness and interval. The technique consists of 2 distinct stages. The first stage is that the coaching method within which a good set of random images shared on social media sites are accustomed produce a training dataset. This method conjointly involves clump the collection of random pictures mistreatment moment-based options as they are invariant to translation, rotation and scaling and generation of visual vocabulary generation. The second stage is a web near- duplicate method of detection. Here, some candidate pictures are to be found specified every candidate image could be a illustration of a definite set (cluster) of near duplicate pictures then LSH-based similarity check between the take a look at image and therefore the known candidate pictures is performed. D wen et al [4] designed a face spoof detection system that finds the identical pictures on numerous styles of pictures for the same person. The person's face is known during this system, and is normalized. this can be cantered on an Study of Image Distortion Analysis (IDA).Four styles of ida options (specular reflection, blurriness, colour moments and variation of colour) were designed to catch image distortion in the spoof face pictures . The normalized image options area unit extracted and compared with the classifiers learned from completely different training information teams. Ultimately, if the image matches all of the images within the classifier, then the program determines that the picture could be a spoof or faux image. Zhili zhou et al [5]presented an effective a good} and efficient global context verification theme for image copy detection. The framework consists of 3 main parts, namely Scale Invariant Feature rework (SIFT) feature matching, OR- GCD extraction, and verification of SIFT matches. To obtain initial SIFT matches, the primary one matches the SIFT features between pictures supported the Bag of Words (BOW) quantization. the world context of each matched SIFT function is outlined within the OR-GCD extraction. Then, by comparing their corresponding OR-GCDs, the matched SIFT features area unit checked by extracting and concatenating 2 kinds of binary vectors — one supported intensity and therefore the other supported gradients, so the verification result will be more accustomed calculate image similarities for copy detection. The approach prompt is expanded to hide the function of partial-duplicate image detection. Potential duplicated region location could be a crucial stage for partial duplicate image detection. SGV strategy is recommended that takes under consideration not solely the relative positions of native features however conjointly their characteristic relationships to filter geometrically inconsistent matches for potential duplicated region location. Z Zhou et al [6]designed to eliminate the near-duplicate image quickly and accurately for visual sensing element networks. This is as a result of visual sensing element nodes, that's the camera nodes, produces heaps of visual information, like digital pictures and videos, that gets transmitted on visual sensing element networks. Among those, there area unit several near-duplicate pictures, which cause a heavy wastage in storage. Here the pictures area unit split into a 3*3 matrix and converted to hash code. Near-duplicate clustering is the 1st and crucial step towards the removal of near duplicates. Next, they counsel a unique seed image selection technique supported the PageRank rule, which can choose the foremost applicable pictures accurately as seed images and delete the opposite redundant pictures to complete the near-duplicate elimination. neighbourhood Sensitive Hashing (LSH) could be a known inverted index file building technique for matching high-dimensional options. The hash values of a given question operate area unit researched from inverted index file entries, so a further comparison is applied between the initial two to more validate whether or not or not features options are a match.

III. Related Work

Remo Duplicate Photo Remover is an easy-to- use application which saves a lot of time by minimizing the tedious efforts used for searching your entire device for duplicate photos. It has the potential to find and list all similar looking photos in sets taken in burst mode, resized or HDR photos, similar photos send by multiple contacts via What's App or any other instant messaging application. Remo's proprietary intelligent De-Dupe Algorithm scans for identical or similar photos on your Phone. this duplicate image finder tool searches entire drive and displays them in sets, serving you with the option to delete the identical photos.

Duplicate Photo Finder helps you free up space in your hard drive by finding and removing duplicate images in just a couple of clicks. The duplicate images will be listed at the bottom of the interface. You can then go over them one by one, and use the preview function to decide which one to keep, and which one to erase. A third option is moving the selected picture to a different folder.

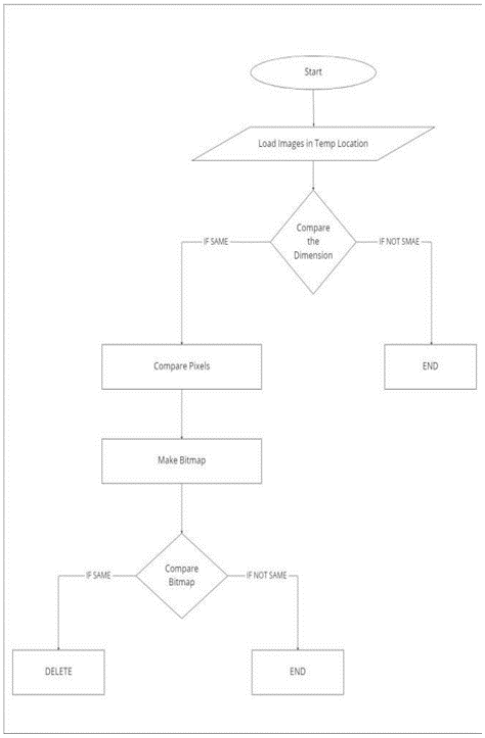
Gallery Doctor is designed to eliminate all your poor quality, blurred, duplicated and even just dull photos. It has a few tricks that can help you find photos you probably don't want any more. First of all, there's the analysis. Gallery Doctor automatically analyses all the photos on your device, and puts them into three categories: Bad photos, Similar Photos and Photos for Review. Bad photos can be categorized as such for being too dark, blurry or even boring. When you use the app, you also train it to recognize what youthink is 'bad' or not. MD 5 Hash Collision Algorithm is also widelyused for image and video deduplication.

IV. Problem Statement

Have you been bombarded with never-ending stream of images? have you felt overwhelmed when thinking of clearing your phone storage? Due to which you never delete anything from the camera's SD card until it is full? We have a solution for you.

V. Proposed Plan

The proposed system is focused on finding the duplicated image in the folder, by using image pixel processing. The process goes like: -



VI. CONCLUSION

The conclusion of this is that a robust solution was given to image deduplication, which can be used for small databases.

VII. . FUTURE ENHANCEMENTS

The process of pixel processing is slow for large databases. Also, it can't handle image of different sizes. The computation required to do such calculation also makes it unavailable for low-end devices.

Abstract – **Home appliances are electrical/mechanical machines which accomplish some household functions, such as cooking or cleaning. The maintenance and repair of these kinds of products. Brown goods usually require high technical knowledge and skills (which get more complex with time, such as going from a soldering iron to a hot-air soldering station), while white goods may need more practical skills and "brute force" to manipulate the devices and heavy wools required to repair them. Today in digital world which makes user easy to get services online on single click. The online platform serves both the buyers and sellers' community by establishing effective communication. To design and develop a system that provides variety of services like plumbers, movers and packers, repair persons services at your doorstep in just one click. A generic platform providing owo-way communications between service provider and service receiver can eliminate the exhausting efforts of searching the suitable service provider and also ensures the intended job for the service provider. Feedback. based rating system can improve the skills of any service provider and service receiver can eventually get better service.**
over prices. Several aspects like painting, pest control, home cleaning, plumbing, electrical works and carpentry services are involved in a system to provide happy and healthy home atmosphere in order to satisfy consumers. The primary objective of the online system for household services is about delivering the home services at the doorstep just by one click. This paper discusses about main theme of the online home services, numerous services provided and how the ordering and delivery of services takes place. Online system for household services can be used by any authorized user intending to seek for household services through an ingenious web-based system or a mobile application. To provide an authenticated and authorized logia module for the users such as service seekers, service providers and the admin, by providing appropriate credentials at the time of registration. To develop a web based online system for opting household services and to develop an identical mobile application for opting the services. To design an interactive User Interface for seeking services on the go. To provide a secured online payment gateway for service seekers. To acknowledge the conformation of services opted by the users.

Several aspects like painting, pest control, home cleaning, plumbing, electrical works and carpentry services are involved in a system to provide happy and healthy home atmosphere in order to satisfy consumers We aim to help is providing optimal solutions to all your household troubles with more efficacy, ease and majorly, a delicate touch. A single click system describes booking
highly skilled in-house professionals and gets your service done in time. Customers' overall willingness to pay is significantly and positively correlated with the expectation that fee-based services would be better and with the belief that “pay for that you get” is the right thing to do.

III. OBJECTIVE

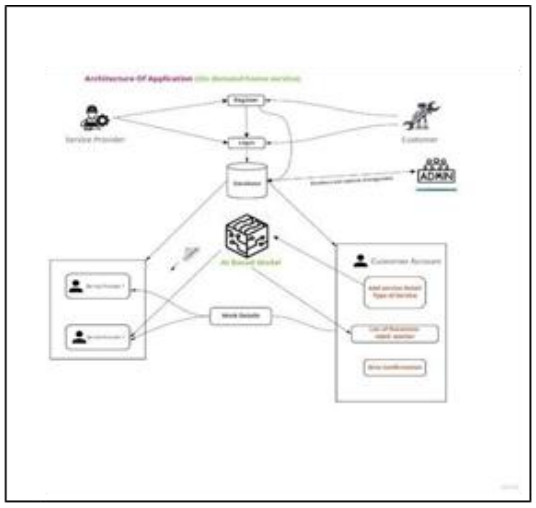
- To reduce time
- Easily available best Vendors on one click
- Easy to use
- Reduce Barden of Fining service provider

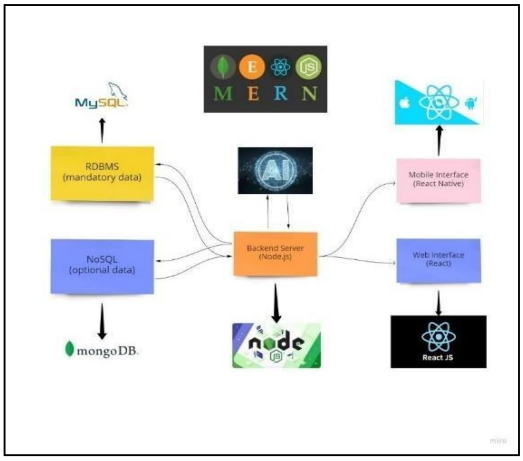
IV. HARDWARE REQUIREMENTS

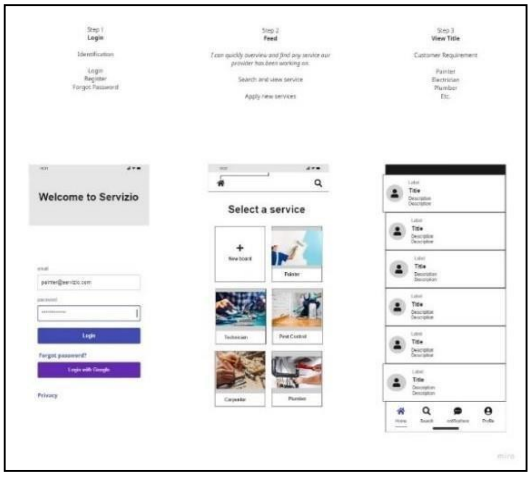
- Smart Phone
- Computer / Laptop

V. SOFTWARE REQUIREMENTS

a. Language: Java
b. Database: MySQL
c. Operating System: Windows 10 XP/7
d. Android Studio
e. Web Browse





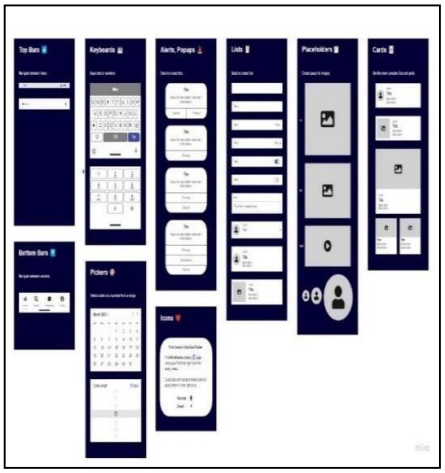


VI. RESULT & DISCUSSION

We intend to provide smooth flow of services to the user and have them updated about each step of the process. Customer relationships will be our core focus as customer experience is what defines a business. The purpose of this system is to streamline and improve the user experience. In our business "Customer is the KING".

VII. CONCLUSIONS

To reduce burden in finding in-house solutions for the services, the proposed system provides several services by providing service specialists at your doorstep in one click. A systematic mobile environment to system clients offers ease in accessing our services in a more comfortable way. With well qualified and background demonstrated professionals we make all your home cleaning. plumbing, furniture maintenance, electrical works, appliance repair, house painting, vehicle



service and many other services to be done in a click anytime from anywhere as easy as available. In Future the system can have prolonged by adding the services such as mobile and computer repair, laundry services, catering services and many more.

A review on routing protocols in wireless sensor networks

Rupinder kaur, Anand Maha

Thakur College of Engineering and Technology Mumbai

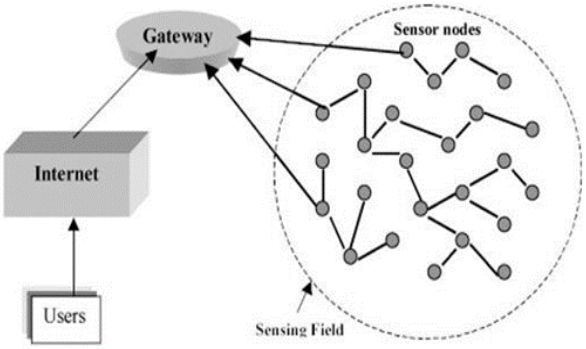
rupindermalhotra20@gmail.com, mahaanand922@gmail.com

Abstract – **Now a days small size and economical sensor nodes advancement with sensing capability in wireless sensor network (WSN) technology is used in different types of physical and environmental conditions, data processing and wireless communication. Advancement in protocols designed in wireless sensor network results in use of energy efficient mechanism. To maintain the efficient route in wireless sensor network and low energy consumptions to ensure reliable multi-hop communication, routing protocols are designed in wireless sensor network. This paper presents network design objective and data centric, hierarchical, and location-based routing protocols are explained.**

Keywords: sensor nodes, design issues, routing protocols, applications..

I. INTRODUCTION

Wireless sensor networks (WSN) is specified for monitoring of an environment. data collected on wireless sensor node is processed and transmitted after sensing. this data is transmitted to sink where the application exists. in the direct communication between a sensor and the sink forces nodes to emit their messages with such a high power that their resource power could be easily depleted. there is a distant communication of the nodes with the sink so collaboration is required in the nodes. here, messages are communicated by intervening nodes so that a route with multiple links or hops to the sink is established.



II. COMPONENTS OF WSN

The sensor nodes, the sink (Base Station), and the events being monitored are the primary components of a general WSN. Where the communication among the nodes is low-power wireless link while the communication between the base stations low latency and higher bandwidth link, as shown in the fig 2

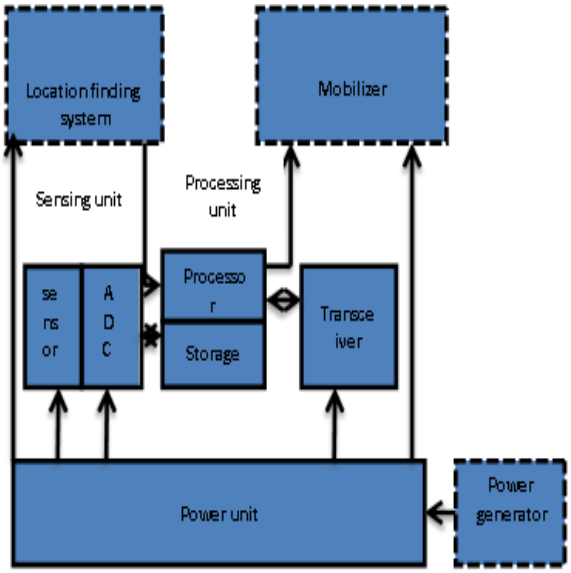


Fig 1: Components of sensing unit

A. Base Station (Sink) (BS)

The sink (some time cluster head) is an interface between the external (management center) world and computational world (sensor network). It is usually a resourceful node with unrestricted computing capability and an abundant supply of energy. In a network, there can be one or more base stations. In practice, having many base stations reduces network latency and improves data collection performance.

B. The Sensor Nodes

As shown in the Fig. 2, a sensor node is composed of four basic components: sensing unit, processing unit, transceiver unit and a power unit [3]. The sensing units are usually composed of two sub-units: Sensors and analogy-to-digital converters (ADCs). The ADC converts the analogue signals sensed by the sensor that are based on the observed occurrence into digital signals, which are subsequently fed to the processing unit.The process unit, that is generally associated a little storage device, manages / handles the procedures which make the sensor node collaborates with the others nodes in order to carry out the assigned sensor task.

III NETWORK DESIGN OBJECTIVES

Most sensor networks are application-specific, with differing needs for each application. Thus, all or part of the following main design objectives is considered in the design of sensor networks [2]

QOS support: In sensor networks, exclusive applications may additionally have specific satisfactory-of provider (QOS) requirements in terms of shipping latency and

packet loss. therefore, network protocol layout must take into account the QOS requirements

Small node size: When you consider that sensor nodes are usually deployed in tough and rigid surroundings in big numbers, lowering node length can facilitate node deployment. It will also reduce the strength consumption and cost of sensor nodes.

Low node cost: Considering sensor nodes are commonly deployed in a harsh or hostile environment in massive numbers and cannot be reused, reducing fee of sensor nodes is critical and could end result into the value discount of entire community.

Energy consumption: Considering that sensor nodes are powered by battery and it's far frequently very tough or maybe not possible to price or recharge their batteries, it is crucial to lessen the energy consumption of sensor nodes so that the lifetime of the sensor nodes, in addition to the entire community is extended.

Scalability: Since the variety sensor nodes in sensor networks are inside the order of tens, loads, or heaps, network protocols designed for sensor networks should be scalable to extraordinary network sizes.

Reliability: Community protocols designed for sensor networks must offer mistakes manage and correction mechanisms to make certain reliable information delivery over noisy, blunders-prone, and time-various wireless channels.

Self-Configurability: In sensor networks, as soon as deployed, sensor nodes must be capable of autonomously prepare themselves right into a communication network and reconfigure their connectivity within the event of topology adjustments and node failures.

Adaptability: In sensor networks, a node may additionally fail, be a part of, or move, which would bring about modifications in node density and network topology. As a consequence, network protocols designed for sensor networks must be adaptive to such density and topology changes.

Channel usage: Given that sensor networks have restrained bandwidth resources, verbal exchange protocols designed for sensor networks ought to efficaciously employ the bandwidth to improve channel usage.

Fault tolerance: Sensor nodes are liable to disasters because of harsh deployment environments and unattended operations. therefore, sensor nodes should be fault tolerant and have the abilities of self-testing, self-calibrating, self-repairing, and self-recuperating.

IV LOCATION BASED PROTOCOLS

The positions of sensor nodes are used to address them. Location information for sensor nodes is required for sensor networks by most of the routing protocols to calculate the space between two particular nodes in order that energy consumption are often estimated[5].

A. Trajectory-based forwarding (TBF):

TBF could be a routing system that requires a dense network and, as a result, the presence of a frame of reference, such as a GPS, so that sensors can locate themselves and estimate distances to their neighbors. The source specifies the trajectory during a packet but does not explicitly indicate the trail on a hop-by-hop basis. supported the situation information of its neighbors, a forwarding sensor makes a greedy decision to work out subsequent hop that is the closest to the trajectory fixed by the source sensor. route maintenance in TBF is unaffected by sensor mobility if a source route may be a trajectory that does not include the names of the forwarding sensors. to extend the reliability and capacity of the network, it is also possible to implement multipath routing in TBF where an alternate path is simply another trajectory. TBF are often used for implementing networking functions, for instance, flooding, discovery, and network management. TBF also can be used for resource discovery. another interesting application of TBF is securing the perimeter of the network.

B. Bounded Voronoi Greedy Forwarding [BVGF]:

BVGF as the only form of geographic routing, geographic routing is especially attractive in sensor networks. on this paper, greedy geographic routing refers to a simple routing scheme in which a routing node always forwards a packet to the neighbor that has the shortest distance to the vacation spot.

C. Small Minimum-Energy Communication Network (SMECN):

SMECN is a routing protocol proposed to enhance MECN, wherein a minimum graph is characterized in regard to the minimum power belongings. This asset implies that for any pair of sensors in a graph related to a network, there is a minimal energy-green path between them; That is, a route that hasthe smallest cost in terms of power intake overall feasible paths among this pair of sensors.Their characterization of a graph with appreciate to the minimal energy assets is intuitive. In SMECN protocol, each sensor discovers its instantaneous buddies by means of broadcasting a neighbor discovery message using some initial strength that is updated incrementally. In particular, the on-the-spot associates of a given sensor are computed analytically After that, a sensor broadcasts a neighbour discovery message with some initial energy p and evaluates if the theoretical set of instantaneous friends is a subset of the set of sensors that responded to that neighbour discovery message.If that is the case, the sensor will use the corresponding energy p to talk with it’s on the spot neighbors. Otherwise, it increments p and rebroadcasts its neighbor discovery message.

V DATA CENTRIC BASED PROTOCOLS

Data centric protocols differ from traditional address-centric protocols within the manner that the information is shipped from source sensors to the sink[4]. In address-centric protocols, each source sensor that has the acceptable data responds by sending its data to the sink independently of all other sensors. When source sensors submit data to the sink in data-centric protocols, intermediary sensors can perform some sort of

aggregation on the information coming from numerous source sensors and send the aggregated data to the sink. This process may result in energy savings due to less transmission required to send the information from the sources to the sink. During this section, we review a number of the data centric routing protocols for WSNs[7].

A SPIN :

Protocol turned into designed to improve conventional flooding protocols and conquer the troubles they will motive, as an instance, implosion and overlap. The spin protocols are primarily based on two key mechanisms particularly negotiation and resource edition. spin enables the sensors to negotiate with every different before any data dissemination can arise so one can keep away from injecting non- beneficial and redundant information in the network.spin uses meta-facts because the descriptors of the information that the sensors want to disseminate. spin is a three-stage protocol as sensor nodes use 3 forms of messages, adv, req,and facts, to talk. adv is used to advertise new statistics, req to request facts, and statistics is the actual message itself [8]. 4 specific spin protocols were simulated and analyzed: SPIN- PP and SPINEC. which might be optimized for a point-to- point community, and SPIN-BC and SPIN-RL, that are optimized for a broadcast community. in factor-to- point networks, the sender declares that it has new facts with an advertisement message to each neighbor. when the neighbor gets the message, the node checks the metadata to recognize if it already stores the records object. if the neighbor is interested by the statistics, it responds with a request message. upon receiving it, the sender transmits the records in a facts message.The neighbor that receives the information, tell approximately its availability to its personal buddies with an advertisement message. the three-handshake protocol is then repeated. the defined process is known as spin-pp. the set of rules SPIN-EC introduces a way within the nodes so when their present-day strength resources do not exceed a predetermined threshold that allows them to complete the 3 hand-shake protocols, they do no longer participate in the technique. the spin-bc and spin-rl editions increase the algorithm to aid broadcast transmissions. on this way, one commercial message can reach all of the buddies.

B Directed diffusion

Directed diffusion is facts-centric and all nodes in a directed diffusion-based network are application-conscious.This enables diffusion to achieve power savings via deciding on empirically true paths and by means of caching and processing records in community (e.g., data aggregation).Dire cted diffusion consists of several factors: pursuits, information messages, gradients, and reinforcements. A hobby message is a query which specifies what a person wishes and contains a summary of a sensing undertaking which is supported through a sensor community for acquiring records. Generally, facts in sensor networks are the gathered information of a physical phenomenon. such data may be an occasion that is a quick description of the sensed phenomenon. in directed diffusion, facts are known as the use of characteristic- cost pairs. The nodes replace an internal hobby cache with the hobby messages obtained.The nodes also hold an information cache in which the current information messages are stored. This structure facilitates on figuring out the information rate. On receiving this message, the nodes set up a reply link to the originator of the hobby.This link is called gradient and it's miles characterized through the records charge, duration and expiration time.

C Cougar

Beneath this technique, the network is foreseen as an allotted database in which a few nodes containing the records are temporary unreachable. given that node stores historical values, the community behaves as statistics warehouse.additionally, it's miles well worth noting that terrible propagation situations may result in the garage of erroneous information inside the nodes.Deliberating this situation,cougar presents a SQL-like interface prolonged to include a few clauses to model the possibility distribution. the sink is answerable for producing a question plan which provides the hints to choose a special node called the leader.The community leaders perform aggregation and transmit the consequences to the sink.

VI HIERARCHICAL BASED PROTOCOLS

Many research projects within the previous couple of years have explored hierarchical clustering in WSN from different perspectives. Clustering is an energy-efficient communication protocol which will be employed by the sensors to report their sensed data to the sink. During this section, we describe a sample of layered protocols during which a network consist of several clumps(or clusters)of sensors. Each clump is managed by a special node called cluster head, which is liable for coordinating the information transmission activities of all sensors in its clumps[6].

A Low-energy adaptive clustering hierarchy (leach):

it's far very strength green routing protocol. On this protocol each WSNS are divided into cluster, and each cluster includes a cluster head (CH) and variety of cluster courting, more than one cluster heads form the excessive-stage network. in terms of operation, a HRP consists of two stages: within the first stage is the set-up, whilst the sensor nodes are prepared to shape hierarchical structural design either in a cluster based totally or chain based way or, within the second degree is the steady state, whilst data are routed from sensor nodes to the base station. the hierarchical structural layout of a cluster-primarily based can be installation by means of the usage of allotted set of rules or centralized set of rules[9].

B Power-efficient gathering in sensor information systems (PEGASIS):

it's far an extension of leach protocol, that kind of a sequence from sensor nodes in order that each node transmits and gets from a neighbor and handiest single node is selected from that chain to transmit to the bottom station (sink). data is moved from node to node, combined and finally ship to the bottom station. In PEGASIS routing protocol,the development segment assumes that all the sensors have global knowledge about the community, mainly, the positions of

the sensors, and use a greedy method. whilst a sensor fails or dies due to low battery power, the chain is constructed the use of the same grasping technique through bypassing the failed sensor. in each spherical, a randomly selected sensor node from the chain will transmit the aggregated data to the Base station, accordingly decreasing the in keeping with round energy expenditure as compared to leach.

C Hybrid, energy-efficient distributed clustering (HEED):

HEED widens the leach protocol with balance energy and node degree as a metric for cluster choice to achieve energy balancing. It executes in multi-hop networks, the use of an adaptive transmission strength within the inter-clustering conversation.HEED became planned with 4 goals which can be

(i)Prolonging network lifetime with the aid of spreading energy intake,
(ii)Finishing the clustering process within a stable quantity of iterations,
(iii)Insignificant manipulate and control overhead, and
(iv) Generating properly dispensed CHS and compact clusters. in this protocol, the prevailing set of rules randomly chooses CHS to a mixture of two clustering arguments.
D threshold sensitive energy efficient sensor network protocol (TEEN):

TEEN is a hierarchical clustering protocol, which organizations sensors into clusters with every led via a CH. the sensors within a cluster document their sensed data to their CH. the CH sends aggregated statistics to better stage CH till the information reaches the sink. as a result, the sensor community in teen is based on a hierarchical grouping in which closer nodes form clusters and this method goes on the second one level until the base station (sink) is reached. TEEN is beneficial for programs in which the users can control a change-off among energy efficiency, records accuracy, and response time dynamically. TEEN uses a data- centric technique with hierarchical method. Vital functions of TEEN encompass its suitability for time critical sensing applications. Also, considering message transmission consumes extra energy than information sensing, So the power intake on this scheme is much less than the proactive networks.

But, teen is not suitable for sensing applications in which periodic reviews are wanted for the reason that person might not get any data in any respect if the thresholds aren't reached.

VII CONCLUSION

We looked at the hierarchical routing protocols leach

,PEGASIS, HEED, and TEEN in this study. Protocols are also evaluated in terms of certain factors, and their benefits and drawbacks are presented. The protocols are all based on a static network. The maximum strength of the leach is greater than the other. When it comes to scalability, the most effective HEED is there, and it's as simple as using multi-hope remember. Routing in sensor networks is a very young research area, with a limited but rapidly expanding range of effects. In this work, routing protocols are classified into three groups depending on community structure: flat-based routing, hierarchical-based totally routing, and location-based totally routing. They all have the same goal in mind: to extend the sensor network's lifetime.

Thakur College of Engineering &Technology, Mumbai
s1032190119@gmail.com, sd822949165@gmail.com ,mihirj21@gmail.com,rekha.sharma@thakureducation.org

Abstract—**The heating, ventilation, and air conditioning (HVAC) system is an essential part of a building's infrastructure, and it needs to operate efficiently to maintain a comfortable indoor environment. The increasing demand for energy-efficient systems has resulted in the development of smart HVAC devices that use sensors to collect data and adjust system settings accordingly. This research paper presents a battery-operated and Wi-Fi enabled sensor data transmission firmware using ESP-IDF for HVAC devices. The firmware is designed to collect data from temperature and humidity sensors and transmit it wirelessly to a central hub for processing and analysis. The system is based on the ESP32 microcontroller and is programmed using the ESP-IDF framework. The firmware's energy-efficient design ensures extended battery life, making it suitable for use in battery-powered devices. In many businesses that store and produce consumable items, temperature and humidity are crucial factors. Additionally, it is now required in organizations to measure temperature and humidity for analytical purposes, perform diagnostic and prescriptive data analysis, and provide results of reduced power consumption, assisting corporate organizations in maximizing their profit by lowering a significant portion of their expenses, namely, energy costs. bills for electricity. During a predetermined period, the temperature is continually measured, and the measurement results are saved before being computed for preventive maintenance procedures. F&B enterprises may properly carry out preventative maintenance, preserve food quality, and increase staff productivity by using this Smart Temperature Monitoring System**
.

Keywords— Battery operated, ESP32, Temperature, Humidity, FREE RTOS

I. INTRODUCTION

The heating, ventilation, and air conditioning (HVAC) systems are critical components of a building's infrastructure, and they are responsible for maintaining a comfortable indoor environment. HVAC systems account for a significant portion of a building's energy consumption, and their inefficiencies can lead to increased energy costs and environmental impact. To optimize HVAC system performance and reduce energy consumption, sensors can be used to collect data on temperature, humidity, and air quality.Traditionally, HVAC systems have been controlled using thermostats and mechanical controls, which are often not energy-efficient and do not provide the fine-tuned control required to optimize system performance. The advent of the Internet of Things (IoT) has provided an opportunity to develop smart HVAC devices that can monitor and control HVAC systems more effectively.Smart HVAC devices use sensors to collect data on temperature, humidity, and air quality and transmit this data wirelessly to a central hub for processing and analysis. The central hub can then use this data to adjust HVAC system settings, optimizing performance and reducing energy consumption. Additionally, remote access to HVAC system data allows building managers to monitor and control HVAC systems from anywhere, enabling more efficient operation and reducing energy costs.However, developing smart HVAC devices that are energy-efficient and able to operate for extended periods without the need for frequent battery replacement is a significant challenge. Battery-powered sensors must be designed to consume as little power as possible to extend battery life, and firmware must be optimized to minimize energy consumption during data collection and transmission.In this research paper, we present a firmware solution for collecting data from temperature and humidity sensors and transmitting it wirelessly to a central hub using Wi-Fi. The firmware is developed using the ESP-IDF framework and is designed to be energy-efficient, with features such as sleep modes and duty cycling to minimize power consumption. The firmware is tested on a prototype device consisting of an ESP32 microcontroller, temperature and humidity sensors, and a battery, and the energy consumption and battery life of the device are measured.

A. Objective

- To develop a plug and play device for acquiring sensor data Remotely.
- To develop a device that is battery operated with extended life
- To develop a device that is operated on a AA/AAA battery
- To develop a firmware that makes the device wireless.

B. Formula

In the Project the major research component involves increasing the life of the battery thereby making the firmware technically and economically viable. The major factors to be considered in calculating the life of the battery are the battery capacity i.e., 42 power rating in mAh of the battery and the power drained by the device connected to it per hour.

Battery Life = Battery Capacity in mAh/Power drained through it.

II. LITERATURE SURVEY

The building of an asynchronous ESP32 web server estimating the DHT22 sensor integrated ESP32 web server's high-power consumption was put out by Macheso Paul, Chisale Sylvester, Daka Chisomo, Dzupire Nelson, Mlatho J.s.P. & Mukanyiligira, Didacienne [1]. Here, a web client can read the temperature and relative humidity from a DHT22 sensor creating a flexible online dashboard with a user-friendly interface to display the sensor data. Components used were: ESP32, DHT22, NodeMCU-32S, Arduino IDE. The temperature and humidity sensor data are displayed on the web browser.

Budijono Santoso & Felita [2] developed a temperature monitoring system using ESP32 and DS18B20 temperature sensor. The DS18B20 temperature sensor will provide data to the microcontroller. The microcontroller will then transmit temperature information to the OLED SSD1306, buzzer, and system cloud for storage. The components used were: ESP32, DS18B20 temperature sensor, OLED SSD1306, buzzer, and cloud. The average temperature results between the temperature of the system and the digital thermometer, measured per degree from 0 to 5 C, were gathered and then entered the linear regression line equation.Babalola Toju, Babalola Abayomi & Olokun Mayowa [3] developed an ESP32 microcontroller Based Weather Reporting Device. After processing readings from environmental sensors, an ESP32 microcontroller displays the results on the ESP serial monitor. The display device displayed data from the sensor on the LCD panel. The LCD and the rest of the system are powered by the voltage from the solar power pack. Here, components used were: ESP32, DHT22, Tipping Bucket, light sensor, resistor, lcd. Precipitation graphs were made after the gadget was tested in public areas both within and outside of the neighborhood. Balaji, Lakshmipraba, Sagar Bawane, Ganesh Pise, and Akanksha Singh [4] developed an Efficient Multi-Protocol Gateway Design Using ESP32 for Industry 4.0 and Electric Vehicle. The components used were: ESP32, CAN module, temperature sensor, moisture sensor, vibration sensor and cloud. The CAN Module, which is attached to the car and receives signals, provides information on the engine's many properties, including the battery, engine, speed, etc. For instance, it will indicate how long the battery will last, or how long the automobile will run on this level of electricity. It will continuously find these characteristics and transmit them to the ESP32. This data will be obtained from the CAN Module and sent via the ESP32 Module, a Wi-Fi module. Along with the data from the CAN Module, the ESP32 will primarily receive data from three sensors: the temperature sensor, humidity sensor, and vibration sensor, which will provide information on the battery's exterior properties. They created a gateway utilizing ESP32 that can be utilized with Industry 4.0 and electric vehicles. This gateway would serve as a communication tool between the point of data collection and data transmission. In Industry 4.0, a gateway's job is to transfer data from a source to a device that can process it before transmitting it to a destination. Depending on the application, a separate protocol may be used between the data collection and reception processes. Souri, Kamran & Makinwa K [5] developed a 0.12mm2 7.4μW micropower temperature sensor with an inaccuracy of ±0.2°C (3σ) from −30°C to 125°C. The zoom ADC is just a 1st-order SC -ADC that has been upgraded with 24-unit sampling capacitors. The integrator is reset at the beginning of each comparison step of the coarse conversion and so acts as a sample-and-hold device. Five metal layers and a typical 0.16 m CMOS process were used to create the temperature sensor. The chip uses 8.2 W from a 1.8 V supply at 25 C and has an active area of 0.12 mm. For flexibility, the control logic, decimation filter, and digital back end were all developed off-chip.

Gaps Identified:

- Power Consumption too high.
- Requires power connection using cable send a notification using other messaging systems like SMS, Email or WhatsApp.
- Hardware size is not optimum for small places. Cabled power connection required.
- The amount power consumption is too high because the device works consistently and sends the data to cloud continuously It requires continuous power supply and internet connectivity.

III. METHODOLOGY

The device will initially connect to Wi-Fi before starting to measure the temperature and humidity. The measured temperature and humidity will then be communicated to the server utilizing ESP32's Wi-Fi and MQTT concept. Once data transmission is complete, the ESP32 microcontroller enters a deep sleep state. The device will awaken after 15 minutes. This will keep doing this until the device's battery is completely depleted. It would have a battery life of at least a year. The key component of the hardware is the HDC1080 via 12C protocol sensor, which is described below along with the methodologies used to construct it. The HDC1080 via 12C protocol sensor interfaces with the microcontroller and transmits data to the server. Once engaged, the microcontroller is programmed to receive signals from the used sensors.Power Supply Unit the ESP32 microcontroller will be supplied with power from a reliable source of voltage. The battery can offer the system's required minimum input voltage. All electrical circuits rely on their power supply unit, which is crucial.Microcontroller Unit Because it interacts with all the parts and sensors of the weather reporting system, the microcontroller unit is also referred to as the processing unit of the system. The microcontroller now has 36 GPIO pins instead of 17, and each pin is given a distinct task to complete. By Proteus, the ESP32 microcontroller is created. Sets of digital and analogue input/output (I/O) pins are included on the board.Sensing Unit A digital humidity sensor with an integrated temperature sensor, the HDC1080 delivers outstanding measurement accuracy at very little power. The HDC1080 is a low-cost, low-power alternative to competing solutions in a variety of widely used applications and 43 operates across a broad supply range. The temperature and humidity sensors are calibrated by the manufacturer.Station mode in ESP32 Station mode (aka STA mode or Wi-Fi client mode). ESP32 connects to an access point. AP mode (aka Soft-AP mode or Access Point mode). Stations connect to the ESP32.MQTT in ESP32 MQTT is a lightweight and flexible IoT message exchange and data transmission protocol, which is dedicated to achieving the balance between flexibility and hardware/network resources for IoT developers. The firmware is designed to run on an ESP32-based microcontroller and collect data from temperature and humidity sensors. The collected data is transmitted wirelessly to a central hub using Wi-Fi. The firmware is programmed using the ESP-IDF framework, which provides a comprehensive set of tools and libraries for developing firmware for ESP32-based devices.The firmware's energy-efficient design is achieved through several techniques, including sleep modes and duty cycling. The microcontroller is put into sleep mode when it is not actively collecting or transmitting data. Duty cycling is used to minimize the time the Wi-Fi module is active, reducing power consumption.The firmware is tested using a prototype device consisting of an ESP32 microcontroller, a temperature sensor, a humidity sensor, and a battery. The device is configured to transmit data to a central hub using Wi-Fi. The firmware's energy consumption is measured using a

power meter, and the battery life is calculated based on the measured power consumption and battery capacity.

- Firmware Development

The firmware is developed using the ESP-IDF framework, which provides a range of tools and libraries for developing firmware for ESP32-based devices. The firmware is designed to collect data from temperature and humidity sensors and transmit it wirelessly to a central hub using Wi-Fi. The firmware's energy-efficient design is achieved through several techniques, including sleep modes and duty cycling.

- Prototype Device Construction

A prototype device is constructed to test the firmware's performance. The device consists of an ESP32 microcontroller, temperature and humidity sensors, and a battery. The sensors are connected to the ESP32 microcontroller, which is programmed with the firmware developed in step 1. The battery is used to power the device.

- Testing of Energy Consumption and Battery Life

The energy consumption and battery life of the prototype device are measured to test the firmware's performance. The device is configured to transmit data to a central hub using Wi-Fi. The firmware's energy consumption is measured using a power meter, and the battery life is calculated based on the measured power consumption and battery capacity. The device is left running for several days to test its battery life.

- Data Analysis

The data collected during testing is analyzed to evaluate the firmware's energy consumption and battery life. The firmware's performance is compared to other existing solutions, and the results are discussed.

IV. Result and discussion

By the series of multiple experiments performed in the due course with the objective to reduce time spent in active mode by ESP32 which was required to send data to the central server via Wi-Fi. The device will be able to collect data from the temperature and humidity sensors and transmit it wirelessly to a central hub using Wi-Fi. The firmware's energy-efficient design ensured extended battery life, with the device able to operate for several months on a single pair battery. The results of the testing indicate that the firmware developed in this research paper has the potential to be used in smart HVAC devices to optimize system performance and reduce energy consumption. The ability to remotely monitor and control HVAC systems using smart devices enables more efficient operation and reduced energy costs. The firmware's energy-efficient design is a significant advantage, as it enables extended battery life and reduces the need for frequent battery replacement.The research presented in this paper provides a foundation for developing energy-efficient smart devices for other applications, further advancing the field of IoT. Future research could explore the use of additional sensors and data analysis techniques to improve the performance of smart HVAC devices. Additionally, the firmware developed in this research could be modified or optimized for use in other types of devices or applications.

V. Conclusion

As a result of experiments, it was found that it was necessary to bring ESP in active mode to send data to the central Server With the help of Wi-fi but Keeping ESP in Active mode reduces battery life drastically. So, it was required to reduce the time taken by ESP 32 to connect to Wi-Fi and send data to central server. It was evident from Figure 3.1 that if ESP remains in active mode for 5 seconds and in deep sleep mode for 15 minutes, the battery will last for merely 75 days which is approx. 2.5 months while if it takes 2 seconds it would last for 167.5 days which is approximately equal to 5.5 months. While in 1 second it would last for 375 Days which is near about or greater than our estimated target. The theoretical values of the power consumption of ESP 32 in its full working condition is 230mA while experimental value in condition required by our ESP i.e., only Wi-Fi and required peripherals is merely 70mA which gives the battery life as 585.9375 days when the round time required by the ESP 32 to awake from deep sleep mode connect to Wi-Fi, send data, and return to deep sleep mode is 2 seconds. Thus, our System could survive for more than a year and we managed to Manage the time in active to be less than 2 seconds by developing a firmware for it. The use of sensors to collect data on temperature, humidity, and air quality can help optimize HVAC system performance and reduce energy consumption. The ESP32 microcontroller and ESP-IDF framework provide a powerful and versatile platform for developing firmware for IoT devices. The firmware presented in this research paper is designed to be energy efficient, ensuring extended battery life for battery-powered devices. The firmware's ability to collect and transmit data wirelessly makes it suitable for use in smart HVAC devices, enabling remote monitoring and control of HVAC systems. Further development of this firmware could lead to the development of more energy efficient.

Acknowledgment

A sincere gratitude to Agile Connects Pvt. Ltd. for providing support for this study. We acknowledge the faculty of Thakur College of Engineering and Technology, whose knowledge and experience were invaluable in helping us finish the project. We appreciate the help with project development provided by Mr. Jimit Damania, Solution Architect of Agile Connects Pvt. Ltd. and the comments made by Mr. Dayal Nigam of Agile connects Pvt. Ltd. that significantly enhanced the manuscript. Although any inaccuracies are our own and shouldn't reflect negatively on the reputations of these great individuals, we are also extremely thankful to all the stakeholders who provided feedback on an earlier draft of the manuscript during the project's development and the writing of the article.

Node Prediction using Graphical Neural Networks (GNN)

Premanand Ghadekar, Dijasmit Patil, Hiranmayee Sant, Vyankatesh Pareek, Srushti Shingade, Devendra Kanade

Vishwakarma Institute of Technology, Pune-411037, Maharashtra, India

Abstract – **Over the past few years, node classification issues on graphs have been handled much better by Graph Neural Networks (GNN) and label propagation-based algorithms. But in addition to their reliance on complex designs and algorithms, there are a number of important technical issues that are occasionally disregarded but may still be necessary for achieving appropriate performance. This article provides an example of a straightforward Graph Neural Network (GNN) model application. On the basis of a publication's words and citation network, the model is used for a node prediction job on the Cora dataset to determine its topic. Two components make up the suggested system, and each one makes use of Graph Neural Networks in some way.**

Keywords: Graph Neural Networks, Node Classification, baseline model..

I. INTRODUCTION

Node classification is one of the most notable examples of the growing attention recently given to machine learning tasks involving graphs. Since graph convolutional networks (GCN) had such remarkable success, a number of high-performance GNN designs have been put out to address the node categorization issue. There are structural linkages between the items in many datasets used in different machine learning (ML) applications, and these interactions can be shown as graphs. Analysis of social and communication networks, traffic forecasting, and fraud detection are some of these applications. Graph illustration Building and training models for graph datasets to be used for a range of ML purposes is the goal of learning.

The proposed work shows a straightforward application of a Graph Neural Network (GNN) model. On the Cora dataset, the model is employed for a node prediction job to identify a paper's topic based on its words and network of citations.

The creation of novel medications (molecules) can be quite expensive and time-consuming. Applying deep learning models to predict the characteristics of known compounds helps speed up the search for effective medication candidates like solubility, toxicity, affinity to the target protein, etc. The space in which we look for and study molecules are only a small portion of the total space due to the astronomically large number of potential molecules.

II. LITERATURE SURVEY

[1]. The proposed system by Wang and others published in December 2021 suggests a new framework for merging feature and label propagation, we analyze several training techniques for deep GNNs, and we propose a robust loss function. These methods can be used with a variety of GNN models, typically requiring only minor adjustments to the architecture, loss function, and data processing.

[2]. The proposed system by Zhang and others focuses on Natural language processing (NLP) and relies heavily on text classification, a task to which Graph Neural Networks (GNN) has lately been put to use. However, neither the existing graph-based works nor the inductive learning of new words can fully capture the contextual word associations within each page. In this paper, we suggest using a GNN for inductive text categorization to solve such issues. The fine-grained word representations are then learned using a GNN based on the local structures of each text's unique graph. This technique can also successfully create embeddings for words that haven't been seen before in the new document. The document embedding is then completed using the word nodes. Extensive tests on four benchmark datasets demonstrate that our solution performs better than cutting-edge text classification techniques.

[3]. The proposed system by Ryu and others tells us that in numerous molecular applications, deep neural networks have outperformed current machine learning algorithms. Because of the uncertainty in predictions caused by inadequate training data in terms of quality and quantity, it is still challenging to make decisions confidently in practical applications. Here, using three numerical experiments, we demonstrate how Bayesian neural networks may be used to measure the uncertainty associated with predicting molecular properties. In particular, it allows us to break down the predicted variance into uncertainty produced by models and data, which clarifies where errors are coming from. We demonstrate that data noise had a more significant impact on the data-driven uncertainty compared to the model-driven uncertainties in the logP forecasts.

[4]. What Situations Require GNN for Node Classification? Instead of seeing the nodes as a collection of randomly distributed samples, Graph Neural Networks (GNNs) enhance basic Neural Networks by using graph structure based on the relational inductive bias. Through GNNs are thought to perform better than basic NNs at real-world tasks, it is known that in some situations, GNNs perform as poorly as graph-agnostic NNs. Two metrics that examine the situations in which the edge bias in features and labels does not offer advantages were presented by the authors to help identify these scenarios. So here basically the measures mentioned are based on the signal processing of graphs and also the hypothesis testing. Also for forecasting the performance advantages it may be based upon the metrics to determine the graph models and also the threshold value.

[5] This paper shows the significance of the estimation of nodes in a knowledge graph in GENI, a

technique for handling the issue of evaluating node importance in KGs, which is presented in this study.GENI enables applications of several downstream applications Several solutions have been created to deal with this issue for generic graphs, but they either don't properly make use of the data in KGs or don't have the flexibility needed to depict complicated relationships between entities and their importance. This paper investigates supervised machine-learning strategies to overcome these constraints.

III. FLOWCHART

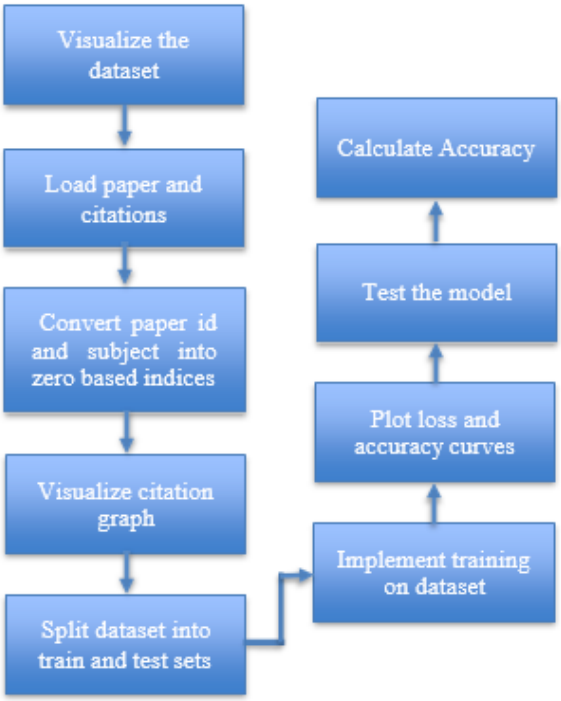

Fig.1: Flowchart of the proposed model

IV. METHODOLOGY

Dataset: So the dataset which we have chosen to train our model is the Cora dataset. The Cora dataset contains papers on 7 different subjects namely Rule Learning, Neural Networks, Probabilistic learning, Theory, Code based, Genetic Algorithm, and Reinforcement Learning. These 7 subjects are 7 classes of the dataset. The dataset in total contains 2708 scientific papersThe dataset also contains citations which have a total of 5429 links and also each paper has 1433 words. The cora dataset is being divided into two separate files namely cora.cites and cora.content. The cora.cites has the citations records and include records in two different columns of citing_paper_id which is the source and cited_paper_is which is the target. The cora.content has all the records of the paper with a total of 1435 columns. 1433 columns are of the words and the extra two columns are of the subject and paper_id respectively.

Algorithms:

1) GNN: Graph Neural Networks (GNNs) is a type of deep learning method that performs inference on graph-described data.They can be used in graphs to perform nodes, edge, graph level prediction tasks.GNNs is an advanced version of Convolutional neural network(CNNs) and can perform lot of application which are not possible with CNN. Nodes are defined by their neighbors and connection this is an assumption in GNN. Basically the connection and neighbors of a node is important information source in GNN. If any of this information was removed GNN won't be possible on such graph.As a result,the complete definition of nodes lies on both neighbors and connection.
Consider this, To represent the characteristic of the node we give a state (X) to the node.This state (X) of node can be used to predict a output(O). The Last state of node (X N) is known as"node embedding." Hence, GNN is used to determine nodes of a particular node.

2) GCN: So basically GCN is a type of Convolutional neural network that can work on graphs directly and takes advantage of their structural information. Most of the GNNs are GCNs. Convolutional in GCN is no different than convolution in convolutional neural networks. To learn form features from its neighboring cells it acts as sliding windows on the whole images. The filter uses weight sharing to learn different facial features in systems(image recognition) nad bring the same functionality to Graph Convolutional networks, where the model learns features from neighboring nodes. It is developed to work on non-euclidean data structures where the order of node edges varies, this is the major difference between GCN and CNN.

Types of GCNs:

i) Spatial GCNs: To learn from graphs it uses spatial features which are located in spatial space.

ii) Spectral GCNs: For information propagation along nodes, it uses the Eigen-decomposition of graph Laplacian matrix. The inspiration for these networks is taken from wave propagation in signals and systems.

The proposed system is an application of a Graph Neural Network. The application is Node classification using Graph Neural Networks in which the nodes are being classified using the GNNs. There are many proposed systems existing in which nodes were being classified using various algorithms and models like GCN etc but here in our proposed system, we make use of GNN to classify the nodes from the data provided.
Node Classification is basically composed of predicting the given information on the basis of given input by classifying the nodes. The dataset which we have used here is the dataset named 'Cora'. This dataset basically consists of 2708 papers on different subjects classified into seven classes. These classes are nothing but the subjects namely Neural networks, Rule learning, Genetic Algorithm, Reinforcement learning, CodeBased, Theory, and Probabilistic methods. The citation comprises 5429 links which is nothing but the edges. Each paper in the dataset has a vector size of 1433 which basically corresponds to words in the dataset. The dataset named Cora which we are using here in our proposed system has 2 separate files: 1)Cora. cites which include the citation record of the target and the source.

2)Cora. content which includes the records of the paper which has 1435 columns.

The first step to start the implementation of the model was to search for a relevant dataset which I found Cora to be. The system basically starts with downloading the dataset in our environment using the URL of the dataset. So after this, the next thing to do is to load the data and visualize the data and its contents present in the dataset. Here the citations are being loaded in the panda framework. Next, we display the citations in the Dataframe. The citations table basically includes the target and the source. The target column contains the paper ids that are being cited by the paper ids which are present in the source column of the citations table. The next thing to be done is to load the data of papers in the data frame. Similarly, as for citations the sample of papers also needs to be displayed in the data frame which includes the paper id and also the subject columns and also displays whether a term exists or not in the respective papers.

```

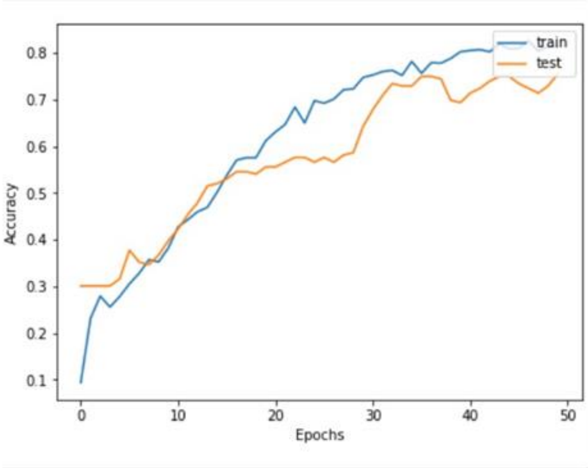
Fig.2: Sample of paper Dataframe

Next is to count the number of papers for each subject and display the count

```
Neural_Networks            818
Probabilistic_Methods      426
Genetic_Algorithms         418
Theory                     351
Case_Based                 298
Reinforcement_Learning     217
Rule_Learning              180
Name: subject, dtype: int64
```

After displaying the count of papers the data need to be converted into zero-based indices. Then comes the plotting of the citation graph and visualizing it.



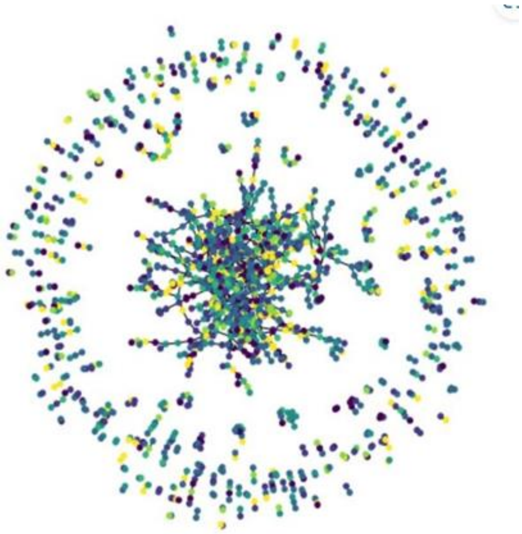


Fig.3: Visualization of citatioNS

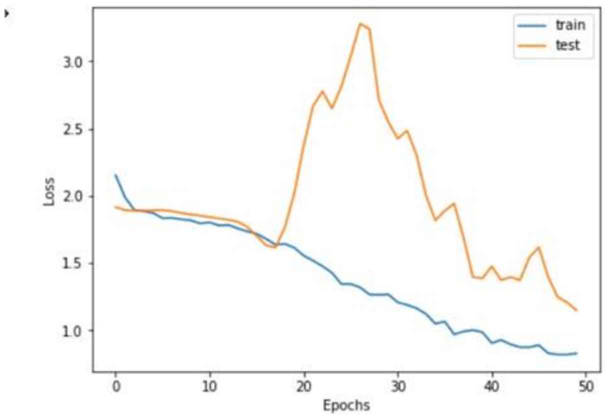
Every node in the figure represents a paper and



different colors are for different subjects. Then the data is split into the training data and the testing data and also the size of both sets is displayed. Train the input model and display the accuracy curves along with loss curves.

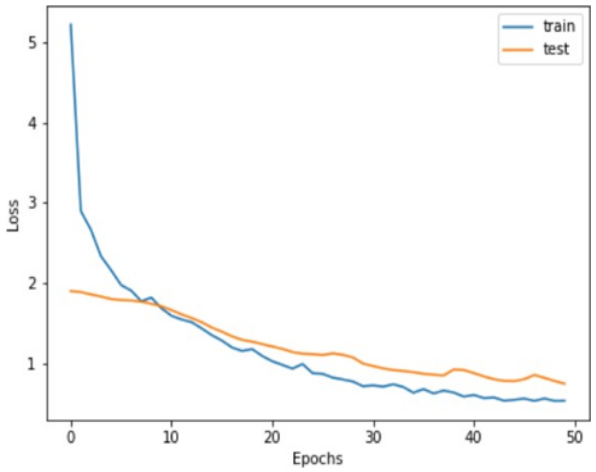


Fig.4: Accuracy and Loss curves of the baseline model

The existing model contained the baseline neural a network model for training the data. So here we used GNN for our proposed system for training our model. In the Baseline NN model, there is a need to implement a baseline classifier in which there are five FFNs i.e. the FeedForward networks along with the skip connections. Plot the curves of the baseline NN model. Lastly, examine the model. As a result instances of the probability of word presence are displayed. The test accuracy calculated of the Baseline model is calculated to be 73.52%. The next step is to build a Graph Neural Network. So first prepare the data. Here, words are the node features and citations are the edges of the links we can say of the dataset. Next prepare, aggregate and update the layers of GNN. Then implement a GNN Node classifier. Train the GNN model for around 250 epochs. Plot the curve.

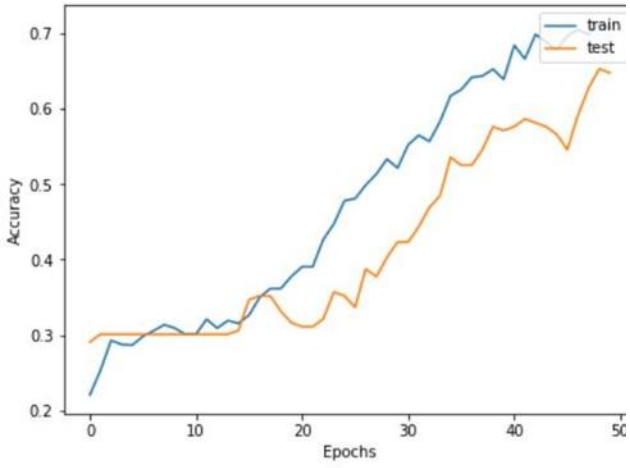

Fig.5: Accuracy and loss curves of the GNN model

Lastly, examine the predictions of the GNN model. The test accuracy being calculated is 84.6%.

V. Result and analysis

So here we randomly took the words from the dataset and generated the instances of the probabilities of the words present in the dataset for each subject. And finally using the baseline model the predictions were as below

```
1/1 [==============================] - 1s 1s/step
Instance 1:

Fig.7: Predictions based on the GNN model

VI. Conclusion

As a result, we draw the conclusion that the GNN model performs better than the baseline model and that its predictions or probabilities are higher. In the topic articles, certain citations were inserted using GNN.

This paper also illustrates the use of GNN for node classification. It includes educating the GNN to forecastnode labels based on their neighborhood structure. The adjacency matrix and node characteristics are used to conditionally define the GNN model. There are structural linkages between the elements in many datasets used in various machine learning applications, and these interactions can be shown as graphs. Applications include traffic forecasting, fraud detection, and social and communication network analysis. Building and training models for graph datasets that may be used for machine learning tasks is the main objective of Graph Representation Learning

I. INTRODUCTION

A digital environment where cross-platform, external cloud services are used to transport every informational detail from one smart device to another. Smart technologies, including smartphones, are playing vital roles in completing daily tasks and official assignments that call for access to many crucial data kinds. There are several research that suggest and develop various authentication and security techniques for Smartphone and cloud computing technologies. Multiple authentication threats and other applicable problems with contemporary smartphone and cloud computing technology have been efficiently solved by using those investigations [1]. The CCS dynamically arranges servers and VMs to function several services, with each provider being broken down into a number of duties which might be done on VMs simultaneously. Although parallel execution and dynamic organization permit the CCS to deliver services efficiently, they also pose a severe threat to CCS security. As a result of the CCS being virtualized, VM security has emerged as a new security component that was absent from the conventional system. Similar elements of VM security include the isolation of distinct VMs and the simultaneous failure of co-located VMs because of an assault on the host server [2].Cloud computing and Software-Defined Networks (SDN) have attracted a lot of interest from both academics and business. The network control plane and data plane are separated by SDN. A control programme may quickly identify the real-time network status and configure high-level state approaches. The advancement of network functions is streamlined by the controller's centralization [3]. The core data plane in SDN can be effectively controlled through network programmability. The essential framework of SDN architecture is focused on applications and network services while network control is decoupled from forwarding capabilities and made programmable. SDN has made significant contributions to the networking paradigm for cloud computing [4]. Threats to data security are frequently used to describe data security. Because it is vulnerable to several dangers, the site of cloud computing is not exceptional. The main cause used for that cloud computation operates by fusing a variety of unique technologies. It is crucial to employ the threat

control procedure to stabilise the advantages of safety risks and cloud computing. Reporting, designing, and implementing the management of patron security and internal security controls is the responsibility of the CSP [5].

II. BACKGROUND

To show where the study is currently going, these authentication difficulties are further summarised and displayed in the form of several graphs. Finally, using those findings as a basis, the author highlights the most recent and current authentication uncertainties, dangers, and other relevant concerns to address outstanding research questions and future directions in authentication for smartphones and cloud computing [1]. This study suggests a correlation metric for measuring the effectiveness of random services. This correlation statistic is more accurate and realistic since it fully accounts for the impact of security considerations. The experimental findings illustrate the significant S-P correlation and the dynamic change in performance brought on by security considerations. Security must therefore be included while modelling and evaluating the QoS metric [2].

This paper proposes a novel methodology for trust assessment of cloud service security and reputation. The security of a cloud service is assessed using the security metrics that are specific to clouds using the security-based trust evaluation approach. Additionally, the reputation-based trust evaluation method uses feedback ratings on cloud service quality to analyse a cloud service's reputation. The proposed trust assessment methodology may more effectively and efficiently evaluate the trustworthiness of a cloud service than current trust assessment approaches, according to tests utilising a real-world author service dataset and a synthesised dataset of security measures [3]. A thorough investigation on DDoS assaults in SDN and cloud computing settings was done by the author of this research. The author considers DDOS attacks in the context of SDN and cloud computing as far as their characteristics go, and they are examined in terms of new patterns and characteristics in distributed

computing and SDN. The author then provides a thorough analysis of the defences against these attacks [4]. In this paper, the author provides a verification method that is mostly based on the concepts of BFT and blockchain technology to overcome those current issues. These CSPs are no longer required to work together or exchange information. These grab hash values can be examined by a customer to determine whether data manipulation has occurred [5].

III. PREVIOUS WORK DONE

To identify current authentication dangers and issues in the literature, the suggested technique undertook an extensive security analysis and assessment of major Smartphone and cloud computing authentication frameworks and protocols. To show where the study is currently going, these authentication difficulties are further summarised and displayed in the form of several graphs. Finally, using those findings as a basis, the author highlights the most recent and current authentication uncertainties, dangers, and other relevant concerns to address outstanding research questions and future directions in authentication for smartphones and cloud computing [1]. This study suggests a correlation metric for measuring the effectiveness of random services. This correlation statistic is more accurate and realistic since it fully accounts for the impact of security considerations. The experimental findings illustrate the significant S-P correlation and the dynamic change in performance brought on by security considerations. Security must therefore be included while modelling and evaluating the QoS metric [2]. In this paper, the author triumph over those existing troubles by providing a verification scheme primarily based on the notions of BFT and blockchain technology. More than one CSP will be hired to save and perform computations on client information. Each CSP will need to periodically compute a grasp hash fee in their database to be stored on a public blockchain consisting of Bitcoin or Ethereum. These CSPs no longer need to collaborate or communicate with one another [5].

IV. EXISTING WORK DONE

Only a broad overview of the security model is given. The absence of any user-defined authentication roles in this framework posed the biggest authentication problem. Furthermore, the framework is dependent on external suppliers for brand-new services, and no external authentication

scenarios are covered. Artificial neural networks are used to introduce a mobile biometric cloud framework. The presentation of a sophisticated mobile-based credential protocol [1]. STRAF is a brand-new methodology for evaluating trust in cloud services that is based on reputation and security. This framework, which is an expansion of the earlier work, may be broken down into three primary parts that collectively comprise [3].

Fundamentally, Mininet has been at the forefront of cutting-edge development and testing of novel controller applications. Mininet is used by some scientists as simulation equipment for lab tests. Each connected hub (switch, have, controller) in Mininet continues to function as a light-authority virtual computer. With the intention of only accessing the assets within its namespace, the virtual machine continues to run in its own Linux component namespace. Since it provides excellent authenticity and constant change from development to deployment, analysts have generally embraced it. These existing approaches are enhanced and developed by the simulation- based approach known as fs-sdn [4].

The multi-CSPs, BC-application, and client— whose functions are described below—will make up the three key components of the verification process, which correspond to the three main phases of the proposed verification method [5].

V. ANALYSIS AND DISCUSSION

The introduction of smartphones has eliminated the need for smartcards in several fields. In contemporary Smartphones like the iPhone and Samsung mobiles, Authentication is weak and is easily compromised via several breaches [1].

Results were obtained by way of analysing the primary and second experiments. The following optimization guidelines approximately balancing the safety and the carrier performance now are proposed.1) When the variety of to be had res theses (such as the CPU and the range of VMs) is restricted in CCS, and writer-depth safety mechanism may also convey a higher carrier overall performance.2) Deploying more VMs improves the service performance faster than enhancing the CPU processing creator of every VM. Three) To concurrently improve the safety and the service performance, making use of a writer CPU with an excessive processing creator is better than deploying more VMs [2]. The method outperforms the opposite strategies, whilst the percentage of malicious remarks rating increases. As predicted, the above experimental consequences suggest that the STRAF combining the security-primarily based accept as true with evaluation technique and the reputation-primarily based believe evaluation technique is indeed beneficial in improving the consider assessment of cloud services [3].Traditional networking devices determine the way to deal with an incoming packet primarily based on its IP destination deal with, however SDN pursues a float-based totally forwarding approach in which many header fields decide a way to take care of the approaching package. The idea of a centralised network manipulate plane is followed via SDN, and programmability is introduced. This can simplify community control and give the chance to organise protection methods at runtime. In this technique, SDN may respond quickly to malicious traffic and community irregularities [4]. The master hash for each CSP's database must be produced, and it is then kept on the BC. Clients will receive the block header for use in verification. The malicious CSP will be identified when

the client checks the master hash values of each CSP since its hash value will be different from the others. As a result, customer data is not altered or destroyed without authorization or detection [5].

VI. PROPOSED METHOD

A handwriting authentication system confirms the user's identification based on his biometric features to ensure secure access to cloud services. An application that serves as a conduit between the cloud and the mobile user is created on the client side. It is used to gather and encrypt biometric information (such as a handwritten password) in preparation for sending it to the cloud. The touch screen of the smartphone is used by the mobile user to enter his password. As a result, in addition to using his right password, the person can also be recognised by his distinctive handwriting. It is vital to encrypt the biometric data before it is delivered to the cloud to guarantee data security and privacy when using cloud services.

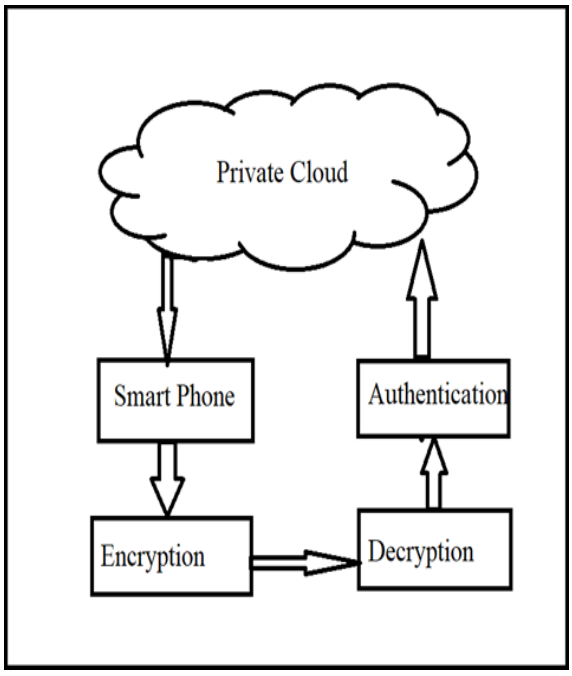

Figure 1: Proposed Method

A.Pre-processing

The new image should be pre-processed before feature extraction because the input image comprises characters of various sizes and spacing.

B.Features Extraction

This module analyses and extracts the characteristics of handwritten characters for use in training and verification. It is a crucial phase since its efficient operation raises the verification rate and lowers misclassification. Handwritten digits can be used to extract two different sorts of information. Binary digit images are used to derive pixel density information. Each digit image is split into nine identically sized windows. Individual zones are the focus of feature extraction rather than the entire image. As a result, it provides greater details regarding the skeleton of the digits. To create the feature vector, the density of black pixels for each zone is calculated. For the remaining digit images, the same procedure is followed.

C. Classifier Process

The feature extractor's feature vectors are used by the classifier process to confirm the user's identification. Two inputs are needed for this verification: a real text test and an optional claimed human identity. After pre-processing and feature extraction on the written data, the system will compare the real feature values to those in the reference database before returning a result set.

VII. RESULT

The overall classification rate and error rate are the most typical metrics for classifier performance. A case's overall classification rate, also known as the recognition rate, is calculated as the proportion of cases that are correctly classified to all cases. A weight voting rule and decision-making system achieves a higher recognition rate than a majority voting rule. The primary cause is that the majority vote rule provides all classifiers 329 identical weights without taking performance accuracy differences into account. Figures 2 to 4 shows off the results of the overall performance evaluation, implementation evaluation, and validation evaluation from the related works, however. Whereas Figure 3 demonstrates the implementation problems that 94% of the authentication techniques have. Figure 4 shows how practically all authentication strategies fall short of adequately validating and verifying their security claims.

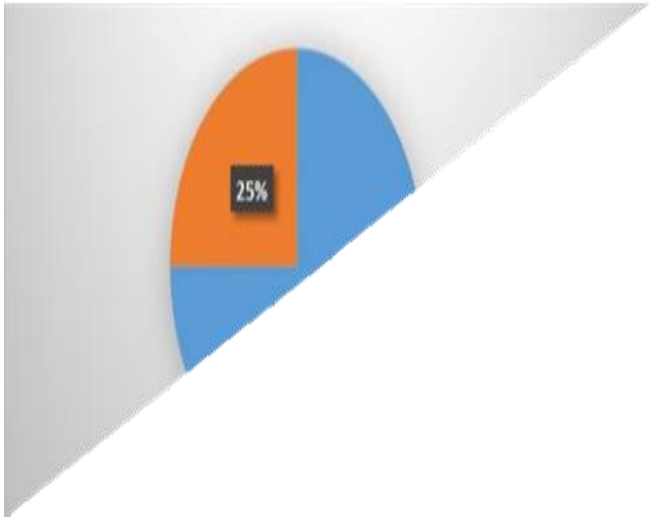

Figure 2: Performance Analysis

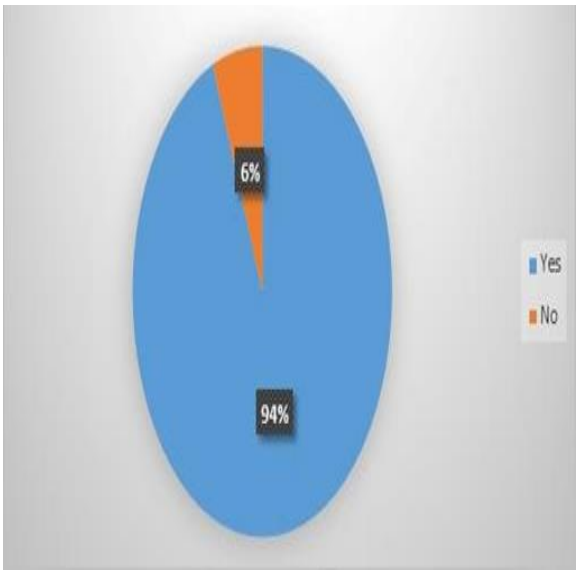

Figure 3: Implementation Analysis

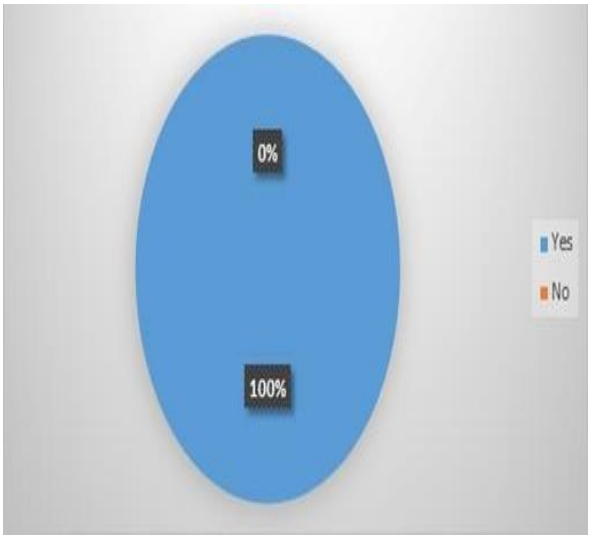

Figure 4: Validation Analysis

VIII. CONCLUSION

In this contribution, a handwriting authentication device has been introduced. The manner permits comfortable get entry to to confined facts in the cloud the use of a cell telephone. It is composed of pre-processing, characteristic extraction, type, and authentication procedure. The classification procedure is primarily based on 3 one-of-a-kind classification strategies: ANN, KNN, and Euclidean Distance classifier. The classifier set of rules employs a parallel combination of classifiers to obtain first-rate accuracy on both recognition and errors charges.

IX. FUTURE SCOPE

The underlined protection uncertainties, assaults, and future directions in existing smartphones and CC authentication frameworks have added a broader view and cognizance of the modern trendy within the domain in addition to their practicality for implementation. Finally, this safety evaluation is anticipated to open similarly studies possibilities as part of future work to deal with the concerns raised in the area of Smartphone and CC authentication frameworks and protocols.

Abstract – **This compilation describes the various Complex network analytical techniques to detect fraud on a healthcare network. These tactics can be used by admins for surveillance and detection of crime. A motif is a small, organized structure within a network that repeatedly, appears in a network. The second part focusses on using various Network Motifs like feedback loop, clique motifs, rogue nodes and to detect fraudulent activities. These strategies are illustrated using a few simplified fraud-detecting Python programs using NetworkX.**

Keyword:-: networks in healthcare, network analysis, network motifs, fraud detection, machine learning, complex network analysis, python, networkx.

I. INTRODUCTION

Fraud detection using network analysis is an important tool for detecting potential financial fraud cases. The method considers the links between the entities in a data set and uses pattern recognition techniques to identify any irregularities that may point to fraudulent activity. By using both qualitative and quantitative measures, fraud supervisors can identify which accounts are connected to each other and po- tentially linked with fraudulent behavior patterns. Moreover, this technique helps uncover suspicious relationships between money transfers, client profiles, service providers, locations and payment methods that may indicate a fraudulent case. Overall, this method of fraud detection aids investigators in identifying new sus- pects as well as protecting companies from existing threats in a much more effi- cient manner compared to traditional methods [1].

II. COMPLEX NETWORK ANALYTICS TO DETECT FRAUD

To find fraud on a network, several techniques can be applied. Many typical tac- tics include:

Anomaly detection. Finding unexpected rhythms of activity or transactions that can point to deception is known as anomaly detection [2].

Link analysis. Link analysis entails examining the relationships between people or things in a network to find trends that might be a sign of fraud. Link analysis is a method for examining the connections among the items in a network. By exam- ining patterns of linkages between network entities and recognising unusual or suspect patterns, it can be used to detect fraudulent behaviour on a network. Either physical labour or specialist software tools can be used to do this. This may entail the need to collect and analyse data on the links between entities in the network, such as communication records, financial transactions, and other sorts of data, to do a link analysis for the aim of identifying fraud on a network. Afterward, this in- formation can be used to produce graphic depictions of the connections between items, like graphs or network diagrams. Suspicious links are those that exhibit, unusually high or low engagement levels between specific nodes, or unexpected or strange relationships between nodes, or resource flows between communities that are out of proportion and (deceitful) nodal behaviour patterns or transactions that recur over time [3,4].

NetworkX for link analysis.

The structure and characteristics of the network can then be examined using a range of NetworkX functions and techniques. The fol- lowing are a few examples of connection analysis tasks that NetworkX can carry out: examining the network's connectedness, such as by finding the shortest route between nodes or figuring out which nodes are most connected to other nodes finding anomalies or odd patterns in the network, for example, by contrasting the observed network attributes with those of a random network With NetworkX, you can carry out a wide range of additional link analysis tasks. The techniques and algorithms employed will depend on the demands of the analysis [5, 6].

Social netork analysis.

Social network analysis entails looking at the connec- tions between people or things in a social network to spot any trends that might point to fraudulent behaviour [7].

III. MACHINE LEARNING ALGORITHMS TO DETECT FRAUD.

Machine learning is the process of applying algorithms to examine network data and spot trends that might be signs of fraud. For spotting network fraud, machine learning can be a useful technique. Machine learning algorithms can learn to recognise patterns that can be predictive of future fraudulent behaviour by studying data from previous fraudulent behav- iour. Then, for further examination, these algorithms can be utilised to highlight possibly fraudulent transactions or behaviour. For detecting fraud on a network, numerous alternative machine learning techniques can be applied. Typical exam- ples include:

1.Decision trees algorithms build models using a succession of decisions, with each branch of the tree denoting a potential result.

2.Neural network algorithms that draw their design cues from the structure and operation of the human brain.

They excel at finding patterns in data.

3.Support Vector Machines (SVMs) which are frequently used for classifica- tion problems, define a border between several classes of data.

It is crucial to remember that no single machine learning method is suitable for uncovering every kind of fraud on a network. Instead, a sagacious combination of algorithms might be required to accurately detect and stop fraud [8].

IV. MEASURES OF CENTRALITY IN NETWORK ANALYTICS

The various measure of centrality of a vertex or node provides information on the role and relative weight of a node relative other nodes in a complex network. The following are measures of centrality.

Betweenness Centrality. A graph's vertex's centrality is determined by its be- tweenness centrality. It is determined by counting how many shortest routes exist between each vertex and every other vertex. Because it resides on numerous shortest paths, a vertex with high betweenness centrality has a significant impact on the flow of information or resources through the graph. Think of a graph of cit- ies connected by roads as an illustration. Since many road journeys pass through a city that is situated on a key transportation route between other cities, its between- ness centrality may be high. Both directed and undirected graphs can calculate be- tweenness centrality [9].

Node strength centrality. Node strength centrality, which is based on the quanti- ty and weight of a node's connections to other nodes, is a measure of a node's significance in a network used in complex network analysis. It is described as the to- tal of all edge weights occurring to the node. It is possible to determine the node strength centrality for both directed and undirected graphs. With many connec- tions to other nodes and/or connections with high weight, a node with a high strength centrality score has many connections overall. This trait can be helpful in several applications, such as locating crucial infrastructure in a transportation net- work or recognising essential nodes in a social network [9].

Clustering centrality. Clustering centrality is a measure of a node's centrality in a graph used in Complex network analysis that is based on how closely related those nodes are to one another. It is described as the percentage of neighbouring pair connections between the nodes. It is possible to determine clustering centrality for both directed and undirected graphs. With numerous neighbours who are connect- ed to one another and a high clustering centrality score, a node is well-connected to the other nodes in the graph. Applications for this trait include locating communities inside a network or recognising important nodes in social networks [10].

Proximity Centrality of a Node. According to Complex network analysis, the proximity centrality of a node in a graph is determined by the average length of the shortest paths connecting it to every other node in the graph. It is described as equal to the reciprocal of the total of the distances between each node in the graph. Graphs that are directed or undirected can both have their closeness centrality computed. A node that has a high proximity centrality score is well-connected to other nodes and has many short pathways to them. This trait can be helpful in sev- eral applications, such as locating crucial infrastructure in a transportation network or recognising essential nodes in a social network [10].

V. Network Motifs in Networks to detect fraudulent activities

A motif is a small, organized structure within a network that repeatedly, appears in a network. A motif in graph analysis is a brief subgraph that reappears regularly in a larger graph. Motifs can be used to locate structures and patterns within a graph and to shed light on the connections and interactions between its constituent parts. An illustration of a prevalent pattern in a social network graph would be a trio of individuals linked together by friendships. Finding and examining motifs can as- sist scholars in comprehending a graph's fundamental structure and operation. Dy- ads (2 vertices) and triads (3 vertices) are examples of small subgraphs or motifs that are made up of a collection of nodes and links between them [11].

Network motifs are connectivity patterns that show up in a network more fre- quently than would be predicted by chance. In the investigation of complex sys- tems, such as social and biological networks, they are frequently employed. Net- work motifs may be utilised in crime analysis to spot linkages or patterns of behaviour among people or groups that might be involved in criminal activities. There is a chance that some network motifs are more common in fraudulent net- works than in genuine ones. For instance, in a fraud network where the central "hub" character is orchestrating the fraudulent activities while others are taking part, a motif with several people who are all related to one another may be more likely to arise [11]. Building a network that represents the connections or interactions between people or groups suspected of engaging in criminal conduct is one method of employing network motifs for crime analysis. The network might be built using data from phone records, social media interactions, or other kinds of association or commu- nication data. Comparing the motifs found in the network to those found in other networks or to recognised patterns of criminal activity is another method for eval- uating network motifs for crime analysis. For instance, it may indicate that a motif is significant in the context of drug trafficking networks if a network of people suspected of being involved in drug trafficking displays a specific sort of theme that has been seen in other networks of drug traffickers. Using algorithms, it is possible to find network motifs in the data after the network has been built [12].

Comparing the network motifs to a null model, a fictitious network produced by a random process that retains some aspects of the actual network (such the number of nodes and edges) but eliminates any innate structure or patterns, is one tech- nique to study the network motifs. It may indicate that patterns are significant in the context of the network under study if they appear more frequently in the real- world network [11].

For instance, it may indicate that a motif is significant in the context of drug traf- ficking networks if a network of people suspected of being involved in drug traf- ficking displays a specific sort of theme that has been seen in other networks of drug traffickers. It is important to keep in mind that network motifs are just one tool that may be utilised in the study of complex systems; to provide a more thor- ough knowledge of the system being investigated, they should be used in conjunc- tion with other techniques and information sources [12].

By locating patterns of behaviour or connections between people or entities en- gaged in fraudulent activities, network motifs can be utilised to detect fraud. Based on information from records like bank statements, credit card statements, or other financial records, for instance, a network reflecting financial transactions might be built. To find anomalies or patterns that might point to fraudulent activi- ty, algorithms could be used to identify network motifs within the data [12]. These motifs could then be compared to known patterns of fraudulent behaviour.

Clique motif.

A group of nodes in a network that are all linked to one another is referred to as a clique. This is a collection of interconnected nodes, is another form of network motif that could be helpful in the identification of fraud. This trend can point to a network of people or organizations that are conspiring to per- petrate fraud.

An example of a clique motif in network analysis is a collection of three or more connected nodes that together make up a whole subgraph. Because they can pro- vide light on a network's structural characteristics and the ways in which various groups of nodes interact with one another, clique motifs are frequently explored in network research. For instance, the presence of clique patterns in a network may be a sign of close-knit communities or the emergence of alliances between various node groupings. Clique motifs can occasionally be used to pinpoint certain pivotal roles in a network including fraud perpetuation.

For instance, nodes that belong to several cliques may be thought of as playing a "hub" role in the network, bridging several communities. Similarly, this, nodes with limited connections to other nodes in the network are said to be "peripheral" if they only belong to one clique [11].

Rogue node motif. A vertex or device connected to a network but not connected to any other nodes is referred to as a rogue node. A rogue node is of zero degree as it has no edges connecting it to other parts of the network. These nodes could end up being exploited to carry out harmful tasks like hacking, virus distribution, or other types of criminality, which could endanger the network's security. Using network modelling and simulation tools is one way to examine how rogue nodes affect a network. With the help of these tools, admins can develop virtual repre- sentations of the network and test various scenarios to determine how they can impact its performance and security. Users may be more susceptible to attack from rogue nodes, for instance, if they click on links in questionable emails and do not manage their passwords according to recommended standards [12].

Feedback loop motif. A feedback loop is a loop or circular edge that begins and finishes at the same node in a graph. The "feedback loop" is a pattern in which a node in the network has both inbounded and outgoing connections to the same other node, is one form of network motif that might be particularly pertinent in the context of fraud detection [13].

Feedback loops can be used to detect network anomalies by observing the behav- ior of the network over time. Feedback loops measure the input and output of the network and compare them to a predefined baseline. If the output deviates from the baseline, it could indicate an anomaly. Additionally, feedback loops can be used to detect anomalies in traffic patterns, as they can observe the time between successive packets and measure the rate of change in the data. By monitoring the data over time, feedback loops can identify any sudden or unexpected changes that could indicate an anomaly [14].This pattern might point to a plan in which one party assumes several identities to scam others. Feedback loops are common in many biological networks and play vital role in maintenance of Network state, a typical example is ‘circadian rhythm,’ or 24-hour periodic sleep wake cycle of Drosophila which is driven by a positive feedback loop between accumulation and degradation of 2 proteins name- ly: Per, and Tim. These loops are concerned with all or none decision making in biological networks, for example in the above case a fruit-fly cell cannot be awake and sleep at the same time [14].Feedback loops in Complex network analysis are used to examine the interactions between two or more components of a system. A feedback loop is a process in which the output of a system is fed back as input into the same system. In complex analysis, feedback loops can help identify emerging patterns and trends, as well as uncover hidden relationships between variables. Feedback loops can also be used to identify potential problems with a system, such as a lack of efficiency or an un- expected increase or decrease in output [15].

VI. NetworkX Python Module for Complex Network Analysis

NetworkX is a Python library for analysing complex networks and graph algorithms. It offers numerous tools and techniques for network analysis and can be applied

to link analysis. It can be used to detect fraud by analysing the network structure of a system. NetworkX can be used to identify clusters of nodes that are connected to each other or to other nodes in the network. It can also detect anomalies by comparing the structure of the current network to that of a baseline network. Additionally, NetworkX can be used to detect patterns of fraudulent activity by analysing the connections between nodes and the flow of data within the network. NetworkX is optional module available via PyPi channel, which provides Complex network analysis capabilities in Python 3.5 and above. This module must be installed via python package manager pip (python –m pip – install networkx or just pip –install networkx). The "simple_cycle" is a NetworkX method can also be used to locate every feedback loop in a graph. A self-loop, or cycle that connects a node to itself, can be detected using NetworkX. This method

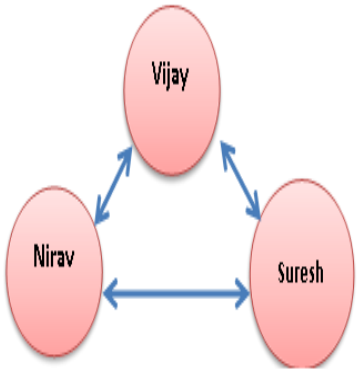

Fig. 1. Feedback Loops in Criminal network of 3 persons Vijay, Suresh, and Nirav. The feedback loops are self-propagating, like so Nirav bribes the bank official who in turn bribes the auditor Vijay who gives a "cut" of his income back to "Nirav". Thus, the criminal network grows in

Another loop method called as nx.simple_cycles module can be used to determine whether a graph contains a feedback loop [17]. If at least one feedback loop is pre- sent in the graph, this method returns True; otherwise, it returns False.

```
# Modules networkx, matplotlib, numpy and PySimpleGUI have to be installed
via pip pip -install networkx

import networkx as nx
import matplotlib.pyplot as plt
import PySimpleGUI as sg
sg.theme("material 2")

# Create a graph with multiple feedback loops
G = nx.DiGraph()

G.add_edge('Vijay', 'Suresh')
G.add_edge('Suresh', 'Nirav')
G.add_edge('Nirav', 'Vijay')

# Find all the feedback loops in the graph and show them to user via Popup
box

for loop in nx.simple_cycles(G):
   sg.popup(loop, title="feedback loops in the graph by simple_cycles",
auto_close=15)

# Create figure and plot for preparation
fig = plt.figure(figsize=(20,10))

# Create the Options dictionary for plotting
options = {'node_color': 'yellow','node_size': 700,'alpha':0.9,'width': 1,
    'edge_color':'red',}

# Plot the network using Kamada Kawai layout algorithm
```

```
# Modules networkx, matplotlib, numpy and PySimpleGUI have to be
installed via pip pip -install networkx

import networkx as nx
import matplotlib.pyplot as plt
import PySimpleGUI as sg
sg.theme("material 2")

edges = [('Home', 'Home'), ('Home', 'Office'),('Office','Home'), (
'Club','Home'), ('Home','Club'), ('Club', 'Home'), ('Club', 'Office'),
('Club', 'Club'),('Farm','Home'),('School','Home'),('Farm','Farm')]
#Create a directed graph

G = nx.DiGraph(edges)
#Detects loops in Original Orientation they appear in the graph
sg.popup(nx.find_cycle(G, orientation="original"))

#Detects loops in but ignore the Orientation they appear in the graph
sg.popup(list(nx.find_cycle(G, orientation="ignore")))

# Create figure and plot for preparation
fig = plt.figure(figsize=(20,10))

# Create the Options dictionary for plotting
options = {'node_color': 'yellow','node_size':
700,'alpha':0.9,'width': 1,
```

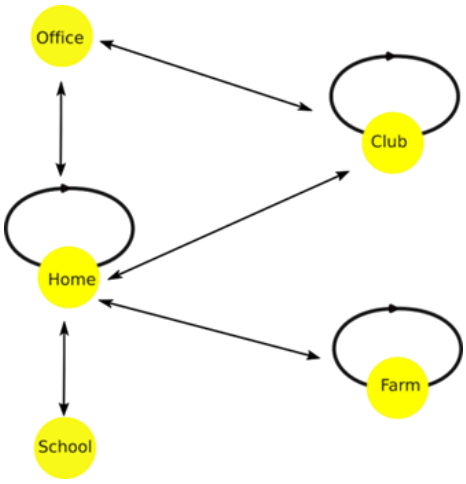

Fig. 2. Another example of Feedback Loops detection in Python NetworkX. This time Orientation of the loops is also considered and ignored by command nx.find_cycle (G, orientation="original")). It can be observed that Home, Club, and farm have self-loops, in addition Home, Club and Office nodes form a loop. NetworkX can greatly simplify a variety of Complex network analytical tasks

VII. .CONCLUSION

As a summary, the use of network science and machine learning can be a powerful tool in the fight against healthcare fraud, helping to identify and prevent fraudu- lent activity and ensure that healthcare resources are used efficiently and effective- ly.

Virtual Machine Load Balancing using Improved ABC for Task Scheduling in Cloud Computing

Hanuman Reddy N, Amit Lathigara, Rajanikanth Aluvalu, Uma Maheswari Viswanadhula4

R K University, Rajkot, IndiaChaitanya Bharathi Institute of Technology, Hyderabad, India

KG Reddy College of Engineering and Technology, Hyderabad, India

Abstract – **Computing resources are now more accessible, powerful, and inexpensive than ever before thanks to the widespread adoption of the Internet and rapid advancements in processing and storage technology. Thanks to this development in expertise, a new kind of computing architecture known as "cloud computing" is now a practical reality. Load balancing task scheduling is an essential issue that has a direct impact on resource utilisation in cloud settings. One of the most important goals of scheduling is to distribute work among virtual machines in such a way that no individual machine is overburdened or underutilised. Considering load balancing scheduling is crucial because of the importance it has on the backend and frontend of the cloud research sector. Any time a cloud environment is able to effectively balance its load, resource utilisation improves. The challenge with load balancing in the cloud is that it is an NP-hard optimization delinquent. To solve this issue, this research suggests a method that combines a heuristic scheduling algorithm with an artificial bee colony; this method is referred to as enhanced Artificial Bee Colony for Task Scheduling (IABC-TS). For better cloud computing scheduling of virtual machines in both homogeneous and heterogeneous contexts, this approach is used. The goal of its implementation was to shorten makespan and distribute weight more evenly. The IABC-TS cloud computing system's scheduling performance was measured against that of competing swarm intelligence techniques. In our lab tests, we used CloudSim to simulate systems with various augmentation techniques to examine their makespan and load balancing ability. Based on the results of the experiments, it is clear that the suggested IABC-TS outperformed the baseline models.**

Keywords: Load balancing; Virtual machines; Improved Artificial Bee Colony; Task Scheduling; CloudSim; Resource utilization.

I. INTRODUCTION

One of the most cutting-edge technologies of our day is cloud computing, in which tens of thousands of computers work together to store and process data and programmes that users access via the internet. Cloud computing combines distributed and parallel computing to enable, and data stored on remote devices. When looking at cloud services from the perspective of programmers, we may classify them into three classes: IaaS, Platform as a Service, and Software as a Service. To run services with virtualization technology, users can take advantage of the cloud provider's infrastructure as a service [2]. High-level services can be developed using the software layer offered by the platform as a service. Cloud application creation, testing, and hosting are all simplified with the aid of this platform. (SaaS) refers to the delivery model in which consumers obtain the necessary programmes via remote access, or the cloud [3].

Software as a service is one of the most popular cloud services because it allows customers to quickly and easily deploy applications via the internet. The previous methods of using software, such as installing it on the computer that needs it, have been rendered obsolete by this new level, which removes the restrictions that previously hindered the installation of substantial software or the provision of software for the users. When users need access to shared resources, the cloud's servers in the data centre make those resources available [5-6]. Renting virtual machines from cloud providers allows multimedia application developers to offer their customers a wider range of features and functionality. Here, subscribers can ask for and get their preferred apps sent straight from the service provider [7].

Through the use of task scheduling, users' workloads can be distributed across multiple virtual computers. Ideally, a customer-focused scheduling algorithm would have the virtual machine do the customer's specified activities in the least amount of time possible [8]. Instead, the service provider needs a scheduler that can make the most of available resources while keeping customers happy. The onus is now on the service provider to choose an appropriate technique of job scheduling [9, 10]. Load balancing is an essential part of scheduling tasks in the cloud. In order to enhance efficiency and throughput, load balancing spreads work over multiple servers. Because of this, we may decrease waiting time and maximise virtual machine utilisation by employing an appropriate load balancing algorithm to avoid load redundancy and scarcity in certain of the serves [11].

In order to solve the task scheduling issue, many different approaches have been offered, each of which attempts to balance a different set of user and service provider requirements. Load balancing across virtual machines is a crucial part of the methods in [12], which address the scheduling problem. Different from earlier works, the proposed method not only aims to improve load balancing but also to present a dynamic multi objective solution for job scheduling on virtual machines [13]. The goals of the proposed strategy are as follows:

First, enhancing the degree to which virtual machines load balance. Making it last less time

Strengthening the system's dependability, third.

Four, maximise u se of existing assets

A scheduling mechanism for distributing work among virtual machines is developed to achieve these aims. To reduce unnecessary work [14], the suggested system assigns tasks to the most suitable virtual machines. After

a task has been assigned to a virtual machine, the suggested method can make predictions about its future state. By preventing any further work from being assigned to that computer, the suggested strategy achieves load balancing among virtual machines. The proposed solution both shortens makespan and improves load distribution. However, the proposed approach monitors the current status of each virtual machine's job execution to increase the system's dependability [15, 16]. This technique chooses VMs with a history of stability and gets rid of VMs that are underperforming. In other words, the node's recent failure rate makes it less likely to accept jobs compared to nodes with better reliability. The simulation findings suggest that compared to previous research, the proposed strategy increases reliability, minimises waiting time, and improves average makespan. As a whole, the proposed method is an improvement above the prior literature because:

Improving the consistency of job scheduling using virtual machines' historical data increasing virtual machine load balancing Taking into explanation both the QoS for the end user and the requirements of the service provider. The remaining sections of this work are laid out as follows. In the following section, we'll examine several complementary works. The proposed algorithm and its mathematical model are presented and discussed in Section 3. The results of the simulations and evaluations are presented in Section 4, while the deductions and suggestions for further research are provided in Section 5..

II. .RELATED WORKS

Recently, a new Credit-Based Resource Aware Balancing Scheduling method (CB-RALB- SA) was introduced by Narwal and Dhingra [17]. Using the FILL and SPILL purposes of Resource Aware and Load with the Honey bee optimization heuristic method, we map the tasks weighted by the credit-based scheduling procedure to the resources, taking into account the load and computational capability of each resource. It has been shown through experimental evaluations and results that the suggested method improves upon the existing CBSA-LB algorithm by 16.90% in makespan time and 48.5% in processing time. Thus, it boosts overall system speed, as well as the performance of individual processes, and saves memory that was previously dedicated to RAM.

A Multi objective trust aware scheduler was developed by Mangalampalli et al. [18], which prioritises jobs and virtual machines (VMs) and allocates them to the most suitable virtual resources, all while reducing makespan and energy consumption. We modelled our scheduler after the whale optimization technique. Cloudsim was used for the entirety of the simulation. This simulation makes use of both synthetic and real-time workloads taken from HPC2N and NASA. We compared our method to the standard metaheuristic methods already in use, such as ACOs, GAs, and PSOs. The simulation results showed that the makespan, energy consumption, overall) all improved significantly.

An ACO-based algorithm, ACO-RNK, has been proposed as a practical answer to the job scheduling problem by Elcock and Edward [19]. In order to lead the solutions, our method makes use of pheromones and a priority-based heuristic called the upward rank value, as well as an insertion-based policy and a pheromone ageing mechanism that tries to prevent premature convergence. We evaluated the performance of our approach to that of the HEFT algorithm and the MGACO procedure on directed acyclic networks that were constructed at random (DAGs). Our method demonstrated performance that was on par with or better than the chosen algorithms in the simulations.

Using data from the (RM), the (NM), and the Application Master, Bawankule [20] proposes a new process for scheduling tasks based on deep reinforcement learning. This method dynamically schedules tasks based on the current state of the nodes, including their load, resource availability, usage, and task information (AM). In order to handle difficult scheduling issues in a heterogeneous setting, the suggested Map Reduce Scheduling utilising the Deep- Q- Networks (MRSDQN) employs a deep reinforcement learning approach. The projected process is evaluated in terms of its efficiency in relation to Hadoop's most valuable benchmark, the HiBench benchmark suite. It validates the efficiency of the suggested method using the latest Hadoop benchmark. Finally, it contrasts the proposed strategy with Hadoop's multiple scheduling strategies, each of which places less value on the timely completion of jobs and the successful completion of tasks in a diverse computing environment. Last but not least, it expedites the completion of tasks in a diverse set of benchmarks by an average of 23% to 36%.

In order to accomplish the goal of smallest makespan in the shortest amount of time, Yadav and Mishra [21] have created and enhanced an ordinal optimization technique. Ordinal optimization, which employs horse race conditions as selection rules, is applied in an improved reiterative fashion to meet the current requirement of optimal schedule for, thereby achieving low overhead through the judicious allocation of work to the most talented schedule. The proposed ordinal optimization method, in conjunction with linear regression, creates schedules that maximise productivity and minimise the time needed to produce a product. More importantly, the proposed exact equation, which was derived using linear regression, forecasts any future dynamic workload in terms of the minimum makespan period aim.

Talmale and Shrawankar's [22] suggested Cluster-Based Real-Time Catastrophe Resource Management Framework makes use of different disaster resources and emergency services. Edge computing resources are pooled together to form a cluster, and then a set of tasks is assigned to the cluster and scheduled on the edge computing cluster to increase resource utilisation and acceptance rate and decrease response time and overhead due to communiqué and migration, thereby solving the problems associated with the current partitioned scheduling.

Nematpour et al. [23] provide a new method of constructing chromosomal representation. After three

iterations of ranking, clustering, and cluster scheduling, the suggested method schedules clusters using a genetic algorithm. To achieve optimal performance, the proposed genetic algorithm incorporates four heuristic philosophies: load balancing, idle time reuse, work duplication, and critical path. Finally, we compare the amounts of optimization over 6 task graphs of 3 different types, and we find that in one type, the quantity of optimization is equal to the findings of the previous best approach, but in the other 3 types, the amount of optimization is between 4.25 and 6.88%..

III. PROPOSED SYSTEM

3.1. SYSTEM MODEL

The suggested method's primary purpose is to allocate tasks to VMs in accordance with the latter's available resources and current workload. The load balancing algorithms work to take work away from VMs that are too busy and distribute it to others. Each physical machine (PM) in the proposed system hosts several virtual machines (VMs) that are responsible for carrying out the user's requests. Each cloud customer has a unique workload requirement for their virtual machine. In this work, we employ a load-balancing technique to distribute the jobs among the VMs. The suggested load-balancing technique is constantly monitoring the workload of every virtual machine (VM) in the cloud. The VM's workload is proportional to the time required to complete each individual activity. Because each job takes a different amount of time to complete, the VM's workload is always changing..

3.2.PROBLEM DEFINITION WITH SOLUTION FRAMEWORK

Take cloud C, for example, where there are "n" data centres or physical machines (PMs) and "m" VMs in each physical host (PH) (VMs).

$C = \{PM1, PM2, \dots, PM\text{n}\}$ (1)

In this equation, C stands for the cloud, PM 1 for the first bodily machine, and PM n for the nth. Following are several ways to designate the PM:;

$PM\text{n} = \{VM1, VM2, \dots, VM\text{m}\}$ (2)

where VM 1 refers to the very first VM and VM m to the very latest VM. It's the same in the cloud: there are I users, and each user has I tasks. The user may be identified in the following ways:;

$U\text{i} = \{T1, T2, \dots T\text{j}, \}$ (3)

The chief goal of this study is to efficiently distribute the workload across all virtual machines (VMs) in a cloud infrastructure while simultaneously reducing the task's execution time and associated costs. Specifically, we are interested in achieving three goals. First, we strive to reduce the amount of time required to complete each task (ET). Secondly, we want to reduce the time and money needed to carry out an action (EC). A third is to divide up the work among all of the cloud-based virtual machines..

Time taken to complete an operation can be determined using Eq (4).

$$ET = \frac{1}{\max(ET)\times \text{number of task}} \sum_{j=1}^{\text{Number of task}} (ET \text{ of corresponding } VM \times \text{Size of the task}) \quad (4)$$

The execution cost (EC) can be intended using Eq. (5).

$$EC = \sum_{j=1}^{\text{Number of task}} \left[\frac{\text{Execution time} \times \text{Communication time}}{\text{Number of task}} \right] \quad (5)$$

Lode can be intended using Eq. (3).

$$Load = \frac{1}{\text{Number of task}}$$

$$\sum_{j=1}^{\text{Number of task}} \left[\frac{\text{size of VM} - ((\text{Toatal size of VM} - \text{Free space of VM}) + \text{siz of task})}{\text{Size of VM}} \right] \quad (6)$$

When planning, it's important to distribute work fairly. In the absence of load balancing, the system will consume the most resources and take the longest to complete the task. In this research, we propose a method for effectively balancing loads that takes into account multiple objectives..

The planned multi-objective function (MOF) is distinct in Eq. (7).

$$MOF = [\alpha 1(ET) + \alpha 2(EC) + \alpha 3(1 - Load)] \quad (7)$$

3.3.Proposed Method

Let $VM = \{vm1, vm2, vm3, \dots, vm\text{m}\}$, variables used in this study and Table 1 definitions the parameter of the study.

Table 1 Variables used in this study and their meanings.

Symbol	Definition
m	The number of virtual machines (VMs)
$VM = \{vm_1, vm_2, vm_3, .vm_\text{m}\}$	The set of VM
K	The total sum of tasks the scheme has to achieve
$Task = \{t_1, t_2, t_3, \dots, t_\text{k}\}$	The set of tasks
N	The total quantity of bees performing in thealgorithmic procedure
C_j	The presentation of the jth virtual machine

Symbol	Definition
Pe	The sum of processors in the VM
Mi	Million Instructions Per Second (MIPS)
Bw	Bandwidth of VM
F	Fitness
Tl	The distance of task in MIa
Pi	Probability that the ith food source is good which be contingent on its fitness value, $\underline{fitness_i} pi = \sum^{NS} fitness_i$ Where, NS is the size of food bases

Configure the system to operate in a non-preemptive, hence interrupt-free mode. Heuristic algorithms were used to sort the tasks into three distinct orders before running the ABC method. By processing the tasks with the ABC method, as was previously described, the optimal setup would require the least amount of computational time. Then, the ABC algorithm used these steps to plan when tasks would access the VMs::

1. First, the population size, denoted by n, of bees was determined. Algorithm 1 depicts the random assignment of VMs to the various food sources (m) that represent them, followed by the calculation of their fitness scores.

2. Second step: the stipulations of the VM. Bees were grouped into 3 categories: Scout Bees, Employed Bees, and Onlooker Bees. A Scout Bee found the initial position of a food source. An Employed Bee went to the food source, recalculated and updated the fitness value of food source. An Onlooker Bee decided which food source was the best food source. The operation of an employed bee is presented in Algorithm 2.

Procedure 2: Employed bee phase

1. *For* $i = 1$ *to* n

2. *Employed bees are sent randomly to food sources (VMs i:*

$$F_{ij} = \frac{\sum_{i=1}^{n} Tl_{ij}}{Evaluvate\ capacity\ of\ VM_j(c_j)} \quad (9)$$

4. *Update the fitness value*

3. *Third step*: *the Employed bees have searched around for food sources, they brought back*

Algorithm 3: *Onlooker bee phase*

1. *The onlooker bee chooses the first m food sources* (VM) *with the highest*
2. *An nsp number of employed bees are sent to bring back new positions of*
3. *The onlooker bee calculates the new fitness values of the food sources a*

$$fit_{ij} = \frac{\sum_{1}^{n} Tl_i + In_{length}^{i}}{Evaluate\ capacity\ of\ VM_j(C_j)} \quad (10)$$

where In_{length} *is the length of the task that is waiting to access a VM at tha*

4. *The onlooker bee chooses the best food source* (VM) *and assigns a task to*

4. *Fourth step*: *the employed bee that was the owner of the best food source was then transf*

Algorithm 4: *Scout bee phase*

1. *If food source* $=$ *null then*
2. *Send the previously transformed scout bee into the system to find an ap*
3. *Calculate the fitness value of that VM by using* (8)
4. *End If*

5. *Fifth step*: *the overall operation of HABC algorithm is described in Algorithm*

Sixth, following VM task scheduling, determine the system load balance value.

Standard Deviation (S.D.) in the range of 11 is used to determine this (12),

$$S.D = \sqrt{\frac{1}{n}\sum_{j=0}^{n}(X_j - \bar{X})^2} \quad (11)$$

$$imbalance = \frac{K_{max} - K_{min}}{K_{avg}} \quad (12)$$

The amount of time needed to process each virtual machine (X j) is determined by (13),

$$X_i = \frac{\sum_{i=1}^{k} task\ lengt}{capacity_i} \quad (13)$$

To determine how long it takes the system on average to execute a virtual machine (X

), we need (14) $$\bar{X} = \frac{\sum_{j=1}^{n} K_i}{n} \quad (14)$$

If the standard deviation is less than X, then the system is in equilibrium; otherwise, it is out of whack.

Stage six: scouting (Algorithm 4)

IV. RESULTS AND DISCUSSION

Cloudsim 3.0.3 is utilised for the performance evaluation proposed here. In Cloudsim, the user initiates actions by submitting requests, or tasks, that occur in a specific order within a series of clouds. Each cloudlet has its own unique set of characteristics, including the number of tasks it must do, the amount and length of any linked files, and so on. The cloudlets are then forwarded to a broker, where they are used to assign IP addresses to the desired virtual machines. This utility can be used with the broker's preexisting regulations. Hosts initiate the creation of brokers' worth of virtual machines. The TSA operates in an operational data centre broker. Code for the proposed technique is implemented in the datacenter broker. Planners for data centres and virtual machines can work together in real time or across great distances..

4.1.PERFORMANCE OF PROPOSED SCHEME IN TERMS OF MAKESPAN

It is primarily aimed at reducing the amount of time needed, i.e. the whole duration of the work schedule, where all work has been completed or the time taken for it from the beginning to the end. The following equation demonstrates the makeup formula.

$$Makespan = \sum n$$

$$Fti \quad (15)$$

Where, F is the finishing time of the task (n).

The existing techniques such as Whale Optimization algorithm (WOA) [18], ACO [19], Butterfly Optimization (BO) and ABC are implemented in this research work and results are averaged, which is shown in Table 2 to 4.

Table 2: Makespan comparison with a different algorithm

Number oftasks	Makespan (time in seconds)				
	WOA	ACO	BO	ABC	IABC-TS
1000	434	428	421	415	395
2000	917	921	836	816	800
3000	1302	1293	1264	1251	1229
4000	1688	1686	1635	1619	1602
5000	1979	2000	1994	1891	1875

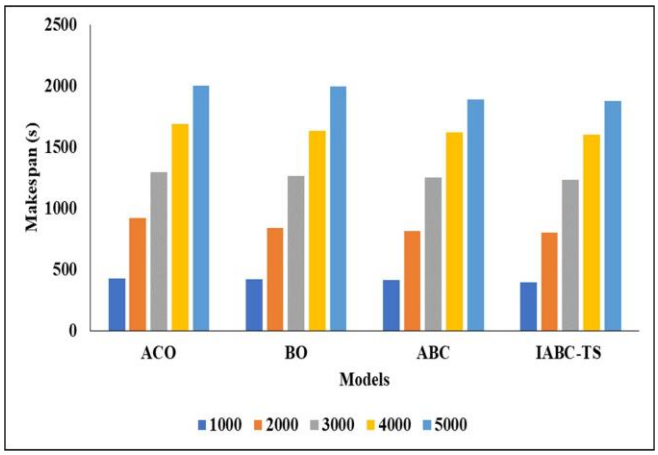

Figure 2: Graphical Representation of Algorithm in terms of Makespan

Analyzing the make span of the projected and existing methods is shown in Fig. 2. Our proposed load balancing method has a shorter make span than the state-of-the-art methods by a significant margin; for 1000 tasks, is around 395 seconds, while ABC's is around 415 seconds, BO's is around 421 seconds, ACO's is around 428 seconds, and WOA's is around 434 seconds. The system's manufacture time is inversely proportional to its throughput. The proposed model has a make span of roughly 800s for 2000 tasks, 1229 for 3000, 1602 for 4000, and 1875 for

5000 activities, while ABC needs 816s, 1251 for 1619, and 1981 for 1981 tasks. The WOA

model has a longer makespan need than the 917s, 1302s, 1688s, and 1979s for the same amount of tasks.

Table 3: The comparison among the TSA using the energy consumption

Algorithms	Number of Tasks					
	1000	2000	3000	4000	5000	6000
WOA	2453	2723	3473	4142	4663	5081

ACO	2273	2657	3845	4361	4534	4921
BO	2265	2558	3518	3965	4307	4709
ABC	2159	2471	3350	3659	3878	4548
IABC-TS	**2055**	**2206**	**3032**	**3435**	**3726**	**3976**

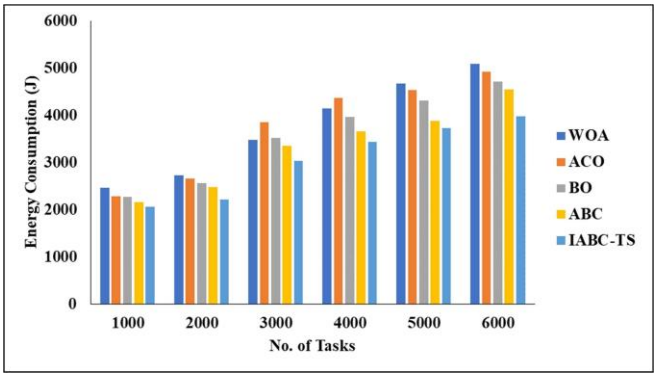

Figure 3: Graphical Representation of Algorithm in terms of Energy Consumption

Energy usage in the projected system is associated to that of existing models in Fig. 3.

The system's energy usage is increasing as the number of nodes and tasks increases. Additionally, the IACO-TS method's energy efficiency improves with network size, as the percentage of total nodes visited increases in proportion to the total network size..

Table 4: The comparison among the TSA using the execution overhead

Algorithms	Number of Tasks					
	1000	2000	3000	4000	5000	6000
WOA	792	875	810	826	846	884
ACO	821	854	844	861	871	892
BO	523	708	567	593	614	627
ABC	605	639	646	649	663	689
IABC-TS	482	503	537	542	551	561

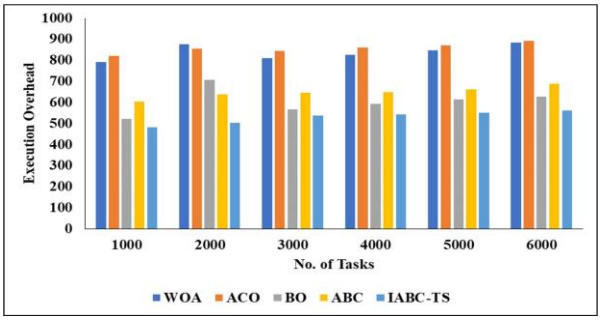

Figure 4: Graphical Representation of Algorithm in terms of Execution Overhead

In order to demonstrate the efficacy of the suggested method, we benchmark our results against four additional algorithms: WOA, ACO, BO, and ABC. To be useful, a technique needs to have a shorter runtime. Our proposed technique takes less time than WOA, ACO, BO, and ABC when evaluating Fig. 4. Figure 4 provides a similar performance analysis, this time based on Execution overhead. The sum of jobs is on the x-axis, while the execution time is on the y- axis. When the workload size is 3000, the suggested IABC-TS method has the lowest execution cost (537), followed by BO (567), ACO (844), WOA (810), and ABC (0.649). The proposed solution is preferable than competing approaches due to its decreased execution overhead. Therefore, it is evident that the proposed IABC-TS approach has outperformed other methods..

V. CONCLUSION

As part of this study, we present an algorithm for cloud-based virtual machines (VMs) based on the IABC-TS for VMs in cloud computing in both contexts with the intention of enhancing job scheduling and load balancing. The implementation of the IABC-TS utilised cloud computing, which improved work scheduling and load balancing across enormous data sets. This study presents a new multi-objective Load balancing approach based on the IABC-TS standard, and puts it through its paces in a series of simulation studies. The goal of the scheduling method we offer is to provide a balanced workload among virtual machines while also minimising delivery time and cost. In addition, the benefits of using the IABC-TS to optimise resource allocation are explained by our suggested approach. Three examples of the problem are studied to gauge the efficacy of the proposed strategy. The proposed model's

simulation results are associated to the standard method in terms of runtime and cost. Upcoming work will involve building a hybrid model and clustering the virtual machines (VMs) using optimization models, both of which will improve the proposed model.

Aspect-Based Sentiment Classification: Survey

Snehal Sarangi, Dr.Subhasis Dash, Dr.Jitendra Ku Rout

KIIT,Bhubaneswar,NIT,Raipur

Abstract – **Through a variety of Internet applications that act as a rich source of information, Web 2.0 makes it easier for people to voice their opinions. The latent information in textual expressions can be processed and analysed to disclose the user's or people's sentiment. Sentiment analysis, also identified as opinion mining, review mining, attitude mining, and other similar terms, practise of computationally obtaining opinions and perspectives from textual data. One of the three primary forms of sentiment analysis is aspect-level sentiment analysis, which uses granule-level processing to determine sentiment orientation by utilising the various characteristics of entities. The development of deep learning and machine learning methods has left a profound influence on aspect-oriented sentiment analysis. This paper surveys and reviews current works on aspect-based sentiment analysis using machine learning methods.**

Keywords: Aspect-based sentiment analysis, Sentiment analysis, Machine learning, Deep learning

I. INTRODUCTION

In today's world, social media is crucial for instantly distributing information about anything and everything. This encouraged regular people to participate in and interact on social media. The astounding number of 500 million tweets in a year, or 6000 tweets per second, revealed by the statistics for the year 2018 confirmed Twitter's status active community platform. Persons express thoughts and feelings through the review of a good or service, for example, and this eventually leads to an enormous volume of data on the Internet. We can extract a lot of latent information from this unstructured digital data using sentiment analysis (SA). Customer reviews have equalised the impact of word-of-mouth advertising in such a way that it now impacts the purchasing outcomes of tens of thousands of customers spread out geographically around the globe. A text can genuinely change a potential customer's mind- set. Processing every customer review comment provided individually is a completely foolish idea. SA is the ideal tool for analysing the trend that underlies any such purchasing behaviour. One of the quickly expanding research topics in Natural Language Processing (NLP) is sentiment analysis. The technique known as SA involves using NLP to extract the attitude or opinions from a text and categorize them according to polarity, such as positive,

negative, or neutral. In contrast to most NLP study fields; SA involves a variety of issues. Sentiment analysis is done at several levels of detail in documents, such as the sentence, aspect, and content. There are comparative reviews and surveys of SA in the literature [1, 2, 3, 4], but only a few authors, like Do et al. [5] have put together work on aspect-based sentiment analysis.

Popular methods for further sentiment analysis include machine learning and deep learning. As a result, we seek to discuss the numerous works in this paper that have employed machine learning and deep learning methods to perform aspect-based sentiment analysis. Aspect- based sentiment analysis has been focused on key domains and a variety of datasets in this study.

The remaining parts of the paper are divided up into these five sections: Section 2 focuses on detailed study of sentiment analysis and annotation. Section 3 focuses on analysis on emotions. Various domains used for sentiment analysis are discussed in Section 4. Detailed discussion on various dataset used for research is presented in Section 5. Different Machine Learning algorithms used in sentiment analysis has been discussed in Section 6. Section 7 provides the challenges occurred during implementation. Finally, Section 8 concludes the paper.

1.1Objectives of Research:

i.Analysis on aspect-based sentiment classification based on various machine learning technique identify which technique is better suited for sentiment analysis.

ii.To improve the accuracy further analysis on deep learning procedure will be done.

iii.To outperform single model in terms of adaption ability performance on hybrid model (NLP)

II. SENTIMENT ANALYSIS

Determining the polarity of the textual data is one of the key goals of the SA job. A text's inclination to favour positive or negative polarity might be observed. For instance, “That was the nastiest movie I've ever seen” has a negative polarity while “I really loved the picture” has a positive polarity. Some sentences may not have either positive or negative polarity. Such statements fall within the heading of neutral polarity. “I neither loved nor despised that movie,” for instance. Factual sentences do not fall under the category of neutral sentences.

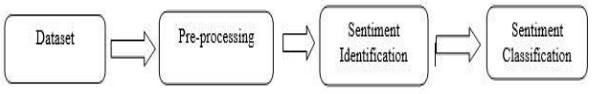

Figure 1: Sentiment analysis procedures

The practice of acquiring unprocessed text information in the form of reviews, blogs, and discussion board posts from several social networking sites, such as Twitter and Facebook, or e-commerce websites, such as Amazon and Flipkart, is known as data collection. These sources include ideas or feelings stated in a variety of sizes, formats, and styles regarding various entities. The subsequent stage involves carrying out the necessary filtering procedures to retrieve pertinent data from the datasets while deleting unnecessary stuff. The most crucial phase is sentiment recognition, which requires simultaneously identifying sentences containing

subjective expressions and implicit sentiments without ignoring them.

It might be challenging to extract opinions from unstructured textual data. An opinion or a fact may both be present in a statement; the former provides objective information about the subject at hand, while the latter provides subjective data. Identifying whether a sentence is subjective, or objective is one of the first tasks in SA. Only subjective statements containing opinions are to be continued. The problem of classifying subjective sentences into positive, negative, or neutral polarity follows the classification of subjectivity. As we work to get sentiments from textual texts, we can divide them into two categories: explicit or implicit opinions and direct or comparative opinions [6][4]. Straightforward language with direct opinions conveys the feelings. Comparative opinions, as opposed to direct opinions, compare various things or aspects of the statement. Instead, an explicit view reveals a person's position on something completely and explicitly, leaving no possibility for the reader to infer anything from the silence. Implicit opinion, however, lacks clarity, necessitating the reading of the underlying meaning to convey the message that was meant to be conveyed but was left unsaid. Contrary to the former, implicit opinions have a wide range of metaphors they can utilise, which makes the entire analytics process even more difficult because they are meant to have a lot of semantic information.

The primary objective of the SA is sentiment classification, which involves correctly categorising subjective phrases into their appropriate polarity kinds, such as positive, neutral, or negative.

2.1 GRANULARITY OF THE TEXT

There are many tasks to face, therefore solving SA is not a single, straightforward task. As shown in Figure 2, sentiment analysis is done at several text granularity levels, such as documents, sentences, and aspects. The most straightforward and fundamental type of SA, document-level SA seeks to identify the whole sentiment polarity of the textual material. The very first SA-related works [7, 8] focused on document-level SA. In comparison to document-level SA, sentence-level SA is a finer level of analysis [9][10]. The sentiment polarity in the document's sentences is computed at the sentence level. The aspect level's task SA is a fine-grained one in which multiple features identifying the entity are discovered in the text and their associated sentiment words and polarity are then resolute.

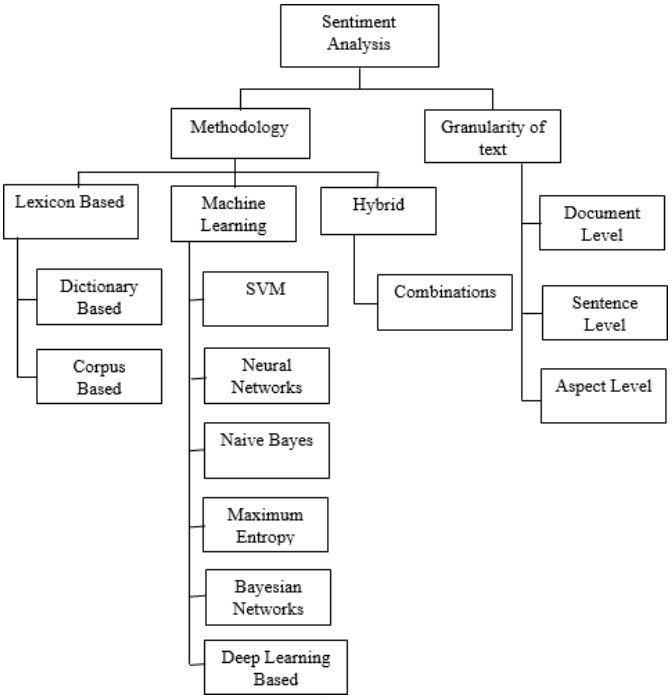

Figure 2: Sentiment analysis classification built on granularity and methodology

2.2 Methodology

The various methodologies discussed in this section provides brief insights on how features can be considered for sentiment analysis based on different datasets.

2.2.1 Lexicon based approach

The lexicon-based approach was used in the initial efforts on SA [11][12][13][14] and can be used to perform the SA. Lexicon-based approaches employ terms that have polarity values annotated, which provides insight into the sentiment-leaning of the text's content. This method's key benefit is that it does not require training data, making it an unsupervised learning strategy. However, the sentiment lexicons do not include all expressions and terms. Here, the task of a SA is aided using lexical resources like Sent WordNet [15] or WordNet

[16] etc. Dictionary-based approach and corpus-based approach are two further categories under which the lexicon-based method can be divided. The construct in the dictionary-based approach is a dictionary that includes opinion terms supported by their sentiment value, but in the corpus-based method, context knowledge replaces such a dictionary. In the corpus-based method, the likelihood that a word will be annotated or appended with both positive and negative descriptive words is more important. The primary difference between dictionary-based and corpus-based approaches is that the previous cannot be used to identify terms with specific domain orientation while the latter can [17].

2.2.2 Machine learning approaches

By using accessible data to train models, machine learning (ML) algorithms can predict or categorise any incoming input that is unknown to them. These algorithms

provide a better level of accuracy in their outcomes. There are primarily two types of data used in ML techniques: training data and test data. An ML classifier receives the training data to begin the training process. Numerous classifiers, including neural networks, NB, K-means, SVM, etc., can forecast the appropriate classifications. Chi-square or Information Gain (IG) feature selection algorithms are used to rank the relevant set of features and omit the inappropriate features to increase classification accuracy. A classifier receives test data following the training phase to determine whether the machine learning model is producing the expected results or not.

2.2.3 Hybrid approaches

There are numerous different types of studies that use hybrid methodologies that combine multiple SA approaches. To achieve better outcomes than the stand-alone strategy, a certain approach will be combined with another approach. A hybrid strategy was created by many studies [18][19][20][21] by combining lexicon-based and machine learning-based methods.

2.3 Evaluation metrics

The metrics Precision (P), Recall (R), F-score (F1), and Accuracy (Acc) are used to evaluate the SA as the problem primarily focuses on the categorization of words based on their sentiment polarity. Both lexicon-based and machine learning-based techniques are evaluated using the same measures. While recall identifies the proportion of relevant outcomes that the SA model correctly classifies, precision provides the percentage of relevant results. Using the precision value and recall value as a starting point, F1 score determines the overall accuracy of the SA model. A high F1 score suggests that the SA model is categorising considerably more accurately because it exhibits fewer false-negative or false-positive results. If the SA model's F1 score is zero, it represents a total failure, whereas a score of one indicates the model is performing at its peak. The percentage of accurate predictions to all available inputs is known as accuracy.

$$Precision, P = \frac{True\ Positives}{Actual\ Results}\ or\ \frac{True\ Positives}{True\ Positives\ +\ False\ Positives}$$

$$Recall, P = \frac{True\ Positives|}{Predicted\ Results}\ or\ \frac{True\ Positives}{True\ Positives\ +\ False\ Positives}$$

$$F1\ Score\ = 2 * \frac{Precision\ *\ Recall}{Precision\ +\ Recall}$$

$$Accuracy, Acc\ = \frac{True\ Positives\ +\ False\ Negatives}{Total}$$

III. AN APPROACH TO ANALYZING EMOTIONS BASED ON PERCEPTIONS

A fine-grained level of SA work called aspect-based sentiment analysis (ABSA) [22] looks for the sentiment of several elements of an item within textual data. An entity in the SA is a distinct individual thing or circumstance. It could be anything, such as a person, place, movie, or thing. The entity may be described in the textual data using several word groups, also known as features detailing the entities; these characteristics are referred to as "aspects" of the related entity. The entity may be described in detail using a few different aspects and several words or even phrases that express certain feelings about those aspects. To uncover the pertinent details about the entity and its supporting statements, ABSA looks for its polarity or attitude. Think about the phrase, “This guitar looks so wonderful, but the sound quality falls short of expectations.” Here, “guitar” is the object of concentration, and "look" and “sound quality” are two factors to be considered. An ABSA for a statement of this kind must, as shown in figure 3, assign a positive feeling to the element of "appearance" and a negative sentiment to the feature of "sound quality."

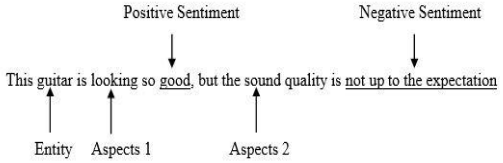

Figure 3: Identification of aspect sentiments Group text and arrows

ABSA employs a multistage analysis in a manner like the conventional SA. Numerous methods and approaches have already demonstrated how well they execute various jobs. The ABSA workflow is depicted in Figure 4, where the text data is first pre-processed to weed out unnecessary expressions. Pre-processing entails putting provided data in an appropriate format so that it may be used for the task at hand. Tokenization, stop word removal, negation handling, and other processes are used in SA to clean up the data and transform it to the appropriate format. Tokenization is the process of breaking the supplied text down into a collection of tokens. Tokenization aids in vector construction and gets rid of words that don't belong in the text. Special letters, standalone punctuation, and numerical tokens are eliminated from the text because they don't provide any meaning. Following tokenization, stemming is used to look for provided terms' true bases in the textual material. Word embedding, a crucial step in SA employing machine learning, is performed after pre- processing. Word embedding is the process of translating a token of words into a vector representation. Despite their close similarity, the words "aircraft" and "aeroplane" have different meanings. Word embeddings are used to change the text into another dimension so that a machine can comprehend the differences in meaning. These vectors can also be used to extract aspect and sentiment using a machine learning model. The third stage involves finding the texts' associated features of the entity, which is followed by finding the contextual phrases that best express the identified aspects' feelings. The precise sentiment orientation of sentiment words is determined in the last phase.

Figure 4: Workflow of aspect level sentiment analysis

Figure 4: Workflow of aspect level sentiment analysis

The task of ABSA can also be split into two halves, specifically aspect category SA and aspect term SA [5]. The former is a little finer-grained level of removal of the same, whereas Aspect Category SA is a coarser-grained one. The arts of music and dance are examples of aspect category SA.

The scalability of ABSA is one of its key benefits. Because ABSA can quickly and automatically do a fine-grained textual analysis. The manual analysis task is challenging since it is nearly impossible to process the enormous amount of text in a timely manner and at a fine-grained level. Additionally, ABSA will be analysing textual elements such as reviews, comments, etc. so that businesses or individuals can concentrate on the precise elements where their customers are voicing complaints or making ideas to enhance their goods or services. The respective businesses or consumers will save a substantial amount of time and money as a result. Since ABSA falls under SA, there are multiple issues to address. ABSA produces more thorough and precise results than sentiment analysis of the document and sentence levels. Today, text analysis in ABSA is quick and simple thanks to the development of machine learning and deep learning algorithms. SVM, CNN, LSTM, and other ML techniques have been employed in several papers for the ABSA challenge [23] [24] [25].

IV. DOMAINS

The different domains that are frequently utilised in ABSA are covered in this section. When explaining the SA, the domain is crucial, particularly when the focus is on aspect level. It is easy to extract aspects from the given text when one has domain knowledge. Because it is challenging to separate the characteristics from the text without context. Think about the phrases “speaker sound is so loud that everyone in the auditorium can hear it” and “vehicle's engine is so loud” from the speaker and car domains. According to the speaker, the loudness in the first case is conveying a positive mood, whereas the loudness of the car's engine in the second example is conveying a negative sentiment. Therefore, it is evident from the example that domain expertise is crucial to SA's job. In other words, the training statistics based on many domains will have an impact on the outcomes of SA. We can claim that SA is rather domain determined. Based on the literature study conducted here, this conclusion was

reached. It is obvious that there will be a distinct strategy that produces improved results on SA for each domain. Most of the work on SA's aspect level focused on consumer reviews of products including laptops, TVs, mobile phones, restaurants, hotels, and movies. Table 1 lists all the research on ABSA that has been done across several fields.

Table 1: ABSA domains and datasets

Domain	**Authors**	**Dataset used**	**Algorithm/ Technique**
TV reviews	Fu et al. [26]	Manually collected ChineseTV online reviews	K-means+Co-clustering
Product reviews	Rezaeinia et al. [28]	CR(Amazon),SST (Stanford sentiment treebank)	LSTM
Movie reviews	Thet et al. [22]	IMDB	CNN, BiLSTM
	Anand et al. [29]	Manually collected movie reviews from IMDB & Amazon	
	Zainuddin et. al [30]	Twitter	SVM
	Manek et al. [23]	Large movie review dataset SAR14, Cornell polaritydataset V1.0, and large movie review dataset V1.0	Attention basedLSTM
	Rezaeinia et al. [28]	MR(IMBD),RT (Rottentomatoesmovies reviews)	LSTM
	Zhang et al. [31]	MR,SST1,SST2, CR, AFFR	LSTM
	Piryani et al. [32]	IMDb	Linguistic approach
Hotel reviews	Al Smadi et al. [33]	Manually collected Arabic hotel reviews	SVM
	Akthar et al. [34]	Manually collected hotel review dataset	LDA, DP, CR, And NER NLP tools

	Pham et al. [35]	Hotel reviews from tripadvisor.com	CNN
	Garcia-Pablos et al. [36]	SemEval 2016 task 5	CRF
	Al Smadi et al. [37]	Arabic hotel reviews-SemEval2016 task 5	Attention based LSTM
	Kumar et al. [38]	Manually collected reviews from booking.com	Neural network
	Garcia-Pablos et al.[36]	SemEval 2016 task 5	CRF
Restaurants	Qiu et al. [39]	Yelp	LDA
	Pham et al. [24]	Manually collected restaurant reviews	LSTM
	Garcia-Pablos et al.[36]	SemEval 2016 task 5	CRF

V. DATASETS

Review-type data are the focus of aspect-based sentiment analysis since they are full of thoughts about the various characteristics of the products being reviewed. Lack of benchmark datasets is one of the early issues in implementing ABSA. More studies in this area have been conducted recently, and the good publicly accessible datasets that are the outcome are shown in Table 2. SemEval 2014 task 4 is a dataset Pontiki et al. [41] generated in 2014 specifically for ABSA. Pontiki et al. [42] included reviews of hotels, laptops, and restaurants—all in the English language—in the SemEval 2015 dataset. 6,940 tweets make up the target-dependent Twitter sentiment classification dataset, which was created in 2014 by Dong et al. [44]. ICWSM 2010 JDPA Sentiment corpus is a dataset that was created by Kessler et al. [45]. Documents pertaining to digital and automotive devices are included in this dataset. Darmstadt Service Review Corpus dataset, developed by Toprak et al. [46], covers reviews of online institutions and their services.

Table 2: ABSA Datasets

No.	Name of the Dataset	Domain	Language	Number of reviews/tweets/micro blogs
1	SemEval 2014	Restaurant, laptops	English	Restaurant – 3841 Laptops - 3845
2	SemEval 2015	Hotel,restaurant,laptops	English	Hotel – 30 Restaurant – 350 Laptops – 450
3	SemEval 2016	Hotel, restaurant, laptops, mobile, camera	English, Arabic, Chinese, Dutch, French, Russian, Spanish and Turkish	Laptop – 350 (English) Hotel – 2291(Arabic) Camera – 200 (Chinese) Mobile – 200 (Chinese),270 (Dutch) Restaurant 339 (Turkish), 313 (Russian), 555(French), 400 (Dutch), 913 (Spanish)
4	Target-dependent twitter sentiment classification dataset	Tweets	English	6,940
5	FiQA ABSA	Financialmicroblogs and financial news headlines	English	Micro blogs – 774 News headlines – 529
6	ICWSM 2010JDPA Sentiment corpus	Automotiveanddigital devices	English	515
7	Darmstadt Service Review Corpus	Online universities and their services	English	118

VI. MACHINE LEARNING (ML) APPROACHES FOR ABSA

Regarding aspect-based sentiment analysis, ML algorithms have been thought to perform accurately. The various ML algorithms are discussed in the following subsections, along with how well they work for ABSA.

6.1 Latent Dirichlet Allocation (LDA):

Latent Dirichlet Allocation, or LDA, is a probabilistic, generative model for a collection of texts that can be thought of as combinations of underlying issues. A topic-developing technique called LDA assists in automatically identifying the core subjects in each material. Documents are viewed by LDA as mixtures of subjects with certain probabilities of words. Kull-back-Leibler (KL) divergence was utilised by Fu et al. [47] to ascertain the relationship between specific paragraphs and topic models, with the main goal being to ascertain the theme

of the paragraph. The authors identified the blogs' themes using the LDA model, and they measured the distance between the themes using KL divergence. To extract the hidden information and features from a manually compiled sample of hotel reviews, Akthar et al.

[34] employed a topic modelling tool named Mallet. W2VLDA is an unsupervised system that deals with multi-domain and multilingual ABSA, according to Garcia-Pablos et al. [36]. W2VLDA uses a substantial amount of unlabelled textual data and starts with a small number of seed words. For distinguishing between different aspects of opinion words, the authors used LDA topic demonstrating in conjunction with an unsupervised pre-trained classification model. Aspect Sentiment Unification Model (ASUM) was created by Amplayo et al. [48] by incorporating product descriptions. Aspect and its accompanying emotion are combined in ASUM, a modified form of LDA [49].

6.2 Conditional Random Field (CRF):

Conditional Random Fields (CRF), a discriminatory model for predicting orders as opposed to generative models like LDA, are employed. For more precise prediction in CRF, data from the prior labels is employed. A prediction methodology was put forth by Qiu et al. [39] for calculating the ratings of unrated reviews from the Yelp dataset. For the generation of pair terms and for calculating their sentiment scores, authors employed a sentiCRF form of the CRF. They developed a cumulative logit model, which forecasts review ratings using attributes and the associated sentiment values from the reviews. Furthermore, they suggested

a heuristic re-sampling approach to address the class imbalance issue at the time of sentiment score calculation.

6.3 Support Vector Machine (SVM):

The supervised machine learning algorithm SVM is promising for the tasks of classification and regression. Every data point in SVM is displayed on an n-dimensional graph, and a hyper plane is created depending on whether classification or regression is needed. The potential hyper plane with the greatest separation from the support vectors will be taken into consideration. A heuristic mix of Parts of Speech (POS) is combined with feature selection techniques as PCA (Principal Component Analysis), Latent Sentiment Analysis, random project, etc. The authors also used Stanford Dependency Parser to extract implicit elements in this work. A model was put out by Al-Smadi et al. [33] to help the ABSA perform better while translating hotel reviews into Arabic.

6.4 Convolutional Neural Network (CNN):

CNN is a feed-forward neural network that was initially employed mostly in image processing before being applied to nearly all other fields. The convolutional layer, which is the initial layer, extracts all the characteristics from the input. CNN was used by Kumar et al. [38] for the ABSA task, and stochastic optimization was carried out in their research. Word- level embedding in this case was carried out using word2vec, and semantic feature extraction was carried out by creating ontologies. Particle Swarm Optimization (PSO) was added by the authors as a multi-objective function for CNN parameter tuning. Particle Swarm Optimization (PSO) was included by the authors as a multi-objective function for CNN parameter tweaking.

6.5 Long Short-Term Memory (LSTM):

The vanishing gradient and inflating gradient problems that Recurrent Neural Networks (RNN) experienced were addressed by the development of the Long Short-Term Memory (LSTM) network, a form of RNN. The main advantage of LSTM is its intelligence, which enables it to recognise long-term dependencies. In other words, LSTMs have a longer retention time for the information. For this, the LSTM network included a cell-class explicit memory unit. LSTM bases its decision on three inputs: the current input, the previous output, and the previous memory. A technique based on LSTM that has a two-stage aspect level classification of feelings was proposed by Ma et al. [50]. A generative model for aspect level

sentiment classification was created by Xu et al. [25] using LSTM over reviews of restaurants and laptops. It is a semi-supervised technique with sentiment and context as its two stochastic variables.

Authors	**Algorithm / Technique**	**Accuracy**
Zainuddin et al. [30]	SVM + ARM	Accuracy = 76.55%
Thet et al. [22]	CNN, BiLSTM	Complete Movie- 86% Direction- 86% Cast-83% Storywriter- 80% Scene play- 90% Music- 81%
Kumar et al. [38]	Neural network	Accuracy = 88.52%,
Manek et al. [23]	Attention based LSTM	Accuracy = 97.32%
Fu et al. [47]	LDA	Accuracy= 89.165%
Fu et al. [26]	K-means+Co-clustering	Accuracy= 78.198%
He et al. [51]	Attention based LSTM	Accuracy = 85.58%
Ma et al. [52]	Hierarchical attention-basedLSTM	Accuracy=89.32% onSentiHood dataset 76.47% on SemEval 2015 dataset

Authors	Algorithm / Technique	Accuracy
Al-Smadi et al. [37]	Attention based LSTM	Accuracy = 95.4%
Yang et al. [53]	JABSTand MaxEnt-JABST	Twitter dataset- 71.2% Sina dataset- 69.8%
Amplayo et al. [48]	Ensemble based on PSO	Accuracy = 85.73%
Al-Smadi et al. [33]	SVM	Accuracy = 95.4%
Song et al. [54]	Attention based LSTM	Wikipedia 91.28% Customer reviews- 92.91% News articles- 92.07%
Ma et al. [50]	LSTM	Laptop- 73.1% Restaurant- 80.1
Tang et al. [55]	JABSTand MaxEnt-JABST	Amazon-83% Yelp-85%
Qiu et al. [39]	CRF	Accuracy = 93.6%

VII. CHALLENGES

In the past four to five years, ABSA, a fine-grained level of SA, has significantly impacted the modern technology-oriented world. This research addressed a few papers in this field, and it is evident from comparing the approaches used by different authors that deep learning works are producing more encouraging outcomes on aspect level SA. However, other studies indicate that machine learning techniques outperform deep learning techniques. For instance, Al-Smadi et al. [37] noted that SVM is outperforming RNN [37] in terms of performance. SA is very important today for several uses, including analysing client feedback. As a result, the domain is important for aspect level SA. It is evident from the works presented in this paper that most research projects are concentrating more on similar areas, such as computers, restaurants, hotels, etc. Several other highly significant categories, such as travel reviews and news, are still unexplored by researchers. Another major issue for researchers in this field is the absence of benchmark datasets on various domains. The language in which SA is conducted is another serious issue. Regional languages are hardly ever employed for SA duties; only a select few languages, such as English, Chinese, etc., are actively used. The widespread use of regional languages in social media has significantly increased the importance of this field, encouraging further research in SA at the aspect level. Further research in this field is being hampered by a lack of high-quality datasets in regional languages.

VIII. CONCLUSION

In the present e-world, SA, which is the process of deleting the opinions, feelings, or emotions from a text, has become well-known. Document level, phrase level, and aspect level SA are three levels of granularity within SA. Third level of analysis, known as ABSA, is far more in-depth and involves the extraction of aspects, words with matching feelings, and their polarity orientation. Since there has been a lot of research done on ABSA over the last three to four years, the organisation is currently attempting to stand on its own. The level of perception and complexity in SA have significantly changed because of the advent of machine learning. The absence of a benchmark dataset and the fact that publicly accessible datasets only cover a limited number of domains are two fundamental problems with ABSA. Deep learning techniques are producing some encouraging results for ABSA because of technology developments, but it is still clear from the literature review that the outcomes fall short of expectations. In other words, we may argue that the development of ABSA using deep learning is just getting started.

Epilepsy Detection with different ML Models using EEG Signals

Darshan Bachhav, Abdul Mueed, Kartik Rupauliha, Aditya Akangire, Sarthak Akkarbote, Zarinabegam Mundargi

Artificial Intelligence and Data Science VIT, Pune

,

Abstract – **The electroencephalogram (EEG) has emerged over the past few decades as one of the most important instruments used by doctors to identify seizures and other neurological abnormalities of the human brain. The particular character of epileptic convulsions and their subsequent negative effects on patients' quality of life made a precise epilepsy diagnosis crucial. As a result, this research suggests a novel deep-learning method based on the categorization of minimally pre-processed raw multichannel EEG signal recordings for detecting seizures in paediatric patients. In our model, the best accuracy we got is for the gradient boosting classifier which is 96% for the time series and 97% for the Fourier series.**

Keywords: **Aspect-based sentiment analysis, Sentiment analysis, Machine learning, Deep learning**

I. INTRODUCTION

One of the most prevalent neurological disorders in people, epilepsy is a non-communicable illness that frequently manifests as abrupt bouts. A quick and early aberration in the electrical activity of the brain that disturbs a part, or the entire body is a sudden episode of seizures. Millions of people globally experience various epileptic seizures. Sometimes these assaults result in mental illnesses that can seriously harm the patient's body. Additionally, humiliation and social isolation can cause mental anguish in those who have epileptic seizures. Therefore, catching epileptic seizures early can benefit patients and enhance their quality of life. Neurologists frequently utilise electroencephalograms (EEGs), which have been available for a while, to identify a variety of brain illnesses, particularly epilepsy, for practical reasons like availability, ease of use, and affordability. The way an EEG works is by placing a number of electrodes along the scalp's surface, then recording and measuring the voltage oscillations produced by the ion current running through the brain. These voltage oscillations, which represent the brain's neuronal activity, are subsequently converted into a number of time series known as signals. Since we can utilise EEG to precisely capture and indicate epileptic signals that are characterised by spikes, sharp waves, or spike-and-wave complexity, it is a very potent non-invasive diagnostic technique. EEG signals have therefore been the most widely used tool for both the detection and prediction of epileptic seizures.

II. LITERATURE REVIEW

[1]An Automated System for Epilepsy Detection using EEG Brain Signals based on Deep Learning Approach-Ihsan Ullah1 , Muhammad Hussain2. These methods do not perform well when classifying ternary cases e.g. ictal vs. normal vs. inter-ictal; the maximum accuracy for this case by the state-of-the-art methods is 97±1%. To overcome this problem, we propose a system based on deep learning, which is an ensemble of pyramidal one-dimensional convolutional neural network (P-1D-CNN) models.

[2]Detection of Epileptic Seizures using EEG Signals-Sarthak Gupta, Siddhant Bagga, Vikas Maheshkar automatic epileptic seizure detection techniques are needed, which are able to provide high-quality results in a short time for this an approach has been proposed that uses Discrete Wavelet Transform to convert the EEG signal into the time-frequency domain. various features are extracted and then classification is carried out on a number of classifiers including convolutional neural networks, random forests etc for the detection of epilepsy seizure. , an accuracy of 99.29 was achieved which outperformed the conventional epileptic seizure detection techniques.

[3]Detection of Epileptic Seizures using Convolutional Neural Network-Surbhi Gupta, Mustafa Sameer, Neeraj Mohan Most neurologists widely use Electroencephalogram (EEG) signals to identify epilepsy by recording the brain's electrical activity directly. They made a lightweight CNN architecture for seizure classification. High accuracy is achieved in only 20 epochs with few trainable parameters for binary classification.

[4]Seizure Detection Using EEG signals-Zakareya Lasefr, Sai Shiva VNR Ayyalasomayajula, and Khaled Elleithy.The authors propose an epilepsy seizures detecting method that can be implemented in a hardware device to help epileptic patients. They utilized an EEG dataset that is used in various research regarding epilepsy detection and processed the EEG signal in both time and frequency domains and applied a Chebyschev filter for preprocessing the signal, then, by using Wavelet Analysis, we decomposed the filtered signal into five sub-bands in both time and frequency domain.

[5]Detection of Epileptic Seizures from EEG Signals by Combining Dimensionality Reduction Algorithms with Machine Learning Models-Muhammad Zubair, Maria Vladimirovna Belykh I, Umesh Kumar Naik. In this paper, more emphasis has been given to developing SPPCA and SUBXPCA dimensionality reduction algorithms to increase the classification accuracy of various machine learning models. Firstly, Discrete Wavelet Transform (DWT) is applied to EEG signals for extracting the time-frequency domain features. , to select the prominent features and to retain their properties, correlation feature sub-pattern-based PCA (SPPCA), and cross subpattern correlation-based PCA (SUBXPCA) are

used as a dimensionality reduction techniques and the best accuracy of 98% for SUBXPCA is achieved by random forest classifier.

[6] Early Detection of Epilepsy using EEG signals-Selvin Pradeep Kumar.S, Ajitha.L ,According to the paper, they have studied pre-ictal (background) and ictal (epileptic) EEG signals using higher order spectra (HOS) and the measures obtained were shown which distinguish epileptic EEG from normal and background EEG with high confidence levels.

[7] Epilepsy Detection and Classification for Smart IoT Devices Using hybrid Technique-Sani Saminu, Guizhi Xu, Shuai Zhang. This paper presents an effective and efficient technique suitable for smart, low-cost, power and real-time devices that can be easily integrated with recent 5G network IoT devices for mobile applications, home and health care centres for monitoring and alerting the doctors and patients about its occurrence to prevent a sudden collapse and consciousness which may cause injury and death. The efficiency and accuracy of these smart devices highly depend on the quality of feature extraction methods and classifier performance. Therefore, this work employed two machine learning classifiers, a support vector machine (SVM) and a feedforward neural network (FFNN).

[8] Enhanced Detection of Epileptic Seizure Using EEG Signals in Combination With Machine Learning Classifiers- WAIL MARDINI, MUNEER MASADEH BANI YASSEIN, SHADI ALJAWARNEH. The proposed framework in this paper uses the 54-DWT mother wavelets analysis of EEG signals using the Genetic algorithm (GA) in combination with other four machine learning (ML) classifiers: Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Artificial Neural Network (ANN), and Naive Bayes (NB). The performance of 14 different combinations of two-class epilepsy detection is investigated using these four ML classifiers. The experimental results show that the four classifiers produce comparable results for the derived statistical features from the 54-DWT mother wavelets; however, the ANN classifier achieved the best accuracy in most dataset combinations.

[9] Machine Learning Approach for Epileptic Seizure Detection Using Wavelet Analysis of EEG Signals-Abhishek Kumar, Maheshkumar H. Kolekar. In this paper, discrete wavelet transform is used for the time-frequency analysis of EEG signals. Using discrete wavelet transform, the EEG signal is decomposed into five different frequency bands namely delta, theta, alpha, beta and gamma. Only theta, alpha and beta carry seizure information. The support vector machine classifies the input EEG signal into the seizure-free signal. Experimental results show that the proposed method classifies EEG signals with excellent accuracy, sensitivity and specificity.

[10] Multichannel Detection of Epilepsy using SVM classifier on EEG signal-Manish N. Tibdewal, Swapnil A. Tale. They proposed an efficient mechanism algorithm based on statistical analysis using features i.e. average value, standard deviation, variance and kurtosis along with the electrical features such as least significant value, most significant value and band power. These features were used on multichannel EEG signals which provide promising results with less complexity, simplicity along with accuracy. Thus, an automatic seizure detection mechanism based on multichannel EEG signal analysis using advanced signal processing techniques with statistical and electric features helps to reduce the physician workload.

III. Methodology

The original dataset can be found at (https://archive.ics.uci.edu/ml/datasets/Epileptic+Seizure+Recognition) in the UCI Machine Learning Repository. This dataset contains the electroencephalogram (EEG) measurements of 500 people, which were broken down into 4097 separate data readings and 23 chunks for each person. As a result, there are 23 x 500

= 11,500 rows of data. The 178 columns in each row correspond to EEG readings taken over the course of one second. The label y in column 179 denotes whether the patient is experiencing a seizure (y = 1) or not (y = 2, 3, or 4,5).

We're interested in learning ways to spot epilepsy as early as possible. From a data science perspective, our issue can be viewed as a classification problem in which we are dividing cases of epilepsy and cases without epilepsy. We expanded this issue and made the decision to use the most effective machine learning model for identifying epilepsy.

We used classification accuracy and FNR as our measures. To reduce the amount of undiagnosed epilepsy, we made the FNR an important variable.

EEG Signals

A signal from an electroencephalogram (EEG) shows the electrical activity of the brain. They have a highly erratic nature and could provide insightful data about the status of the brain. However, it is quite challenging to infer anything helpful from these signals in the temporal domain simply by seeing them. In essence, they have a non-linear and non- stationary nature. Consequently, crucial features can be retrieved by utilising cutting-edge signal processing techniques for the diagnosis of various disorders.

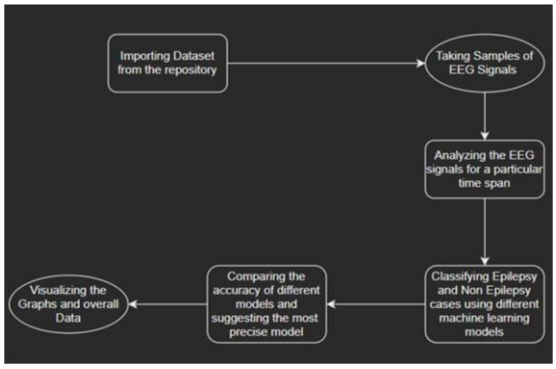
Gradient Boosting Classifier

The combination of gradient descent and boost is known as gradient boosting. Each new model in gradient boosting employs the gradient descent method to reduce the loss function from its forerunner. This process is repeated until the target variable's estimation is more accurate. In contrast to previous ensemble techniques, gradient boosting builds a succession of trees, each one attempting to fix the flaws of the one before it.

Anomaly Detection Algorithm

Finding something that deviates from a dataset's expected behaviour is done using the anomaly detection technique. Anomaly detection, in other words, locates data points in a dataset that differ from the rest of the data. They are referred to as outliers, quirks, exceptions, surprises, and so on.

IV. Flowchart



V. Time Series

Step 1: Balancing the Dataset for Time Series

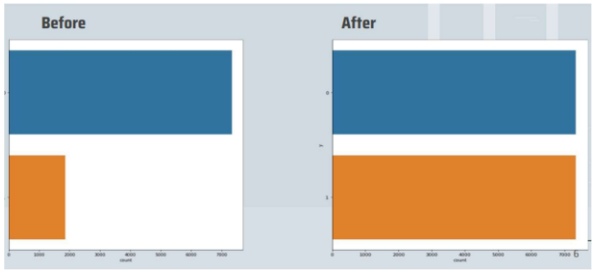


Fig [1]

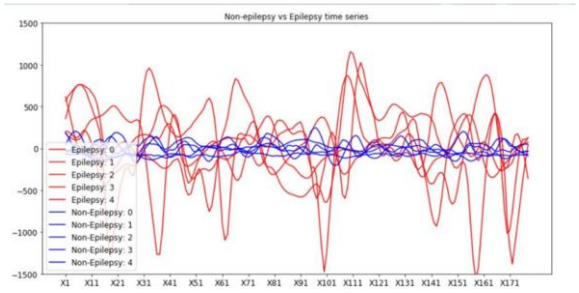
Step 2: Analysing Non-Epilepsy vs Epilepsy patients through Time series



Step 3: Analysing the KNN, Logistic, Anomaly and Gradient Boosting Classifier Machine Learning algorithms through Time series.

Step 4: Comparing the 4 machine learning models accuracy and False Negative Rate for the Time series.

VI. Fourier Series

Step 1: Visualizing Dataset for Fourier Series

Step 2: Analysing Non-Epilepsy vs Epilepsy patients through Fourier series

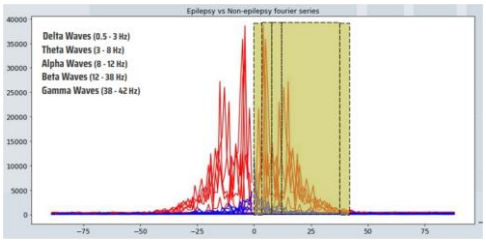


Fig [2]

Step 3: Analysing the KNN, Logistic, Anomaly and Gradient Boosting Classifier Machine Learning algorithms through Fourier series.

Step 4: Comparing the 4 machine learning models accuracy and False Negative Rate for the Fourier series.

VII. Results

The figure shows the accuracy of all the 4 machine learning models.

	Model	Time Acc	Fourier Acc
0	Logistic Regression	0.4935	0.9265
1	K-Nearest Neighbors	0.9278	0.9634
2	Gradient Boosting Classifier	0.9696	0.9757
3	Anomaly Detection	0.9452	0.9573

Fig [3]

The figure shows the False Negative Rates of all 4 machine learning models.

	Model	Time FNR	Fourier FNR
0	Logistic Regression	0.5326	0.0545
1	K-Nearest Neighbors	0.3478	0.0260
2	Gradient Boosting Classifier	0.0435	0.0392
3	Anomaly Detection	0.0482	0.0910

Fig[4]

VIII. CONCLUSION

This review serves as an introduction to epileptic seizures and identification of highlighting the main factor restricting the detection, i.e., a method for identifying epileptic seizure data from different EEG circumstances. In order to highlight the significance of various machine-learning techniques, a brief history of several machine-learning models for epileptic detection is given.

Music Overflow: A Music Genre Classification Web Application

Pallavi Bharambe,Shubham Bane, Tejas Indulkar,Yash Desai

SSJCOE Dombivli (E), India

pallavi.bharmbe87@gmail.com,shubham.bane13@gmail.com, tejas.indulkar2001@gmail.com,yashd.342@gmail.com

Abstract – **"Music Overflow": An automated classification model for music genres is proposed to be created using a Music Genre Classification Web Application. A traditional class that identifies some portions of music as belonging to a not unusual way of life or set of conventions is known as a music genre. It must be distinguished from musical style and shape. there are numerous methods that tune may be divided into distinctive genres. Pop, Hip-Hop, Rock, Jazz, Blues, country, and steel are popular forms of track. Content-based music genre classification is an essential component of music information retrieval systems. With the rise of digital music on the Internet, it has gained prominence and received a growing amount of attention. Automatic music genre classification has received little attention to date, and the reported classification accuracies are also quite low. To determine a music piece's genre, we examine how various classifiers perform on various audio feature sets. Lastly, we experiment with combining various classifiers to improve classification accuracy. On a 10 style set of one thousand song pieces, we first obtain a take a look at style category accuracy of round 73.2 percent with a set of different classifiers. This performance is higher than the great that has been reported for this statistics set, that is 71.1 percent. we discover that the classifier used determines which function set is first-rate.**

Keywords: ***Model View Template (MVT), Django Template Language (DTL), Mel Frequency Cepstral Coefficients (MFCC), Music Information Retrieval (MIR), Hypertext Markup Language (HTML), Database Management System (DBMS).***

I INTRODUCTION

Genre classification is the process of grouping similar types of data into a single identity and giving that identity a name (based on its rhythm, played instrument, or harmonic content). The music industry is increasing around the globe and every day new songs are written. Because categorizing these songs on a daily basis will become tiresome, technology can be used to cure the music and make categorizing it easier or more efficient by utilizing its rhythms, beats, and lyrical composition. An audio signal can be used to represent a song. The frequency, spectral roll-off, root-mean-square (RMS) level, bandwidth, zero-crossing rate, spectral centroid, and other characteristics of this audio signal are just a few examples. The computer in different format such as wav or mp3 reads this audio signal. Different music streaming apps like Spotify, Wynk, Apple Music, etc. use genre classification to recommend songs to its user. Anessential component of a comprehensive music information retrieval system for audio signals is the automatic classification of musical genres, which has the potential to automate this process. For classification, we hire pattern recognition algorithms as function vectors. For our class hassle, we attempted some extraordinary supervised studying algorithms. [1]

II.Literature Survey

Since the beginning of the Internet, the classification of music genres has been the subject of extensive research. Using supervised machine learning techniques like the Gaussian Mixture model and knearest neighbor classifiers, Tzanetakis and Cook (2002) solved this issue. [1]

They introduced three sets of features: timbral structure, rhythmic content, and pitch content. Music genre classification has also been investigated using Hidden Markov Models (HMMs), which have been extensively utilized for speech recognition tasks (Scaringella and Zoia, 2005; Soltau and others, 1998). [2]

For genre classification, Mandel and Ellis (2005) study and compare support vector machines (SVMs) with various distance metrics. According to Zwicker and Fastl (1999), the authors of Lidy and Rauber (2005) talk about the role that psycho-acoustic features play in determining the genre of music, particularly the significance of STFT taken on the Bark Scale. [3]

The features used by were Mel-frequency cepstral coefficients (MFCCs), spectral contrast, and spectral roll-off (Tzanetakis and Cook, 2002). [4]

In Nanni et al., SVM and AdaBoost classifiers are trained using a combination of visual and acoustic features. (2016).[5]

A number of studies employ deep neural network techniques to analyze speech and other kinds of audio data in light of their recent success (AbdelHamid et al., 2014; Gemmeke and others, 2017). Due to the high sampling rate of audio signals, it is difficult to represent audio in the time domain for neural network input. [6]

However, Van Den Oord et al. (have addressed it. 2016) for tasks related to making audio. The spectrogram of a signal, which includes information about both time and frequency,is an alternative representation that is frequently used. [7] Music genre classification is an important and highly studied field of research in the music industry. The goal of this literature survey is to examine and summarize the current state of research in this area. In conclusion, it can be seen that music genre classification is an important and highly studied field of research. A variety of approaches have been explored for this task and the combination of content-based analysis and machine learning algorithms has been found to be effective.

III. Motivation

Web Application Development is one of the most rising & promising arenas due to the increase in computation power and the never-ending problems which lay the foundation for building the web applications. The

software is for music lovers. By allowing music fans to simultaneously listen to songs with their closest friends, a music streaming app can improve its social features. People who enjoy listening to music and want to share their experience with close friends use web apps that stream music online. A music information retrieval (MIR) task whose goal is the computational comprehension of music semantics is to comprehend and apply music classification. The classifier predicts relevant musical attributes for a given tune. There are nearly limitless classification tasks based on the assignment definition, ranging from genres, moods, and gadgets to extra preferred principles like musical options and similarity. numerous extra applications, which includes playlist generation, semantic search, and music recommendation, can employ the retrieved statistics.

IV. Problem Statement and Objectives

Even though categorizing a song into a genre is a task that is inherently subjective, the human ear finds it easy to do. A new song's timbre, instruments, beat, chord progression, lyrics, and genre are all easily identifiable in a matter of seconds. For machines then again this is a seriously mind boggling and overwhelming errand as the entirety "human" experience of paying attention to a tune is changed into a vector of elements about the melody. In the past, many of these musical characteristics that humans recognize in music have not been reliably detected by machines. We are considering a 10-genre classification problem with the following categories: classical (cl), country(co), disco(d), hip-hop(h), jazz(j), rock(ro), blues(b), reggae(re), pop(p), metal(m). Finally, we have chosen six popular genres namely classical, hip-hop, jazz, metal, pop and rock to get more accuracy for our final web-app. Mel Frequency Cepstral Coefficients (MFCC) are the feature vectors used in our pattern recognition algorithms for classification. Over traditional music players, we are planning to make an entertainment music web app. Objective:

The objectives of music genre classification are as follows: -

•To extract the features from the given music.

•To classify the input music based on the extracted features and label a class(genre) name to it.

•To quantify the match of any input music to the listed genres.

•To make genre classification more accurate.

•To discover the more than one genres to which a song belongs to.

•Our group is highly enthusiastic to build web apps.

•To learn and implement MVT architecture components.

•To make a music lovers community web app.

V.METHODOLOGY STEP

1: Data Preparation

In our paper, the GTZAN dataset is used, which was first used by authors in [10]. This dataset has 10 classes, Blues, Classical, Country, Hip-Hop, Pop, Jazz, Metal, Disco, Reggae and Rock. Each class containing 100 audio clips, each clip being 30 seconds long in .wav format and is samples at 22050Hz, 16bit.

Step 2: Data Pre-Processing

Sr no.	Class	Clips
1	Blues	100
2	Classical	100
3	Country	100
4	Disco	100
5	Hip-hop	100
6	Jazz	100
7	Metal	100
8	Pop	100
9	Reggae	100
10	Rock	100
	Total	**1000**

Table 1. Brief information of dataset

Train-Test Split

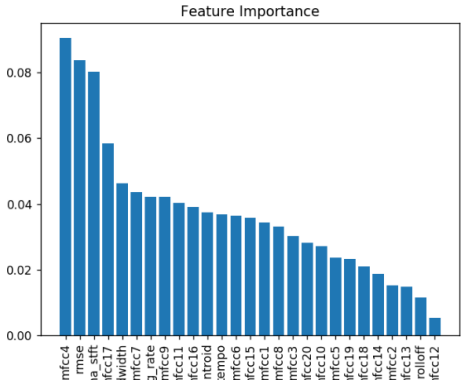
while machine learning algorithms are used to make predictions on records that has not been used to train a model, a split train test method is used to estimate how well they perform using the consequences of this quick and smooth technique, you could examine the overall performance of machine learning algorithms for your predictive modelling trouble. even though the method is straightforward to apprehend and use, there are instances when you should no longer use it, such as when you have a small dataset or whilst you want additional configuration, inclusive of whilst it is used for class and the dataset isn't always balanced.

Min-Max Normalization

The fundamental idea behind normalization and standardization never changes. Variables that are measured at different scales may result in a bias because they do not all contribute equally to the model fit and learned function. Consequently, prior to model fitting, feature-wise normalization like MinMax Scaling is typically utilized to address this potential issue.

Feature Importance

The degree to which each feature contributes to the prediction of the model is shown by the feature (variable) importance. It basically determines how useful a particular variable is for the current model and prediction. For instance, if we want to predict a person's weight using their height, age, and name, it is clear that the variable height will have the greatest impact, while the variable name has no bearing on the person's weight. In general, we use a numerical value that we refer to as the score to represent the importance of features. The higher the score value, the more significant a feature is. A feature importance score has numerous advantages. For instance, the relationship between the independent variables (features) and the dependent variables (targets) can be determined. We would be able to identify and exclude



irrelevant features by analyzing variable importance scores. The model may run faster or even perform better if the number of not meaningful variables is decreased.

Fig.1 Feature importance

Step 3: Extraction of features

Mel-Frequency Cepstral Coefficients

The maximum current methods for sound recognition and type employ MFCC, which is a hard and fast of brief-term power spectrum traits of the sound. It exemplifies human voice characteristics. The final feature vector (13 coefficients) contains a significant portion of this feature.

The following is how to use this feature:

–Breaking up the signal into a number of brief frames. This step aims to keep a constant audio sign.

–The periodogram estimate of the energy spectrum became calculated for every frame. that is to study the frequencies within the brief frames.

–Injecting the power spectra into the mel filterbank and summing the energy from each filter The number of energy residing in the various frequency regions will then be known.

$$m = 2595 \log_{10}\left(1 + \frac{f}{700}\right)$$

–Using the previous method of calculating the logarithm of the filterbank energies, we can bring our facial features closer to what we can hear.

–Determining the result's Discrete Cosine Transform (DCT). It links the energies of the filterbanks together.

Chroma Frequencies

The presence of each chromatic key is represented by the chroma frequency vector, which divides the spectrum into chromatic keys. A 12-length function vector is taken from the histogram of cutting-edge notes on a 12-observe scale. The song concept explains the chroma frequency. The chord performed in that window can be correctly defined through looking at the histogram above the 12-note scale. It affords a sturdy technique for describing a degree of musical similarity.

Spectral Centroid

It specifies the area of the "centre of mass" for sound. It is basically the weighted mean of the sound's frequencies.Take a look at two songs—one from metal and one from blues. A blues tune is by and large steady all through it length while a metal melody ordinarily has more frequencies collected towards the end part. Consequently, a blues music's spectral centroid will normally be towards the center of its spectrum than a metal music's.

$$\text{Centroid} = \frac{\sum_{n=0}^{N-1} f(n)x(n)}{\sum_{n=0}^{N-1} x(n)}$$

Zero Crossing Rate

The wide style of instances the waveform crosses zero is represented via this. It generally has better values for sounds with a whole lot of percussion, like rock and metal.

$$zcr = \frac{1}{T-1}\sum_{t=1}^{T-1} 1_{\mathbb{R}_{<0}}(s_t s_{t-1})$$

Spectral Roll-off

It is a measurement of the signal's shape. It's the frequency at which the high frequencies drop to zero. To get it, we need to figure out how many bins in the power spectrum have 85 percent of their power in lower frequencies.

Step 4: Model Selection

Support Vector Machine Support Vector Machine, also known as SVM, is one of the most widely used supervised learning algorithms. It can be used to solve regression and classification problems. However, in Machine Learning, it is primarily utilized for Classification issues.

The SVM algorithm's objective is to find the most effective line or decision boundary for classifying n-dimensional space, allowing us to quickly place a new data point in the appropriate category in the future. A hyperplane is the name given to this best decision boundary.

The extreme points and vectors that aid in the creation of the hyperplane are selected by SVM. The algorithm is known as a support Vector machine because of the reality the ones severe instances are known as support vectors.

Step 5: Train and Test

Dataset has 10 classes, Blues, Country, Pop, Classical, Hip- Hop, Metal, Disco, Jazz, Rock and Reggae. Each class containing 100 audio clips, each clip being 30 seconds long in .wav format.

Of which,75% of data is used for training and 25% of data is used for testing.750 examples are used for training the model and 250 examples are used for testing the accuracy of the model.

We get highest testing accuracy with SVM ML model is 73.2%.

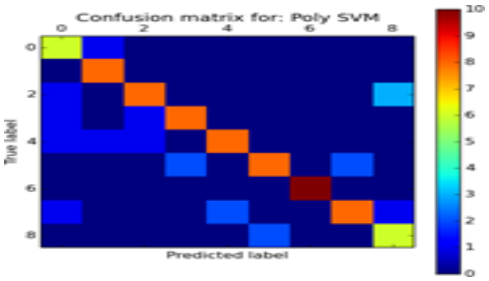


Fig. 2 Confusion Matrix for SVM classifier

VI.PROPOSED SYSTEM

So, this will be the general process flow of the project. User gives music file as an input, with is then processed which includes check for null data or any garbage value in dataset.subsequent step is feature Extraction using mel frequency cepstral coefficients (MF1CC) which extracts characteristic vector from music record. Next step is Classifier in which we create ML model using different machine learning algorithms which results into generation of genre label.

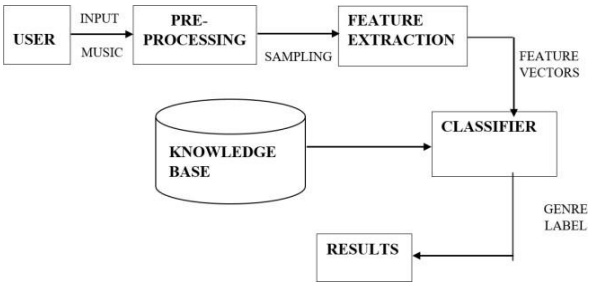

Fig. 3 Process Diagram

VII. DJANGO MVT ARCHITECTURE

A software design pattern is MVT (Model View Template). Model View and Template are two of its three key components. The Model makes managing databases easier. The data is handled by a data access layer.

The User Interface component is entirely handled by the Template, a presentation layer. The View renders a template, interacts with a model to carry data, and carries out the business logic.

Even though Django adheres to the MVC pattern, it still adheres to its own conventions. As a result, the framework itself handles control.

The entire application is built on Model View and Template, so there is no separate controller. It is therefore known as an MVT application.

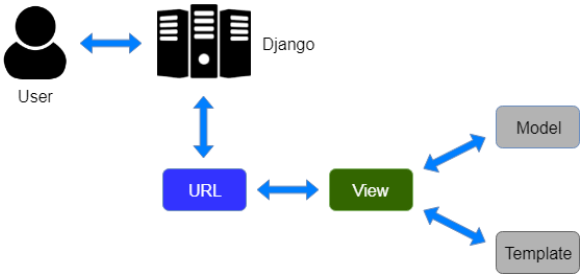

Fig. 4 MVT Architecture

VIII. RESULTS

The results explanation related to the snapshots of the various modules to the entire process of execution. The different modules can explain the working of procedure.

The user has to select the option depending upon the requirements. The choice-based option contains upload music and find genre.

Figure 5 shows the front face of the Web App.

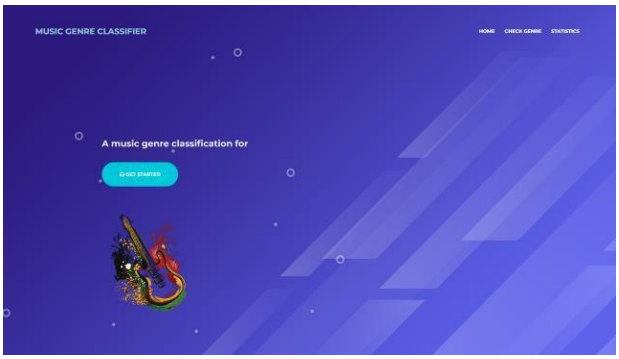

Fig. 5 Front face of web app

Figure 6 illustrates the uploading of the music. As the user clicks the 'upload file' button the Web App shows the file explorer to select the file or directly drag and drop file.

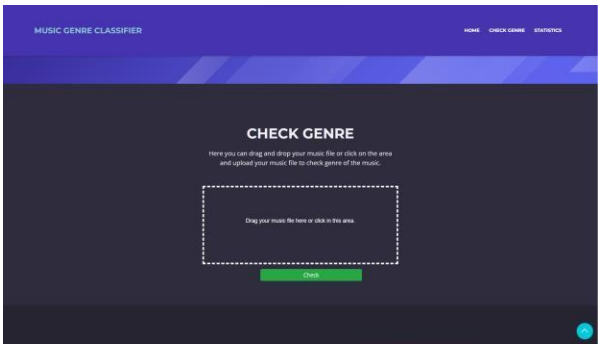

Fig. 6 Upload the music

Figure 7 illustrates the file being classified according to genre. As the user clicks the 'check' button the Web App. It will take 2-5 minutes according to the input file and display the genre of the uploaded file.

Fig. 7 Finding the genre

IX. CONCLUSION

The user can classify music files according to genre with the help of the proposed research.

Utilizing a variety of machine learning algorithms, this project on the classification of music genres was

completed. We wanted to get the best accuracy.

In order to develop and train our model, we have implemented a number of best practices. We have learned a variety of framework patterns and best practices that are currently utilized in industry throughout the model's development.

It has been found to be impossible to test a large number of combinations in order to obtain an accurate application evaluation.

The analysis of the results indicates that the current model functions properly and has attained the desired format of 73.2 percent accuracy. In order to develop and train our model, we have implemented a number of best practices. Throughout the model's development, we learned about various architecture patterns and best practices currently used in industry.

X. FUTURE SCOPE

We can deploy Web App on the cloud so that we can scale our web app. We can also provide API for developers. Another thing we can try to improve the accuracy is trying a different dataset or dynamically increase the dataset as the user input new music.

XI. ACKNOWLEDGEMENT

We would like to thank our school director Dr. Pramod R. Rodge for providing laboratory equipment and permission to continue our project.

We also extend our deepest thanks to our H.O.D. Dr. Uttara Gogate who is benevolent is helping us to make computer equipment available to us for our project in our lab and to make it a real success. Without his kind and enthusiastic cooperation, our project would have stalled.

We would like to thank our project coordinator Prof. Reena Deshmukh for all the support we need from her for our project.

Finally, we would like to sincerely thank our project guide Prof. Pallavi Bharambe for her encouraging and provoking steerage which helped us to make our project a success. Our project guide makes us persevere along with her professional steerage, kind advice and timely motivation to assist us decide on our undertaking. We would also want to thank our colleagues who directly or in a roundabout way helped us in the course of our project.

Ensemble Model For Spam Detection

Vikrant Gawale, Janhavi Jain, Vedika Jamdar, Prof. Savita Sangam
Shivajirao S Jondhale College of Engineering University of Mumbai ,dombivli, INDIA.

Abstract— **E-mail has become a globally used application for official communication. This is because it is easy to use and the transfer speed is faster than any other communication app. However, its lack of intelligence to detect whether received mail is spam or ham reduces its main effectiveness. Currently, there have been several reported cases of identity theft or phishing activities via email from a user, leaving the user helpless. E-mail spam has become a big problem nowadays, with the rapid growth of internet users, e- mail spam is also increasing. People use them for illegal and unethical behavior, phishing and fraud. This project will discuss how machine learning can play a major role in spam detection. Machine learning is an application of artificial intelligence that provides the ability to automatically learn and improve data without being explicitly programmed. We use a binary classifier to classify text into two different categories; spam and ham. The algorithm predicts the score more accurately. Now, no single algorithm can be fully relied upon to categorize an email as spam or not. Many important emails will be missed if they are falsely marked as spam. This can cause heavy losses and negligence. Many spam classifiers currently available classify emails, but their reliability is questionable. The goal of developing this model is to detect and evaluate a word faster and more accurately using multiple algorithms and provide a single accurate classification based on the ensemble model.**

Keyword- spam, ham, KNN, Naïve Bayes, Support Vector Machine, Ensemble Classifier, Voting, Bagging, Boosting.

I. INTRODUCTION

Spam email is email that the recipient does not want to receive. Multiple identical messages are sent to multiple email recipients. Spam usually results from providing email addresses on unauthorized or immoral websites. Spam has many consequences. Fill your inbox with ridiculous emails. It greatly reduces your internet speed.It steals useful information like details from your contact list. Change search results in any computer program. Spam is a huge waste of time for everyone and can be very annoying if you get spam in bulk. Identifying these spammers and their spam content is a daunting task. Although a large amount of research has been done, the methods described so far still barely distinguish spam surveys and do not show the benefits of all factors removed. Despite the growth of network communication and massive memory loss, spammessages are also used in some attacks. Spam email, also known as non-proprietary email, is unsolicited commercial or malicious email sent to influence individuals, businesses or groups. In addition to advertisements, it may contain links to phishing sites that have been found to steal confidential information or to sites hosting malware. Various spam filtering methods are used to solve this problem. Spam filtering methods usually protect mailboxes from spam.

Ensemble Learning - A generic technique to machine learning called ensemble learning combines the predictions from various models to get superior predictive performance. There are three techniques that rule the world of ensemble learning, even though there are an apparent infinite amount of ensembles you can create for your predictive modelling issue. So much so that it is a topic of study that has given rise to numerous more specialised approaches rather than algorithms. Bagging, stacking, and boosting are the three primary classes of ensemble learning techniques, and it's critical to understand each one well and take it into account in any predictive modelling project. Spam e-mails, known as unsolicited e-mail messages, have become an increasing problem for information security.

Email spam intrusions annoy users and waste network resources. Traditionally, machine learning and statistical filtering systems have been used to filter email spam. However, there is no unique method that can be successfully used to classify spam messages. Detecting spam and effectively filtering out the growing number of spam emails requires several approaches. In this article, we use an ensemble approach based on decision trees, support vector machines, and back propagation networks to classify spam emails. The proposed approach is based on the nature of spam messages. Spam emails are classified according to 14 characteristics and then an ensemble approach is applied to classify them. Simulation results show that the proposed ensemble approach outperforms the other approaches on both test datasets. No single algorithm can produce perfect predictions for a given set of data. Machine learning algorithms have limitations, and building models with high accuracy is challenging. Creating and combining multiple model can improve overall accuracy.Ensemble Methods - An ensemble method is one in which multiple models are created and then combined to produce improved results. Ensemble methods usually produces more accurate solutions than a single model would as they combine different single methods. Majority Voting Every model makes a prediction (votes) for each test instance and the final output prediction is the one that receives more than half of the votes. If none of the predictions get more than half of the votes, we may say that the ensemble method could not make a stable prediction for this instance. Although this is a widely used technique, one may try the most voted prediction (even if that is less than half of the votes) as the final prediction. In some articles, one may see this method being called “plurality voting.”

Machine Learning Algorithms Used

A. SUPPORT VECTOR MACHINE

Support Vector Machine (SVM) is a machine learning algorithm that is commonly used for email spam detection. The algorithm is used to classify an email as

either spam or not spam (ham). The basic idea behind SVM for email spam detection is to represent each email as a vector of features and then use these features to train the SVM algorithm to distinguish between spam and ham emails. The features used in the vector representation can be words, phrases, or any other characteristics of the emails that are informative for the classification task. In the training phase, the SVM algorithm learns to separate the spam and ham emails in the feature space by finding the optimal boundary that maximizes the margin between the two classes. This boundary is known as the maximum margin hyperplane, and it defines the decision boundary that the SVM uses to classify new emails. In the testing phase, new emails are transformed into feature vectors and then classified by the SVM algorithm based on their position relative to the maximum margin hyperplane. If an email is on the spam side of the boundary, it is classified as spam, and if it is on the ham side, it is classified as ham. SVM has proven to be an effective method for email spam detection and is widely used in industry for this purpose. Its ability to handle high- dimensional data and find non-linear decision boundaries makes it well-suited for text classification tasks like email spam detection.

B. MULTINOMIAL NAÏVE BAYES

Multinomial Naive Bayes is a classification algorithm used to detect email spam. It is based on the Bayes theorem of probability and assumes that features of an email (e.g. words) are independent of each other. The algorithm calculates the probability of an email being spam or ham (legitimate email) based on the frequency of words in each category.The algorithm starts by training a model on a large dataset of labeled emails (spam or ham). It creates a vocabulary of all the words used in the emails and calculates the frequency of each word in each category. During the classification phase, the algorithm uses these probabilities to determine the likelihood of a new email being spam or ham. The Multinomial Naive Bayes algorithm is specifically designed for text classification problems like email spam detection, where the features are discrete values representing word frequencies. It works well in practice and is commonly used in spam filters due to its high accuracy and efficiency. Formula: P(A|B) = P(A) * P(B|A)/P(B)

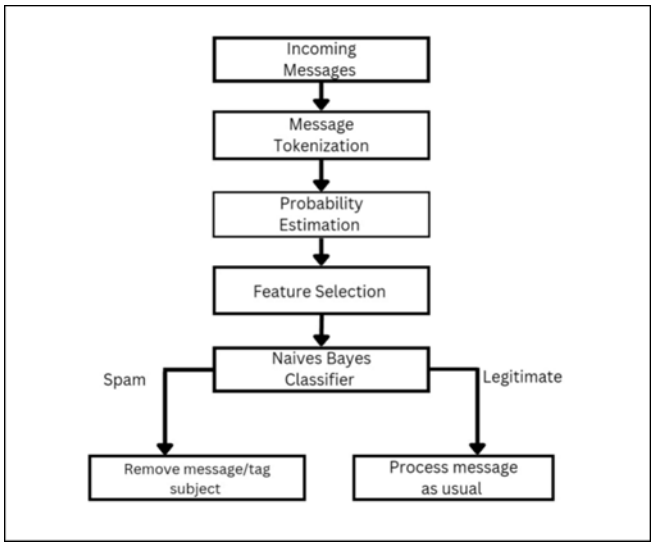

Fig 1: Multinomial Naïve Bayes

C. EXTREMELY RANDOMIZED TREES CLASSIFIER

Extremely Randomized Trees Classifier is a machine learning technique that can be used for email spam detection. It is an ensemble learning method that belongs to the random forest family of algorithms. In email spam detection, the goal is to classify incoming emails as either spam or not spam (ham). Extremely Randomized Trees Classifier works by training a large number of decision trees on a random subset of the features of the email. Each tree votes on the class of the email, and the class with the most votes is the prediction of the ensemble. The "extremely randomized" part of the name refers to the way the trees are constructed. In a traditional random forest, the features are randomly selected for each split. In an extremely randomized tree, the feature selection is random, as well as the threshold value used to split the data. This randomization leads to more diverse trees, which results in a more robust and accurate prediction. Overall, Extremely Randomized Trees Classifier is a powerful and efficient tool for email spam detection, and has been shown to perform well in practice. Its ability to handle high-dimensional and sparse data makes it well-suited for the task of classifying emails.

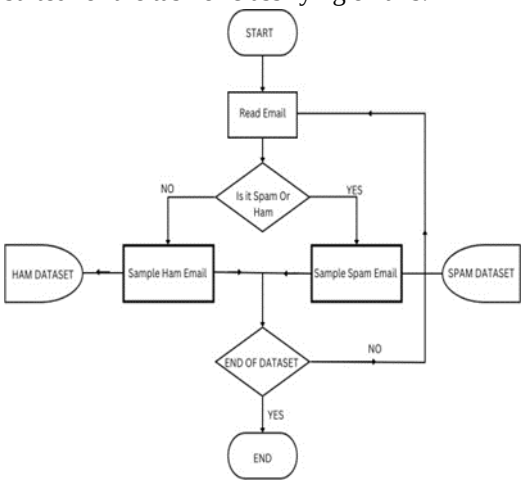

Fig 2: EXTREMELY RANDOMIZED TREES CLASSIFIER

A tight competition between filtering method and

spammers is going on per day, as spammers began to use tricky methods to overcome the spam filters like using random sender addresses or append random characters at the beginning or end of mails subject line. There is a lack of machine learning models that focus on the model development that can predict the activity. Many algorithms fail in such tests and give inaccurate classification. Here we try to solve the problem of this inaccuracy based on single algorithm. The ensemble model is the single voter model that runs the spam detection activity with multiple different algorithms and provides the improved accuracy. The email now has to go through many filters. As spam is a waste of time to the user since they have to sort the unwanted junk mail and it consumes storage space and communication bandwidth. It is hard to manually compare the accuracy of classified data.

II. RELATED WORK

E-mail spam acts as a plague of network technology as it affects both individuals and business users with receiving more spam e-mails. Email spam comes in various formats such as shortened URLs, attachments, advertisements, spyware, trojans, etc. Researchers are constantly working on techniques to control and limit email spam. In this research paper, we have discussed the latest and quality publications by researchers who have presented some significant works for email spam detection. The research publications considered are discussed here.

Hassan [8] tested a combination approach of k-means clustering with supervised learning classifiers. The author conducted research experiments to verify the change in evaluation accuracy results with the addition of a clustering approach with classifiers. Research experiments were conducted on the Enron-Spam dataset. The combined approach includes clustering with supervised decision tree (DT), logistic regression (LR), k-nearest-neighbor (KNN), support vector machine (SVM), and naive bay (NB) classifiers. The evaluation results showed that no major change in accuracy was observed. Only a small improvement was noted for the combined clustering and LR approach. All methods were unaffected.

Olatunji [9] performed email spam detection by considering Extreme Learning Machines (ELM) and SVM approach. In the research experiments, the ELM approach consumes less time compared to the SVM algorithm, but the SVM outperformed in terms of accuracy compared to the ELM. ELM & SVM concepts are also compared with Fuzzy logic, BART, NSA, PSO & NSA-PSO concepts and show better results than others for email spam classification.

Kumaresan and Palanisamy [10] adapted the algorithm of Cuckoo Search by adding the StepSize feature to it and introduced as Cuckoo Search with Stepsize (SCS) approach. In this work, authors have also used the classification approach of SVM. Here, feature selection is performed with proposed SCS approach and classification with SVM approach. The performance efficacy results indicate the dominance of proposed SCS-SVM approach as compared to existing CS-SVM.

Chawathe [11] used a fuzzy rule (FURIA) to improve the security of an email system. Here, a system based on fuzzy rules for email spam detection is proposed and the SpamBase database is used for experimentation. The author performed the experiment on a Java virtual machine and the Weka tool. The PART and JRip algorithms were also considered for classification comparison. The author monitored the comparable performance of the proposed concepts with other concepts.

Cohen et al. [12] utilized extensive email features related to header, content, and other attachments to analyze the content of malicious email. There is a manual collection of email dataset by analyzing emails using VirusTotal tool to define the status of emails. The authors conducted various experiments based on feature set, email depth with spam impact analysis, etc. The authors used several machine learning classifiers to analyze the results with an integrated detection rate parameter and reported an effective evaluation using a random forest classifier.

Agarwal and Kumar [13] combined the concepts of Particle Swarm Optimization (PSO) and Naïve Bayes algorithm to detect spam emails. In this approach, the PSO algorithm was used to improve the classification efficiency evaluated using the Naïve Bayes approach. The authors took into account the ling spam corpus and conducted an experiment with 1000 randomly selected e-mails. The evaluation of the system was carried out in terms of evaluation metrics. The integrated approach suggests the superiority of the concept compared to the individual Naïve Bayes classifier.

Naem et al. [14] conducted e-mail spam detection experiments by combining the concepts of access reinforcement and Ant-Lion optimization (ALO). The combined approach was named ALO-Boosting and was experimented on Spam Assassin and CSDMC2010 datasets. In the combined approach, the ALO algorithm is used for feature selection and the Boosting approach is used for the classification procedure. The proposed integrated approach was compared with ALO-Bagging, ALO-SVM, ALO-KNN, Boosting, Bagging and individual SVM & KNN classifiers.

III.IMPLEMENTATION

Jupyter Notebook is used to implement this model and, in this module, a dataset from “Kaggle” website is used as a training dataset and perform necessary preprocessing that needed to be transformed in an useful format so that it can used for further analysis. We divided the Dataset into two parts: Training (80%) and Testing (20%).

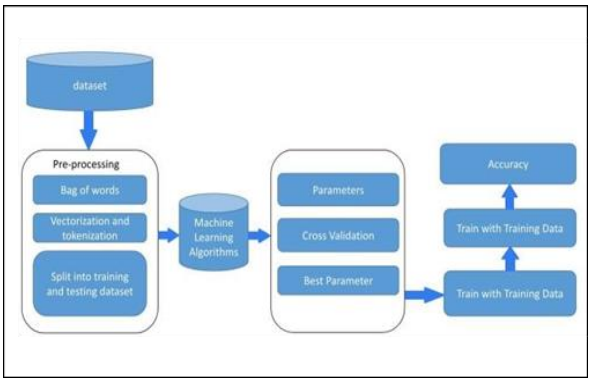

Fig 3: System Design

1. Data Cleansing – It is the process of correcting or removing incorrect, duplicate or incomplete data within a dataset. When combining multiple data sources, there are many opportunities where data can be duplicated or mislabeled. We encountered many duplicate emails/messages in our dataset which were removed using the drop_duplicates() function just as it works in python 3.0. All missing values were checked using the isnull() function, and unnecessary columns that did not add any value to the analysis were removed from the dataset.
2. EDA – Exploratory Data Analysis (EDA) is an approach to data analysis using visual techniques. Used to discover trends, patterns, or check assumptions using statistical summary and graphical representation.
3. Text pre-processing – Text pre-processing is an approach to cleaning and preparing text data for use in a specific context, or the text can be converted into a suitable format so that it can be fed into a model for analysis purposes. This is done using different steps, we lowercase all alphabets and then tokenization, tokenization is basically separating each word of a sentence, it helps the model to evaluate each word so that it can accurately recognize the word tag(spam/ not spam). Special characters, punctuation and ignored words (words that are used in the construction of a sentence and have no meaning; for example – as, for, of, in, is) have been removed, which do not add much value in the parsing process. And finally, we use stemming, which essentially converts all words to their root form.
4. Creation of the model - The construction of the model is focused on the required algorithms. Model validation is important to develop a sense of confidence before using it. The definition of a good model includes robustness and well-defined accuracy. Since it contains text data, Naives Bayes works best with text, but we also use different algorithms to find accuracy. Since most algorithms work best on numbers, we converted the text to vectors using the vectorization function of the Sklearn library. We use different algorithms like Multinomial Naives Bayes (MNB), Gaussian Naives Bayes (GNB), Bernoulli Naives Bayes (BNB), Decision Tree Classifier, Random Forest Classifier, Extra Tree Classifier, Adaboost Classifier and Support Vector Machine (SVM). We use tf-idf vectorization to calculate accuracy and precision.
5. Evaluation- Evaluation is a process that critically examines a program. It involves collecting and analyzing information about a program's activities, characteristics, and outcomes. Its purpose is to make judgments about a program, to improve its effectiveness, and/or to inform programming decisions.
6. Improvement- One of the best ways to improve the performance of your machine learning model is to feed it high-quality training data. But this is easiersaid than done. Training data for machine learning can be challenging to find, collect, and annotate.
7. Website- The interface where the spam classification can be displayed to user.

Accuracy is defined as the proportion of correct predictions made by a model, out of all the predictions it has made. It can be calculated as:

Accuracy = (Number of Correct Predictions) / (Total Number of Predictions)

Precision, on the other hand, refers to the fraction of positive predictions that are actually correct. It is a measure of the model's ability to identify positive instances correctly. Precision can be calculated as:

Precision = (Number of True Positives) / (Number of True Positives + False Positives)

IV. RESULTS

Our model has been trained using multiple classifiers to check and compare the results for greater accuracy. Each classifier will give its evaluated results. After all the classifiers return its result the best performing classifier are then combine for better accuracy and precision. Each classifier result are shown in tables for better understanding

Sr. No.	Methods	Accuracy	Precision
1	Multinomial Naive Bayes	97.19%	1.0000
2	Support Vector Machine	97.29%	0.9741
3	Extremely Randomized Trees Classifier	97.77%	0.9914
4	Random Forest	97.00%	0.9908
5	AdaBoost	96.22%	0.9541
6	Decision Tree	93.52%	0.8380

Table 1: Results

We combine best top three classifier using voting classifier to formed Ensemble Model giving the accuracy of 98.1% and precision of 0.9917.

V. CONCLUSION AND FUTURE SCOPE

In this paper, we have presented different Spam Detection Techniques that have been used to detect spam. In existing Projects they mostly make use of only one algorithm for Spam Detection, while in our Project

we are making use of different algorithm like Multinomial Naive Bayes having Accuracy 97.19% and precision 1.0000, and other algorithm like Support Vector Machine having Accuracy 97.29% and precision 0.9741, Extremely Randomized Trees Classifier having accuracy 97.77% and precision 0.9914. And combining all three algorithm using voting classifier we are building, Ensemble Model for Email Spam detection which slightly provides better accuracy (i.e 98.1%), precision (i.e 0.9917) by providing a better feature than existing systems. Existing System are making using Of Single algorithm while our system is making use of different algorithm for creating Ensemble Model for Spam Detection. In Such way it make our system to have outstand feature or improved version of existing systems. Email spam detection is a crucial component of modern email systems, and it is likely to continue to play an important role in the future.

Machine learning algorithms have already been widely used for email spam detection, and there is potential for further advancements in this area to improve the accuracy and effectiveness of these solutions.

Integrating with other technologies: Email spam detection could be integrated with other technologies such as artificial intelligence, natural language processing, and computer vision to provide a more comprehensive solution.

Improved filtering: The development of more sophisticated filters, such as content-based filters and reputation-based filters, could lead to a more effective email spam detection system.

Real-time monitoring: As the volume of emails sent continues to grow, there is a need for real-time monitoring of email traffic to quickly identify and prevent the spread of spam.

Combating image-based spam: Image-based spam is becoming an increasingly common form of spam, and there is a need for effective email spam detection solutions that can handle this type of spam.

Overall, the future of email spam detection is likely to be shaped by advances in machine learning, integration with other technologies, and the development of new and innovative filtering techniques. The goal is to provide a more effective and efficient email spam detection system that can keep pace with the ever-changing landscape of email spam.

Abstract – **A relatively new method in the realm of information technologies is called Blockchain technology. As one of its initial applications, Bitcoin as a cryptocurrency has increased in popularity a lot of focus. In addition cryptochain for cryptocurrency, Blockchain Using smart contracts as the centre piece of their implementation, the current crypto currency development at its core. Many people view Blockchain as a disruptive fundamental technology. Blockchain research is still in its infancy, even though many researchers have realised the significance of blockchain. As a result, this paper studies the current Blockchain technology and the new solutions over the flaws of the Blockchain.**

Keywords: Blockchain, Ethereum, Bitcoin, Cryptocurrency.

I. INTRODUCTION

Bitcoin and blockchain technologies are shaping and defining new areas of computer science and information technology. The requirement for a decentralised currency has been used mostly as a theoretical idea, however in the past decade, it became feasible, due to the well-known paper of Satoshi Nakamoto introduced the technology of Bitcoin and blockchain in 2008 [1]. While there are disagreements over Nakamoto's genuine identity, one thing is certain: he introduced something revolutionary to the world, and it is up to the users to determine what to do with it. Some may use this chance to create their own application to solve various social problems, while others will invest in those ideas or just trade the market's ups and downs in cryptocurrency values. We considered including a brief introduction to blockchain and cryptocurrency We begin with a brief overview of some of the most well-known methods for decentralized digital money prior to Bitcoin. The bulk of cryptocurrency is held by two cryptocurrencies. capitalization of the market Of course, like with all new things, technology, certain limitations and issues arose, and They were also described[2].

1.1 Blockchain

Blockchain is a technology, a universal online database that can be used by anyone and anywhere using internet connectivity. Blockchain does not allow supporting faking documents, transactions and other information. Blockchain is a technology, a universal online database that can be used by anyone and anywhere using internet connectivity. Blockchain does not allow supporting faking documents, transactions and other information. Blockchain is a spreadsheet a revolutionary picture which has generated thousands of clones across computer network. After that computer network which is designed using blockchain, to update the spreadsheet regularly and you should have the basic perception about the understanding of blockchain concept [1].

Blockchain contains the collective information and frequently submissive database. The Blockchain is a distributed database in which every block can get the copy of newly entered record which means that the information it keeps is truly publically accessible for everyone but no one can change any of the record . Each block has an enticement for processing and verifying the transactions . So, that's why these characteristics make the blockchain wonderful to keep the records transparent and everyone can use it [2].

Blockchain technology can be characterized as a completely decentralized, trustless peer-to-peer data storage that is distributed throughout all participants also known as nodes. The blockchain is made to store immutable information it is consequently a decentralized, distributed, and immutable database where data is logically arranged as a series of smaller bits once it is committed to the chain(blocks). A cryptographic hash function called H(Bi1) links each block Bi>0 immutably to a single preceding block Bi1. Bi and all subsequent blocks would contain an invalid hash if Bi1 were changed. The genesis block, which is the sole block without a predecessor, is the very first block B0. A block is typically didgitally signed to ensure bith the integrity of the block and the data it contains [2].

II. . LITERATURE SURVEY

1. In this paper, author describe the how we can implementthe blockchain from scratch for fulfilling the requirments. It has advantages like Problems of previous version solved and the basic of blockchain are covered with implementation but alsohave some disadvantages like It contains the security and scalability issues, it was time consuming [1].

2. In this paper, author expressed the Blockchain security propertiesand the challenges faced by the Blockchain. So in this paper we found that It express the challenges which can be improved by adding various feature, also that It express the challengesand improving features but can't state that how to overcome the security problems [2].

3. This article summarizes the research of all blockchain domains and how blockchain is used in it. They review the papers which was helpful to understand how many domains there in existing system are. But It helps theoretically not practically and the review wasn't good enough to solve the existing problems [3].

4. This article summarizes the existing blockchain technology in detail. They review the blockchain technology in details, so it is easy to understand. But They didn't specify how we can overcome the existing system. It's easy to understand but they didn't review the crypto market [4].

5. In this article, author research on the various domains of blockchain and gathered all the information of existing blockchain. They give brief information about various Domains. But the advantagesand disadvantages are missing [5].

III. . PROBLEM DEFINITION

Blockchain systems have weaknesses in many domains, making mass adoption of blockchain a far-fetched idea. Records of transactions can be manipulated easily or changed. To resolve this issue, Blockchain comes in. We found that the current technology have different issues like Transparency, Scalability, Regulations, Transaction speed, Energy consumption and main issue on which we are focusing is the Security

IV. SYSTEM ARCHITECTURE

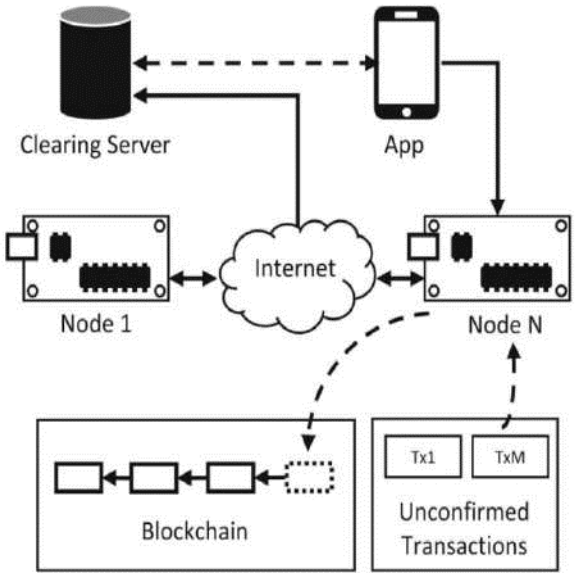

Fig . 1 System architecture of blockchain

The Fig, 1 of system architecture of Blockchain consists following field:

4.1.1 Blockchain setup

1. Set up the overall blockchain application.
2. Create the basic building block of the blockchain - with blocks themselves
3. Start a test-driven development approach to the project.
4. Built the genesis block - to get the blockchain going.
5. Add functionality to mine a block - create a new block for the blockchain.
6. Develop the important sha-256 hash function.
7. Apply hash to mine a block.
8. Implement the proof of work system by adding a difficulty and nonce value to each block.
9. Adjust the difficulty for a block to ensure that blocks are mined at a rate which approaches a set mining rate for the system. 10. Investigate the proof of work system by writing a script which checked how will the dynamic difficulty adjusted the system to approach the mine rate.
11. Switch the hexadecimal character-based difficulty criteria to a more fine-grained binary bit- based difficulty criteria.
12. Prevent a potential difficulty jump attack by adding extra validation for the blockchain.

4.1.2 API section

1. Set up an express API to allow for interaction to the backend through HTTP requests.
2. Created a GET request to read the blockchain.
3. Added a POST request to write new blocks to the blockchain.
4. Implemented a real-time messaging network through Redis or PubNub. 5. Added the ability to broadcast chains.
6. Started peers through alternate ports, and broadcasted chains when blocks were mined through the API.
7. Synchronized chains when new peers connected to the network.
8. Optimized the implementation to avoid redundant interaction.

4.1.3 Wallet and Transaction

1. Created the core wallet class for the cryptocurrency.
2. Developed the cryptographic key pair and public key addressing system.
3. Implementing signature generation and verification to make transactions official.
4. Built the main transaction class - with the output map and input structure.
5. Developed functionality to actually validate transactions.
6. Tied transaction creation with the wallet class.
7. Allowed transactions to be updated with multiple outputs to efficiently use existing objects.
8. Improved the hash function to recognize objects with new properties as changes in incoming data.
9. Covered edges cases with transaction updates to prevent vulnerabilities.

4.1.4 Transaction pool

1. Created the core transaction pool with an ability to set transactions.
2. Handled transaction through the API and added API-generated transactions to the pool.
3. Made sure invalid transactions did not go to the pool.
4. Handled updates to transactions through the API.
5. Exposed a new API method to read the transaction pool data.
6. Broadcasted transactions as they occurred through the API.
7. Synced the transaction pool map as a network-dependent object like the blockchain

4.1.5 Mine transaction

1. Created the core transaction miner class to capture how miners should add transactions to the blockchain.
2. Added the ability to grab valid transactions from the transaction pool. 3. Added a way to clear blockchain transactions to ensure that only unique transaction objects could be recorded.
4. Added a mining transactions endpoint to enable transaction mining through the API. 5. Cleared recorded transactions on a successful replacement of the blockchain. 6. Calculated the wallet balance based on the blockchain history.
7. Applied these wallet balances whenever conducting a new transaction.
8. Exposed the wallet information including the public key and balance through the API. 9. Validated transaction data incoming into the blockchain.
10. Validated incoming transaction input balances.
11. Prevented duplicate transactions from appearing in a block's data.
12. Validated the entire transaction itself when accepting new user-contributed blockchains.

V. SOFTWARE AND HARDWARE REQUIREMENTS

Software Requirements

Front-end : React.js, Express API

Back-end : Node.js

Web server : Redis (Optional) Operating System : windows XP/7/8

Hardware Requirements

Processor : Pentium III

RAM : 4 GB

Hard Disk : 20 GB (minimum)

VI. RESULTS

Fig.2 Frontend Blockchain

The Fig.2, gives the idea of address of your wallet and the balance.

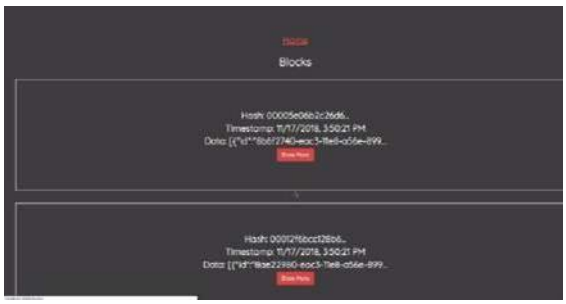

Fig.3 Block part in frontend

The Fig.3, give the idea of various blocks with the hash values, timestamp and data

CONCLUSION

Bitcoin and Ethereum today are the most known and valuable cryptocurrencies. They are based on blockchain technology that is intended to promote a trust mechanism in a peer-topeer network based on the consensus of the majority of the nodes. We have shown in the early stages of the digital money implementation, as well as the foundations of blockchain technology, and it's most promising (or popular) implementations, Bitcoin and Ethereum.

In the past few years, there has been a rapid growth of numerous cryptocurrencies, hashing algorithms, and consensus agreements in the networks. Some of the cryptocurrencies worth mentioning are Ripple, Cardano, NEO, Stellar, Litecoin, EOS, IOTA, Dash, Monero, TRON, Qtum, Lisk, Tether, Stratis, Zcash, Steem, Siacoin, Verge, Electroneum, Nxt, Dogecoin, and many more.

Future research should delve into these topics and new applied applications, as well as study adoption rates of the technology. For those who do adapt blockchain, further study would grant us insight as to what increases (if any) in productivity have been recorded. Studies may also focus on roadblocks as to why this technology has not been adopted as well as investigate trends in consumer confidence. Additionally, as technology increases, future studies may help shed light on any security issues not initially discovered.

jainamanr@gmail.com, hanikjain333@gmail.com, ravikumargupta391999@gmail.com, rekha.sharma@thakureducation.org

Abstract – **Chatbot has become widely popular recently and it is gaining speed as an application of computer communication. Few programs reply intelligently like human. Such program is called a Chatbot. This paper addresses the design and implementation of a Chatbot system**

Keywords: Chatbot, Natural Language Processing, Artificial Intelligence

I. PROBLEM STATEMENT

As technology is progressing we have seen websites, apps are getting better, larger and more complex everyday. From simple static read only website we have now websites with multiple pages, multiple components and many different ways to interact with the site. This has drastically increased the complexity of the website and now having a good user friendly website is a huge task. Most users who visit a website most of the time are looking for one or two information/services on the website. Because of the nature of the website now has become very complicated even to perform simple tasks or to find specific information on the website has become a complicated process for the user. Therefore services like Chatbot can be very useful. Rather than navigating throughout the website, the user can directly send its query to the chat bot and the bot replies immediately with the required result. A chatbot can be designed to fulfil many purpose like a customer service bot can handle customer problems etc. Also a chatbot can be design for cross platform like Android or iOS or it can be integrated with third party apps like WhatsApp, Messenger, telegram etc.

II. INTRODUCTION

A chatbot can be defined as an AI (Artificial Intelligence) based computer program that simulates human conversations. They are also known as digital assistants that understand human capabilities. These bots interpret the user intent, process their requests, and give prompt relevant answers. 80% of marketers plan to start using a chatbot in some way or another. It is a significant reason why brands are investing in improving the customer experience. Diagram below depicts use cases of a chatbot. You can see how they add value in the healthcare industry.

The first conceptualization of the chatbot is attributed to Alan Turing, who asked “Can machines think?” in 1950. Since Turing, chatbot technology has improved with advances in natural language processing and machine learning. Likewise, chatbot adoption has also increased, especially with the launch of chatbot platforms by Facebook, Kik, Slack, Skype, WeChat, Line, and Telegram. By September 2016, Facebook Messenger hosted 30,000 bots and had 34,000 developers on its platform. The Kik Bot Shop announced in August 2016 that the 20,000 bots created on its platform had “exchanged over 1.8 million messages.”

As per Transparency Market Research, The overall market size for chatbots worldwide would be over $1.2 billion by 2023 and around $2.4 billion by 2027. Now, as you are aware of what a chatbot is and how important bot technology is for any business. You will certainly agree that bots have drastically changed the way businesses interact with their customers. Chatbot technologies will become a vital part of customer engagement strategy going forward. Near to future bots will advance to enhance human capabilities and human agents to be more innovative, in handling strategic activities. Hence, it is inevitable that the chatbot industry will become the driving force of business communications.

III. THEORY

A chatbot is built on the foundation of many computer science core concepts. The following concepts are the foundation of a chatbot.

Key Concepts

Client-Server Model:

A Client-server model is a distributed system framework that separates tasks or responsibilities between service providers or services, called servers, and service requesters, called clients. The client and the servers communicate over computer networks. Both client and the server runs on a different machine. The client which is a user, in this case, who wants to establish communication with the chatbot sends a request to the server. The server then responded with the request. The client can be a desktop, mobile, API, cross- platform OS like android, IOS etc.

N.L.P. :

Natural language processing is part of linguistics, computer science, and practical intelligence related to the interaction between computers and human language, especially how to configure computers to process and analyze large amounts of native language data. In the case of a chatbot, NLP is used to translate text once any kind of random data. The NLP can process text, translate it into computer language as well produce results in a language that people can understand.

Text-to-Speech (TTS):

Text-to-speech (TTS) is a form of technical assistance that is readable digital text aloud. It is sometimes called "reading aloud" technology. By clicking a button or with the touch of
a finger, TTS can take words from a computer or other digital device and convert them into text. TTS is very useful for giving the option to users to listen to the text messages of the bot.

Automatic Speech Recognition (ASR):

ASR technology that converts spoken words into text. With ASR, voice technology can detect spoken sounds of the user and recognize them as words. ASR allows computers to finally understand a natural form of communication: speech.
U.I. of a chatbot allows users to communicate with their voice. With a click of a button, the user can send a message to the bot with the voice commands.

A.P.I. :

An Application Programming Interface is a communication between computers or between computer programs. It is a type of software interface, which provides service to other pieces of software. A document or standard that describes how to build or use such a connection or visual interface is called API specification. With the help of an API, the chatbot sends user messages to the server. That message is then sent to another server like Dialogflow etc. via API or is then processed on the same server depending on the Client-Server architecture. The response of the chatbot is sent to the client machine via API.

Javascript:

Javascript is a programming language used for the frontend of the website and can also be used in the backend of the architecture. Other programming languages python, GO, C++ etc, can also be used for the backend.

Python:

Python is a programming language is used for data science, machine learning, systems automation, web and API development.

Application of different technology:

In terms of technology, a chatbot is a continuous command system that knows to retrieve the input data and then process and retrieve the corresponding output data through the user interface at a given time. Input and output data is now invoice format, so it still is properly processed under various technologies such as Automatic Speech Recognition (ASR), Indigenous Language Processing (NLP) and Text-to-Speech (TTS). Basically, ASR is used to translate user words into text in a few types of conversations such as speech-to-text in private conversation, captions for online meetings and phone conversations. Then, the NLP focuses primarily on understanding machine learning to understand the content of the text to extract relevant instructions based on the understanding of the text. Finally, TTS reads a sentence or a paragraph to readers aloud such as reading email news or news etc. The chatbot process is similar to an online chat system for client creation a way for the server to receive the signal and transmit it to the server. The server module waits for the first client to send a connection request. If a connection is provided, the client can share the contact server.
In chatbot mode, the web browser plays the role of the client in order to find the input method signal. This signal is then sent to a server to process, analyze and generate responses.
Server response production can be divided into two categories: data retrieval and information output.

Methods:
Before using any chatbot, we need to know which chatbots are currently available. There are many different types of Chabot for business today that can help in different types of work like customer service bot, sales bot, question & answer bot, general-purpose bot, query bot etc. As there are many types of bots there are many different ways to build a chatbot.
Following are some ways to build chatbots. Frontend:

A front-end of a chatbot can be a website, a mobile app or any other app like Whatsapp, telegram, messenger, slack etc. The most commonly used Programming language to build a chatbot's frontend for the web is javascript, for the mobile app it is swift, javascript, java, kotlin etc. From the frontend the data is send to the backend.

Backend:

Programming languages like Java, Clojure, Python, C++, PHP, Ruby, and Lisp is used for building architecture of a chatbot. Using other known chatbot development platforms such as RASA, Botsify, Chatfuel, Manychat, Flow XO, Chatterbot, Pandorabots, Botkit, and Botlytics.

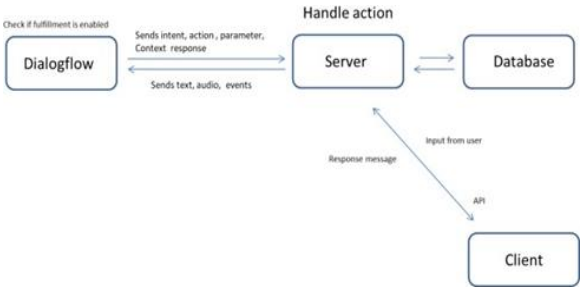
A.I. :

We distinguished six leading NLP cloud platforms that we can use to create applications able to understand natural languages: Google's DialogFlow, Facebook's wit.ai, Microsoft LUIS, IBM Watson Conversation, Amazon Lex, and SAP Conversation AI. All these platforms are supported by machine learning, N.L.P., TTS, ARS. They share some standard functionality (cloud-based, support various programming and natural languages) but differ significantly in other aspects.

Designing of chatbot:

As there as many different types of chatbot which can build in many different ways. In this paper we will be focusing on a query bot for a website using dialogflow.

Chatbot Architecture:



There are four key steps which should be kept in mind during designing a Chatbot.

Client-side chatbot:

Client-side chatbot is where user interact with the bot. It has chat interface where user can send its query and bot can response. Client-side or frontend of our chatbot can be built with the help HTML, CSS, JAVASCRIPT, REACTJS. API is used to communicate with the server. With the help of react JS we can build different components like input component, button component, message component ,components to shows various products etc. It gives us the flexibility to reuse components which helps us in development and making code more modular and scalable.
API calls are used to send and receive message to the server when the user inputs any message the API call gets executed and the message is then sent to the server for the processing.

Server:

In the server the chatbot communicates with different services like dialogflow or our database or third party API's etc. When it receives message from the user it sends that message to the dialogflow the dialogflow checks the fulfillment if the fulfillment is true it sends actions parameters intents to the server the server then process that action parameter intents and fetch the needed data from the database and then passes it to the client via API.

Dialogflow:

In dialogflow the developer creates intents and entities. When the server sends the user message to the dialogflow the dialogflow matches it to the intent the intent consists of the action, parameters and response of that message. It sends back response to the server.

Database:

A database where all the entity and the response related to the entity and other data stored. We will be using mongoDB as our database.

Dialogflow Architecture Key terms:

Dialogflow: Dialogflow is an end-to-end tool powered by natural language understanding to facilitate rich and natural conversations. Dialogflow sits in the middle of the stack. A user can communicate with all the common channels including text, website, apps etc.

Dialogflow Agent:

Dialogflow Agent is basically your entire chatbot application. Experience of what user is saying mapping to an intent, taking an action on it and then providing user with the response. It all starts with the trigger event called utterance.

Utterance:

This is how users invoke a chatbot. If you say, “Hey Google, how are you?”, the whole sentence is utterance and the phrase “Hey google” is the trigger.

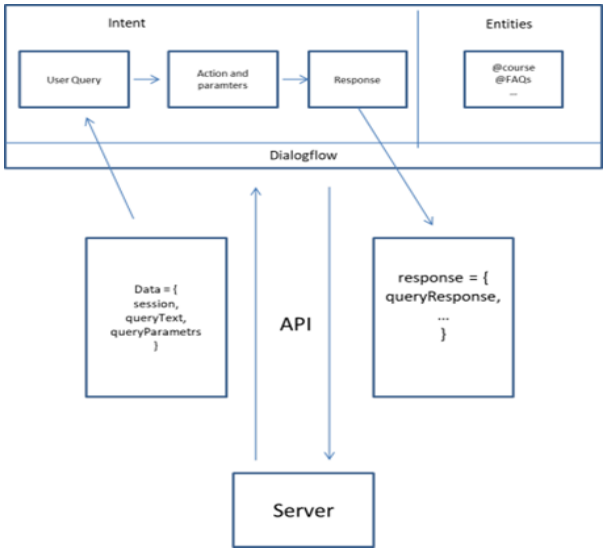
Intent: Intent is way to identified why our user want to talk to our chatbot. Like if a user says “I want to learn javascript”, the phrase “learn javascript” is the intent.

Action and Parameters:

We can use actions and parameters to defines variables you want to collect and store. Action and parameters help us to give user a response.

Entities:

When user says “I want to learn javascript”, the word “javascript” is critical piece of information in that statement that we would need to give response to user. Those variables are defines as entities. Dialogflow offers different types of entities.

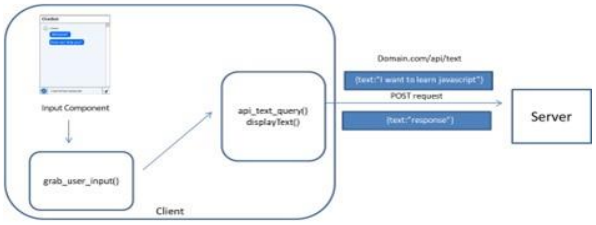


IV. IMPLEMENTATION OF CHATBOT:

In this section we will focus on how the entire architecture works with an example.

Goal

Process



Phase 1 Client to server

Client to server:

On the client machine we have user interface of the chatbot. The user interface of the chatbot has many different components like chat box message component input component button component etc. Design this component with the help of HTML CSS JavaScript and reactJS. Different components are used for different purpose one can design many other components as per the usability.

Input Component:

Input component is design to grab user query. This component can be robust enough to grab user query in many different ways like text, image, audio, video etc. For simplicity you can design simple import component which grabs user text.

grab_user_input()

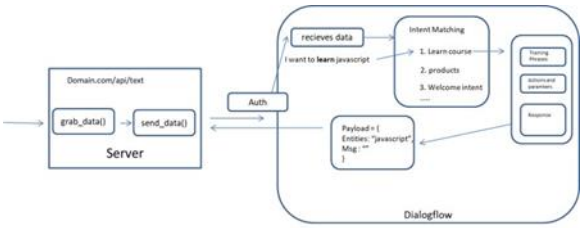
This function collects the user input and store them into a variable then we can use this variable for further use. This function also validate whether the user input is appropriate like is it empty strings etc.

Here the user input is "I want to learn javascript".

api_text_query()

This function takes the data and sends it to the server via post request on domain.com/api/text URL. This is an asynchronous function because it is sending and receiving data on another server. To send post request we can use fetch API which is provided by the browser default or we can use third party modules like axios etc. Once the request and the data is sent it waits for the response from the server.

displayText() This function is responsible to display text of user and bot in the chat box. This function uses react hooks to update the user and bot messages into an array. Then it uses a for loop to display all the messages in the chat box.



Phase 2 Server to dailogflow

Server to dailogflow:

Server to dailogflow Once the user text is send to the URL domain.com/api/text,we grab that data and then send it to the dialogflow with essential credentials.

grab_data()

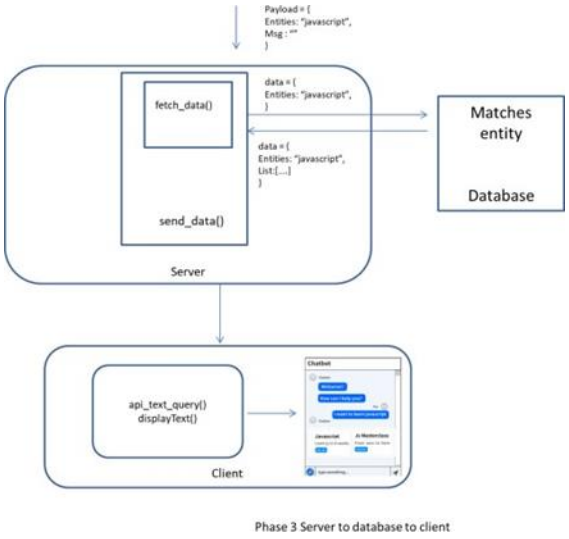
This function stores the data which comes from the client into a variable. The data is then further used.

Here the data we get from client is "I want to learn javascript".

send_data() This is an asynchronous function. In this function we send the user data which has come from the grab_data()

function to the dialogflow server. Apart from the data we also send necessary credential required to authenticate in dialogflow server. After sending post request to the server with then wait for the response from the dialogflow. We use try catch method in JavaScript to handle errors and edge cases if they occur.

Dialogflow: When dialogflow receives a request it first authenticate our request. After successful authentication, dialogflow matches the intent from our data text (text="I want to learn javascript"). Here learn course intent gets matched with our text. After successfully matching the intent it sends the respective response which is been stored in the intent in the dialogflow by the developer. This response can be either text message for a custom payload developed by the developer. In this intent with send custom payload with an entity(which is payload = {entities: “javascript”, …}). If the intent doesn't matches the dialogflow sends the default intent which in this case is welcome intent.
Dialog flow is it responsible for all the machine learning, natural language processing, spelling detection, auto correction, multilingual messages etc. From dialogflow we get payload as a response. That payload contains entities messages etc.



Server-database-client

send_data() This function receives the payload from the dialogflow. This function then execute the fetch_data() function which takes payload as an argument.

fetch_data()

This function then execute search operation on the database with the query as entity from the payload which we recieved from the dialogflow server. Here the entity is "javascript" (note here javascript is a keyword and not a language). In the database, the developer has already stored the collection of data which is associated to an entity. For example in the database we can have list of courses available which is stored in the form of array where each individual item is a Javascript object.

```
{
"javascript": [
        {
          "title" : "Javascript",
          "description":"Learn js in 4 weeks.",
          "course_id": "1234"
        },
        {
          "title" : "Js Masterclass",
          "description":"From zero to hero.",
          "course_id": "4321"
        },
        ...
    ],
    ...
}
```

After fetching the results the fetch_data() function returns the response.

send_data()

After receiving the result from the fetch_data() function. The send data function then send the result the client.

api_text_query()

This function after making the post request get the result from the server this result is then been shown to the user via displayText () function.

displayText()

This function displays the data in different components depending on what kind of data it is receiving. In this case it is showing the data in the form of a card component. Similarly a developer can create different kinds of components which can be used in different use cases

V. IMPORTANT FINDINGS

As we explained above, chatbots are automated and efficient programs that can work together as well communicate with people in a common language using text or voice-based audio conversation. As a standard chat app, chatbot installs an app layer, website and Driving APIs for jobs.

Users can easily send an application to the chatbot app with the Conversation UI, then ML / AI Instance is responsible for analyzing and processing user request, access website or ways to call APIs if necessary, and ultimately generate the right response for the user.

ML / AI Instance lists all processes related to Natural Language Processing (NLP). NLP it mainly focuses on quoting the expression and expressing purpose and organizations. To The NLP unit is able to map words to targets, trained and organized by examples of purposeful maps.

In this paper, we do not go into detail on how to train or adjust a machine reading. Instead, we will focus on building and researching the use of chatbot as a web site an application that uses the AI Assistant API

VI. RESULT AND DISCUSSION

We received feedback from testing the last prototype that participants did not have a problem getting information from a chatbot rather than a human. It is possible that the fact that the chatbot provided a source for the information it provided did not make them less trusting of the information they got. Interacting with the chatbot and reporting on how they use it has been interesting to investigate. In view of the scope of the project, we were unable to conduct enough user testing and redesign of the chatbot as we would have liked. Through the project, we have touched on some theory, but this should also be emphasized more for higher validity . Despite the fact that our participants trusted the information provided in this project, we cannot say that they trust a chatbot as much as a human does.

VII. RESEARCH OUTCOMES

While there is a developing collection of examination accessible on chatbot client experience there actually is an absence of information on the most proficient method to use the discoveries from this exploration in chatbot plans that reliably please and connect with clients . Clients actually experience issues in chatbot connection, both as far as even minded encounters where chatbots neglect to

comprehend or to assist clients with accomplishing their expected objectives and as far as gluttonous encounters where chatbots neglect to draw in clients over the long run. These issues may to some degree be viewed as because of the more broad test of planning human-AI collaboration . For sure signs that these difficulties are being alleviated, for instance on account of enhancements in client care chatbots and in the take-up of social chatbots like Replika . Notwithstanding, the fortifying of chatbot client encounters stays a key examination challenge. Connected with the test of fortifying chatbot client experience, is the test of estimating and surveying chatbots as far as client experience and from a more comprehensive point of view to decide if chatbots are really gainful. Applicable perspectives for this are, for example, handiness, productivity and cycle support. While there is countless investigations on chatbot client experience accessible, there is an absence of normal definitions, measurements and approved scales for key parts of chatbot assessments . Besides, while a wide scope of approaches are utilized there is an absence of ordinarily applied ways to deal with assessment.

VIII. FUTURE SCOPE

Man-made consciousness is the most smoking argument for business clients hoping to work on their productivity, convey groundbreaking thoughts and make the following strides in the progress to an advanced undertaking. Simulated intelligence and chatbots are democratizing business, engage new companies and assist with building new associations, something that each association needs to plan for.Presently as we move into the 2020s, endeavors and new businesses the same are making the following stride, embracing AI and bringing brilliant administrations into their associations. It has effectively begun with chatbots and investigation instruments, however is now extending to business- empowering innovation, utilizing a blend of AI, profound learning, PC vision, regular language handling, machine thinking (MR), and profound or solid AI.Organizations will keep on conveying AI for astute mechanical cycle mechanization, PC vision assignments, and AI applications. Contingent upon the business, there are different pieces of the business where AI will become quicker.

As per a McKinsey research overview, 75% of telecoms respondents are centered around AI for administration activities. 59% work on item advancement for cutting edge organizations and money organizations consider 40% zeroed cursor on a screen for extremely lengthy, currently the utilization of symbols is working on their discernment, yet use through Amazon Alexa, Apple Siri, etc will assist with carrying them to a more extensive crowd. Message to- discourse and voice-to-message are fundamental elements coming soon for chatbots.

IX. CONCLUSION

The chatbot's motivation is to have a shrewd, exact, what's more continuous discussion with the understudies. Thusly, understudies talk with the bot to ask about specific things they look to buy and pay online for the things before they visit the shopping center. (e chatbot is available through compact cell phones or PCs, which understudies can sign in to anyplace and whenever nearby, accordingly giving a 24-hour online assistance. Preceding this examination, design based chatbots have had a sketchy degree of knowledge. In spite of the fact that chatbot is design based, it has a high learning rate, and that implies that it advances quickly from any internet business thing that is added to its data set. We have overviewed a few chatbot frameworks which prevail in pragmatic areas like schooling, data recovery, business, web based business, as well concerning entertainment. Innovation like PC variable based math frameworks, mixed media introductions or 'chatbots' can fill in as enhancers however not supplant a great aide". By and large, the point of chatbot fashioners ought to be: to construct devices that help individuals, work with their work, and their connection with PCs utilizing normal language; yet not to supplant the human job absolutely, or impersonate human discussion impeccably. On the off chance that one had an ideal reproduction of a human familiar, it would be human-human discussion and not human computer discussion with its occasionally odd yet appropriate properties.

X. ACKNOWLEDGMENT

We gratefully acknowledge the support, guidance and encouragement of our Dissertation Guide Associate Professor Dr. Rekha Sharma ma’am for this novel work.

Review On 5g Wireless Technology

Achal Thengane, Vijay.M. Rakhade
Shri Sai College of Engineering & Technology, Bhadrawati,India

Abstract— **5G stands for fifth-generation wireless Technology. The latest iteration of cellular technology has three main features: greater speed, lower latency, and the ability to connect several devices simultaneously. 5G wireless network will aspect new contents, as well as growing claim on network capacity to support a lot more devices running applications necessitating high data rates and always-on connectivity; hugely and supportive of the emerging business models in the wireless network market demanding network to be more open. New challenges initiate new resolutions and involve changed plans in the network positioning, management, and operation of 5G wireless networks equated to those of current wireless networks. One of the key purposes of the 5G wireless network is to completely provide service- customized networks to a wide variety of services using integrated cloud reserve and wireless and wired network possession, which may be presented by several infrastructure providers and operates. The term 5G is used alternatingly with the worldwide wireless web (WWWW), which is a platform that enables us to connect to any kind of device, anytime and anywhere**

Keyword- 5G, Wireless, 5G Architecture, Evolution of 5G.

I. INTRODUCTION

Everybody loves speed and further over speedy internet so it's no surprise that every major Telecom in the world is working to make it indeed hastily. Smartphones, watches, homes, and buses are decreasingly taking stable internet connections. To survive in a world where every second the speed changes and where we prompt for further and further technology, then comes the fifth generation's technology 5G. 5G represents the coming major face of mobile telecommunication ethics. Beyond the forthcoming 4G networks technology is contributing the service in product manufacturing attestation supporting Electronics Communication business, etc. As the Purchaser becomes further and further apprehensive of the smartphone Technology youthful generation will look for a decent package or together including all the advanced features a cellular phone can have. Hence the hunt for new technology is always the main provocation of the top smartphone titan to number their challengers. The end of a 5 G- grounded telecommunication network would impeccably answer the challenges that a 4G prototype would present once it has entered ubiquitous use. Huawei will begin charging smartphone makers a majesty to use its patented 5G technology. The Chinese telecom company will charge a “per unit majesty cap” of$2.50 for smartphones able of connecting to 5G and former generations of mobile networks. Huawei has 007 declared 5G patent families, the loftiest out of any company in the world. The wireless system uses orthogonal frequency division multiplexing with expansive area content, a high quantum of milli- cadence swells “10 mm 21 mm” covering a frequency range of 30 GHz to 300 GHz, but current 5G communication includes frequency below 30 GHz, analogous to 28- GHz band and frequentness up to about 100 GHz as the upper limit, and permitting a 20 Mbps data rate to distances of 2 km. The millimeter surge band is the most active result of the current swell in wireless internet operation; this provision is suitable for furnishing wireless world wide web operations.

II. EVOLUTION

a. First generation (1G)

First Generation developed in the 1980s and was completed in the early 1990s. grounded on the Analog system. Speed up to 2.4 kbps. AMPS (advanced mobile phone system) was launched by the US and it was the first-Generation mobile system to allow users to make voice calls in one country. But it had low capacity, unreliable handoff, poor voice links, and no security since voice calls were played back in radio halls, making them susceptible to unwanted wiretapping by third parties.

b. Second Generation (2G)

Second Generation developed in the late 1980s and was completed in the late 1990s. Commercially launched on the GSM (Global System for Mobile communication) standard in Finland (1991). grounded on a digital system. Speed up to 64

kbps. Services such as digital voice and SMS with further clarity. Text dispatches are digitally translated. Semi-global installation. 2G are the handsets we are using moment with 2.5G having further capabilities.

c. Third Generation (3G)

The Third Generation developed between the late 1990s and early 2001s. It uses Wideband Wireless Network with which clarity is increased. The data are transferred through the technology called Packet Switching. Transmission speed from 125 kbps to 2 Mbps. Superior voice quality, and good clarity in a videotape conference. Email, PDA, information surfing. online shopping, E-banking, online/offline games, etc. Global roaming.

d. Fourth Generation (4G)

Fourth Generation developed in 2009. 4G offers both cellular and broadband multimedia services far and wide. Faster and further dependable. Speed up to 100 Mbps. High-performance easy roaming. 4G provides the same point as 3G and fresh services like multimedia journals, to watch television programs with further clarity and Send data much faster than previous generations. LTE is considered a 4G technology.

What is 5G-

5G technology is a breakthrough. The coming generation of telecom networks, the fifth generation, started beating the market in 2018 and will continue to increase worldwide. Elsewhere the speed of development and technology is predictable to unleash a massive 5G IoT (internet of things) ecosystem. Their networks can assist communication wants for billions of 5G technology driven by 8 specification connected devices, with the right trade between requirements.

Fifth Generation's next measure phase of mobile telecommunication and wireless systems is 10 times more capacity than others. Expected speed up to 1gbps. It Is faster and more reliable than 4G and 3G. With an increment, in the demand of the users exponentially, 4G can now be easily replaced with 5G with new advanced access technology. Lower cost than previous generations. Consistent quality and end-to-end latency have been lowered.

5G Network Architecture-

There was wide agreement on the fact that as compared to 4G network and 5G network should achieve the below benefits over it, a thousand times the system capacity, ten times the spectral effectiveness and Energy effectiveness, data rate, 25 times the average cell outturn drastic change in the policy of designing the 5G wireless cellular armature is demanded to meet the difficulty of the stoner and triumph over challenges that have been put forward in 5G system. The fifth-generation mobile systems model is an each- IP- grounded model for wireless and mobile network interoperability The - IP Network (AIPN) can fulfill the added demands of the cellular dispatch request. It's a common platform for all radio access technologies. The AIPN uses packet switching and its nonstop elaboration provides optimized performance and cost. In fifth generation Network Architecture consists of a stoner terminal (which has a pivotal part in the new armature) and several independent, independent radio access technologies (RAT). In 5G Network Architecture all IP- grounded mobile operations and services similar to Mobile doors, Mobile commerce, Mobile health care, Mobile Government, Mobile banking, and others, are offered via Cloud Computing coffers (CCR). pall computing is a model for accessible on-demand network access to configurable computing coffers (e.g., networks, waiters, storehouses operations, and services). pall computing allows consumers to use operations without installation and access their data on any computer with internet access. CCR links the Reconfigurable Multi Technology Core (RMTC) with remote reconfiguration data from RRD attached to Reconfiguration Data models. The main challenge for an RMTC is to deal with adding different radio access technologies. The core is a confluence of nanotechnology, pall computing, and radio, and is grounded on the All- IP Platform. Core changes its communication functions depending on the status of the network and/ or stoner demands. RMTC is connected to different radio access technologies ranging from 2G/ GERAN to 3G/ UTRAN and 4G/ EUTRAN, in addition, to802.11 x WLAN and 802.16 x WMAN. Other norms are also enabled similar to IS/ 95, EV- DO, CDMA2000.etc. Interoperability process criteria and mechanisms enable both terminal and RMTC to elect from miscellaneous access systems.

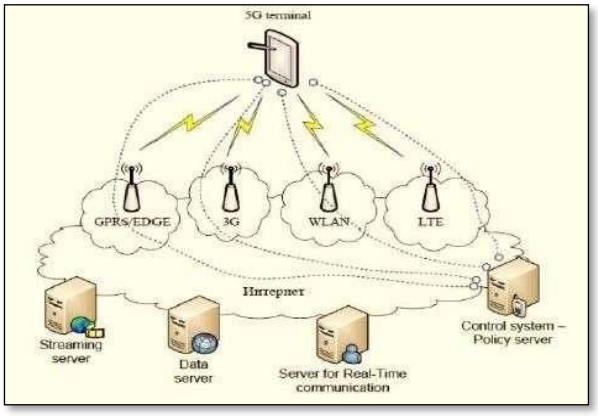

Fig. 5G Network Architecture

FUTURE SCOPE

5G Network Technology will reveal a new era in mobile communication technology. The upcoming 5G will offer higher qualities of services, lower latencies, and higher bandwidth which will help improve the User experience both in the consumer and business space from Cloud gaming to telehealth use cases. Several types of research and discussions are going on across the world among technologists, researchers, academicians, operators, and governments about the innovations, implementation, and security concerns of 5G. The 5G network will reform the internet of things (IoT) but it will take some years for the technology to cover most of the planet. As proposed, loaded with multiple advanced features starting from super high-speed internet service to smooth ubiquitous service, 5G will unlock many of the problems. In many countries, the original frequency band for 5G is 1 GHz, 1-6 GHz, and above 6 GHz, and similar frequency to the remaining mobile and Wi-Fi networks. The low-band frequencies include 600 MHz to 2500 MHz while the mid-band frequency is 3300 MHz lastly, the spectrum also includes a high-band frequency of up to 72 GHz, known as mm-wave. The high-band 5G uses frequencies of 24–47 GHz in India. 5G technology will provide supper and perfect utilization of cellular communication in the future. Embedded Technology will evolve.

Advantages of 5G Technology-

1. More active and effective
2. Easily manageable with previous generations.
3. Technology to wrinkle the network on one platform.
4. High determination and bi-directional large bandwidth shaping.
5. Possible to afford a uniform, uninterrupted, and unfailing connectivity across the world.
6. The 5G technology provides a billing limit in

advance that is one of the most beautiful and successful of the modern era.

7. The information from the data transfer technology 5G organizes a more accurate and reliable result.

III. CONCLUSION

In this paper, we have discussed the being and unborn wireless mobile communication generations and cellular systems focusing on the main key factors like switching schemes, bandwidth, data rates, evolution, and radio access, also 5 G's main development advantages. Explain the necessity for 5G and the future scope of the 5G network. We conclude that the 5G network is very fast and reliable. The fifth generation is based on 4G technology. It is expected that the initial Internet philosophy of keeping the network as simple as possible and giving more functionalities to the end nodes, will become reality in the future generation of mobile networks. 5G technologies include all types of innovative structures which make 5G mobile technology the most important and will be in huge demand soon.

Avoiding Phishing Attack Using Visual Cryptography

Sasmit V. Nakhate, Ashish B. Deharkar, Vijay M. Rakhade
Shri Sai College of Engineering andTechnology, Bhadrawati, Maharashtra

Abstract – **Phishing is one amongst the foremost common social engineering attacks that users over the web fall for. Associate degree example is balloting systems, and since such systems ought to be correct and error free, phishing interference techniques square measure crucial. Visual Cryptography (VC) is employed for economical electoral system authentication to solid votes. VC is one amongst the foremost secure approaches for privacy protection because it ensures the confidentiality of the electoral system. This paper discusses planned phishing interference strategies and compares totally different proposed strategies.**

Keywords: Remote Voting System (RVS), Voting System (VS), Shares Ballots, Commons Attribution International Authentication, Visual Cryptography, Phishing, Captcha..

I. INTRODUCTION

Elections are control round the world, voters in democratic countries have the power to elect a representative for his or her party to settle things in an exceedingly democratic way. However, voters should solid their ballots at a polling location. This might weaken citizen support, so, web-based ballot makes this process easier. Electronic ballot systems supply numerous options that build them different from ancient ballot strategies, as they conjointly increased legal system features over ancient ballot strategies as well as quality, privacy, simplicity, accuracy, and flexibility. On the opposite hand, ballot systems may be exposed to a fresh threat like phishing that affects the system security. When fraudsters gain your personal info, they will use it to commit numerous varieties of identity fraud, jeopardizing voters, and name. Having a secure and reliable choice system, crypto graphical and steganographic techniques ought to be applied. One among the suggested solutions is VC. Systems square measure won't to safeguard into from hackers. It's a mechanism for encrypting visual knowledge that may be decrypted by the human sensory system while not the utilization of computers.

II. LITRATURE SURVEY

2.1) Online voting system using biometric verification

2.1.1) Features

This paper offers the info concerning the system that's wholly automatic, unbiased and on-line forecasting the tactic of choice, increasing security and reducing the count time. The system is split into a pair of sections those area unit elector registration section and actual choice section. At intervals the elector registration technique the data of the elector area unit saved at intervals the repository beside the voter's distinctive identification and finger prints knowledge. Throughout actual choice the user area unit verified with the help of a biometric device. The biometric device checks the info of the user saved in repository by local area network communication and if the user is documented the user is approved to vote. This technique is straightforward to implement and straightforward to

2.1.2) Disadvantages:

1)In gift day situation, EVM results may be tampered by the program keep in EVM and by putting in a glance alike part which may be taught to tamper results.

2)Errors square measure a part of all human beings; it's impossible for humans to be 100% economical in knowledge entry.

3)The obscurity of the citizen is preserved and there are no thanks to link the citizen to the vote casted by the voter.

2.2) An efficient and securable online voting system

2.2.1) Features:

An online electoral system that involves the procedures like registration of voters, polling, vote count and declaring the results would represent a decent answer to switch current system and also the planned system during this provides the knowledge concerning their own system or organized by government the system contains totally different ways for ballot like electronic ballot that helps the voters to solid votes in AN electronic approach means that in computerized instrumentality. The system additionally includes the pc within which electronic ballot machines trying like ATM or personal computers wont to solid the votes by bit screen or a pointer.

2.2.2) Disadvantages:

1)The process of collecting data and entering the data into database takes too much time and is expensive to conduct.

2)The process involves too much paper work and paper storage.

3)The system is totally insecure as malicious user can easily attack by doing any changes throughout the system.

2.3) Title: Online voting system using mobile

2.3.1) Features:

The traditional electoral system will be modified to a more modern and effective approach termed as mobile option.The mobile electoral system provides the convenient, simple and economical thanks to vote eliminating the defect a conventional approach. during this paper the planned to create the E- electoral system that is essentially an internet electoral system through the good phones or web site. to attain the protection they're victimization just the one time password (OTP) principle. The system will be used anytime and from anyplace by

the voters. nobody will forged votes on behalf of others and multiple votes. It saves time and having distinctive identification by victimization aadhar card or elector id.

2.3.2) Advantages:

1) There's no documentary proof and tangible results for election.

2) It's potential for hackers to access and modify the results once obtaining any user id.

III TYPES OF SECURITY ATTACK

Before planning this technique we have a tendency to studied completely different attacks which may be done on the legal system. The attacks area unit as follows

A. Phishing Attack:-Phishing attack could be a technique during which the malicious user will produce a pretend web site as kind of like the first web site to get info of elector.

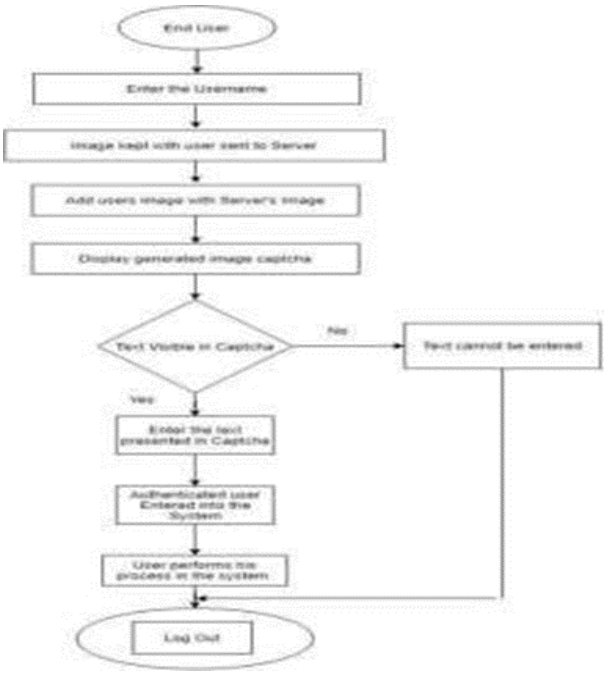
B. Pharming Attack:-In pharming attack malicious user can send the first web site.

C. SQL injection:-In this malicious user can destroy all the information of original web site by mistreatment sql question.

D. Password Attack:-Password attacks are often enforced mistreatment many ways, as well as brute-force attacks, worm programs, IP spoofing, key loggers, packet sniffers, and wordbook attacks. Though packet sniffers and informatics spoofing will yield user accounts and passwords, word attacks sometimes check with continual makes an attempt to spot a user account, password, or both. These continual makes an attempt area unit referred to as brute force attacks.

E. Man in the middle Attack:-A complex sort of informatics spoofing is named man-in-the middle attack, wherever the hacker monitors the traffic that comes across the network and introduces himself as a stealing intermediator between the sender and also the receiver

IV. PROPOSED ONLINE VOTING SYSTEM



In this system, first off the phishing detection are going to be done as explained in section three. The hindrance are going to be exhausted the system as show within the figure. The choice method are going to be divided into 2 parts. Initial the registration part then the particular choice part. In the registration part, the image can divided into 2 halves and shared between the user and therefore the server. Throughout choice part, the user can enter its username. The a part of the image unbroken with the user are going to be sent to server. This user's half are going to be superimposed with server's image and generated captcha image are going to be displayed. If the text is visible in captcha then the user is AN documented user and he/she is allowed to enter the system by coming into the text in captcha. Else if the text isn't visible then the text in captcha cannot be entered and user cannot enter the system.

V. CONCLUSION

Voting plays a vital role for any democratic country. If this planned system is enforced, then the citizen doesn't got to go to the choice center. this method is extremely helpful for those peoples World Health Organization live in other countries conjointly for the peoples World Health Organization square measure physically disabled. Since Visual Cryptography Technique is employed, user will ready to conclude whether or not he's in phishing web site or original web site simply. planned on-line legal system is extremely effective and it'll helpful for voters and organization in some ways and it will scale back the price and time.

Review On Security Issues And Challenges In Cloud Computing

Grishma S. Pise, Vijay M. Rakhade, Lowlesh N. Yadav
Shri Sai College Of Engineering And Technology, Bhadrawati, Maharashtra, India

Abstract – **Cloud computing services enabled through data communication technology delivered to a client as services over the net on a hired basis have the potential to increase up or down their service necessities or desires. during this model, the infrastructure is in hand by a 3rd party merchant and therefore the cloud computing services square measure delivered to the requested customers. Cloud computing model has several blessings together with measurability, flexibility, elasticity, efficiency, and supports outsourcing non-core activities of a company. Cloud computing offers Associate in Nursing innovative business conception for organizations to adopt IT enabled services while not advance investment. This model allows convenient, on-request network accessibility to a shared pool of IT computing resources like networks, servers, storage, applications, and services. Cloud computing may be quickly provisioned and discharged with negligible management effort or service supplier interaction. despite the fact that organizations get several advantages of cloud computing services, several organizations square measure slow in acceptive cloud computing service model due to security issues and challenges related to management of this technology. Security, being the main problems that hinder the expansion of cloud computing service model thanks to the availability of handling confidential information by the third party is risky specified the shoppers got to be a lot of attentive in understanding the risks of knowledge breaches during this new setting. during this paper, we've mentioned the protection problems, the challenges and therefore the opportunities within the adoption and management of cloud computing services model in a company.**

Keywords: Cloud Computing, Cloud Security Issues, Cloud Deployment model, Cloud Computing Services.

I. INTRODUCTION

The Internet has been used on system graphs since many years by a cloud image once Associate in Nursing assortment of recently other innovation began to hap that permissible computing resources to be accessed over the web termed as cloud computing technology. Cloud computing is principally involved with accessing on-line package applications, knowledge storage and process power of the system. Cloud computing supports the organizations to reinforce their capability dynamically while not investment in new infrastructure, coaching new IT personnel, or buying new authorized package that area unit needed for the automation of assorted processes. It extends the capabilities of data Technology. throughout recent years, cloud computing model has developed from being a promising business construct to 1 of the quick rising innovations of the IT business. Since all info of people and firms area unit placed on the cloud, the priority starts to grow regarding security problems. Cloud computing has profited several organizations by decreasing IT expenses and allowing them to specialize in their core business competency and skills instead of IT infrastructure. Cloud-based services area unit ideal for the organizations with growing or unsteady information measure demands from shoppers. reckoning on the requirement of the user, it's attainable to expand cloud services capability so it's attainable to scale down once more thanks to the rationale that the ability is baked into the cloud service. This level of lightness will provide organizations utilizing cloud computing a true advantage over contenders.Despite several benefits of the cloud computing model, customers area unit still hesitant to deploy their business operations on the cloud owing to security issues of business knowledge. Since Cloud services area unit net based mostly and should serve many purchasers day by day, they'll become inundated and should even return up against technical blackouts. this will cause suspension of business processes briefly at the purpose once net association is disconnected, and thus the user won't have the capability to urge to any of his applications, server or info from the cloud. the protection might improve owing to knowledge centralization and security on resources however the issues continue regarding the loss of management over bound sensitive knowledge and also the security of hold on info handed over to the cloud service suppliers. If those suppliers haven't supplied with the economical security system in their own environments, the shoppers might be in problem. activity the standard of security measures enforced by the cloud suppliers is tough as a result of several cloud suppliers won't expose their infrastructure facilities to customers. Section a pair of narrates the literaturereview on connected works on security problems in cloud computing. Section three analyses security problems in cloud computing birthing accentuation on package as a service, Platform as a service and Infrastructure as a service and cloud computing readying ways. Section four addresses the challenges of the organizations on cloud computing resource management and section five conclude the complete work

II. CHARACTERISTIC OF CLOUD COMPUTING

2.1 Broad Network Access: Capabilities out there in cloud are often accessed by wide variety of devices. Tablets, sensible phones, Laptops and desktop are often wont to access the resources. Devices used for accessing could have thin/thick shopper platforms.

2.2 Speedy physical property: Cloud computing give the good physical property capabilities by providing the unlimited resources. Users will demand the resources offered at the time of needed and same may be discharged once the necessity is over. even supposing, providers even have the restricted re sour consumers it seems as unlimited resources area unit offered. ces except for.

2.3 Measured service : consumers should be measured for the request purpose. Cloud systems give the

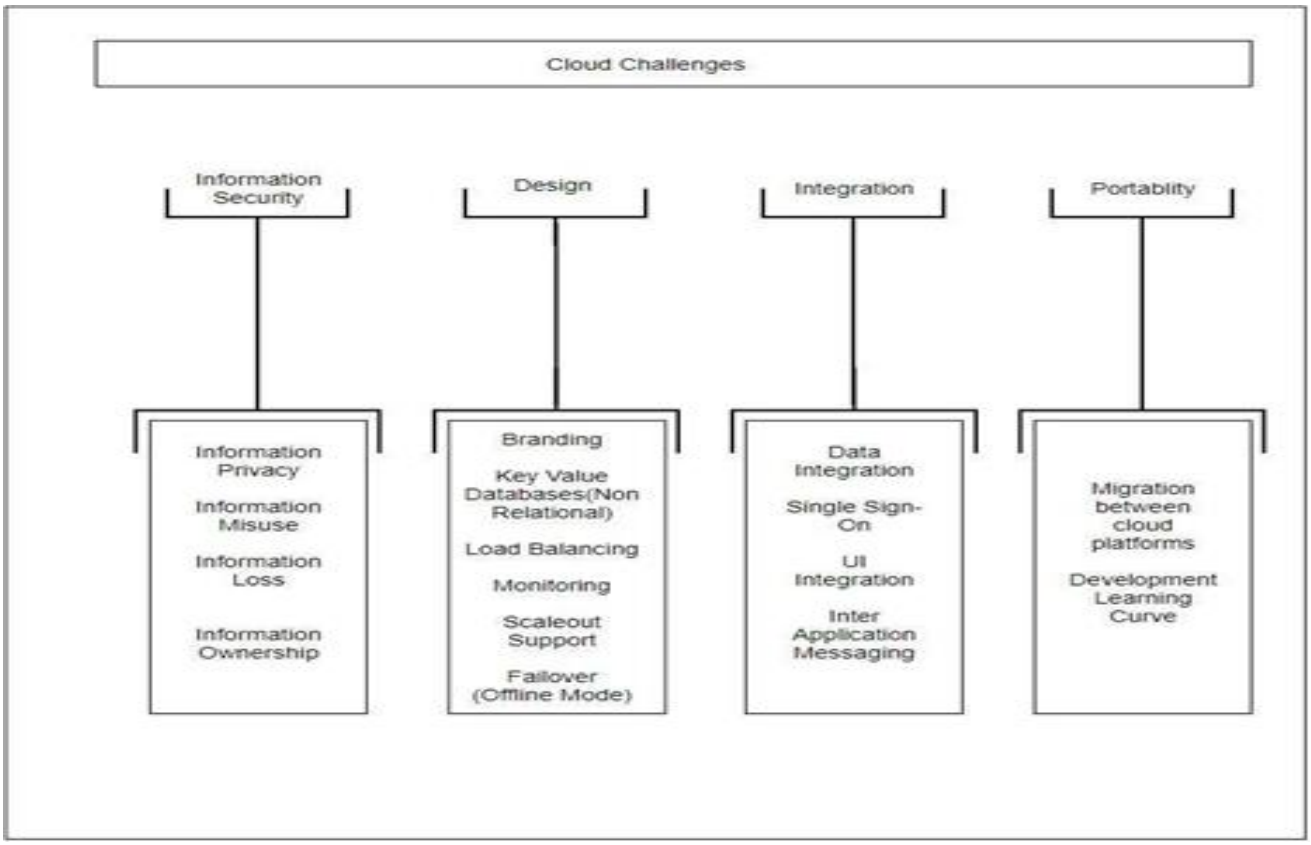
aptitude to live the quantity of resources used. Majority of the services offered are measure the resources like Virtual machine, Memory, storage, range and kind of mainframe accessed and the period of their usage. This measuring helps in generating the bill as per the usage according. Measured services should be clear for each the user and therefore the provider to avoid any quite competition, later on.

2.4 Agility : Cloud computing is way sought-after within the business circle due to its nimbleness. In ancient primarily based system procuring the resources need a protracted procedure of obtaining the requirement approved, attractive the quotation, choosing the best quotation, ordering and delivering. just in case of cloud computing resources are often demanded at any time and therefore the same are out there to the users. users in hours instead of in week and month just in case of ancient system. This rapid provisioning of the resources is is aware of as nimbleness and it reduces time period and useful in up the customers satisfaction and growing business advantage.

2.5 Resource Pooling : Cloud computing works on distributed model wherever resources area unit distributed throughout the information center. In case of excessive would like of resources, they'll be pooled with totally different physical and virtual resources to serve multiple customers. These resources area unit assigned and reassigned per client demand. Locations, from wherever resources area unit pooled aren't notable to the consumer, user will solely specify location at higher level of abstraction (e.g. country, state or information center). samples of resources that may be pooled embody storage, processing, memory and network information measure.

III. CHALLENGES OF CLOUD COMPUTING

Despite the potential gains achieved from the cloud computing, the organizations area unit slow in acceptive it thanks to the following limitations: information loss, information cleanup, account hijacking, less management over the method, corporate executive attacks by the auditability, less QoS .These limitations result in the problems or challenges like –security, ability, virtualization, information leak, resource sharing, load equalization ,multi-tenancy, and repair Level Agreement (SLA). There area unit several advantages as mentioned higher than, although cloud computing has several challenges. whereas moving from owning web site to cloud area, firms should aware of the advantages and challenges of cloud computing. While analyzing these challenges, security of information is that the most tedious add cloud computing. consistent with a survey carried out by Gartner quite seventieth of Chief Technical Officers believed that the first reason for not exploitation cloud computing services is that of the info security and privacy considerations. Convincing the organizations particularly little ones about security concern could be a tedious work; they're not able to throw away their infrastructure and immediate move to cloud. Most of the organizations area unit closely looking this issue and not able to shift to cloud area, this can be main reason in the lack of maturity the other unauthorized user sharing the appliance or platform within the cloud, this cause the integrity failure. As information area unit the bottom for providing cloud computing services, like information as a Service, code as a Service, Platform as a Service, keeping information integrity could be a basic task.



IV. CLOUD SECURITY ISSUES

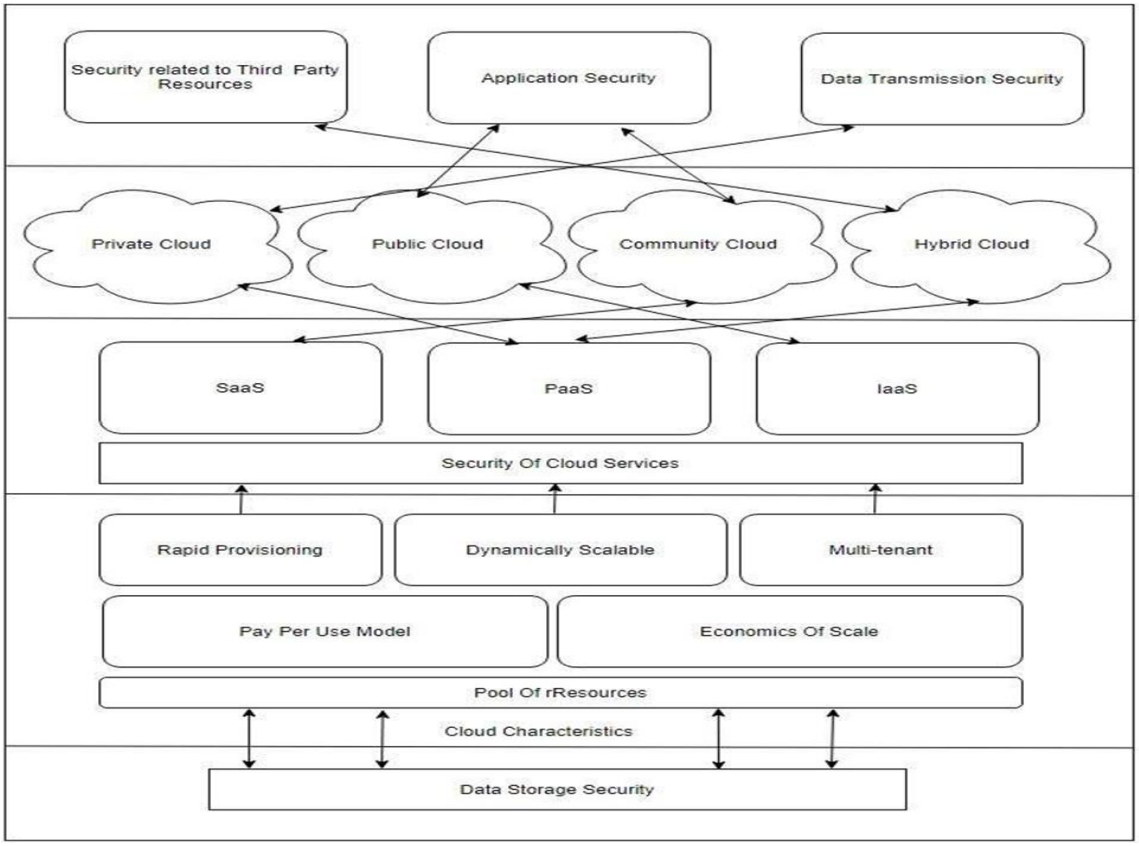
4.1 Cloud Deployments Models :

In the cloud readying model, networking, platform, storage, and package infrastructure square measure provided as services that resale or down betting on the demand as delineate in figure a pair of. The Cloud Computing model has 3 main readying models that are:

4.1.1 Private cloud:Private cloud may be a new term that some vendors have recently accustomed describe offerings that emulate cloud computing on personal networks. it's established inside Associate in Nursing organization's internal enterprise data center. within the personal cloud, climbable resources and virtual applications provided by the cloud merchant square measure pooled along and offered for cloud users to share and use. It differs from the general public cloud therein all the cloud resources and applications square measure managed by the organization itself, just like computer network practicality. Utilization on the personal cloud will be a lot of more secure than that of the general public cloud due to its given internal exposure. Only the organization and selected stakeholders could have access to control on a particular personal cloud.

4.1.2 Public cloud : Public cloud describes cloud computing within the ancient thought sense, whereby resources are dynamically provisioned on a fine-grained, self-service basis over the net, via web applications/web services, from Associate in Nursing off-site third-party supplier WHO shares resources and bills on a fine-grained utility computing basis. it's usually supported a pay-per-use model, just like a prepaid electricity metering system that is versatile enough to cater for spikes in demand for cloud improvement. Public clouds square measure less secure than the opposite cloud models as a result of it places an extra burden of making certain all applications and information accessed on the general public cloud are not subjected to malicious attacks.

4.1.3 Hybrid cloud : Hybrid cloud may be a personal cloud joined to 1 or a lot of external cloud services, centrally managed, provisioned as one unit, and circumscribed by a secure network. It provides virtual IT solutions through a combination of each public and personal clouds. Hybrid Cloud provides safer management of data} and applications and permits varied parties to access information over the Internet. It conjointly has Associate in Nursing open design that enables interfaces with alternative management systems. Hybrid cloud will describe configuration combining an area device, like a Plug PC with cloud services. It also can describe configurations combining virtual and physical, collocated assets -for example, a largely visualized atmosphere that needs physical servers, routers, or other hardware like a network appliance acting as a firewall or spam filter.



4.2 Cloud Computing Services :

Following on the cloud preparation models, successive security thought relates to the assorted cloud computing service delivery models. The 3 main cloud service delivery models are: Infrastructure-as-a-Service (IaaS), Platform-as-a Service (PaaS) and Software-as-a-Service (SaaS).

4.2.1 Infrastructure as a Service (IaaS) : Infrastructure as a Service could be a single tenant cloud layer wherever the Cloud computing vendor's dedicated resources are solely shared with contracted shoppers at a pay-per-use fee. This greatly minimizes the requirement for Brobdingnagian initial investment in computing hardware like servers, networking devices and process power. They additionally permit varied degrees of economic and functional flexibility not found in internal information centers or with collocation services, because computing resources is superimposed or free rather more quickly And cost-effectively than in an internal information center or with a collocation service. IaaS and alternative associated services have enabled startups and alternative businesses target their core competencies without concern abundant about the provisioning and management of infrastructure. IaaS fully abstracted the hardware to a lower place it and allowed users to consume infrastructure as a service while not bothering anything regarding the underlying complexities. The cloud encompasses a compelling worth proposition in terms of value, however 'out of the box' IaaS solely provides basic security (perimeter firewall, load balancing, etc.) and applications stepping into the cloud can want higher levels of security provided at the host.

4.2.2 Platform as a service (PaaS) : Platform-as-a-Service (PaaS) could be a set of code and development tools hosted on the provider's servers. it's one layer on top of IaaS on the stack and abstracts away everything up to OS, middleware, etc. This offers AN integrated set of developer atmosphere that a developer will faucet to build their applications while not having any clue regarding what's occurring beneath the service. It offers developers a service that gives a whole code development life cycle management, from attending to style to putting together applications to preparation to testing to maintenance. Everything else is abstracted aloof from the "view" of the developers. Platform as a service cloud layer works like IaaS however it provides a further level of 'rented' practicality. Clients victimization PaaS services transfer even a lot of prices from capital investment to operational expenses however should acknowledge the extra constraints and probably some extent of lock-in posed by the extra practicality layers. The employment of virtual machines act as a catalyst in the PaaS layer in Cloud computing. Virtual machines should be protected against malicious attacks such as cloud malware. so maintaining the integrity of applications and well implementing accurate authentication checks throughout the transfer of knowledge across the whole networking channels is elementary.

4.2.3 Software-as-a-Service (SaaS): Software-as-a-Service could be a code distribution model during which applications are hosted by a vendor or service supplier and created out there to customers over a network, generally the web. SaaS is changing into AN progressively current delivery model as underlying technologies that support internet services and service-oriented design (SOA) mature and new biological process approaches become well-liked. SaaS is additionally typically related to a pay-as-you-go subscription licensing model. Meanwhile, broadband service has become progressively out there to support user access from a lot of areas round the world. SaaS is most frequently enforced to supply business code practicality to enterprise customers at a coffee value whereas permitting those customers to get a similar advantages of commercially commissioned, internally operated code without the associated quality of installation, management, support, licensing, and high initial cost. The design of SaaS-based applications is specifically designed to support several concurrent users (multi-tenancy) directly. code as a service applications ar accessed victimization web browsers over {the internet|the internet|the net} so application program security is vitally necessary. Info security officers can got to think about varied ways of securing SaaS applications. Web Services (WS) security, long language (XML) coding, Secure Socket Layer (SSL) and out there choices that ar utilized in implementing information protection transmitted over the Internet.

V. CONCLUSION

Cloud computing is AN Internet-based computing service provided by the third party permitting share of resources and data among devices. it's wide utilized in several organizations today and changing into a lot of common as a result of it changes the means of however the data Technology (IT) of a company is organized and managed. It provides several benefits like simplicity and lower prices, virtually unlimited storage, least maintenance, straightforward utilization, backup and recovery, continuous convenience, quality of service, machine-driven package integration, measurability, flexibility and reliability, quick access to data, elasticity, fast readying and lower barrier to entry. during this new era the employment of cloud computing service is increasing speedily, however the safety problems with the cloud computing became a challenge. Cloud computing should be safe and secure enough to make sure the privacy of the users. during this paper first off we've got illustrated the architecture of the cloud computing, then discuss the foremost common security problems with victimization cloud then we've got proposed a knowledge recovery algorithmic rule for cloud computing setting. The heading of the Acknowledgment section and the References section must not be numbered. Causal Productions wishes to acknowledge Michael Shell and other contributors for developing and maintaining the IEEE LaTeX style files which have been used in the preparation of this template.

Cloud Security for Securing Data using Technology

Shraddha G. Pimpalkar , Lowlesh N. Yadav, Vijay M. Rakhade, Neehal B. Jiwane

Shri Sai College of Engineering and Technology, Bhadrawati, Maharashtra, India

Abstract – **Security is one of the main issues hindering the growth of cloud The idea of handing off important data to another company worries me. Consumers should therefore be vigilant to understand the risks of data breaches in this new environment. This white paper provides an in-depth analysis of cloud computing security issues and challenges, focusing on types of cloud computing and types of service offerings. Cloud computing is a set of IT services provided to customers over a network on leased bases, allowing the service requirements to be scaled up or down. Cloud computing services are typically provided by a third party that owns the infrastructure. Notable benefits include scalability, resilience, flexibility, efficiency, and outsourcing of non-core activities. Cloud computing offers organizations an innovative business model for adopting IT services with no upfront investment. Despite the potential benefits to be gained from cloud computing, security issues and related challenges have delayed the adoption of cloud computing by organizations..**

I. INTRODUCTION

Cloud computing is considered service oriented rather than application-oriented. This Service oriented nature of cloud computing not only reduces infrastructure overhead and operating costs, but also provides flexibility and improved performance for end users. Security and privacy are the main concerns when adapting the cloud to data. This is very important for cloud services to ensure data integrity, privacy, and protection. To this end, several service providers use different policies and mechanisms, depending on the type, nature and size of the data. One of the advantages of cloud computing is the ability to share data between different organizations. However, this advantage itself brings risks to your data. To avoid potential risks to your data, you should protect your data store. Cloud security, also known as cloud computing security, is a collection of security measures designed to protect cloud-based infrastructure, applications, and data. These measures ensure user and device authentication, data and resource access control, and data protection.

II. LITERATURE SURVEY

In order to understand the basics of cloud computing and storing data securing on the cloud, several resources have been consulted. This section provides a review of literature to set a foundation of discussing various data security aspects. Over the past decade, cloud computing has played an important role. Cloud computing is a computing, software, data access, and storage service that does not require end-user knowledge of the physical location and configuration of the systems that provide the services. Cloud computing is the fastest new paradigm for delivering on-demand services over the Internet and can be described as Internet-centric software. Cloud computing represents a new add-on, consumption, and delivery model for IT services based on internet protocols, typically involving the provisioning of dynamically scalable and often virtualized resources. This is a by-product and result of access to remote computing sites served by the Internet. This often takes the form of a web-based tool or application that users can access through a web browser and use like a program installed locally on their computer. This document has covered all the basic concepts of cloud computing. Doing research in this area is very beneficial.

III. RELATED PROPOSED WORK DEPENDS ON EXISTING WORK

We can refer to the following topics on security in cloud computing. These are the trending Issues in security so we will do In Our Proposed work in the field.

Anomaly Classification in Multi-Cloud Dynamic Programming and Scheduling in Cloud.

Secure Multi-Party Computation by Agent. Cyber Security Threats Detection.

Secure Data Storage.

A.Data Modernization.

DDoS Attacks Detection. This clearly shows that there is a lot of room for future research in the area of cloud computing security. So we can count on us for complete research support. Here are some key points to include in your cloud computing security research proposal:

Research proposals on topics such as "Data Deduplication Security" should include the top threats to data deduplication. Your research goal itself is to overcome these threats. The threats to users in the case of data deduplication are: Cloud storage servers (encryption and decryption of data) Malicious users (getting sensitive data from sources) These threats are very easy to defeat with our expert guidance. we can do it. Grow your potential resource base with the large amount of reliable resources we provide. Our extensive performance in leading cloud security research projects means we have a wealth of ideas, resources, and advice for your research. Here, we elaborate on the research gaps in cloud security.

The threats to users in the case of data deduplication are: Cloud storage servers (encryption and decryption of data) Malicious users (getting sensitive data from sources) These threats are very easy to defeat with our expert guidance. we can do it. Grow your potential resource base with the large amount of reliable resources we provide. Our extensive performance in leading cloud security research projects means we have a wealth of ideas, resources, and advice for your research. Here, we elaborate on the research gaps in cloud security.

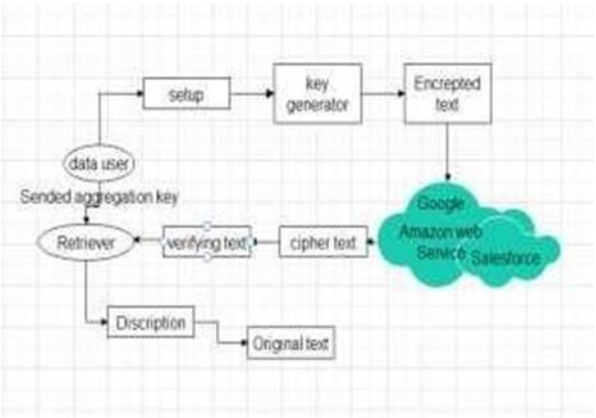

Fig.1. Overivew Of Cloud Computing

A. Amazon Web Services:

Amazon Web Services is an online platform that provides scalable and cost-effective cloud computing solutions. AWS is a widely used cloud platform that provides multiple on-demand operations such as compute power, database storage, and content delivery to help your business scale and grow.

B. Microsoft Azure:

Azure Firewall is a cloud-native, intelligent network firewall security service that protects cloud workloads running in Azure from threats. It is a fully stateful firewall-as-a-service with built-in high availability and unlimited cloud scalability.

C. Google:

Google Cloud Storage is an enterprise-grade public cloud storage platform for large unstructured datasets. Organizations can purchase storage for primary or infrequently accessed data. Storage customers can access data through a web browser or command line interface. Customers can also choose the geographic location where their data resides. Storage service within Google Cloud Platform. Provides a unified object store for live or archived data. Objects stored in Google Cloud Storage are grouped into buckets. A bucket is a container in the cloud that can be individually assigned to a storage class.

Salesforce Cloud:

Cloud computing technology allows users to access storage, files, software, and servers from Internet-connected devices (computers, smartphones, tablets, and wearables). Cloud computing providers store and process data separately from end users. Basically, cloud computing refers to the ability to store and access data and programs over the Internet instead of on your hard drive. This means businesses of all sizes can leverage powerful software and IT infrastructure to become bigger, leaner, more agile, and compete with much larger companies. Unlike traditional hardware and software, cloud computing helps businesses stay at the forefront of technology without making large investments in purchasing, maintaining, and servicing equipment

V. PURPOSE: SERVICES OF CLOUD SECURITY

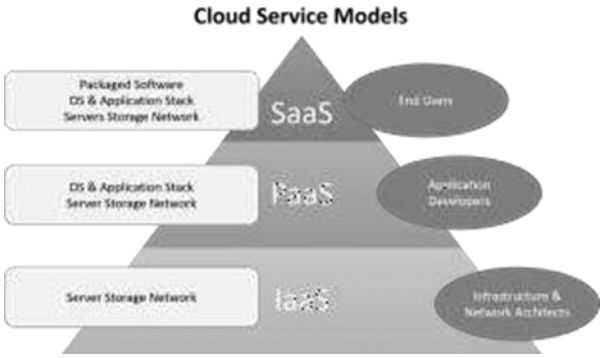

Fig.2. Services Provided By Cloud Computing Security

A. Application and Information clouds Software as a Service (SaaS):

The opportunity presented to consumers is to use the provider's applications running on cloud infrastructure. Applications can be accessed from a variety of client devices through thin client interfaces such as: Web browser. You have access to web-based email. Consumers do not manage or control the underlying cloud infrastructure such as networks, servers, operating systems, storage, or even individual application functions.

B. Development data clouds Platform as a Service (PaaS):

The ability provided to consumers is to deploy consumer-created or purchased applications built using providersupported programming languages and tools on cloud infrastructure. Consumers do not manage or control the underlying cloud infrastructure, such as networks, servers, operating systems, or storage, but they do control the configuration of deployed applications and, in some cases, the application hosting environment.

C. Infrastructure clouds computing Infrastructure as a Service (IaaS):

The functions provided to consumers are to provide processing, storage, networking, and other basic computing resources so that consumers can deploy and run any software, including operating systems and applications. Consumers do not manage or control the underlying cloud infrastructure, but they do control the operating system.

VI .DESIGN and ARCHIECTURE OF CLOUD SECURITY

While there are many security concerns associated with cloud computing, these issues fall into two broad categories: security issues faced by cloud providers and security issues faced by their customers.

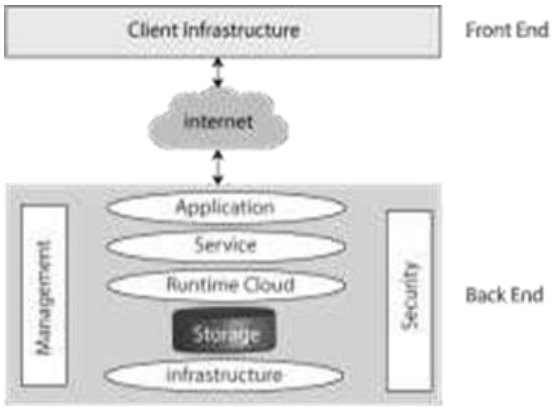

Fig.3.Architecture of Cloud Security

Providers now need to ensure that their infrastructure is secure and that their customers' data and applications are protected, but customers are responsible for ensuring that providers have appropriate security measures in place to protect that information. I need to make sure I'm taking it. Safety has always been paramount. A cloud security architecture is only effective if the right defenses are implemented. An effective cloud security architecture must be aware of the issues that arise in security management. Cloud Security Management addresses these security management issues. These controls are in place to protect against vulnerabilities in your system and to mitigate the effects of attacks. There are different types of controls behind any cloud security architecture, but they typically fall into one of the following categories:

A Deterrence Control:

These controls are put in place to prevent intentional attacks against cloud systems. Like fences and property warning signs, these controls do not mitigate actual vulnerabilities in your system.

B. Preventive Controls:

These controls increase the strength of the system by managing vulnerabilities. Proactive controls protect against vulnerabilities in your system. In the event of an attack, preventative controls are put in place to cover the attack and reduce damage and system security breaches.

C. Detective Controls:

Detective Controls are used to detect possible

attacks on your system. In a case of attack, detective control signals preventive or corrective control to address the problem.

VII. ADVANTAGES

The following are some of the major advantages of cloud computing: A.Elasticity:

Elastic nature of the infrastructure allows rapidly allocating and de-allocating massively scalable resources to business services on a demand basis.

B.Virtualization:

Virtualization is defined as decoupling and separation of the business service from the infrastructure needed to run it.

C. Cloud computing benefits are:

- Expand scalability

•Lower infrastructure costs

- Improve end-user productivity
- Improve reliability
- Increase security

VIII. DISADVANTAGES

Loss of control dependency.

CONCLUSION

We have identified several security risks related to cloud computing. Data manipulation and loss is one of the identified risks. Consumer trust, data offload, and associated risks are the key challenges identified in this SLR. This SLR identified commercial cloud service providers and highlighted the security issues faced during the deployment and implementation of cloud services. Cloud user trust is a challenge for consumers of commercial cloud service providers. In addition to the above issues, An data unavailability, inadequate security measures and vendors dependencies and the lack of interoperability and standards have been identified. Additionally, we found that Tweeter data were generated and used to evaluate the proposed Cloud Computing approach. This SLR found that researchers used little Facebook or Instagram And other Social media data to evaluate the proposed strategy. During Cloud Computing deployment and implementation, data security and privacy are concerns that cloud adopters must consider before using cloud services. A literature review supported our claims, and we propose to propose appropriate implementations of security policies and standards for cloud computing. that can be practiced and implemented in future work.

ACKNOWLEDGEMENT

These Research of Cloud Security For Securing data Using Technology. paper was partially supported and Gratefully Acknowledge received from Shri Sai College of Engineering And Technology, Dr. Babasaheb Technological University, Lonere India. I would like to show our Gratitude to Prof. L.N.Yadav HOD of CSE Department & Prof. N.B.Jiwane of Cse Department for Sharing Their Pearl of wisdom with us during course of this Research paper.

A Review OnVirtualization in Cloud Computing

Ritika A. Bahel, Ashish B. Deharkar, Vijay M. Rakhade

Shri Sai College of Engineering and Technology, Bhadrawati, Maharashtra, India

Abstract – **Virtualization refers to the act of one thing as well as virtual laptop makes a unreal image of the storage space devices servers or network resources in order that they'll be used on multiple machines at a similar time. With the latest growth in cloud computing technologies, security of the info becomes necessary. it's Associate in Nursing modify technology allowing the look of Associate in Nursing intelligent abstraction layer that hides the density of underlying computer code or hardware virtualization technology that may build things easier operations yet as enable data Technology organizations to react quicker to dynamical business demands. It permits multiple virtual computers to run on prime of 1 physical computer and to share the hardware resources, like printers, scanners, and modems.**

This will increase the economical use of {the laptop\the pc} by low prices since only 1 physical computer is required and running. Cloud computing technology is one of the biggest milestones in leading United States to next generation technology and winning up business and data Technology field. It helps to rise higher than the matter for the loss of information, accessing knowledge whenever needed and knowledge security. This technology is especially service familiarised and focuses on reduction in low value, hardware reduction and pay just for service conception.

Keywords: Virtualization, Cloud Computing, VM, Data security

I. INTRODUCTION

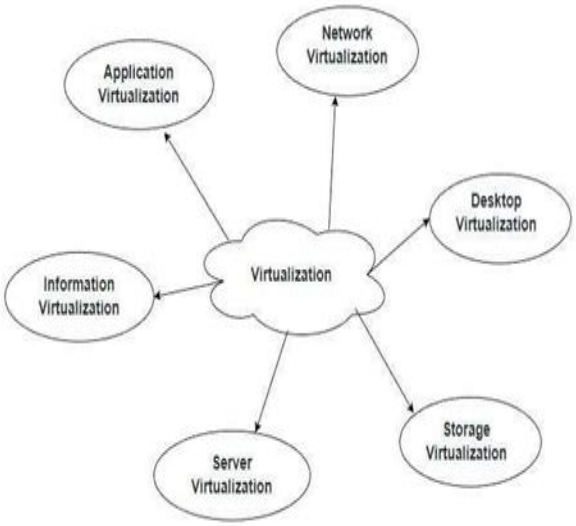
Virtualization is that the growing technology within the IT world. it's getting used by a growing variety of organizations to merge their workloads, to form their IT surroundings ascendable and a lot of versatile.

In computing, virtualization is that the creation of a virtual quite than real report of a resource or device, sort of a server, associate software package, a memory device or network. It simply provides high accessibility for important applications also as streamlines application use& migrations. It has the aptitude to run multiple virtual machines on a specific a part of hardware.

The hardware runs code which allows you to line up multiple in operation systems that square measure ready to run at the same time and severally, in their own secure setting, with token reduction in performance.

Cloud computing technology is predicated on 3 types- grid computing, utility computing and automatic computing. All the information is hold on on the servers and may be accessed just by authenticate with the assistance of the net any place within the world. Apple, Google, Microsoft, etc. square measure the most important cloud service suppliers offer terribly massive storage to its users and creating the work easier.

II. TYPES OF VIRTULIZATION



a) Application Virtualization: Application virtualization helps a user to possess remote access of Associate in Nursing application from a server. The server stores all personal data and different characteristics of the appliance however will still run on a neighborhood digital computer through the net. Example of this is able to be a user World Health Organization must run 2 completely different versions of a similar computer code. Technologies that use application virtualization area unit hosted applications and packaged applications.

b) Network Virtualization: The ability to run multiple virtual networks with every features a separate management and information set up. It co-exists along on high of 1 physical network. It may be managed by individual parties that probably confidential to every different. Network virtualization provides a facility to form and provision virtual networks—logical switches, routers, firewalls, load balancer, Virtual personal Network (VPN), and employment security among days or maybe in weeks.

c) Desktop Virtualization: Desktop virtualization permits the users' OS to be remotely keep on a server within the information centre. It permits the user to access their desktop just about, from any location by a special machine. Users World Health Organization wish specific operational systems aside from Windows Server can got to have a virtual desktop. Main edges of desktop virtualization area unit user quality, movability, simple management of computer code installation, updates, and patches.

d) Storage Virtualization: Storage virtualization is Associate in Nursing array of servers that area unit managed by a computer memory system. The servers aren't attentive to specifically wherever their information is keep, and instead operate additional like employee bees

in a very hive. It makes managing storage from multiple sources to be managed and utilised as one repository. storage virtualization computer code maintains sleek operations, consistent performance and a nonstop suite of advanced functions despite changes, break down and variations within the underlying instrumentality.

e) Server Virtualization: This is a form of virtualization within which masking of server resources takes place. Here, the central-server(physical server) is split into multiple completely different virtual servers by ever-changing the identity variety, processors. So, every system will operate its own operational systems in isolate manner. wherever every subserver is aware of the identity of the central server. It causes a rise within the performance and reduces the budget items by the readying of main server resources into a sub-server resource. It's useful in virtual migration, scale back energy consumption, scale back infrastructural value, etc.

f) Information virtualization:

This is the sort of virtualization within which {the information|the info|the data} is collected from varied sources and managed that at one place while not knowing additional concerning the technical information like however data is collected, keep & formatted then organized that information logically in order that its virtual read may be accessed by its interested folks and stakeholders, and users through the assorted cloud services remotely. several huge big corporations area unit providing their services like Oracle, IBM, At scale, Cdata, etc

III. CHARACTERISTICS OF VIRTUALIZATION

Virtualization offers many options or characteristics as listed below: –

a) Distribution of resources: Virtualization and Cloud Computing technology guarantee end-users develop a singular computing setting. it's achieved through the creation of 1 host machine. Through this host machine, the end-user will limit the amount of active users. By doing thus, it facilitates straightforward of management. they will even be wont to bring down power consumption.

b) Accessibility of server resources: Virtualization delivers many distinctive options that guarantee no would like for physical servers. Such options guarantee a lift to period, and there's less fault tolerance and availableness of resources. Resource Isolation: Virtualization provides isolated virtual machines. every virtual machine will have several guest users, and guest users may be either in operation systems, devices, or applications. The virtual machine provides such guest users with associate degree isolated virtual setting. This ensures that the sensitive info remains protected, and, at similar time, guest users stay inter-connected with each other.

c) Security and authenticity: The virtualization systems guarantee continuous period of systems, and it will automatic load reconciliation and ensures there's less disruption of services.

d) Aggregation: Aggregation in Virtualization is achieved through cluster management computer code. This computer code ensures that the uniform sets of computers or networks area unit connected and act united unified resource.

IV. POSITIVE EFFECTS OF VIRTULIZATION SECURITY

a) Granular Access Control: IT groups and admins have way more management over network access than with a access hardware-based infrastructure. groups will use micro-segmentation techniques to grant user access to specific applications or resources at the employment level.

b) Application Isolation: A key security advantage of virtualization is that the ability to isolate applications from each other on the network. Keeping apps isolated will defend information from being shared across them, or from malware or viruses which will have infected alternative components of the system. Isolation is usually accomplished via containerization and sandboxing.

c) Increased management Over Desktop and Application Updates: operative systems (OSs) and applications ar perpetually surfing security patches, however your workers may not be maintaining with these updates on their devices. By virtualizing desktops, it'll have full management to confirm OSs and applications ar updated.

d) Virtual Machine (VM) Isolation: Running many virtual machines on one server permits for a high level of isolation. If security is compromised inside one server, this separation provides protection for the opposite virtual servers. Network Isolation and Segmentation: freelance workloads or apps on a network is divided and shared across metameric virtual networks that ar isolated from one another. This ensures that data and access aren't shared across the complete network

e) Hypervisor Maintenance: Hypervisors that make and run VMs usually need fewer resources than hardware-based solutions, giving them a smaller attack surface. Plus, hypervisors typically update mechanically.

V. ADVANTAGES OF VIRTUALIZATION

- Virtualization offers many edges, like it helps in price reduction and boosting productivity towards the event method.
- It will away with the requirement to possess a extremely advanced IT infrastructure.
- It facilitates remote access to resources and ensures that it promotes quicker quantifiability.
- It is extremely versatile, and it permits the users to execute multiple desktops in operation systems on one commonplace machine.
- It removes the risks concerned in terms of system failures, and it conjointly boosts versatile knowledge transfer between completely different virtual servers.
- The operating method in Virtualization is very efficient and agile, that ensures that the users work and operate most economically.

VI. DISADVANTAGES OF VIRTUALIZATION

- The transition of the prevailing hardware setup to a virtualized setup needs an intensive time investment, and thence this will be thought to be a time-intensive method.
- There is a scarcity of availableness of good resources that helps in terms of transition of existing or actual setup to virtual setup.
- Since there's a limitation in terms of getting less good resources, the implementation of Virtualization necessitate high-cost implementations.
- If the transition method isn't handled meticulously, it conjointly poses a security risk to sensitive knowledge.

VII. VIRTUALIZATION AS AN INSPIRATION OF CLOUD COMPUTING

In cloud computing, Virtualization facilitates the creation of virtual machines and ensures the graceful functioning of multiple in operation systems. It conjointly helps produce a virtual scheme for server in operation systems and multiple storage devices, and it runs multiple in operation systems.

Cloud Computing is known as associate degree application or service that involves a virtual scheme. Such associate degree scheme may be of public or non-public nature. With Virtualization, the requirement to possess a physical infrastructure is reduced. The terms Cloud Computing and Virtualization area unit currently getting used interchangeably, and that they area unit being unified quickly.

Virtualization and Cloud Computing work hand in hand to make sure that you simply can get advanced and complex levels of computing. It ensures that applications is shared across multiple network threads of various enterprise and active users.

VIII. ROLE OF VIRTUALIZATION IN CLOUD COMPUTING

In Virtualization, a smart or proper noun is aligned with the physical server. The pointers area unit then directed towards that physical server, that is finished on demand. Virtualization facilitates the execution of applications that area unit uniform.

It conjointly provides a virtual and isolated networking, storage, and memory space setting. The Virtualization is achieved through a number machine and guest machine. a number machine is outlined because the machine on that a virtual machine is developed, and also the virtual machine thus developed is termed as a guest machine.

Hardware virtualization plays a essential role by delivering infrastructure as a service answer most expeditiously and effectively below a Cloud Computing method.

This type of Virtualization ensures movability. The guest machine is prepacked as a virtual instance of a picture, and such virtual pictures is removed simply as and once the requirement arises.

IX. CONCLUSION

To have each physical and not real controls within the surroundings of cloud computing one should keep information by implementing robust encrypting techniques victimisation protected connections and be valid information loss rejection policies. Right of entrance management policies square measure to be recognized and shopper identity square measure to be checked. information middle platforms, communications and shopper devices square measure to be safe by trustworthy laptop policies. permit safe migration from non-public cloud surroundings to public cloud suppliers. while not virtualization, cloud computing is accomplishable however it'll be inefficient and hard. It provides flexibility, quantifiability and low value benefits to cloud computing. There square measure several levels and many types to implement virtualization.

Review Paper on Network Security

Pratiksha Rajurkar, Vijay M. Rakhade, Ashish B. Deharkar

Shri Sai College of Engineering & Technology, Bhadrawati, India

Abstract – **: Network security has become major crucial to personal computer users, bureaucratic, and the services. With the arrival of the internet, security became a crucial anxiety as well as the past of security approve a better understanding of the disclosure of security technology. The internet complex itself allows for many securities risks to happen. If the architecture of the internet is adapted, it can bring to the possible attacks that can be sent over the network. Aware the attack methods allow us to emerge with proper security**

Keywords: Firewall, Threats, Network Security, Network Security Architecture.

I. INTRODUCTION

The world is fetching more interconnected due to Internet and new networking technology. There is a big amount of personal, commercial, military, and government data on networking infrastructures worldwide. Network security is fetching of greatest importance because of intellectual property that can be easily developed through the internet. There can be breach in intellectual property. Network Security defends your network and data from breaches, intrusions and additional threats. This is a huge and overarching term that describes hardware and software solutions as well as procedures or rules and configurations relating to network use, accessibility, and overall threat protection.

II. NETWORK SECURITY

Network Security keeps your network and data since breaches, intrusions and other threats. This is a huge and overarching term that describes hardware and software solutions as well as procedures or rules and configurations relating to network use, accessibility, and overall threat protection.

Network Security contains access control, virus and antivirus software, application security, network analytics, types of network-related security (endpoint, web, wireless), firewalls, VPN encryption and more. System and network technology is a key technology for a extensive variety of applications. Networks and applications essential security. While, network security is a serious requirement, there is a significant lack of security systems that can be implemented easily.

III. NETWORK SECURITY ARCHITECTURE

Networks essential have security embedded into their very design. A network security architecture provides a basis for an organization's cyber defences and helps to protect all of the company's IT assets. Now, we debate the components of a network security architecture, how it benefits businesses, and dissimilar models for generating a secure network architecture.

Elements of a Network Security Architecture

A network security architecture contains both network and security elements, such as the subsequent:

- Network Elements: Network nodes (computers, routers, etc.), communications protocols (TCP/IP, HTTP, DNS, etc.), connection media (wired, wireless), and topologies (bus, star, mesh, etc.).
- Security Elements: Cybersecurity devices and software, secure communications protocols (e.g., IPsec VPN and TLS), and data privacy technologies (classification, encryption, key management, etc.).

The Purpose of a Network Security Architecture

A well-designed cybersecurity architecture allows businesses to keep resiliency in the face of a cyberattack or a disaster of one or additional components of their infrastructure. The architecture should be enhanced for daily use through normal business operations and make the company to handle reasonable bursts, spikes, or surges in traffic and to properly manage potential cyber threats to the organization.

The labels a process for developing a network security architecture that contains four primary phases:

- Assess: This phase of the procedure is for business and architecture reviews. The key phases in this phase include data capture, business modelling, and risk assessments.
- Design: This phase is proposed to develop a response to the requirements and to build customized logical design blueprints and approvals.
- Implement: This phase is for professional services, partners, etc. to enhance low-level design specifics and deliver statement-of-works for real-world solutions.
- Manage: This phase is pitched towards continuous development and incremental improvements of the security posture.

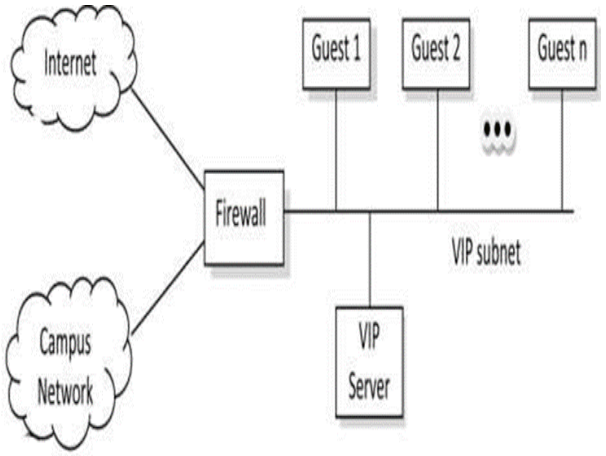

Fig.: Network Security Architecture

IV. FIREWALL

A Firewall is a network security device that monitors and filters incoming and outgoing network traffic founded on an organization's previously recognised security policies. At its maximum basic, a firewall is essentially the barrier that sits between a private internal network and the public Internet. A firewall's key purpose is to agree non-threatening traffic in and to possess dangerous traffic out.

The Different Types of Firewalls

There are numerous types of firewalls, and one of the major tasks that companies face when trying to protected their sensitive data is finding the right one. First off, a firewall – a network firewall – is a network appliance designed to express and enforce a perimeter. They can be organised at the connection between an organization's internal network and the public Internet or internally inside a network to perform network segmentation.

Hardware Firewalls: These firewalls are executed as a physical appliance deployed in an organization's server room or data centre. While these firewalls have the benefit of running as "bare metal" and on hardware designed specifically for them, they are also embarrassed by the limitations of their hardware (number of network interface cards (NICs), bandwidth limitations, etc.).

Software Firewalls: Software firewalls are executed as code on a computer. These firewalls contain both the firewalls built into common operating systems and virtual appliances that contain the full functionality of a hardware firewall but are implemented as a virtual machine.

Cloud Firewalls: Organizations are gradually moving serious data and resources to the cloud, and cloud-native firewalls are designed to follow suit. These virtual appliances are explicitly designed to be deployed in the cloud and may be accessible as either standalone virtual machines or as a Software as a Service (SaaS) offering.

Individually of these different firewall form factors has its advantages and disadvantages. While a hardware firewall has contact to optimized hardware, its abilities can also be constrained by the hardware it uses. A software firewall may have a little lower performance but can be easily updated or extended. A cloud firewall, but, takes advantage of all of the profits of the cloud and can be deployed near to an organization's cloud-based properties.

V. THREATS

Information Security threats can be several like Software attacks, theft of intellectual property, identity theft, theft of equipment or information, sabotage, and information extortion.

Threat can be whatever that can take benefit of a vulnerability to breach security and negatively alter, erase, harm object or objects of interest.

Software attacks resources attack by Viruses, Worms, Trojan Horses etc. Numerous users believe that malware, virus, wombats are all similar things. But they are not similar, only similarity is that they all are malicious software that acts differently.

Malware is a combination of 2 standings- Malicious and Software. So, Malware essentially means malicious software that can be an intrusive program code or anything that is designed to perform malicious operations on system.

Types of security threats

The NIST definition above conditions that a threat can be an event or a condition. An incident, in this case, also contains natural disasters, fire, and power outage. It is a same general concept. In cybersecurity, it is extra common to talk round threats such as viruses, trojan horses, denial of service attacks.

Phishing emails is a social engineering threat that can reason, e.g., loss of passwords, credit card numbers and further sensitive data. Threats to information properties can cause loss of confidentiality, integrity or availability of data. This is likewise known as the CIA triad.

The CIA triad, together with three other well-known security concepts, is the origin for the STRIDE threat model. When listing possible threats, it is convenient to use an existing classification as a starting point. STRIDE is the most recognised classification, proposed by Microsoft in 1999. The name comes from the initial letters of the dissimilar categories, which also kinds it easier to recall them.

VI. CONCLUSION

Network security is a significant field that is increasingly gaining attention as the internet expands. The security threats and internet protocol were analysed to determine the necessary variations in security technology. The security technology is frequently software based, but many common hardware devices aroused. The current development in network security is not very remarkable.

Smart College Campus Enabled with IoT: For E- Campus Environment

Bhuvan Nanduji Banpukar, Neehal B. Jiwane, Lowlesh N. Yadav ,Vijay M. Rakhade
Shri Sai College of Engineering and Technology, Bhadrawati, Maharashtra, India

Abstract – **Technology used like IoT increasing day by day in today's world. This article put a light on what is meant by E-campus Environment. How it is useful for student and teachers to enables campus from anywhere. By operating during this manner access and communication with the various type of gadgets and devices like camera, audio recorder, sensible watches, google glass, digital broad displays, sensors …. etc. The IoT will nurture the development of learning circumstance that make use of the large subject Information generated by those objects to provide dynamic services to lecturers, learners and even to contain developers in trendy field, sensible field permits us to North American country IoT methodologies to create it accessible for room notes everyplace within network space our objectives. Square measure to create simply shareable notes share victimisation web-based environment s/w which permit North American country to share via IoT enabled to accesses among network limit. We and to don't have any IoT enabled resources in school and university campuses for this purpose thus far in learning setting.**

Keywords: IoT, E-Campus, Sensors, Camera, Audio recorder, Sensible watches etc..

I. INTRODUCTION

Internet of Things (IoT) may be a new communication paradigm that refers to and envisions the concept of connecting everyday are assembled with microcontrollers, transceivers to support communication. they're con Fig. with protocol stacks that will understand the interaction of the objects with each other to arrive at common objectives while not the intervention of humans. Thus, IoT makes the web a lot of immersive and pervasive [1-5]. This paradigm offers a platform for sensors and devices to speak seamlessly among a wise environment and supports data sharing across platforms during a convenient approach [6]. The strength of this paradigm comes from the actual fact that it's interacting with a wide range of devices like drones, robots, security alarms, surveillance cameras, observation sensors, actuators, household appliances, sensible vehicles, workplace instrumentality, displays, power generation systems, heating and air conditioning systems, etc., that generates huge knowledge to provide new service to folks and company bodies [1-2].IoT can be applied to many domains, such as, industrial automation, mobile care, care observation and assistance devices, medical aids, home automation, smart grids, automotive, intelligent energy management, elderly assistance, water and waste management, traffic management, among others [1-2][7]. Smart field is a crucial analysis direction in urban IoT. this is often as a result of on paper a field may be a settlement. Therefore, the applying of IoT to sensible field provides valuable insight for the applying of urban IoT [1]. This concept is in gear towards developing a field that utilizes resources expeditiously, delivers top quality services to the campus community with extremely reduces operational prices. Furthermore, sensible field provides the subsequent further benefits: 1) provision of interactive and inventive setting for students and school members, 2) provision of secured payment systems, 3) provision of clear pick systems,4) promotion of sensible energy management, 5) giving of Realtime incidence warnings and effective police investigation systems, 6) provision of machine-driven maintenance and business processes, and 7) maintenance of economical parking and access control management, etc. [1]

This paper may be abstract paper on net of Things (IoT) for sensible field. It shows the applications of IoT to smart field, the usage of IoT on sensible field and provides the open challenges facing IoT for sensible field whereas proffering the potential approach forward out of those challenges.

This paper is organized as follows: half II examines sensible campus construct and services, half III provides sensible field architecture, half IV shows the open challenges facing IoT for smart field and provides the approach forward, and half V ends the paper with a conclusion.

II. SMART CAMPUS SERVICE

The services we can provide to the smart campus include all the facilities in campus is available to everyone. The effects of the services delivered is not restricted to only academics or the academia, but also to environmental, financial, and social areas of the campus [1]. IoT for smart campus is inevitable. A typical smart campus incorporates the following: smart grid, water and waste management, learning environment, intelligent buildings, parking, transportation and traffic, business processes, location services, safety and security, housing and dinning, social and sports activities, health and fitness, and special needs services, etc.

A. Smart learning

Smart Learning Environments seeks tutorial articles on the problems associated with the reform of the ways in which of teaching and learning through advancing current learning environments towards good learning environments. It provides opportunities for discussions and constructive dialogue among varied stakeholders on the restrictions of existing learning environments, would like for reform, innovative uses of rising pedagogic approaches and technologies, and sharing and promotion of best practices, resulting in the evolution, style and implementation of good learning environments.The aim of the journal is to assist varied stakeholders of good learning environments higher perceive different |one another}'s role within the overall method of education and the way they will support every other.

B. Smart Governance

IoT improves the internal and external efficiency of the university campus governance. It enables the campus community (staff and students) and other relevant persons to access official documents and policies. IoT ensures that public services work efficiently and enable the monitoring and managing of public safety. It helps in responding quickly and effectively in emergency situations on campus. IoT enables e-governance and transparency in governance on campus.

C. Water and Waste management

Using IoT, waste and water management, 2 essentials, but costly services rendered by a university to its community, will be price effective. previous analysis within the space of waste management suggests the planting of sensors at waste bins, and waste trucks for the gathering of period data for analysis will enhance sensible waste management.Sequel to the analysis, the system can recommend clean-up schedules that area unit higher. it'll additionally recommend a cost-effective and higher route for waste contractors. in line with the authors, this method was efficient as compared to the traditional waste management methodology [1] [16-18]. Another space wherever IoT has verified to be helpful is in water management. Its application will increase potency and productivity.It automates knowledge assortment and manages and coordinates several alternative subsystems [1][19]. additionally, a user-centric sensible water management system that monitors consumption and analyses collected knowledge and presents results graphically for improved readability [1][20]. this sort of system may be enforced on field to produce users with data regarding water consumption. moreover, a description was fabricated from a property model for sensible metering devices and therefore the associated network. The experimental project was double-geared towards building a metering device that's property [21]. There was another experiment on water management system. It targeted on the observation of water distribution on a medium field scale victimisation ultrasonic water level sensing element to live water levels and communication network. although the gathered knowledge was for short term observation, the observation system showed results.

D. Energy Consumption

Along with air quality observance service, IoT can be utilized to watch the energy consumption of a complete campus. this permits field authorities and community to get a transparent and careful read of the quantity of energy required by the various services (public lighting, transportation, traffic lights, management cameras, heating/cooling of buildings, etc.) Thus, this makes it potential to spot the most energy consumption sources and to line priorities so as to optimize their behaviour. so as to get such a service, power draw monitoring devices should be integrated with the ability grid in the field [2]. as an example, the sensors square measure to blame for checking all the occasions that emerge in their current circumstance and causation the info to a capability framework.

The framework stores the info during a personal cloud wherever all the information is handled and altered to introduce quality information for the subsequent stage [56]. The large information architecture is answerable for selecting and analyse the info,through analysis method, it provides the grounds the knowledge important to make a decision. As an example, on a hot day, the sensor framework screens the temperature and also the atmosphere of every one of the school rooms [56]. A mixture of current technologies with property and environmentally friendly resources along will solely act because the catalyst to reshape the present academic institutes by the construct of good cities in general and good field especially

E. Smart Parking

IoT are often utilised to dramatically modification the approach cars are parked on field to a wise parking one. The good parking service is predicated on road sensors and intelligent displays that direct motorists on the most effective path for parking within the field [2][24]. This service results in a quicker time to find a parking slot and this suggests a fewer carbon-dioxide emission from a happier field community and guests. what is more, by victimization short-range communication technologies, like frequency permits in slots reserved for field residents or disabled hence providing an improved service to the field community, dwellers and guests that may lawfully use.A proof-of-concept system that uses unbearable sensing technology and info system employed in distribution parking spots to students living in dorms supported their preference was implemented in KFUPM [1][25]. this method, however,works just for cars that are pre-known. this is often as a result of the system needs that car and drivers' data are keep in the info.

III. ARCTITECTURE OF SMART CAMPUS

The proposed model is composed of sensors and actuators which is embedded for campus environment monitoring and control management, smart services platform, data integration, intelligent guideline and service applications, etc. Smart campus system integrates hardware and software devices also cloud storage is responsible for store collected data from sensing devices.Smart field design. We imagine that the engineering of good field visible of IoT is made out of 3 level of process that are Trace, Knowledge and Application. The design underneath these three processes composed four completely different layers, i.e., sensing and interconnecting layer, information layer and repair layer.

IV. OPEN CHALENGES AND FUTURE DIRECTION

The realization of IoT networks is faces with 2 main challenges: initial, the IoT novelty and heterogeneous nature portend some technical difficulties thanks to the dearth of best practices; second, the dearth of approved and complete business model that encourages investment additionally presents some business difficulties [1][31-

32]. what is more, the good field implementation is featured and challenged by 3 forms of obstacles, namely,technical, money and political. These challenges area unit almost like those faces by good town implementation [1-2][34].Technical: Barriers during this perspective include: interoperability, standardization and configuration, privacy, security and safety [1][35]. Any technology that may be adopted for the promotion field services should be safe for public use on field. The usage of low energy devices, intensive communication, and therefore the heterogeneous field environment makes meeting the safety and privacy requirements for good field somewhat tough. On the other hand, the ability and standardization in an exceedingly heterogeneous setting just like the field leave the evaluation and comparison of devices, competition between manufacturers, promote the introduction of the device into the campus scheme, and ultimately maximize the advantages of all user groups within the field [1]. However, the adoption of IoT on field can cause the employment of a whole bunch and even Configuring manually is a colossal burden. Hence, there is the need for thorough investigation of latest ways in which machine-driven configuration of IoT devices [1][36-37].Financial: With relevancy money barriers, the limitation the economy of the globe and therefore the shrinking investments in public services hinders good field markets coming back into fruition and reality, regardless of immature experiences encountered up to now. a transparent business model is lacking. However, a potential reply of the challenge is to initial development those services that conjugate social utility with terribly clear come on investment such good building and good parking. this may act as a catalyst for different intercalary values services [1-2].Political: potential obstacle is occasioned by the attribution of higher cognitive process power to the various stakeholders [2]. Even though political obstacles might not be as powerful as financial and technical barriers as a result of the decision maker of the university will in most cases resolve such crises as they present themselves, it's all the same a challenge. the dearth of collaboration between completely different departments and faculties, the business method re-engineering, and therefore the opposition of antitechnology staff similarly as official red tapes area unit potential obstacles and challenges that require to be resolved [1].

V. CONCLUSION

IoT provides a platform for sens (objects) to interface and communicate seamlessly inside a smart field setting. It allows a convenient sharing of information across platforms. additionally, wireless technologies and therefore the opportunities offered by the web technology places IoT because the next revolutionary technology. IoT provides varied edges for a wise field through the integration of intelligent systems like good offices, smart buildings, good parking, good water and waste management, good control, good care, and smart energy consumption, etc., inside a wise field environment [6] [3940]. to form keen good field services, it's basic to interrupt {the different |the varied} between various real factors, completely different service supplier and various information sources [57].within the in the meantime, field will utilize their advanced framework to convey completely different applications and administrations that raise life on grounds. Once the field has connected gadgets, sensors, applications and investigation over a typical framework, they can counter like means finding and site primarily based services, good parking and traffics, associated lighting and building management frameworks, and the sky is that the limit from there secure and safer with associated intelligence operation cameras, savvy locks and edge controls. controls to diminish power and water utilization consumption sensors and grounds framework to preserve power and reduce carbon impression.This paper mentioned conceptually the web of Things (IoT) for good field. It examined good field construct and services, and provided potential good field architecture. It showed the applications of IoT to good campus, and IoT usage on a wise field setting. for college kids and employees in good field, these varieties of Smart field applications raise the scholastic involvement in effective ways in which. Students will learn and educators will instruct within the means that's best for them. field would a lot of be ready to effectively exploit of the universe of knowledge and fingertips and alter them to search out new voices and bits of information that they ne'er approached.Students in associate degree assortment of subjects will utilize information from their own specific lives and conditions to make their course work a lot of important, fascinating and locks in. what is a lot of, with universal movability and network, students would a lot of be ready to effectively incorporate examination and cooperative work into their lives and reinvest time that typically could are lost. The paper additionally provides some open challenges facing IoT for smart field and additionally offered some potential means forward.

Social Media: Impact And Changing Communication Patterns

Rakshika A. Sakharkar, Vijay M. Rakhade, Lowlesh N. Yadav

Shri Sai College of Engineering and Technology, Bhadrawati, India

Abstract – **: Given the pace, at which we are encountering new media as a democratic means of communication, the prospect of NICs being the most indispensable part of our lives is not far away. From this perspective, the paper attempts to study the changing communication patterns of the 21st-century tech-savvy generation. It has been claimed that new media has brought sea changes in intrapersonal, interpersonal, group, and mass communication processes and content. Once upon a time, traditional media was setting the agenda of public discourse observing forward to new media for breaking news. In the absence of a proper content regulatory authority, new media is diminishing the gatekeeping function in media, making it more participatory yet less authentic in content. In the virtual world, youth is existing a virtual life rather than proper life. The paper explores how new media is redefining social roles that are more vulnerable to dissolution as interpersonal communication is scheduled on public platforms. In the crowd of hundreds and thousands of friends on social media, youths find themselves alienated from the real world. The author concludes that in the age of announcement, a new kind of social order is being developed, establishing public and mass communication but weakening interpersonal communication. The next part of the thing is dedicated to the clarification of the elementary ideas of social media studies, emphasizing such concepts as new media, new new media. And The paper will observe how the use of social media has presented uncertainty in channels of communication and its influence on organizations. The paper will also discourse the implications of the occurrence of social media and discourse on the properties it has had on the excellence of organizational communication management.**

Keywords: Reasons of social media is effective, communication levels, communication studies, Communication Management..

I. INTRODUCTION

What's an app? Follow me on Twitter! Check my status on my Facebook page! These are the buzzwords of today's age group. In the age of Material and Communiqué Knowledge, whosoever is ignorant of these relations is considered illiterate or outdated. Once obsessed with capital-intensive mass broadcasting technologies expansion developers over and above publicists are finding new means and tools to reach out to their tech-savvy target audience. Educators are engrossed in new means to use the updated technology in their classrooms. In an age when there are one billion users interconnected through Facebook, this is one of the most influential participatory mediums of communiqué. In this situation, whosoever is cultured and is having means to use this humble knowledge can't overlook it.

In India, the number of people actively using Social Media is about 467.0 million but then it is growing faster with the availability of cheaper broadband connections and internet-enabled handsets at actual short prices. Social media is transforming the contours of social attraction. Sentiments like love, bond, household attachment, familiarity, also language are finding various platforms and forms of expression. No other media has become so popular in such a short period as social media. Credit for this tremendous success goes to the user-friendly features of Social Media.

The next part of the thing is dedicated to the clarification of the elementary ideas of social media studies, emphasizing such concepts as new media, new new media. And remaining part is about Social Media and Communication Management and Opportunities of Social Media.

II. REASONS OF SOCIAL MEDIA IS EFFECTIVE

If you have slightly doubted whether non-social media is basically an objective flash in the pan or the upcoming internet advertising before remain reading. Nowadays, if you've previously made your mind up about social media don't abandon ship. You might discover that there's more than meets the lens.

A. Meets Human Needs: People want communication and joining with other people. This is the core goal why social media has become so popular over the last decade. Through social media, brands can generate chances to stake and distinguish faithful supporters with higher recompenses and inducements. These movements kind clients a sense of superiority and it displays to them that they're treasured by the product. Thus, how does this translate into the screening that social media is effective? Well, unique recognition and preferred treatment stayed detected by Hitwise in 2009 during Black Friday holiday shopping festivities. This study revealed that 4.3% of Facebook operators and 2.3% of Twitter users made an online official visit to the main vendor after they visited their social media site.

B. Cost-Effective Marketing: Social media isn't free, but it is significantly cheaper than traditional advertising methods, which don't include feedback from people regarding their personal experiences. Mayhap this is why design media has been anguish completed the previous rare years. Newspaper revenue has fallen 26% during the past year bringing the total loss since 2006 to 41%. Formerly there was the publishing business which said 367 U.S. journals nearby up shop and stop all production. Not nearly as bad as the more than 500

publications that so-called its daytime in 2008. The uncertainty of outdated publicizing has twisted consumers into skeptics. Fortunately, the Internet makes it easy to read up and review just about anything and everything before committing to purchase, subscribe, or otherwise. Online advertising is definitely more affordable and it allows for more targeted reach. Combine that with a brand's social media attendance and people can investigate what others are proverb about a brand very rapidly, positive they can query them unswervingly for supplementary material

C. Builds Brand Loyalty: Based on 2009 data testified from comScore and GroupM search, social media plays an imperative role in paid and organic search. Click Through Rates (CTR) increase by 50% when consumers are unprotected from a brand's social media profile. Additionally, when a consumer has been obtainable with a brand's social media movement the study discovered that they're 2.4 times more likely to click on organic links to the brand's site. Using this research, you can see how social media directly underwrites building brand appreciation and loyalty. Knowing that social media can have a helpful result on the bottom line is one more reason for businesses to integrate a social media movement into their marketing efforts.

III. IMPACT ON VARIOUS COMMUNICATION LEVELS

When the telegram was invented, the importance of pigeon couriers started undermining. In the same way, when television arrived in the communication foray, radio went backstage. History of communication demonstrates that when any innovative intermediate arrives on the communication stage it affects the communication patterns of the world.

A. Intrapersonal communication: Social media has become an imperative tool for self-expression and self-presentation. Whatever we think is important we are collaborating with others. Be it a birthday party, marriage ceremony, outing, dinner, or level shopping. This expression to build an image in the eyes of others is foremost to narcissism. We want to project we are existing the best life irrespective of realism we keep on posting actual, created, or edited pictures of ourselves and our surroundings. The desire for self-gratification is foremost to peer pressure. The desire for placement and inspection comments after every moment is the creation of youth addicted to social media. The presence and affordability of smartphones are catalyzing this phenomenon of addiction.

B.)Group communication: In the past, there used to be only just 15-20 friends a person with whom he used to interact regularly, but with the development of social media, the number of friends whose updates one can have is running into hundreds. Something that was joint amongst friends in the internal circle, the very information gets disclosed instantly. Earlier relationships were maintained in secrecy and breakups were having silent tones. With changing society has an ongoing commitment to Facebook and that commitment is cracked in Facebook the situation. Previously these all were a matter of embarrassment and people used to hide such instances. Today people announce them on Facebook with elaboration. Now the concept of Interpersonal communication is fading as people have created many groups on Facebook. Anything and everything is communicated among all the group members.

C.)Public communication: Indian TV channels have underway election movements on TV freshly. But Narender Modi became the first leader who effectively connected with its youth voters on the Internet. He gave a live chat on Google Plus that attracted youth and middle-class net users. Not only is he a lively user of social networking sites he tells the ability of new media and how to use it in its favor while molding the opinion of the masses. Nowadays when there is a boundary between innovative and outdated media, politicians have an ongoing thought of the reputation of being present in new media. Altogether the main political parties and leaders have their Facebook pages and they keep on positioning their messages on Twitter.

d) Mass communication: In comparison to the age of mass communication which is more than four centuries old, social media is in Its infancy. Despite this fact, it is influencing traditional mass media in every aspect – programmed formats, content, treatment, and language. Most of the large newspapers, TV channels, and radio channels display the content of prevalent social networking sites Facebook and Twitter to get the newest apprise happening around the world. The 24X7 inform of information on numerous news sites is giving enormous competition to outmoded media.

IV. SOCIAL MEDIA AND COMMUNICATION STUDIES

The current chapter is dedicated to the explanation of a few important ideas in the field of modern communication studies, such as new new media (the repetition of the period is non a typewriting error here) by means of Paul Levinson, the network society the Facebook philosophy.

A. The new media: New media likes five individual characteristics: digitality – dematerialization of media transcript; converging – new media converges the forms and, purposes of information, media, electronic communication, and electronic computing; interactivity - liberty in manufacturing and repeating the contented and form of the information during the interaction; hyper textuality - new life experience for human beings, which in turn will lead to the transformation of economic events, educational patterns, interactional flairs, and other aspects of humanoid society; virtuality –formation of virtual communal that marks all the limitations of a humanoid society absolutely will task the way we observe truth and have usually defined identity.

B. The new new media: The idea, planned by Paul Levinson in his book "New new media" at the opening sight may seem a tiny puzzling, still, the author highlights that it bears a superior significance, that is, in terms of the new modes and tackles of communication that include

interactivity and mutuality (in this logic it can be associated to McLuhan's beginning of cool media), they have looked within the last five years and they are newer than traditional new media in the method of email and Web sites. What are the elementary underlying moralities of the new new media? Let us remark on some of them: (1) Every consumer is a producer. (2) Non professionalism. (3) The free choice of medium.

(4) Free of charge. (5) Competition and compatibility. (6) The social character.

V. SOCIAL MEDIA AND COMMUNICATION MANAGEMENT

Communications management is the methodical planning, implementation, monitoring, and review of all the channels of communication within an association, and among an association and other administrations or customers. Organizational communication expressions at communication and administrative behavior and is worried about the symbolic usage of language, how organizations occupation, and what their goals are. The discipline of organizational communication attentions on administrations and their communication progressions which are used to equally "designate and explain an association" and an approach to "communication as a marvel" in organizations. From the abovementioned points, we can achieve that social media is a very feeble form of communication. Feeble communication is often an outcome of a lack of preparation, unclarified suppositions, semantic alteration, poorly expressed messages, communication barriers in international environments, poor listening, premature assessment, impersonal communication, suspicion, fear, an unsatisfactory period for adjustment to change, and information overwork. Social media leaves significant room for all these features to interfere with operative communication.

VI. OPPORTUNITIES OF SOCIAL MEDIA

Social media has become an important portion of integrated organizational communication tactics, mainly due to its reasonable and instinctive means of sharing user-produced material. The usage of social media within an association can have a positive effect on the customer's experience since of its active capability, permitting for adjustment affording to their needs which change ended time. When the conversation becomes more interpersonal, the emotional ties become stronger, and clients become advocates for vendors in communications with other clients and non-clients.

Dissimilar outmoded marketing techniques, this exchange of information between customers and user-generated content has improved both fulfillment and advocacy and constructed stronger customer appointments for organizations that have accepted the use of social media as a marketing policy. The best samples of this are customer assessments and other content like pictures and videos shared online about countless products and services.

VII. CONCLUSION

A large source of material, edification, communication, and path entertainment social media is working to be The next large contest for the dissimilar features of our social and private lives. Social media is making a new caring of social order, it is the establishment of social networks but failing interpersonal relations. If the pattern of new media reveals five characteristic features as digitality, converging, hyper textuality, interactivity, and virtuality, the idea of the new new media mentions the social character, free optimal of media, authorship, and free-of-custody use. The Facebook way of life states the next: social media affects how we use the word "friends"; social media affects how we think about our disconnected social networks. It would be treasured for forthcoming investigations to explore measuring the monetary impact of social media on an association – defining how administrative communication management deviations due to the acceptance of social media affected incomes and profits.

Customer Churn Prediction In Telecom Industry Using Machine Learning

Poonam Narkhede, Dipti Shetye,Shraddha Rane, Zeerak Shaikh

SSJCOE Dombivli(E),India

poonamjtalele@gmail.com,diptipshetye@gmail.com,shraddharane1901@gmail.com,zeerakshaikh732@gmail.com

Abstract – **Every day, the telecom business is expanding quickly. The term "churning" refers to clients who cease utilising certain services or cancel their contract and subscription with a business in order to work with a rival. There are various causes and influences for customer churn. These factors include service quality and cost. Data is essential in this circumstance for understanding client behaviour. Market dynamics and competition are very strong. Customers can change service providers quickly and easily in search of better costs or services. Every year, 20–40% of clients leave telecommunications businesses. Companies are aware that acquiring new clients is far more expensive than maintaining existing ones.**

I. INTRODUCTION

One of the key sectors in developed nations is now telecommunications. The degree of competition has increased due to technology advancements and an increase in operators. Businesses are putting a lot of effort into surviving in this cutthroat market by utilising a variety of techniques. To boost revenue, three key tactics have been suggested: (1) gaining new clients, (2) upselling to current clients, and (3) lengthening client retention. The third strategy, which proves that keeping an existing customer costs much less than acquiring a new one and is also considered to be much easier than the upselling strategy, is the most profitable strategy, according to a comparison of these strategies that took the value of return on investment (RoI) of each into account.Customer turnover is a serious issue in service industries that are highly competitive.

On the other hand, if done early on, identifying consumers who are likely to quit the business could offer a sizable new revenue source. Numerous studies have shown that machine learning technology is very effective at predicting this circumstance. Applying this method involves learning from prior data.

II. LITERATURE SURVEY

[1]It was used by Senthilnayaki, Swetha, and Nivedha Random Forest has the highest cross validation score (96.3%), followed by KNN and Logistic Regression with scores of 88.8% and 81.72%, respectively.

[2]In their study of the issue of unbalanced datasets in churn prediction models, Burez and Van den Poel examined the effectiveness of Random Sampling, Advanced UnderSampling, Gradient Boosting Model, and Weighted Random Forests. To assess the model, they used (AUC, Lift) measures. According to the results, the under sampling strategy performed better than the other examined techniques.

[3]In order to anticipate which consumers are most likely to terminate their subscriptions, Kavitha V et al., Hemanth G, Mohan S.V, and Harish M employed a Decision Tree, Random Forest, and XGBoost. This allowed them to provide these clients with better services and lower the churn rate. The data set for training and testing is prepared by preprocessing and feature selection. To improve the effectiveness and accuracy of the aforementioned algorithm, some feature engineering is required.

[4]Our machine learning models were implemented in Python by Yasin Osman and Benjamin Ghaffari utilising a variety of data analysis packages, including NumPy, Pandas, and Scikit- learn. A Python programme called Scikit-learn is used to analyse predictive data and includes built-in functions for training, implementing algorithms, and evaluating results. XGBoost, an algorithm that uses boosting, and Random Forest, an approach that uses bagging. From a commercial standpoint, the two responsibilities that make up churn management as a component of customer relationship management. Identifying retention techniques comes after predicting which customers are likely to leave.

[5]At order to address the issue of customer churn in a significant Chinese telecom firm with 5.23 million users, He Y, He Z, and Zhang D [5] proposed a model for prediction based on the Neural Network algorithm. The overall accuracy rate, which was used as a measure of forecast accuracy, was 91.1%.

III. CHALLENGES

1.Marketers and customer success experts must be able to foresee which consumers will leave your firm and set up a plan of marketing actions that will have the highest retention impact on each client in order to be successful at retaining customers who are prepared to do so. Being proactive and interacting with these clients is crucial in this situation. Though straightforward in theory, accomplishing this "proactive retention" goal is rather difficult in practise.

2.Marketers and customer success experts must be able to foresee which consumers will leave your firm and set up a plan of marketing actions that will have the highest retention impact on each client in order to be successful at retaining customers who are prepared to do so.

3.Being proactive and interacting with these clients is crucial in this situation. Though straightforward in theory, accomplishing this "proactive retention" goal is rather difficult in practise.

4. Rather of using static data to calculate the probability of churning, your churn prediction model should rely on (nearly) real-time data. Even with static data, you will be able to identify a certain percentage of clients who are at danger, but your projections will be off.

5. The raw data was transformed into features that could be used in machine learning techniques. Because there

were so many columns, this operation took the longest to complete.

IV. PROBLEM DEFINITION

The purpose of this kind of study in the telecom industry is to assist businesses in increasing their profits. It is well known that one of the most significant revenue streams for telecom firms is churn prediction. Therefore, the goal of this research was to develop a system that can forecast client attrition.

Thus, our dataset comprises 21 columns and 7043 rows. As this model makes use of a large data platform and machine learning, there are 17 categorical features. The sample data is split into 30% for testing and 70% for training in order to test and train the model. Because it has the highest F1 score and 90% accuracy, we choose the random forest machine learning model, which we deployed using Flask.

V. EXISTING SYSTEM

The method begins with the test process, which then develops a comprehensive strategy to evaluate the particular features and general functionality on a variety of platform combinations. The methods are rigorously quality monitored.

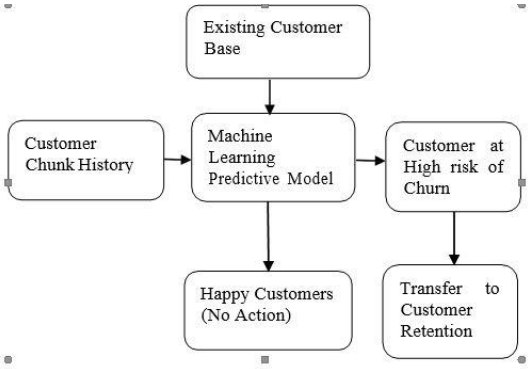

Fig 1. Existing System Architecture

In Fig 1. A model is trained using previous customer churn data (event period for X features and performance window for target variable). Active customer data is sent each month to a machine learning predictive model, which then calculates the likelihood that each client will leave. The customer retention teams will start engaging with the consumer to stem the churn, typically by offering some form of incentive or gift card to lock in a few more years after the list is sorted from highest to lowest probability value. Customers who have a very low likelihood of leaving (or, more accurately, those for whom the model forecasts 0% churn) are content ones. Nothing is done regarding them.

We examine the previous research on attrition prediction from three different angles: datasets, approaches, and measures for the banking industry. First, we provide information on machine learning. Customer Chunk History Customers at High Risk of Churn Existing Customer Base Predictive Model Happy Customers (No Action)

Inform Customer Retention Department about the public datasets that are accessible and the types of customer information that are contained in each dataset for predicting customer churn. Then, we quantitatively assess the performances of the various predictive modelling approaches that have been utilised in the literature to forecast customer churners using various types of customer information. Finally, we provide a summary of the performance indicators that have been applied to assess the effectiveness of the current churn prediction techniques. For telecom firms to design a more effective churn prediction system, it is imperative to analyse all three perspectives. [1]

VI. PROPOSED SYSTEM

The steps in the proposed system are as follows: gathering datasets, extracting features, training a model, testing it, and model optimization. A dataset will be used by our suggested system. Additionally, we will scrape information from available sources.

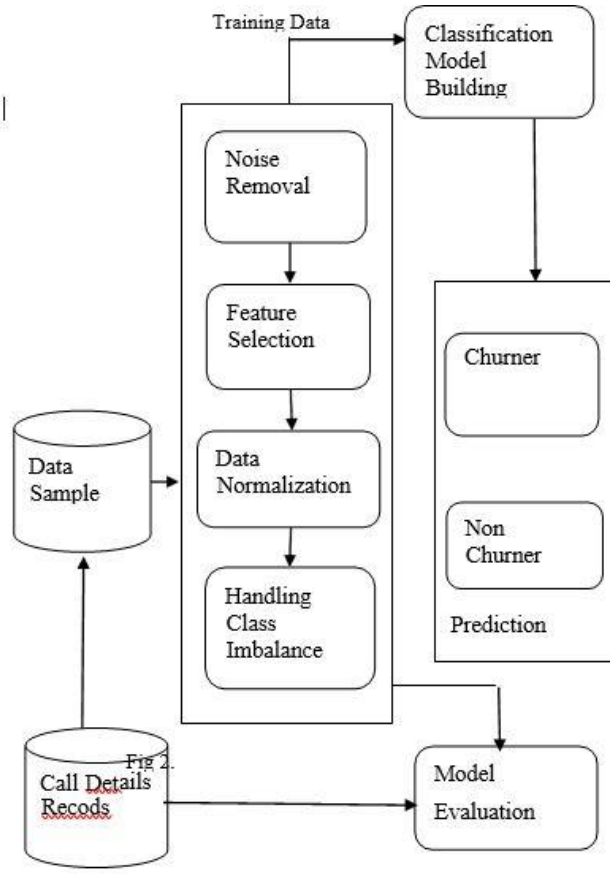

Fig 2. Flowchart of Proposed System

1.Handling Missing Value: To fill in a missing value in a dataset, count the number of missing values and list the columns that contain those values. Then, give the dataframe to the helper function get cols split to obtain the column categories. For some sets of columns, missing values appear to indicate that the data is unavailable. by giving them a value of 0. Some of the date columns have missing values. But let's leave that alone for the time being; we'll use it later.

2.Exploratory Data Analysis: Because of data imbalance, the dataset as a whole has a low churn rate. A column of key features is analysed in order to make the necessary

corrections. The top percentile of these columns appears to contain outliers, which are handled according to the outliers treatment.

3.Model Generation: With the class now evenly distributed, the dataset is divided into train (70%) and test (30%) sets.

4.Model Evaluation: Assessing the models using the proper evaluation measures, such as accuracy, precision, and recall, which are more crucial to effectively identifying churners than nonchurners. This problem is approached with two machine learning algorithms. Decision Tree & Random Forest

The dataset consists of 21 columns and 7043 rows. There are 17 distinct characteristics:

1CustomerID: Each customer has a different Customer ID.

2 gender: Whether or whether the client is a man or a woman

3 Senior Citizen: Determine whether the client is a senior citizen (1, 0)

4 Partner: Whether or not the client has a partner (Yes, No)

5 Dependent: Whether or not the client has dependents (Yes, No)

6 Phone Service: Whether or not the client has a phone service (Yes, No)

7 Multiple Lines: Whether the consumer has numerous lines or not is indicated by the number (Yes, No, No phone service)

8 Internet Service: Internet service provider for the client (DSL, Fiber optic, No)

9 Online Security: The customer's access to online security (Yes, No, No internet service)

10 Online Backup: The customer's availability of an online backup (Yes, No, No internet service)

11 Device Protection: To what extent does the consumer have device protection? (Yes, No, No internet service)

12 TechSupport: The availability of tech help for the customer (Yes, No, No internet service)

13 StreamingTV: Whether a consumer has streaming TV (Yes, No, No internet service)

14 StreamingMovies: Whether the customer has streaming movies or not is determined by (Yes, No, No internet service)

15 Contract: The customer's contract duration (Month-to-month, One year, Two years)

16 No paper Billing: The length of the customer's contract (Month-to-month, One year, Two years)

17 Payment Method: The chosen payment method by the customer (credit card, automatic bank transfer, electronic check, paper check)

18 Tenure: The length of time the customer has been a client of the business.

19 Monthly Charges: The monthly sum that the client is charged.

20 TotalCharges: The sum of all charges made to the customer. There is also a prediction feature: Churn:

The state of a customer's churn (Yes or No)

These features can also be subdivided into:

1 Customer demographic data: Gender, Senior Citizen, Partner, Dependents.

2 Few of the services each customer has signed up for: PhoneService, MultipleLines, InternetService, OnlineSecurity, OnlineBackup, DeviceProtection, TechSupport, StreamingTV, StreamingMovies .

3Information about the customer account: tenure, contract, paperless billing, payment method, monthly charges, and total charges.

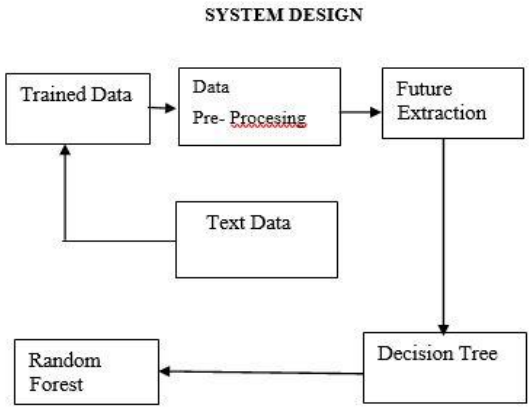

Fig 3. System Architecture

In Fig 3. Making the data usable is vital since undesirable or null values may result in results that are less accurate or unsatisfactory. The data set contains a large number of erroneous and missing values. We examined the entire dataset and only included the useful features in our list. When features are listed, accuracy can be improved, and only useful aspects are included so that particular information, such as the owner, registration location, and address, can be generated. A critical step in choosing the necessary elements from the data set based on the knowledge is feature selection.

The dataset that was used in this study has a large number of features, from which we selected the ones that were most important to improving performance assessment and helping us make decisions. If the dataset contains only valuable and highly predictable variables, classification performance improves. Thus, limiting the amount of irrelevant attributes and using just significant features improves classification performance. For the purpose of predicting customer churn in the telecom sector, numerous methodologies have been put forth.

Here, we can forecast the likelihood that a client will cancel their subscription by using Decision Tree and Random Forest, and we can assess the models using performance measures like accuracy, precision, and recall score.

VII. RESULTS

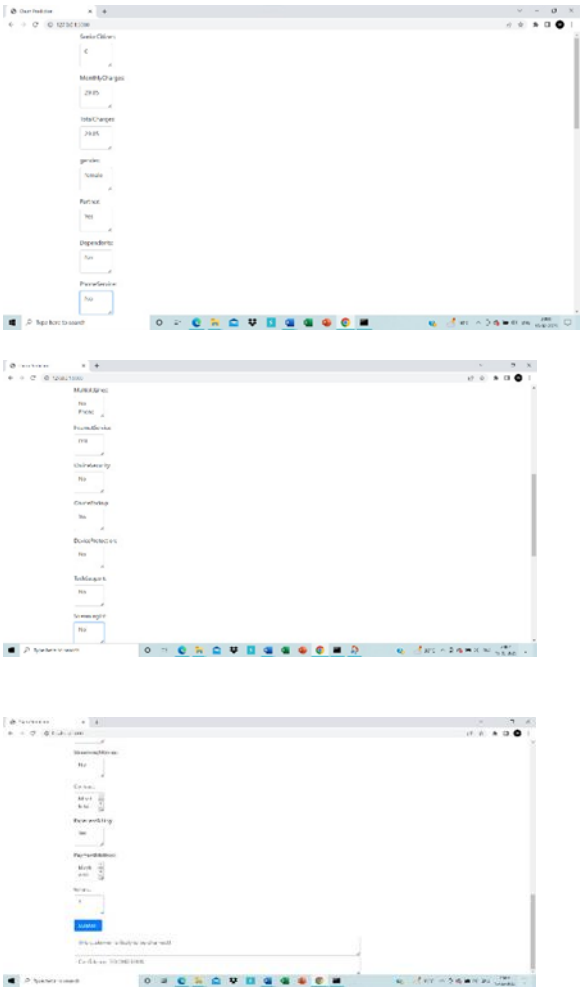

Fig 4. Output

By entering the provided data information in Fig. 4, it may be predicted if the consumer is likely to make a purchase or not. An essential metric for subscription-based businesses is churn rate. Managers can learn about weak points in products or pricing strategies, operational problems, and consumer preferences and expectations by identifying unhappy customers. Knowing all of that makes it simpler to implement proactive churn reduction strategies.The System metrics are explained below**:**

Accuracy: Classification When we say something is accurate, we usually mean it to be accurate. It measures the proportion of accurate predictions to all input samples. It is the proportion of accurate predictions to all observations.

Precision - The proportion of accurately predicted positive observations to all expected positive observations is known as precision. Precision equals TP/TP + FP.

F1 score - The weighted average of Precision and Recall is the F1 Score. Therefore, both false positives and false negatives are considered while calculating this score. F1 is not intuitively as simple to understand as accuracy, but F1 is typically more practical.

F1 Score = 2*(Recall * Precision) / (Recall + Precision).

VIII. CONCLUSION

Telecom Companies can have a clear vision and offer them some exciting offers to stay in that service. The acquired results demonstrate that our suggested churn model performed better and generated better results when applying machine learning techniques. In order to improve accuracy and performance, removing even more features in the future will be required.

IX. ACKNOWLEDGEMENT

We truly appreciate **Prof. Poonam Narkhede's** direction in helping us complete our project, which was made possible by her encouragement and inspiration. Our project manager keeps us going strong with her knowledgeable direction, considerate counsel, and timely encouragement that assisted us in choosing our project.

We would like to express our gratitude to **Prof. Reena Deshmukh,** our project coordinator, for providing us with all the assistance we required. We also like to extend our sincere gratitude to our HOD, Dr. Uttara Gogate, for her kind assistance in making our project in the lab successful by making computer resources available to us. Without his thoughtful and diligent assistance, our project would have been completely halted.

Finally, we want to thank the principal of our college. Dr. **P.R. Rodge** for providing lab space and granting permission for our experiment to continue. We also want to express our gratitude to our colleagues who supported us through the project, either directly or indirectly.

Twitter Sentiment Analysis

Aman Ajugia , Mohd. Moazzam Ali Ansari, Dimple Chaudhary, Dr. Rashmi Thakur
Thakur College of Engineering & Technology, Mumbai, India

amanaj2001@gmail.com, sa285191@gmail.com, 1032190114@tcetmumbai.in

Abstract – **In this paper, we investigate the utility of linguistic features for detecting the sentiment of Twitter messages. We evaluate the usefulness of existing lexical resources as well as features that capture information about the informal and creative language used in microblogging. We take a supervised approach to the problem, but leverage existing hashtags in the Twitter data for building training data.**

I. INTRODUCTION

In the past few years, there has been a huge growth in the use of microblogging platforms such as Twitter. Spurred by that growth, companies and media organizations are increasingly seeking ways to mine Twitter for information about what people think and feel about their products and services. Companies such as Twitter (twitrratr.com), tweetfeel (www.tweetfeel.com), and Social Mention (www.socialmention.com) are just a few who advertise Twitter sentiment analysis as one of their services.While there has been a fair amount of research on how sentiments are expressed in genres such as online reviews and news articles, how sentiments are expressed given the informal language and message-length constraints of microblogging has been much less studied. Features such as automatic part-of-speech tags and resources such as sentiment lexicons have proved useful for sentiment analysis in other domains, but will they also prove useful for sentiment analysis in Twitter? In this paper, we begin to investigate this question.Another challenge of microblogging is the incredible breadth of topic that is covered. It is not an exaggeration to say that people tweet about anything and everything. Therefore, to be able to build systems to mine Twitter sentiment about any given topic, we need a method for quickly identifying data that can be used for training. In this paper, we explore one method for building such data: using Twitter hashtags (e.g., #bestfeeling, #epicfail, #news) to identify positive, negative, and neutral tweets to use for training threeway sentiment classifiers.

II. RELATED WORK

Sentiment analysis is a growing area of Natural Language Processing with research ranging from document level classification (Pang and Lee 2008) to learning the polarity of words and phrases (e.g., (Hatzivassiloglou and McKeown 1997; Esuli and Sebastiani 2006)). Given the character limitations on tweets, classifying the sentiment of Twitter messages is most similar to sentence-level sentiment analysis (e.g., (Yu and Hatzivassiloglou 2003; Kim and Hovy 2004)); however, the informal and specialized language used in tweets, as well as the very nature of the microblogging domain make Twitter sentiment analysis a very different task. It'san open question how well the features and techniques used on more well-formed data will transfer to the microblogging domain.Just in the past year there have been a number of papers looking at Twitter sentiment and buzz (Jansen et al. 2009; Pak and Paroubek 2010; O'Connor et al. 2010; Tumasjan et al. 2010; Bifet and Frank 2010; Barbosa and Feng 2010; Davidov, Tsur, and Rappoport 2010). Other researchers have begun to explore the use of part-of-speech features but results remain mixed. Features common to microblogging (e.g., emoticons) are alo common, but there has been little investigation into the usefulness of existing sentiment resources developed on non-microblogging data.Researchers have also begun to investigate various ways of automatically collecting training data. Several researchers rely on emoticons for defining their training data (Pak and Paroubek 2010; Bifet and Frank 2010). (Barbosa and Feng 2010) exploit existing Twitter sentiment sites for collecting training data. (Davidov, Tsur, and Rappoport 2010) also use hashtags for creating training data, but they limit their experiments to sentiment/non-sentiment classification, rather than 3-way polarity classification, as we do.

III. DATA

We use three different corpora of Twitter messages in our experiments. For development and training, we use the the hashtagged data set (HASH), which we compile from the Edinburgh Twitter corpus1, and the emoticon data set (EMOT) from http://twittersentiment.

	Positive	Negative	Neutral	Total
HASH	31,861 (14%)	64,850 (29%)	125,859 (57%)	222,570
EMOT	230,811 (61%)	150,570 (39%)	–	381,381
ISIEVE	1,520 (38%)	200 (5%)	2,295 (57%)	4,015

Table 1: Corpus statistics

Hashtag	Frequency	Synonyms
#followfriday	226,530	#ff
#nowplaying	209,970	
#job	136,734	#tweetajob
#fb	106,814	#facebook
#musicmonday	78,585	#mm
#tinychat	56,376	
#tcot	42,110	
#quote	33,554	
#letsbehonest	32,732	#tobehonest
#omgfacts	30,042	
#fail	23,007	#epicfail
#factsaboutme	19,167	
#news	17,190	

#random	17,180	
#shoutout	16,446	

Table 2: Most frequent hashtags in the Edinburgh corpus

appspot.com. For evaluation we use a manually annotated data set produced by the iSieve Corporation1(ISIEVE). The number of Twitter messages and the distribution across classes is given in Table 1.

Hashtagged Data Set

The hashtagged data set is a subset of the Edinburgh Twitter corpus. The Edinburgh corpus contains 97 million tweets collected over a period of two months. To create the hashtagged data set, we first filter out duplicate tweets, nonEnglish tweets, and tweets that do not contain hashtags. From the remaining set (about 4 million), we investigate the distribution of hashtags and identify what we hope will be sets of frequent hashtags that are indicative of positive, negative, and neutral messages. These hashtags are used toselect the tweets that will be used for development and training.Table 2 lists the 15 most-used hashtags in the Edinburgh corpus. In addition to the very common hashtags that are part of the Twitter folksonomy (e.g., #followfriday, #musicmonday), we find hashtags that would seem to indicate message polarity: #fail, #omgthatsotrue, #iloveitwhen, etc.To select the final set of messages to be included in the HASH dataset, we identify all hashtags that appear at least 1,000 times in the Edinburgh corpus. From these, we selected the top hashtags that we felt would be most useful for identifying positive, negative and neutral tweets. These hashtags are given in Table 3. Messages with these hashtags were included in the final dataset, and the polarity of each message is determined by its hashtag.

Positive	#iloveitwhen, #thingsilike, #bestfeeling, #bestfeelingever, #omgthatssotrue, #imthankfulfor, #thingsilove, #success
Negative	#fail, #epicfail, #nevertrust, #worst, #worse, #worstlies, #imtiredof, #itsnotokay, #worstfeeling, #notcute, #somethingaintright, #somethingsnotright, #ihate
Neutral	#job, #tweetajob, #omgfacts, #news, #listeningto, #lastfm, #hiring, #cnn

Table 3: Top positive, negative and neutral hashtags used to create the HASH data set

Emoticon data set-

The Emoticon data set was created by Go, Bhayani, and Huang for a project at Stanford University by collecting tweets with positive ':)' and negative ':(' emoticons. Messages containing both positive and negative emoticons were omitted. They also hand-tagged a number of tweets to use for evaluation, but for our experiments, we only use their training data. This set contains 381,381 tweets, 230,811 positive and 150,570 negative. Interestingly, the majority of these messages do not contain any hashtags.

iSieve data set

The iSieve data contains approximately 4,000 tweets. It was collected and hand-annotated by the iSieve Corporation. The data in this collection was selected to be on certain topics, and the label of each tweet reflects its sentiment (positive, negative, or neutral) towards the tweet's topic. We use this data set exclusively for evaluation.

Preprocessing

Data preprocessing consists of three steps: 1) tokenization,2) normalization, and 3) part-of-speech (POS) tagging. Emoticons and abbreviations (e.g., OMG, WTF, BRB) are identified as part of the tokenization process and treated as individual tokens. For the normalization process, the presence of abbreviations within a tweet is noted and then abbreviations are replaced by their actual meaning (e.g., BRB– > be right back). We also identify informal intensifiers such as all-caps (e.g., I LOVE this show!!! and character repetitions (e.g., I've got a mortgage!! happyyyyyy"), note their presence in the tweet. All-caps words are made into lower case, and instances of repeated charaters are replaced by a single character. Finally, the presence of any special Twitter tokens is noted (e.g., #hashtags, usertags, and URLs) and placeholders indicating the token type are substituted. Our hope is that this normalization improves the performance of the POS tagger, which is the last preprocessing step.

IV. FEATURES

We use a variety of features for our classification experiments. For the baseline, we use unigrams and bigrams. We also include features typically used in sentiment analysis, namely features representing

n-gram features-

To identify a set of useful n-grams, we first remove stopwords. We then perform rudimentary negation detection by attaching the the word not to a word that preceeds or follows a negation term. This has proved useful in previous work (Pak and Paroubek 2010). Finally, all unigrams and bigrams are identified in the training data and ranked according to their information gain, measured using Chi- squared. For our experiments, we use the top 1,000 n-grams in a bagof-words fashion.3

Lexicon features-

Words listed the MPQA subjectivity lexicon (Wilson, Wiebe, and Hoffmann 2009) are tagged with their prior polarity: positive, negative, or neutral. We create three features based on the presence of any words from the lexicon.

Part-of-speech features-

For each tweet, we have features for counts of the number of verbs, adverbs, adjectives, nouns, and any other parts of speech.

Micro-blogging features-

We create binary features that capture the presence of

positive, negative, and neutral emoticons and abbreviations and the presence of intensifiers (e.g., all-caps and character repetitions). For the emoticons and abbreviations, we use the Internet Lingo Dictionary (Wasden 2006) and various internet slang dictionaries available online.

V. EXPERIMENTS AND RESULTS

Our goal for these experiments is two-fold. First, we want to evaluate whether our training data with labels derived from hashtags and emoticons is useful for training sentiment classifiers for Twitter. Second, we want to evaluate the effectiveness of the features from section for sentiment analysis in Twitter data. How useful is the sentiment lexicon developed for formal text on the short and informal tweets? How much gain do we get from the domain-specific features?For our first set of experiments we use the HASH and EMOT data sets. We start by randomly sampling 10% of the HASH data to use as a validation set. This validation set is used for n-gram feature selection and for parameter tuning. The remainder of the HASH data is used for training. To train a classifier, we sample 22,2474 tweets from the training data and use this data to train AdaBoost.MH (Schapire and Singer 2000) models with 500 rounds of boosting.56 We repeat this process ten times and average the performance of the models.

The number n-grams to include as features was determined empirically using the training data. 4

This is equivalent to 10% of the training data. We experimented with different sample sizes for training the classifier, and this gave the best results based on the validation data. 5

The rounds of boosting was determined empirically using the validation set. 6

We also experimented with SVMs, which gave similar trends, but lower results overall.

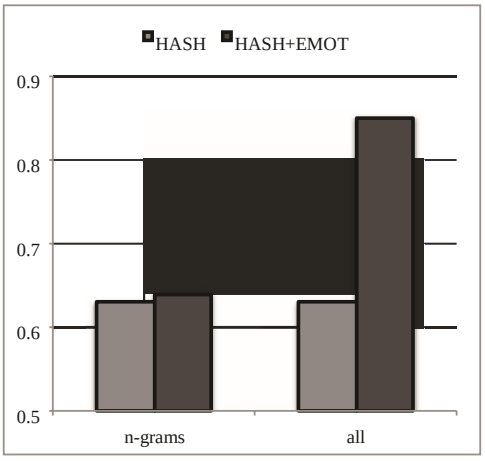

Figure 1: Average F-measure on the validation set over models trained on the HASH and HASH+EMOT data

Because the EMOT data set has no neutral data and our experiments involve 3-way classification, it is not included in the initial experiments. Instead, we explore whether it is useful to use the EMOT data to expand the HASH data and improve sentiment classification. 19,000 messages from the EMOT data set, divided equally between positive and negative, are randomly selected and added to the HASH data and the experiments are repeated.

To get a sense for an upper-bound on the performance we can expect for the HASH-trained models and whether including the EMOT data may yield improvements, we first check the results of the models on the validation set. Figure 1 shows the average F-measure for the n-gram baseline and all the features on the HASH and the HASH+EMOT data. On this data, adding the EMOT data to the training does lead to improvements, particularly when all the features are used. Turning to the test data, we evaluate the models trained on the HASH and the HASH+EMOT data on the ISIEVE data set. Figure 2 shows the average F-measure for the baseline and four combinations of features: n-grams and lexicon features (n-gram+lex), n-grams and part-of-speech features (n-gram+POS), n-grams, lexicon features and microblogging features (n-grams+lex+twit), and finally all the features combined. Figure 3 shows the accuracy for these

same experiments.

Interestingly, the best performance on the evaluation data comes from using the n-grams together with the lexicon features and the microblogging features. Including the partof-speech features actually gives a drop in performance. Whether this is due to the accuracy of the POS tagger on the tweets or whether POS tags are less useful on microblogging data will require further investigation.Also, while including the EMOT data for training gives a nice improvement in performance in the absense of microblogging features, once the microblogging features are included, the improvements drop or disappear. The best results on the evaluation data comes from the n-grams, lexical and Twitter features trained on the hashtagged data alone.

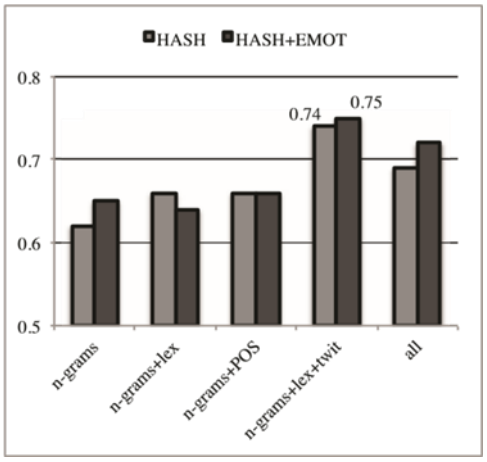

Figure 2-Average accuracy on the test set over models trained on the HASH and HASH+EMOT data

VI. CONCLUSIONS

Our experiments on twitter sentiment analysis show that part-of-speech features may not be useful for sentiment analysis in the microblogging domain. More research is needed to determine whether the POS features are just of poor quality due to the results of the tagger or whether

POS features are just less useful for sentiment analysis in this domain. Features from an existing sentiment lexicon were somewhat useful in conjunction with microblogging features, but the microblogging features (i.e., the presence of intensifiers and positive/negative/neutral emoticons and abbreviations) were clearly the most useful.

Using hashtags to collect training data did prove useful, as did using data collected based on positive and negative emoticons. However, which method produces the better training data and whether the two sources of training data are complementary may depend on the type of features used. Our experiments show that when microblogging features are included, the benefit of emoticon training data is lessened.

Challenges of Virtualization of Cloud Computing

Neha Pankaj Rai, Vijay M. Rakhade, Ashish B. Deharkar
Shri Sai College of Engineering and Technology, Bhadrawati, Maharashtra, India

Abstract – **: Virtualization is used to make simulated environment through a physical hardware system. The software that controls cloud technology is virtualization, while cloud computing is a digital facility. Virtualization and cloud computing knowledges share a exclusive relationship and often work together. The virtualization process in cloud computing is where a name is allotted to the physical storage and is available on demand. A single dedicated hardware can do a great job in virtualization. There is a host machine and a visitor machine**

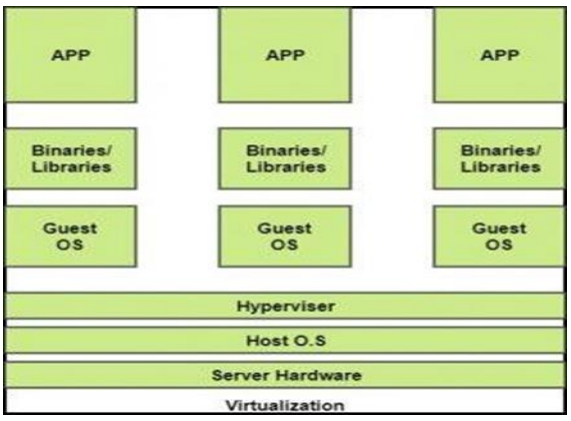
Keywords: Virtualization cloud computing host.

I. INTRODUCTION

Virtualization of cloud computing primarily stems from the need to split up resources to make them more efficient and add security layers to silos of computing power. For instance, you can segment server capacities into small parts to allow for the distribution of the server's capabilities among several environments and users. Virtualization of Cloud Computing is a broad term that refers to the abstraction of computer resources. Essentially, it creates a virtual resource successively on a layer abstract from physical hardware. Cloud computing is one of the more common use cases. Virtualization Hides the physical characteristics of computing resources from there users, be they application, or end users. This includes making a single physical resource. Virtualization allows a computing environment to simultaneously run several independent systems also called virtual machines. These virtual machines (VMs) share the same physical IT infrastructure and are accomplished and coordinated by an extra software interface named hypervisor.

II. ARCHITECTURE

The architecture in virtualization is defined as a model that describe virtualization of cloud computing conceptually.



III. VIRTUALIZATION

Virtualization can be defined as a procedure that enables the manufacture of virtual version of desktop, operating system, network resources, or server. In other word, Virtualization is a technique, which allows to share single physical instance of an application or resource among multiple organizations or tenant's customer. It does so by assigning a logical name to a physical resource and providing a pointer to that physical resource on demand. The invention of virtualization was intated during the era of mainframe practice, and as time evolved with progression in new-age knowledges, virtualization was achieved with the mean of specific software. The technology that works behind virtualization is known as a virtual machine monitor or virtual manager which separates compute environments from the actual physical infrastructure. There are mainly four types of virtualization hardware virtualization, operating system virtualization, server virtualization, storage virtualization.

IV. TYPES OF VIRTUALIZAION OF CLOUD COMPUTING

a) Operating system virtualization:

In operating system virtualization of cloud computing, the virtual machine software installs in the operating system of host rather than directly on the hardware system.

b) Hardware virtualization:

Hardware virtualization of cloud computing used in server platform as it is flexible to use virtual machine rather than physical machines.

c) Server virtualization:

In server virtualization of cloud computing, the software directly installs on the server system and use for a single physical server can divide into many servers can divide into many serers on the request basis and stability the load.

d) Storage virtualization:

In storage virtualization of cloud computing, a grouping is done of physical storage which is from multiple network storage devices this is done so it looks like a single storage device.

V. BENEFITS OF VIRTUALIZATION OF CLOUD COMPUTING

Virtualization of cloud computing has numerous benefits lets discuss them one by one:

a. Security:During the procedure of virtualization security is one of the significant concerns. The security can be providing with the help of

firewalls, which will help to prevent illegal access and will keep the data intimate.

b. Flexible operations:With the help of virtualization of cloud computing technical problems can solve in physical systems. It removes the problem of recovering the data from stopped or corrupted devices and hence saves time.

c. Economical:Virtualization of cloud computing, save the cost for a physical system such as hardware and servers. It stores all the data in the virtual server, which are quite economical.

d. Removes the risk of system disaster:While performing virtually task there are chances that the system might crash down at the wrong time. this failure can reason damage to the company but the virtualizations help you to perform the same task in multiple devices at the similar time.

e. Flexible transfer of data:The data can allocation to the virtual server and retrieve anytime. The customers or cloud earner don't have to waste time discovery out hard drives to find data. With the help of virtualization, it will very easy to detect the required data and handover them to the allotted authorities.

VI. ROLE OF VIRTUALIZATION IN CLOUD COMPUTING

In cloud computing technology virtualization perform very critical role. Characteristically, users share the data in the clouds such as applications but with virtualization operators share the organization.The primary purpose of virtualization technology is to spring typical versions of applications to cloud users; if the next version of that application is released, the cloud earner must give those users the freshest version, which is officially feasible because it is classier. Cloud earner employ virtualization create situations that can fulfill each user's unique needs. Cloud providers can spin up more virtual instances to meet request as more users come in. Virtualization is an effective way of managing computing resources, maximizing utilization and minimizing interruption.

VII. CLOUD COMPUTING AND VIRTUALIZATION

Virtualization is a technique of have to separate a service from the underlying physical delivery of that service. It is the procedure of creating a virtual version of something like mainframe hardware. In computing, virtualization refers to the act of crating computing resources that have no physical presence, that is, they are virtual. These virtual resources are essentially pieces of software that act like their concrete counterparts. It includes using particular software to create a virtual or software created version of a computing resource rather than the actual version of the same resource. with the help of virtualization, multiple operating system and applications can run on same machine and its same hardware at the same time, increasing the flexibility of hardware [3].

VIII. CLOUD COMPUTING

A cloud mentions to a distinct IT environment that is designed for the purpose of remotely provisioning scalable and measured IT resources. The term originated as a metaphor for the internet which is, in essence, a network of network providing remote access to a set of decentralized IT resources. Cloud computing can be both public cloud services provide their services over the internet for a fee . private cloud services, on the other hand, only provide service to a certain number of people. These services are a scheme of networks that source hosted service. there is also a hybrid option, which combines basics of both the public and private facilities. Cloud computing taken all the heavy lifting involved in crunching and processing data away from the device you carry around are sit and work at. It similarly transfers all of that work to huge computer groups far away in cyberspace.

IX. DEPLOYMENT MODELS

There are several forms of clouds, each of which is changed from the other. Public clouds suggestion their facilities on servers and storage on the internet. These are worked by third-party companies, who handle and control all the hardware, software, and control all the hardware, software, and the general infrastructure. hybrid cloud is, as the name indicates, a mixture of both public and private services. This form of model allows the user extra flexibility and benefits optimize the operator's infrastructure and security.

X. CHARACTERISTIS OF CLOUD COMPUTING

There are basically five types of characteristics of cloud computing.

i. On -demand self-services
ii. Broad network access
iii. Rapid elasticity
iv. Resource pooling
v. Measured service

1.On -demand self-services:the cloud computing services does not require any human managers, user themselves are able to facility, monitor and succeed computing resources as wanted.
2. Broad network access:The computing service are generally provided over standard networks and heterogeneous devices.
3. Rapid elasticity:The computing service should have IT properties that are clever to scale out and in quickly and on as needed basis.

Whenever the user requires services, it is provided to him and it is scale out as soon as its must gets over.

4. Resource pooling:The IT resource (e.g., network, servers, storage, applications, and services) present are shared across multiple application and occupant in an uncommitted manner.
5. Measured service:The resources utilization is tracked for each application and occupant it will provide both the user and the resource provider with an account of what has been used. This is done for various reasons like monitoring promoting and effective use of resource.

XI. CONCLUSION

Virtualization of cloud computing is a great technique for any organization that wants to build its cloud security . definitely, its implementation is easy but it is not a cakewalk also. The organizations essential to strategize, appreciate and , be ready before the implementation . It is becoming more of a need than a choice for any business that aims to establish cloud security thus creating virtual resources is the new go-to choice for businesses The virtualization is a part of cloud computing where manual management is done for interacting with a hypervisor virtualization essentially means running numerous operating systems on a single machine while sharing all hardware resources.

Communication Between Two Cloud Using Depsky and Program Data Processors System

Dharini Pachare, Vijay M. Rakhade ,Lawlesh N. Yadav , Neehal.B. Jiwane , Ashish. B. Deharkar

Shri Sai College of Engineering & Technology, Bhadrawati, India

Abstract – **In today's life cloud, computing plays important role for the computing environment for reducing the cost of the computational cost and resources cost of the computing methods such as to storing the data and using the computing resources. It enables the use of the inter cloud communication for accessing the various information or data from different cloud. Inter cloud or multi cloud is term related to cloud of cloud, which provides the huge amount of data within the same cloud by adding the different cloud within single cloud. This method provides the service availability, storage of data and services within the same unit. Which provide the security to the whole data within the cloud by using the third-party auditing method, which requires applying the encryption key on data only one time, which can reduce the attacks on the cloud data? This paper also introduces the new method of multi cloud storage technique to store the data on the different small cloud within the system, which allows reducing the redundancy of data within the cloud.**

Keywords: Cloud Computing, Cloud Services, DepSky

I. INTRODUCTION

The use of cloud computing has increased rapidly in many organizations including because these services provide fast access to their applications and reduce their infrastructure costs [1, 2]. This paper focuses on the issues related to the data security aspect of cloud computing. As data and information will be shared with a third party, cloud computing users want to avoid anentrusted cloud provider [3]. Protecting private and important information, such as credit card details or a patient' s medical records from attackers or malicious insiders is of critical importance. In addition, the potential for migration from a single cloud to a multi-cloud environment is examined and research related to security issues in single and multi-clouds in cloud computing are surveyed. Cloud computing describe as " a model for enabling convenienton-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction" . Although cloud service providers can offer benefits to users, security risks play a major role in the cloud computing environment [4]. Users of online data sharing or network facilities are aware of the potential loss of privacy. According to a recent IDC survey [5] the top challenge for 74% of CIOs in relation to cloud computing is security. Protecting private and important information such as credit card details or patients' medical records from attackers or malicious insiders is of critical importance. Moving databases to a large data centre involves many security challenges such as virtualization vulnerability, accessibility vulnerability, privacy and control issues related to data accessed from a third party, integrity, confidentiality, and data loss or theft. In different cloud service models, the security responsibility between users and providers is different. According to Amazon, their EC2[6] addresses security control in relation to physical, environmental, and virtualization security, whereas the users remain responsible for addressing security control of the IT system including the operating systems, applications and data. the way the responsibility for privacy and security in a cloud computing environment is shared between consumers and cloud service providers differs between delivery models. In SaaS, cloud providers are more responsible for the security and privacy of application services than the users. This responsibility is more relevant to the public than the private cloud environment because the clients need more strict security requirements in the public cloud. In PaaS, users are responsible for taking care of the applications that they build and run on the platform, while cloud providers are responsible for protecting one user' s applications from others. In IaaS, users are responsible for protecting operating systems and applications, whereas cloud providers must provide protection for the users' data.

II. SECURITY RISKS IN CLOUD COMPUTING

The impact of security issues in the public cloud is greater than the impact in the private cloud. For instance, any damage which occurs to the security of the physical infrastructure or any failure in relation to the management of the security of the infrastructure will cause many problems. In the cloud environment, the physical infrastructure that is responsible for data processing and data storage can be affected by a security risk.

In addition, the path for the transmitted data can be also affected, especially when the data is transmitted to many third-party infrastructure devices [7]. As the cloud services have been built over the Internet, any issue that is related to internet security will also affect cloud services. Resources in the cloud are accessed through the Internet; consequently, even if the cloud provider focuses on security in the cloud infrastructure, the data is still transmitted to the users through networks which may be insecure. As a result, internet security problems will affect the cloud, with greater risks due to valuable resources stored within the cloud and cloud vulnerability. The technology used in the cloud is similar to the technology used on the Internet. Encryption techniques and secure protocols are not sufficient to protect data transmission in the cloud. Data intrusion of the cloud through the Internet by hackers and cybercriminals needs to be addressed and the cloud environment needs to be secure and private for clients [8].

One of the most important issues related to cloud security

risks is data integrity. The data stored the cloud may suffer from damage during transition operations from or to the cloud storage provider. The examples of the risk of attacks from both inside and outside the cloud provider, such as the recently attacked Red Hat Linux' s distribution servers.

According to Garfinkel [19], another security risk that may occur with a cloud provider, such as the Amazon cloud service, is a hacked password or data intrusion. If someone gains access to an Amazon account password, they will be able to access all the account' s instances and resources. Thus, the stolen password allows the hacker to erase all the information inside any virtual machine instance for the stolen user account, modify it, or even disable its services. Furthermore, there is a possibility for the user' s email (Amazon username) to be hacked (see [18] for a discussion of the potential risks of email), and since Amazon allows a lost password to be reset by email, the hacker may still be able to log in to the account after receiving the new reset password.

Another major concern in cloud services is service availability. Amazon [6] mentions in its licensing agreement that it is possible that the service might be unavailable from time to time. The user' s web service may terminate for any reason at any time if any user' s files break the cloud storage policy. In addition, if any damage occurs to any Amazon web service and the service fails, in this case there will be no charge to the Amazon Company for this failure. Companies seeking to protect services from such failure need measures such as backups or use of multiple providers [19]. Both Google Mail and Hotmail experienced service down- time recently [12]. If a delay affects payments from users for cloud storage, the users may not be able to access their data. Due to a system administrator error, 45% of stored client data was lost in LinkUp (Media Max) as a cloud storage provider

III. MULTI-CLOUDS: PRELIMINARY

The term " multi-clouds" is similar to the terms " inter clouds" or " cloud-of-clouds" that were introduced by Vukolic [11,15]. These terms suggest that cloud computing should not end with a single cloud. Using their illustration, a cloudy sky incorporates different colors and shapes of clouds which leads to different implementations and administrative domains.

Recent research has focused on the multi-cloud environment [3],[8],[10],[11] which control several clouds and avoids dependency on any one individual cloud.

Cachin et al. [11] identify two layers in the multi- cloud environment: the bottom layer is the inner cloud, while the second layer is the inter-cloud. In the inter- cloud, the Byzantine fault tolerance finds its place. We will first summarize the previous Byzantine protocols over the last three decades.

BFT protocols are not suitable for single clouds. Vukolic argues that one of the limitations of BFT for the inner-cloud is that BFT requires a high level of failure independence, as do all fault- tolerant protocols. If Byzantine failure occurs to a particular node in the cloud, it is reasonable to have a different operating system, different implementation, and different hardware to ensure such failure does not spread to other nodes in the same cloud. In addition, if an attack happens to a particular cloud, this may allow the attacker to hijack the particular inner-cloud infrastructure.

IV. DEPSKYARCHITECTURE

The DepSky architecture [8] consists of four clouds and each cloud uses its own particular interface. The DepSky algorithm exists in the clients' machines as a software library to communicate with each cloud (Figure 1). These four clouds are storage clouds, so there are no codes to be executed. The DepSky library permits reading and writing operations with the storage clouds. DepSky Data model. As the DepSky system deals with different cloud providers, the DepSky library deals with different cloud interface providers and consequently, the data format is accepted by each cloud. The DepSky data model consists of three abstraction levels: the conceptual data unit, a generic data unit, and the data unit implementation. DepSKy System model. The DepSky system model contains three parts: readers, writers, and four cloud storage providers, where readers and writers are the client' s tasks. Bessani et al. [8] explain the difference between readers and writers for cloud storage. Readers can fail arbitrarily (for example, they can fail by crashing, they can fail from time to time and then display any behavior) whereas writers only fail by crashing. Cloud storage providers in the DepSky system model. The Byzantine protocols involve a set of storage clouds (n) where n = 3 f +1, and f is maximum number of clouds which could be faulty. In addition, any subset of (n – f) storage cloud creates byzantine quorum protocols [8].

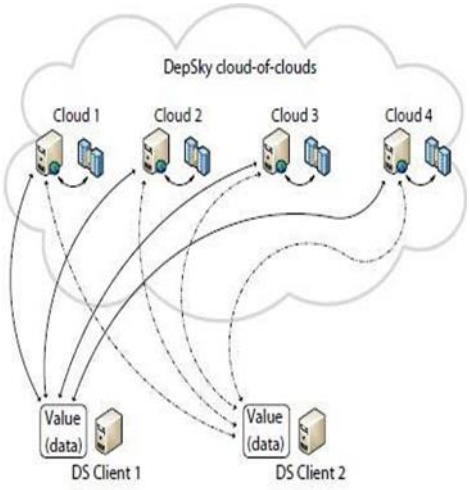

Figure 1. DepSky Data model.

PDP in DepSky. The efficient PDP scheme is the fundamental construct underlying an archival introspection system that we are developing for the long-term preservation of data. Efficient PDP schemes will ensure that the computational requirements of remote data checking do not unduly burden the remote storage sites. Provable data possession (PDP), which is a cryptographic technique for verifying the integrity of data without

retrieving it at an un-trusted server, can be used to realize audit services. Introduction of PDP in DepSky eliminate the extra n additional auditing requirement for each cloud data separately. By using the single PDP system and a single key for encryption the system can encrypt the data from the different cloud. The data can then decrypt or access by the user according to the inter cloud identification. While storing the data into the DepSky, which uses the different internal cloud using the hash method for dividing the same data into number of different blocks of same size, and store in the cloud. This method lets to increase the services availability by accessing the data from the different inter cloud. When storing the data, it adds some header information to identify the data block and access the data.

V. CURRENT SOLUTIONS OF SECURITY RISKS

To reduce the risk in cloud storage, customers can use cryptographic methods to protect the stored data in the cloud [12]. Using a hash function [35] is a good solution for data integrity by keeping a short hash in local memory. In this way, authentication of the server responses is done by recalculating the hash of the received data which is compared with the local stored data [12]. If the amount of data is large, then a hash tree is the solution . Many storage system prototypes have implemented hash tree functions, such as SiRiUS [20] and TDBthis is an active area in research on cryptographic methods for stored data authentication. Cachinet al. [12] argue that although the previous methods allow consumers to ensure the integrity of their data which has been returned by servers, they do not guarantee that the server will answer a query without knowing what that query is and whether the data is stored correctly in the server or not. Proofs of Retrievability (PORs) and Proofs of Data Possession (PDP) are protocols introduced by Juels and Kaliski and Ateniese et al. [7] to ensure high probability for the retrieval of the user' s data. Cachinet al. [12] suggest using multiple cloud providers to ensure data integrity in cloud storage and running Byzantine-fault-tolerant protocols on them where each cloud maintains a single replica [14]. Computing resources are required in this approach and not only storage in the cloud, but such a service also provided in Amazon EC2, whereas if only storage service is available, Cachin et al. [12] suggest working with Byzantine Quorum Systems by using Byzantine Disk Paxos[2] and using at least four different clouds to ensure users' atomicity operations and to avoid the risk of one cloud failure.

VI. CONCLUSION

Although the use of cloud computing has rapidly increased, cloud computing security is still considered the major issue in the cloud computing environment. Customers do not want to lose their private information as a result of malicious insiders in the cloud. In addition, the loss of service availability has caused many problems for many customers recently. Furthermore, data intrusion leads to many problems for the users of cloud computing. The purpose of this work is to survey the recent research on single clouds and multi-clouds to address the security risks and solutions. We have found that much research has been done to ensure the security of the single cloud and cloud storage whereas multi- clouds have received less attention in the area of security. We support the migration to multi-clouds due to its ability to decrease security risks that affect the cloud computing user.

Design of Virtual-Real Software-Defined Network for Cloud

Dr. J .Divya Lakshm, Dr. Mallikarjun P Y
Department of Electronics and, Communication Engineering, Sri Krishna Institute of Technology, Bengaluru
1divyalakshmiece@skit.org.in, mallikarjunpy@gmail.com

Abstract – **In the construction of network simulation experiment scenarios, complex physical terminals are challenging to realize virtual simulation, and physical terminals need to be accessed. However, the existing access methods are difficult to deploy, have bottlenecks in network performance, and cannot be applied to large-scale network scenarios. To effectively solve the above problems, a virtual-real fusion network simulation construction method based on SDN (software defined-network) is proposed, using the SDN controller combined with the flow table construction algorithm to realize the link management and data connection of the virtual and real network and design A prototype system for virtual-real fusion network simulation has been developed. Through the SDN controller, the virtual instance in the cloud platform and the physical terminal outside the cloud can be jointly networked to build a virtual-real fusion network simulation experiment scene. Using this prototype system, experiments have proved that the SDN-based network simulation method can realize efficient large-scale networking of virtual instances and physical terminals in the cloud platform and has good network performance.**

Keywords: Cloud Computing, Software Defined-Network, Virtual-Real Fusion Network, Large-Scale Networking, Data Connection

I. INTRODUCTION'

The network simulation experimental field has become an essential scientific device in the field of network security, which can provide support means for the observation, measurement and analysis of network space behavior in a safe and controllable environment and provide support for the testing and evaluation of network attack and defense behavior[1-2], network security tools Flexible and efficient hardware and software infrastructure is provided for professional testing and verification, and technical and tactical training drills for professionals. Currently, the mainstream network simulation experiment field mainly relies on digital simulation, virtualization and other technologies to build simulation entities in virtual environments [3]. There is no virtual simulation model or image, and some complex terminals (such as various secret-related target information systems and customized special terminals) are challenging to build virtual simulations. Therefore, it is urgent to integrate physical terminals with virtual networks. Flexible integration jointly creates a virtual and real fusion network simulation experiment field and provides a highly realistic scene environment for network attack and defense drills [4-6].

Software-defined networking is a network technology that has emerged in recent years. It provides network devices with a forwarding layer based on hardware and a control plane based on software control by separating the control plane and the data forwarding plane [7-10]. The SDN controller realizes the power and management of the global network. Given the SDN separation of management and control characteristics, the network has better flexibility and scalability.

This article proposes a method for constructing a virtual-real fusion network simulation experiment field based on SDN. The core idea is to realize the joint networking of virtual instances and physical terminals in creating network simulation scenarios so that the constructed network simulation scenarios are more comprehensive, realistic, and better[11-13]. Experiments have found that the SDN-based network simulation experimental field construction method can quickly realize the construction of virtual-real fusion scenarios. Compared with traditional construction methods, it can meet the needs of large-scale complex network scene generation and effectively avoid network node link congestion and other phenomena [14]. Connecting physical terminals to the virtual network environment through SDN can effectively reduce the construction cost of complex networks; realize the flexible expansion of network scale, and natural and effective network simulation [15-18].

The main contributions of the article include three aspects:

(1)Based on SDN, a method for constructing a virtual-real fusion network simulation experiment field is proposed. A prototype system for virtual-real fusion network simulation is designed and developed.

(2)Based on the Ryu controller, a flow table generation algorithm is proposed to realize the interconnection between virtual and real devices.

(3)Through experiments, it is proved that the construction method of the SDN- based virtual-real fusion network simulation experiment field and the flow table generation algorithm are practical and feasible.

II. SDN-based virtual and actual network architecture design

It mainly introduces the construction of a virtual-real fusion network simulation experiment field based on SDN software and hardware switches. This design relies on the overlay network and realizes the access of physical terminals by building vxlan tunnels. The Vxlan network has similar functions to the vlan

network and can provide Layer 2 Ethernet services, but vxlan has better flexibility and scalability than vlan. It uses a 24-bit tag vxlan_id to support more Layer 2. The network has reached more than 16 million layer-2 network segments, so it can meet the needs of building network scenarios in large-scale and complex cloud platforms [19-20].

2.1 Trend of virtual instance data in the cloud platform

In the OVS cloud platform, the data packet transmission of the virtual instance will pass through a series of virtual bridge devices. The following is a detailed description of the data packet direction of the virtual model in the computing node[21-25].

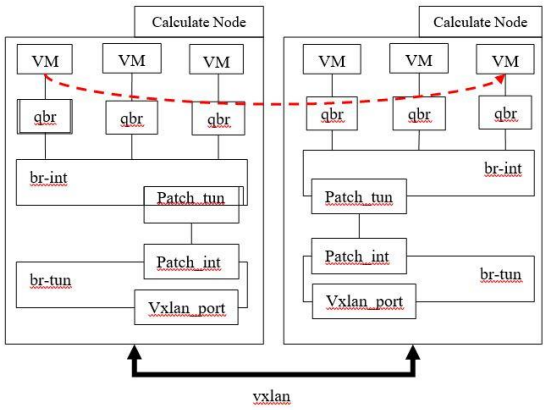

Figure 1 Example data trend

As shown in Figure 1, the virtual instance in the cloud platform transmits the data packet through the br-int bridge of OVS to the br-tun bridge through the virtual network card and other devices. When the data packet reaches the br-tun bridge of OVS, it will Forwarding is performed according to the multi-level OpenFlow flow table rules in the bridge, and the flow table forwarding rules are shown in Figure 2.

The functions of each OpenFlow flow table in Figure 2 are:

table0: Do splitting processing, according to the source of the message, is the br-int bridge inside the cloud platform or outside the cloud platform (the data sent

from the outside means that the data is transmitted from other nodes or devices to this node, not through the virtual instance in this node. The data packets transmitted by the br-int bridge) are forwarded to different flow tables for subsequent processing. The data packets sent by the internal br-int bridge are forwarded to Table 2 for processing. The data packets sent from the outside, It is delivered to table4 for processing;

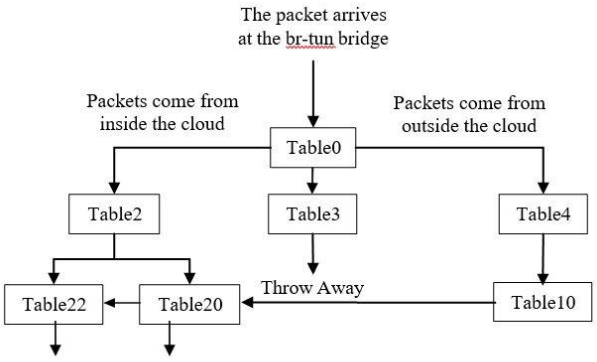

Figure 2 The direction between flow tables

table2: For the data packets that the virtual instance is going to send out, if it is a unicast packet, it will be transferred to table20; if it is a multicast packet, it will be transferred to table22 for processing;

table3: directly discard the data packets that meet the matching conditions of the flow table;

table4: used to process the data packets sent from the outside, specifically strip the tun-id of vxlan, add vlan tag, realize the mapping conversion between vxlan and vlan inside the cloud platform, and transfer it to table10 for processing;

table10: This flow table is a self-learning flow table, which realizes the learning of the mac address table in the data message, and puts the learned content into table20;

table20: According to the matching field of the message (vlan, destination mac, etc.), strip the vlan_id, add the tun-id of vxlan, and forward it from the specified vxlan port. If the corresponding match cannot be achieved, go to table22 for processing;

table22: Also according to the matching field of the message (vlan, destination mac, etc.), the vlan_id is stripped, the tun-id of vxlan is added, and then flood broadcast is performed to send the data message to all vxlan tunnels to realize the

data message Transmission between different nodes in the cloud platform. Through the above forwarding rules of the OpenFlow flow table, mutual communication among the virtual instances in the cloud platform is realized.

3 Key technologies of SDN-based virtual-real fusion network simulation

III. Construct vxlan tunnel

The Vxlan tunnel [26-28]is the bridge of the entire virtual-real fusion system. The controller has complete control over the physical SDN switch, and through the vxlan tunnel, the link between the physical SDN switch and the brut tunnel bridge in each computing node OVS of the cloud platform is opened, which is also realized. The prerequisite for the connection and interaction between the cloud platform and the physical terminal. The specific implementation steps are:

•**Step 1** Add corresponding vtep_port port pairs on the br-tun tunnel bridge and the physical SDN switch of the OVS virtual switch of each computing node on the cloud platform.

•**Step 2** Through OVS-related commands, use the vtep_port port pair in step 1 to create a vxlan tunnel to realize the connection between the physical SDN switch and the br-tun tunnel bridge in the OVS of each computing node on the cloud platform and then realize the virtual instance in the cloud platform Link connectivity with entity terminals.

•**Step 3** Add a daemon process to the br-tun tunnel bridge of each computing node on the cloud platform, and add the newly added vtep_port information into the flow tables at all levels of the br-tun tunnel bridge.

IV. Experiments and Results

The proposed virtual-real fusion solution's performance will be tested through many simulation experiments, and the solution will be evaluated in terms of connectivity, isolation, packet-sending delay, and throughput.

4.1Correctness test of flow table construction results

According to the virtual-real fusion network simulation [29-30] the flow table automatic configuration code is designed based on the SDN controller flow table generation algorithm. First, the physical terminal node is pinged from the virtual instance node, and the Ryu controller will automatically Construct and issue flow table rules. After the virtual and real nodes are successfully pinged, log in to the physical SDN switch to view the configuration of the switch flow table

information; on the computing node server where the virtual instance node is located, use the command to view the flow table rules, as shown in table 1.

Table 1 Connectivity test results of some instances

Source host	Destination host	Is itconnected?
192.168.16.197	VM 1	yes
192.168.16.198	VM 2	yes
192.168.16.199	VM 3	yes
VM4	192.168.16.97	yes
VM5	192.168.16.98	yes
VM6	192.168.16.99	yes

From the above flow table information, it can be seen that through the designed flow table structure and distribution algorithm, the generated flow table can enable the virtual instance and the physical terminal to realize the seamless intercommunication of virtual and actual links.

4.2Network Isolation Test for Virtual Reality Convergence

In actual network experiments, there are often multiple virtual and real network scenarios with the same network configuration parameters belonging to different vxlan networks. Still, in these different scenarios, the IPs of the virtual instances belong to the same network segment. Combined with the network creates a virtual network of 192.168.16.0/24 under different vxlans and generates multiple virtual instances with IP segments of 192.168.16.0/24. The vxlan_ids of the two networks are vxlan100 and vxlan200, respectively, and the IP devices of physical terminals 1 and 2 are 192.168.16.199 and 192.168.16.200, respectively. Physical terminals 1 and 2 are isolated through the flow table to realize the network interconnection between physical terminal 1 and vxlan100 intercommunication, the physical terminal 2 and vxlan200 network interconnection and intercommunication. The experimental isolation test results are shown in Table 2.

Table 2 Isolation test results

Source host	vxlan to which the destination host belongs	Is it connected?
Entity Terminal 1	vxlan100	yes
Entity Terminal 1	vxlan200	no
Entity terminal 2	vxlan100	no
Entity terminal 2	vxlan200	yes

Based on the automatic construction and delivery of the previous flow table algorithm, a new group of virtual-real fusion networks with the same network segments except for vxlan is added to the scene.

4.3 Network Performance Test for Virtual Reality Convergence

To verify the actual network performance of the proposed scheme in virtual and real networks, different numbers of virtual instances are generated in the same virtual and real network for experimental testing. In this experiment, the Flavor configuration parameters of virtual models in OpenStack were divided into three levels, namely trim (RAM=512 MB, Root Disk=5 GB), medium (RAM=2 GB, Root Disk=10 GB), Large (RAM=4 GB, Root Disk=20 GB), the scale ratio of small, medium and large virtual instances is selected as 5:3:2, and for the generated virtual and real network scenarios of different scales, the communication delay, throughput, packet loss rate, etc. The network performance test is carried out on the aspect, and the test results are shown in Figures 3-5

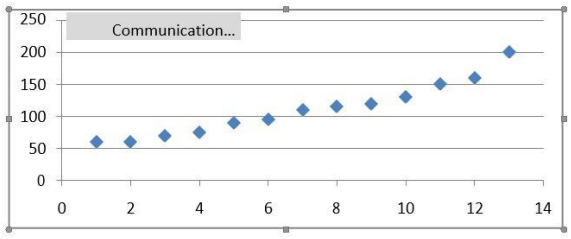

Figure 3 Relationship curve between network delay and number of virtual instances

Figure 3 is a curve diagram of the relationship between the communication delay of the virtual and real networks and the number of virtual instance nodes in this paper. For each number of virtual instances, the test is performed ten times, and the average value is taken. It can be seen from the figure that as the number of virtual nodes increases, the communication delay of the method in this paper also increases slightly.

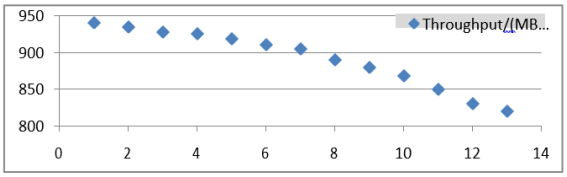

Figure 4 The relationship between throughput and the number of virtual instances

Still, the overall uncertainty remains at a superficial level. Figure 4 is a graph of the relationship between the throughput of the virtual and real network and the number of virtual instance nodes. The same test is performed ten times for each method, and the average value is taken. Since the servers and physical terminals in the experimental environment work should be close to 1000 Mb/s. The method described in this article is based on the vxlan network model.

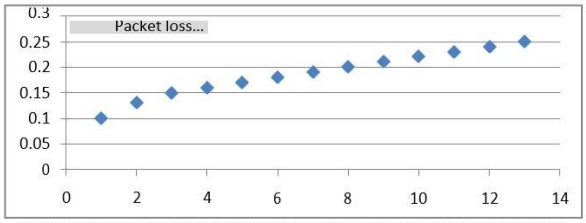

Figure 5 The relationship between the packet loss rate and the number of virtual instances

The data packets of the virtual instance are sent directly from the network card of the computing node and directly communicate with the physical terminal through the physical SDN switch. Since there are three computing nodes in the experiment, it can be seen from the figure the throughput is less affected by the size of the virtual instance. Figure 5 shows is virtual and real relationship curve between the packet loss rate of the network and the number of virtual instance nodes. In the packet loss rate test, the network bandwidth is determined by continuously sending UDP packets between the virtual instance and the physical terminal and constantly adjusting the sending bandwidth of the source host, the bottleneck.

V. Conclusion

A virtual-real fusion network simulation construction method based on SDN is proposed. Through the physical SDN switch and the Ryu controller, the physical terminal and the virtual instance constructed by the OpenStack cloud platform are used to integrate the network. The experiment proves that the SDN-based method can be effectively applied to large-scale The construction of large-scale virtual and real network scenarios has better performance than traditional methods in terms of network connectivity, delay, throughput, and packet loss rate. Furthermore, this method does not transmit all virtual and real traffic through network nodes in the

cloud platform, eliminating the possibility of network node congestion. At the same time, this method realizes network isolation based on vxlan, which ensures high reliability of virtual and real scenarios and solves the problem of limited scale.

Abstract – **: In recent years, support vector machine has become one of the most important classification techniques in pattern recognition, machine learning, and data mining due to its superior classification effect and solid theoretical base. However, its training time will increase dramatically as the number of samples increases, and training will become more sophisticated when dealing with problems involving multiple classifications. A quick training data reduction approach MOIS appropriate for multi-classification tasks is presented as a solution for the aforementioned issues. While eliminating redundant training samples, the boundary samples that play a vital role are chosen in order to considerably reduce training data and the problem of unequal distribution between categories. The experimental results demonstrate that MOIS may maintain or even improve the classification performance of support vector machines while substantially enhancing training efficiency. On the Opt digit dataset, the suggested method improves classification accuracy from 98.94% to 99.05%, while training time is reduced to 15% of the original; in HCL2000, the proposed method improves classification accuracy from 98.94% to 99.05%. When the accuracy rate is marginally increased (from 99.29% to 99.30%) on the first 100 categories dataset, the training time is dramatically reduced to less than 6% of the original. Additionally, MOIS has a high operational efficiency.**

Keywords:Machine Learning, Pattern Recognition, Data Mining, Classification, Multi-Classification

I. INTRODUCTION

In pattern recognition, machine learning and data mining, Support Vector Machine (SVM) [1] has become a high-profile classification method in recent years due to its excellent classification effect and solid theoretical foundation. Structural risk minimization and convex quadratic programming make SVM more robust classification performance than other classification methods. The kernel method makes SVM also have an excellent classification effect on nonlinear separable problems. SVM has been successfully applied to text recognition [2], image classification [3], financial prediction [4], medical diagnosis [5] and many other scientific and technological fields.

However, the application of quadratic programming in the training process makes the SVM training complexity increase significantly with the rise in the number of training samples. In general, for a training set containing n samples, the time for SVM training on it is complex. The degree is O (n3). In addition, SVM is proposed for the two-class problem. For multi-class problems, the usual practice is to convert the multi-class problem into multiple two-class issues in a one-to-one or one-to-many manner. The one-to-one conversion method requires training an SVM classification model between two classes, and the classification process is more complicated. The one-to-many approach requires much fewer models to be taught, and the classification process is more straightforward, but each model is trained on a severely imbalanced dataset. The model training will be more complicated no matter which transformation method is adopted.

In recent years, with the development of information technology, the scale of data sets is also increasing, among which multi-classification problems exist widely. High training complexity has become the main bottleneck of SVM in many practical applications. How to improve the training efficiency of SVM, Especially for multi-classification problems, is an important and urgent research topic. To reduce the training complexity of SVM, researchers mainly explore two ways: to improve the efficiency of quadratic programming and sample selection. To improve planning efficiency, researchers try to decompose the quadratic planning process on the entire training set into a series of small-scale optimization processes. The typical algorithms in this regard are SMO (Sequential Minimal Optimization) [6], SOR (Successive Over Relaxation) [7], Chunking [8], LIBSVM (LIBrary for SVM)[9] and other algorithms. The method based on sample selection is to select the samples that play a decisive role in the training results from the training set to form a smaller training subset and train the SVM classification model on it. Since the training complexity of SVM is highly dependent on the number of training samples, the method of sample selection has a more significant effect on improving the training efficiency. Because of this, this paper will follow this idea, take the cluster centre as the reference point, and construct an SVM acceleration algorithm suitable for multi-classification problems through sample selection. This paper first summarizes the related research on improving the efficiency of SVM through sample selection; then introduces the proposed algorithm and verifies its effectiveness through experiments; finally, it outlines the work and suggests further research ideas.

II. II.Related work

In the training process of SVM, only the boundary samples as support vectors affect the training results [10]. The remaining samples are either redundant samples that do not work or noise samples that damage the training results. Based on The SVM acceleration method of sample selection is to delete redundant and noisy

instances and select boundary samples that may be support vectors. Based on this idea, author [11] proposed the SVM-KM algorithm. The algorithm first clusters the training samples.

If a cluster only contains samples of the same class, the cluster centre of the cluster replaces all samples in it; if a collection contains samples of different types; all models in the collection are retained. SVM-KM has a higher [12] proposed training sample deletion algorithm. First, an initial SVM was obtained by training a small-scale sample subset, and then the original sample set was separated from the initial SVM. The training samples that are far from the classification hyperplane are deleted. This method can delete some pieces irrelevant to the classification, but the selection effect depends on the initial SVM. author [13] proposed a fast sample selection method NPPS (Neighborhood Property Based Pattern Selection Algorithm), using the neighborhood information of training samples for analysis, NPPS selects selections near the classification hyperplane to form the final training set. This method can significantly improve the training speed, but noise data quickly disturbs election results. Angiulli (ConsistentSub-Set) gave a sample selection algorithm FCNN (Fast Condensed Nearest Neighbor Rule) [14]. This algorithm reduces the sample size to a large extent, which is easy to reduce the classification accuracy. Author [15] used the class distribution information and geometry of the K nearest neighbors of the sample. The feature gives the BEPS (Border Edge Pattern Selection) algorithm to select critical samples. This algorithm can fully use the distribution information of the pieces in the training set. Still, it is easy to choose more samples, and the values of 4 hyper parameters need to be given, increasing the algorithm's application. [16] Randomly selected a certain proportion of samples from the training set to form multiple training subsets, trained an SVM model on each subgroup, and then used these models to evaluate each sample based on the evaluation results selection of samples. Since the evaluation result of each piece is generated by the SVM trained on a randomly selected subset of models, the selection result inevitably has a certain degree of randomness.

The above research has achieved apparent results in improving the efficiency of SVM for binary classification problems. However, for multi-classification problems, these algorithms often find it difficult to achieve satisfactory results in terms of efficiency and effect. To solve this problem, this paper constructs a suitable fast sample selection method MOIS (Multi-class-fication Oriented Instance Selection). This algorithm has apparent advantages over existing algorithms in terms of efficiency and effect for multi-classification problems.

III. MOIS ALGORITHM

3.1 MOIS Algorithm Framework

As mentioned above, to use SVM for multi-classification problems, the original problem needs to be transformed into multiple binary classification problems. Compared with the one-to-one conversion method, the one-to-many approach not only trains the model much less but also makes the classification process Simpler and more efficient, just solving the imbalance between positive and negative classes caused by this method. Therefore, the MOIS algorithm will use a one-to-many conversion method.

Assume that the training set A is composed of L types of samples, the total number of samples in A is N, and the number of c ($1 \le c \le L$) type samples is Mc. Then, according to the one-to-many transformation method, each type of sample in A takes turns to be a positive class sample, and the rest of the samples are taken as the current negative class sample. In the following, we consider the boundary sample selection process when the lth ($1 \le l \le L$) class is used as the current positive class, where Tl represents the result of the selection.

First, use a specific clustering method (k-means clustering method is used in this paper) to cluster the current positive samples, the lth class samples, and assume that the k cluster centers are D1, D2, .., Dk. Then, for each Di ($1 \le i \le k$), calculate its distance e(x, Di) to each sample x. Finally, select a proportion of the more significant d(x, Di) from the lth class positive class samples. At the same time, a certain proportion of negative class samples with minor e(x, Di) from each other class. The basis of this approach is:

For positive examples, the closer it is to the cluster centre of the positive class, the more likely it is an interior point; otherwise, the more likely it is a boundary point. For negative examples, the closer it is to the centre of a positive cluster, the more likely it is a boundary point Big.

3.2 Determination of parameters in MOIS

The following key question is how to determine the total sample selection ratio and the selection ratio of positive and negative samples.

3.2.1Determination of the selection ratio of the total sample and the number of clusters

This section presents a simple and effective method to determine the total sample selection ratio and the number of groups. This method allows the user to choose the appropriate balance and number of groups according to the computing resources and the size of the dataset. Generally, a small data set with fewer samples has higher sparseness and a higher proportion of selected models. On the contrary, for a data set with a large number of pieces but not a high dimension, due to the denser parts, a lower ratio is often selected, i.e. the ideal effect can be achieved. Therefore, we can first determine the range of the scale value according to the size of the data set and then select an appropriate value within this range to verify through experiments. For example, a small data set can be in {0. 2, 0.25, 0.3, 0.35, 0.4, 0.45, 0.5, 0.55, 0.6, 0.65, 0.7} through experimental verification to select an appropriate one value.

For the number of clusters k in the positive class, it is also selected according to the size of the positive course. When there are few positive class samples, the value of k is generally smaller; otherwise, a more significant deal of k

is required. It is found through experiments that the ideal selection effect can be obtained when the value of k is between 1 and 7.

3.2.2 Determination of the selection ratio of positive and negative examples

When determining the selection ratio of positive and negative examples, considering that the current negative class is composed of multiple courses other than the lth class, it is very likely that the number of positive samples is significantly less than the number of negative examples. The selection ratio should help to eliminate this high imbalance between positive and negative classes. At the same time, considering that the boundaries of antagonistic classes composed of multiple types are generally more complex, the number of negative examples should be appropriately selected more than positive models. For instance, in the MOIS algorithm, the number of negative cases is twice that of positive points.

Also, when selecting negative examples, should I choose from the entire negative class, or should I choose from each category that makes up the negative class? Since the multiple courses that make up the negative class tend to be of different sizes, we should choose from each negative example. The number of negative examples should be proportional to the class size. Assuming that the total number of negative criteria set is , then the negative examples chosen from the i-th (1≤i≤M, I≠l) class. The number M_i^s is:

$$M_i^s = \frac{M_-^s M_i}{\sum_{1\le c\le K, c\ne l} M_c} \quad (1)$$

Based on the above analysis, the steps of the MOIS algorithm are shown in Algorithm 1. Algorithm 1 MOIS Algorithm

Input: A training set U consisting of M samples divided into K classes, the sample selection ratio r Output: the selection result Sl when the l (1≤l≤K) class is the current positive class

Step 1: Cluster the lth (1≤l≤K) class samples as the current positive class, and obtain k cluster centers D1, D2, .., Dk Step 2: For each cluster centre Di(1≤i≤l), calculate the distance e(x, Di) to each sample x.

Step 3 Calculate the number of positive examples to be selected , *Ms* as follows:

$$M_+^s = \min\{\tfrac{1}{3}M \cdot r, M_1\}, M_-^s = \tfrac{2}{3}M \cdot r_{\circ}$$

Step 4: Select Ms samples with more significant e(x, Di) from the current positive class and put them in Tl. Step 5: Select Ms negative examples with small e(x, Di) from the i-th (1≤i≤K, i≠l) class

Enter Tl. Among them, Ms is determined by the formula (1).

By training SVM on the obtained selection result Tl, the l classification model can be obtained, and if l is set to 1, 2, .., K classification models will be accepted.

3.3 Complexity Analysis of MOIS Algorithm

In Step 1 of Algorithm 1, the complexity of the clustering process on the positive class is O(UkM/K). Among them, the value of l is not greater than 7, which is the number of cluster centers; U is the number of clustering centers in the clustering process the number of cycles. When k is set to 1, the complexity is reduced to O(M/K). The complexity of step 2 in algorithm 1 is O(lM). Steps 3 to 5 in algorithm 1 are mainly for each sample type. Sorting according to the distance metric, the complexity is O(kMlog(M/K). In summary, the complexity of MOIS is O(Mlog(M/K). It can be seen that MOIS has high efficiency. The following the effectiveness of the MOIS algorithm will be verified by experiments.

IV. Experimental verification

To verify the effectiveness of the MOIS algorithm, it is compared with the most representative three algorithms, NPPS [13], FCNN [14] and BEPS [15], in the experiment. These three algorithms are used to accelerate the SVM. , and achieved significant results. In the experiment, the above four algorithms involved in the comparison will be evaluated from the following aspects: 1) the impact on the classification effect; 2) the simplification of the data set;

3) the effect on the training efficiency 4) The execution efficiency of the algorithm itself.

4.1 Experimental dataset

Several standard multi-classification datasets and a practical handwritten Character recognition dataset are used in the experiment. Table 1 lists the number of samples (Size), number of features (#Fea), number of categories (# Cls), the number of training samples (#Trn), and the number of test samples (#Tes). Except for HCL2000, the rest of the datasets are from the UCI machine learning database [17], and each dataset has been divided into a training set and a

Test set. HCL2000 is a handwritten character set with 3755 classes; each class contains 1000 samples, 700 for training and 300 for testing. The test time is too long, so only the first 100 kinds of models are used for the experiment. By extracting the 8-directional gradient features, the number of elements of each sample is 512.

Table 1 Experimental dataset

Data set	Size	#Fea.	#Cls	#Trn.	#Tes.
Dermatology	368	44	16	292	86
Glass	224	19	16	178	56

USPS	9308	266	20	7301	2017

4.2 Experimental parameter settings

To avoid running too long on high-dimensional datasets,

the usual dimensionality reduction measures are adopted for high-dimensional datasets such as HCL2000, Iso-let and USPS. Among them, HCL2000 is reduced to 99 dimensions by the LDA method, and Isolate and USPS use PCA, respectively. Down to 150 and 80 sizes.

The kernel function of the SVM used in the experiment is always the Gaussian function defined by Equation (2).

$$(yi, yj) = \exp(-"yi - yj"2/2\sigma 2) \quad (2)$$

The error limit parameter on each dataset and the parameter σ in Eq. (2) is optimized through experimental verification. The selection ratio and the number of clusters in MCIS are set according to the instructions in Section

3.2. The NPPS algorithm the number of neighbors in lb, le, λ and γ in BEPS are all set according to the method in the original text. Here, only the FCNN algorithm does not need parameter settings.

4.3 Experimental results

To compare the performance of various algorithms on the experimental data set, Table 2-Table 5 lists the classification accuracy, sample selection ratio, model training time and sample selection time obtained by different algorithms on each data set. ." All" in the table indicates the case of using the entire training set for training.

Pendigit	4.92	2.47	1.16	6.05
Usps	9.55	5.55	1.59	12.52

From Table 2, it can be found that among the four sample selection algorithms, MOIS maintains the highest classification accuracy on all experimental datasets except USPS, and even on HCL2000 and Optdigits datasets, MOIS makes the classification accuracy more elevated than the original. This is because the data set has been improved. Only on the USPS, MOIS has slightly lower classification accuracy than the other three algorithms. In contrast, the three different algorithms do not maintain classification accuracy very well.

Judging from the sample selection ratio listed in Table 3, the selection ratio of MOIS is only higher than that of FCNN in general but significantly lowers than that of NPPS and BEPS. It is worth noting that the high simplification of FCNN can easily lead to a significant drop in classification accuracy. Observing the SVM training time listed in Table 4, it can be found that the four sample selection algorithms can significantly shorten the training time. In contrast, MOIS's ability to shrink the training time is slightly inferior to that of FCNN and substantially better than NPPS and BEPS.

Since the running times of the four selection algorithms on small-scale datasets are very short, it is difficult to detect significant differences in their running times. Therefore, table 5 only lists the running times of these algorithms on larger-scale datasets. It can be found in Table 5 that the running time of MOIS is significantly

shorter than that of other algorithms, generally only a fraction or even several tenths of the different algorithms, which fully shows that the running efficiency of MOIS is significantly higher than that of other algorithms.

Conclusion As one of the most crucial classification methods in pattern recognition, machine learning and data mining, the support vector machine has an excellent classification effect. However, the model training time of this method will increase significantly with the increase of samples, especially when processing many In the case of classification problems, the model training will be more complicated. Therefore, not only does the number of trained models increase significantly, but the model's training effect needs to be improved. To solve the above problems, this paper presents a fast training data reduction algorithm MOIS suitable for multi-classification problems. The method first clusters the current positive class, then takes the obtained cluster centre as a reference point, removes redundant samples, selects the boundary samples that play a decisive role, and reduces the selection ratio by appropriately controlling the selection ratio of positive and negative examples unbalanced distribution among categories. Different from the previous data reduction methods based on clustering, MOIS clustering only one category of samples and the clustering speed is much faster than the previous algorithm. In addition, by deleting redundant pieces and selecting boundary samples by doing, the data reduction effect of MOIS is better. Compared with several algorithms with excellent performance in the past, it is found that MOIS is significantly better than other algorithms in maintaining the classification effect of support vector machines, and its operational efficiency is also considerably higher.

Abstract – **To protect wireless sensor networks from selective forwarding attacks, a lightweight WSN selective forwarding attack detection technique (LSFAD) is presented. The proposed approach identify selective forwarding attack paths by based on the average packet loss rate (PLR). It compare the PLR of attacked path with its normal PLR, and it can detect and pinpoint malicious links by doing the same for each node. The LSFAD technique detects malicious pathways during regular data packet sending and receiving without disrupting the normal operation of the entire network. Its simple design eliminates the need for listening nodes and sophisticated evaluation models. According to the results of the security and performance investigation, the LSFAD scheme is secure against passive and active selective forwarding attacks launched by malicious nodes. The LSFAD method has a significantly lower communication overhead compared to similar schemes. Despite an average PLR of 0.125 on the link, the LSFAD method detected the selective forwarding attack path in experimental simulations. Identifying the malicious nodes that launch a selective forwarding attack is possible when the link's usual PLR is more than 0.025. It is effectively detected and localized, and the network's energy consumption for doing so is not significantly higher than under normal conditions.**

Keywords: Wireless Sensor Network, Selective Forwarding Attack, Energy Consumption, Data Packet, Lower Communication Overhead.

I. INTRODUCTION

Wireless sensor networks (WSNs) are employed in the military, environmental monitoring, transportation, agriculture, medical, and home furnishing [1]. Security issues have always been a study focus. WSNs are multi-hop networks of sensor nodes. Sensor nodes are vulnerable to internal and external attacks, including selective forwarding attacks [2]. It is a severe internal assault [3], and the wireless channel's instability makes it hard to identify the network link's average packet loss from the selective forwarding attack's malicious packet loss, which has high concealment. Thus, detecting, locating, and isolating rogue nodes that initiate forwarding attacks is critical.Recently, scholars have presented effective selective forwarding attack detection techniques. Multi-hop confirmation-based forwarding attack detection techniques were presented [4-8]. Multi-hop confirmation requires more confirmation packets, which increases communication costs and reduces network life. Trust evaluation- based detection techniques [9-13] can identify harmful network nodes. Most detection techniques have a static trust threshold and misinterpret regular nodes. Thus, malevolent nodes are frequently misidentified, requiring more monitoring nodes and increasing network overhead. Literature [14] proposed malicious node detection schemes based on learning automata. However, literature [15] did not perform well in detecting selective forwarding attacks that do not generate malicious data packets. Literature [16] proposes two abnormal node detection schemes to detect particular forwarding attacks effectively. Still, the reward and punishment parameters of the learning automata of these two schemes are fixed values artificially set according to the voting situation of node neighbors, and the detection method is not flexible. To solve this problem, literature [17] proposes a detection scheme that can dynamically adjust the reward and punishment parameters of the learning automaton, which improves the flexibility and applicability of the detection method. Still, this scheme needs to be determined by the number of confirmation packets replied to by the neighbor nodes. Defining the environment's feedback to the learning automaton consumes many network resources.The proposed LSFAD strategy is based on this crucial observation. When a malicious node is on a selective forwarding attack route, the base station (BS) receives far fewer data packets from the originating node. Based on this observation, the BS records each source node's total data packets and routing path. The average and regular Packet loss rate (PLR) are determined by it. If the course's average PLR is higher than the way's, the current form is under selective forwarding attack. Each intermediate forwarding node tracks the data packets provided by the forwarding source node to the BS to identify the malicious node or connection that starts the forwarding assault. If a selective forwarding attack is found, the BS will notify eac node of the quantity of data packets sent by the source node to the BS. The BS then estimates PLRs. The node with the highest average PLR is malevolent.

II. Related Work

Currently, the selective forwarding attack detection schemes proposed by scholars at home and abroad can be roughly divided into projects based on the multi-hop confirmation model, methods based on the trust evaluation model and strategies based on learning automata.Author [18] presented a two-hop acknowledgment detection system based on the confirmation node since each node is a confirmation node

and sends an Acknowledging packet every time it gets a data packet, which dramatically increases network message collisions and collisions. Author [19] presented a multi-hop confirmation detection technique. This approach can greatly reduce network message collisions if more than two malicious nodes are chosen. Malicious nodes collaborate to confirm the nodes, invalidating the plan. This difficulty was solved by the author [20]'s multi-hop confirmation mechanism system (per-hop acknowledgment-based method, PHACK). PHACK places all nodes on the forwarding path except for average forwarding data. A confirmation packet for each forwarded packet must be generated and sent to the source node over several paths to detect and find rogue nodes. Author [21] proposed a selective forwarding attack detection strategy using the multi-hop confirmation and trust evaluation model to reduce network overhead and enhance the detection rate of numerous malicious nodes on the path. Author [22] also developed a wireless ad hoc network-based selective forwarding attack detection technique that uses a hop-by-hop confirmation mechanism and an upgraded two-hop confirmation mechanism to detect demanding forwarding behavior to reduce resource overhead. The source node receives the confirmation packet over the original data forwarding mechanism.Author [23] proposed two wireless sensor network intrusion detection schemes based on learning automata. Since these two schemes are not malicious behaviors of detection nodes, although detecting malicious data packets is very effective, they are not suitable for generating malicious data packets. Selective forwarding of packages does not seem well.

III. System Model

(a)Network Model:-

The sensor network comprises a base station, ordinary nodes and malicious nodes. unique identity mark IDi is given to each node_i at beginning of deployment and a symmetric key Li,BS shared with BS. They assume that all nodes are no longer moving after the network is deployed to the target area. With BS as the root, all nodes form a tree structure; as the network runs, some nodes may die due to battery exhaustion, causing the network path changes, so every once in a while, BS will update the topology of the entire network in time. When I perceive the data, it will send it to BS in a multi-hop manner. While sending the data packet from source node I to BS, each intermediate forwarding node will record that it has forwarded the data transmitted by source node I. The number of packages BS will record the total number of data packets sent by each source node I and the forwarding routing path of these data packets. On the forwarding path of data packets, not only malicious nodes on the way will discard the data packets it should forward with a certain probability, but also because of the instability of the physical layer wireless channel and the collision of MAC (media access control) layer data packets, any A communication link between two intermediate forwarding nodes may also drop packets typically. Scholars at home and abroad have proposed many schemes for generating and fusion sensing data [19-20]. This paper will not describe this in detail here. This paper mainly focuses on detecting the selective forwarding attack path and locating the malicious node or node that initiates the attack malicious link. For the convenience of reading and explanation, Table 1 describes the symbols used in this paper.

(b)Attack Model and Security Goals:-

Assume that in the network, except for the BS, any other node may be captured by the enemy. Once captured, these nodes will become malicious nodes, and the enemy will obtain security information such as identities and keys, and use these nodes to launch a series of attacks, such as injecting false data attacks, wormhole attacks, cloning attacks, Sybil attacks, and selective forwarding attacks, etc. This paper considers only particular forwarding attacks initiated by malicious nodes. Special forwarding attacks can be divided into passive and active, selective attacks. A passive special forwarding attack means malicious nodes only discard regular data packets with a certain probability and ignore the demanding forwarding attack detection behavior in the network. On the other hand, the active, particular forwarding attack not only loses regular data packets with a certain chance but also interferes with the detection behavior of special forwarding attacks to avoid being detected. This paper's LSFAD technique resists malicious passive selective forwarding attacks and deliberate nodes' active, specialised forwarding attacks

IV. LSFAD Scheme

This study proposes a four-step LSFAD scheme: the source node generates the data packet, the intermediate node forwards it, and the BS detects the selective forwarding attack path and locates the malicious node.

(a)Generate Data Packets:-

After producing the data packet P, the source node I will create two fields to record the unique identifying tag of the data packet source node I and the sequence of the current data packet Number while sending sensing data to BS. Then, node I hold its identity tag IDi and data packet sequence number Seq_Numberi into the corresponding fields, where the sequence numbers of data packets are continuous, and finally sends the data packet to the next intermediate forwarding node

(b)Forwarding Packets:-

As illustrated in Table 1, all intermediate forwarding nodes retain a packet source node forwarding table (forward data table, DFT) with the Source ID field identifying the source node and the ForWord Count field indicating the number of packets passed.

Table 1 Packet forwarding table

Source_ID	ForWord_Count
…	…
ID	$ForWard\_Count_i$
…	…

When the intermediate forwarding node j receives a data packet Q, it first checks in its data forwarding table DFT

whether there is a record whose source node identity is Q.IDi; if not, then creates a new one in the data forwarding table DFT record, make DFT.Source_ID = Q.IDi, DFT.ForWord_Count = 1; if it exists, add 1 to the ForWord_Count field value of the corresponding record, and make DFT.ForWord_Count = DFT.ForWord_Count + 1, forward the data packet P to the next intermediate forwarding node.

(c)Detecting Selective Forwarding Attack Paths

After collecting the network's topological structure, the BS saves the identities of all source nodes and intermediary nodes in DST. Source ID, DST. Empty Path Array fields and other sections are initialised. If a node dies due to battery exhaustion, the path from some source nodes to the BS may change. The BS will update the network topology and adjust the Path Array field of the data packet sending table DST. When the BS receives a data packet Q, it will execute Algorithm 1 to detect the selective forwarding attack path. It first finds the record of the source node identity Q.IDi in the data packet transmission table DST; if the Seq_Number field is empty, it is the first time receives the data packet sent by the source node, and it will set DST.Seq_Number = Q.Seq_Numberi,

DST.Sum_Count = 1, DST.Drop_Count = 0; if the Seq_Number field is not empty, compare whether the sequence number of the last received data packet is continuous with the sequence number of the currently received data packet; if continuous, it means that there is no packet loss, it will update the values of the DST.Seq_Number and DST.Sum_Count fields so that DST.

Seq_Number = Q.Seq_Numberi, DST.Sum_Count = DST.Sum_Count + 1; If the packet sequence number is not consecutive, it means there is packet loss; it will make DST. Seq_Number = Q.Seq_Numberi, DST.Sum_Count = DST.Sum_Count + 1, DST.Drop_Count = DST.Drop_Count(Q.Seq_ Numberi - DST.Seq_Number - 1), where Q.Seq_ Numberi - DST.Seq_Number - 1 represents the number of lost data packets. Then the BS executes the formula (1) to determine the average PLR DPaverage of the current path and DPnormal of the recent course (2). The BS will use Algorithm 2 to find malicious nodes if the average PLR DPaverage is higher than DPnormal. DST. Sum Count+DST. The source node, DST, sends Drop Count data packets. Drop Count is the number of packages lost in the current path, q is a node in formula (2), and The average PLR of the previous nodes, h is the path length from the source node to the BS.

$$DP_{\text{average}} = \frac{\text{DST.Drop\_Count}}{\text{DST.Sum\_Count} + \text{DST.Drop\_Count}} \quad (1)$$

$$DP_{\text{normal}} = \sum_{i=1}^{h} r_i \prod_{j=1}^{i-1} (1 - r_j) \quad (2)$$

Algorithm 1 Selective forwarding attack path detection

Input: data packet Q, data packet transmission table DST, average PLR q of the link between nodes.

Output: Selective forwarding attack path.

1. For each record in DST, do
2. If Q.IDi == DST.IDi then
3. If DST.Seq_Number = null, then

a. DST.Seq_Number = Q.Seq_Numberi

b. DST.Sum_Count = 1

c. DST.Drop_Count = 0

4. Else if P.Seq_Numberi - DST.SeqNumber == 1 then

a. DST.Seq_Number = Q.Seq_Numberi

b. DST.Sum_Count = DST.Sum_Count + 1

5. Else

a. DST.Seq_Number = Q.Seq_Numberi

b. DST.Sum_Count = DST.Sum_Count + 1

c. DST.DropCount = DST.DropCount + (Q.Seq_Numberi - DST.Seq_Number - 1)

d. Calculate the DP average by formula (1)

e. Calculate DPnormal by formula (2)

f. If DPaverage > DPnormal, then

i. Return DST.PathID_Arrayi

g. End if

6. End if

7. End if

8. End for

(d) Locating Malicious Nodes

The BS detects DST selective forwarding. PathID Arrayi, assuming the path DST.PathID Arrayi has m hops from the source node to the BS, is represented by (x1,x2,..., xm, BS), where x1 represents the data packet's source node and the remainder Nodes indicate intermediate forwarding nodes. The BS first alerts each node to send the number of data packets in the data forwarding table DFT forwarded by the source node n1 to the BS sequentially along the route, starting from the source node (3). (3) represents node ni's identification, IDi. DFT. For Ward Count is the number of data packets forwarded by node ni, pi - 1 represents data packets transmitted by the previous hop, and Timestamp represents Timestamp, || denotes join operation.

$qi = FL4{,}1\ (IDi \parallel ni.DFT.ForWard\_\text{Count} \parallel qi{-}1 \parallel \text{Timestamp})$ (3)

V. Performance Analysis

This paper will analyze and compare the LSFAD scheme proposed in this paper and the scheme proposed in the literature [24] from the aspects of communication overhead and storage overhead and analyzes the detection

probability of selective forwarding attack paths. Since the scheme in this paper assumes that the calculation, storage and communication capabilities of the BS are not due to limitations, the BS's communication overhead [25] and storage overhead[26]are not discussed here.

(a)Communication Overhead:-

This paper analyzes the communication overhead caused by malicious node detection. It takes the number of data packets each node needs to forward or send as an indicator to measure the communication overhead. The PHACK scheme proposed in [27] is a detection method based on multi-hop confirmation. In addition to forwarding regular data packets, each node on the forwarding path needs to generate proof for each box to detect and locate malicious nodes. The data packets are sent back to the source node in different ways. Suppose a source node sends M data packets at a time. In the PHACK scheme, the communication overhead of each node is 2M. In the CLAIDS scheme proposed in the literature [28], assuming each node has N neighbor nodes and a node sends M data packets to each of its neighbor nodes, each node needs to return M confirmation packets. Therefore, in the CLAIDS scheme, the communication overhead of each node is 2M × N. In the DSFLACQ method introduced in [29], each node has N neighbor nodes and sends M data packets to them. Each neighbor node only needs to reply one confirmation packet[30], hence the communication overhead of each node is (M + 1)×N. This paper's LSFAD technique does not monitor adjacent nodes or transmit confirmation packets to the source node. BS detects attack path. If the BS discovers the attack path after receiving M packets from the source node, each node on the forwarding path will sequentially submit a statistical data packet for a malicious node location. This paper's LSFAD technique has M + 1 communication overhead per node. Table 2 shows each node's communication overhead for the LSFAD scheme, CLAIDS, DSFLACQ, and PHACK schemes. Table 4 shows that the LSFAD system suggested in this paper has substantially lower communication overhead than other schemes.

Table 2 Comparison of communication overhead

CLAIDS	DSFLACQ	PHACK	LSFAD
2M × N	(M+1)×N	2M	M+1

VI. SIMULATION EXPERIMENT

In this study, the LSFAD scheme's malicious path detection probability, malicious node placement probability, and energy consumption are simulated and analyzed. The OMNeT++ platform does simulation experiments. 100 nodes are randomly arranged in a 500 m X 500 m square. Each node has an ID. 90 m is each node's communication range. After deployment, the node won't move because the BS is in the center of the region. Select data source, malicious, and intermediate forwarding nodes at random. The data source node provides 256-byte data packets to the BS via multi-hop every 1 s. Each node has 1 J of starting energy and consumes 50 nJ/bit for sending and receiving. 0.2~0.8 % of malicious intermediate forwarding nodes reject data packets they seek to forward. Table 3 lists the simulation parameters.

Table 3 simulation parameters

Parameter	Value or range
N/w area/m2	500×500
No. Of nodes in n/w	100
Radius/m	90
Initial energy of the node/j	1
Sending and receiving energy consumption/(nj/bit)	50
Data packet sending interval/s	1

Algorithm 1 detects the selective forwarding attack path when the BS receives the source node's data packet. It estimates the present course's average PLR DPaverage and the recent system's formula (1). (2). The existing form has a selective forwarding attack if the system's average PLR DPaverage is greater than the way's DPnormal. Figure 1 shows that the link's average PLR is 0.005, 0.025, 0.045, 0.065, 0.085, and 0.105, and the malicious node's is 0.2, 0.4, 0.6, and 0.8. Figure 1 shows that when there is only one malicious node in the path, the regular PLR and the average PLR are higher than the regular PLR DPnormal of the way. means that selective forwarding attack pathways begun by hostile nodes on the way with PLRs q = 0.2, 0.4, 0.6, and 0.8 can be detected. Selective forwarding attack path verification is more likely if the association's normal PLR is low and malicious nodes' PLR is high.In the LSFAD scheme, the energy consumed by a node on the path is mostly from receiving and sending data packets, so the sum of the energy consumed by all nodes on a forwarding path is UE=(i=1)^n^M×N i×(f r+f s), where n is the path length, M is the data packet length, Mi is the number of data packets forwarded by node I, and er and es are the energy consumed to receive and send 1-bit data, respectively. Figure 1 shows the energy usage of all forwarding path nodes in normal and detecting modes. Table 4 shows that when the average PLR of the link is 0.025, the PLR of malicious nodes is 0.2, and 50 packets are sent at a time, when the path lengths are 4~12, the energy consumption of the whole way in normal mode and detection mode increases. The detecting state consumes 1.8 μJ more energy than the regular form.

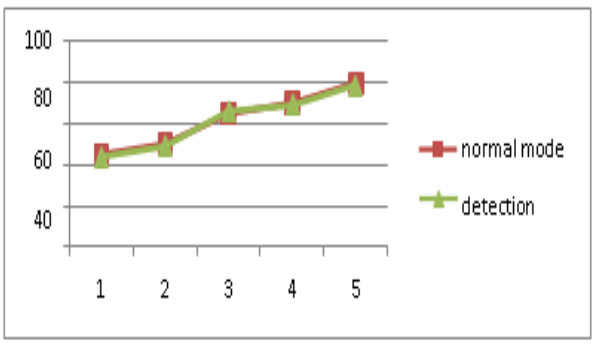

Figure 1 Energy consumption in normal mode and

detection mode

This is because when the BS finds a selective forwarding attack on a particular path, it will start the detection mechanism to locate the malicious node. After all, each node on the course needs to send information about the number of data packets forwarded by the source node along the forwarding path to the BS locates malicious nodes. The network consumes slightly more energy in detecting and locating malicious nodes than under normal conditions, but the overall energy consumption is not much different.

VII. Conclusion

This research provides a lightweight wireless sensor network selective forwarding attack detection technique (LSFAD). In the LSFAD scheme, the BS records the total number of data packets sent by each source node and the routing path of these data packets forwarding through Calculate and comparing the average PLR of the way with the regular PLR to determine if there is a selective forwarding attack on the current form. The base station assesses each node's average and regular PLR to find malicious nodes or links that launch forwarding attacks. The previous node link is a malicious link if its average PLR is higher than expected. The LSFAD scheme is simple, requires no listening nodes, does not need a sophisticated evaluation model to generate node trust values, and is easy to implement. LSFAD can also withstand passive and active selective forwarding assaults by hostile nodes. Performance study and experimental simulations reveal that the LSFAD method has substantially lower communication overhead than competing techniques. LSFAD's selective forwarding attack path can be detected even with a 0.125 connection PLR. Malicious nodes that launch forwarding attacks can be found when the packet rate exceeds 0.025. The network uses similar energy to detect and locate malicious nodes.

Abstract – **With the development of artificial intelligence technology, intelligent interference sources can improve the interference effect by changing their transmission power, which leads to the failure of traditional positioning technology based on received signal strength. Therefore, a sensor wake-up mechanism is introduced to study multi-interference sources based on block-compressed sensing positioning method. First, wake up the sensor nodes periodically, while improving the utilization effectiveness of the sensor nodes and the accuracy of positioning information collection; secondly, considering that the distance between the distance and the received signal strength cannot be determined when the transmission power of the interference source is unknown and changes. Then, based on the compressive sensing theory, the positioning problem is modeled as a block sparse vector reconstruction problem; finally, a variation-based algorithm is designed by exploring the law of power variation. The Wake-VBEM reconstruction algorithm based on Bayesian mean expectation accurately reconstructs the target position vector. The simulation proves that the proposed method can simultaneously realize the position estimation of multiple interference sources and effectively improve the service life of the network when the interference source power is unknown and changes.**

I. INTRODUCTION

Wireless Sensor Networks (Wireless Sensor Networks, WSN) are composed of low-cost, low-power sensor nodes and are widely used in daily production, life, and national defense and military fields [1]. However, it affects the transmission of wireless signals, thus destroying the security and reliability of information interaction in WSNs. Existing spectrum anti-jamming measures ensure communication quality by improving technical solutions, such as direct sequence spread spectrum, frequency hopping technology, and intelligent anti-jamming technology [2-3]. However, such methods are highly complex and require a large amount of bandwidth. And storage resources cannot fundamentally eliminate the problem of malicious interference. Interference source location can provide technical support for anti- jamming technology, such as directional interference elimination but also help to achieve precise strikes on interference sources [4], fundamentally eliminating malicious interference Source of interference.

The interference source location technology based on received signal strength (Received Signal Strength, RSS) locates by collecting the RSS of the interference source, without the need for any sensor nodes to send any signals, and has the advantages of simple operation, high security, and wide application [5]. In the case of hiding itself, the location of the interference source is realized [6], so it has become an effective measure for locating the source. The literature [7] proposed a distributed RSS-based interference source location algorithm. According to the gradient idea, the interference source is approached along the rising direction of RSS, but this algorithm can only realize a single interference source location. Literature [8] studies the interference source location method in short-distance communication and uses the clustering method to learn the site according to whether it is affected by the interference source. , the positioning accuracy is low. With the continuous improvement of the intellectual level of malicious interference sources, the interference source can change its transmission power to enhance the interference effect [9]. The RSS-based positioning method relies on signal attenuation to estimate its position, but the interference source transmission power after the change

The power attenuation is difficult to calculate, so the positioning cannot be completed. In addition, to improve positioning accuracy, it is usually necessary to deploy many sensor nodes, but batteries power the sensor nodes, and their energy is limited. Therefore, any applications will seriously hinder the development of sensor networks [10].

Based on this, this paper studies the energy-saving positioning method for multi-intelligent interference sources and designs the Wake-VBEM algorithm based on the variation Bayesian Expectation-Mean (Varia-tional Bayesian Expect- Mean, VBEM) [11] under the sensor wake-up mechanism. Sensor nodes are used to improve the service life of the network and obtain more positioning data. At the same time, introduce reference power to solve the problem of inability to locate caused by interference source power changes. The main innovations are as follows:

(1)Design the sensor sleep-wake mechanism and periodically wake up the sensor to collect more positioning information and prolong the service life of the sensor node.

(2) Introduce the reference power to solve the problem that the perception dictionary cannot be obtained due to the power change of the interference source, and then adopt the Block Compressive Sensing (BCS) principle [12] to model the localization problem as a block sparse vector reconstruction problem.

(3) Design a correlation matrix based on the VBEM algorithm to explore the law of interference source power changes and design a correlation matrix based on interference source power changes to achieve accurate position vector reconstruction.

II MODEL ESTABLISHMENT

The sensor wake-up mechanism is used to collect data to solve the positioning problem under the intelligent change of interference source power. First, the compressed sensing theory is introduced to establish a positioning model. Then, in reconstructing the position vector, a reconstruction algorithm is designed under the framework of VBEM. The specific operation process is as follows Figure 1 shows.

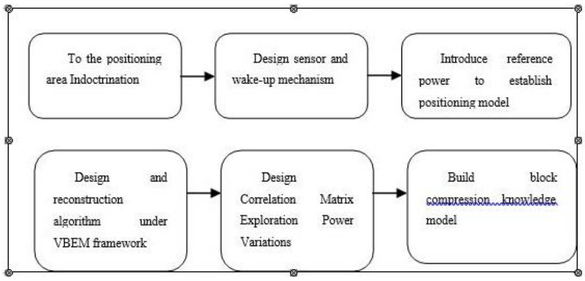

Figure 1 Flow chart of intelligent interference source location under the sensor wake-up mechanism

2.1 Compressed sensing localization model

Compressed sensing theory [13] reconstructs discrete sparse signals, and introducing it into positioning requires discretization of the positioning area. Therefore, as shown in Figure 2, the positioning area is divided into N grids and numbered sequentially (here, Take a square area as an example, other positioning areas of arbitrary shapes are handled this way).

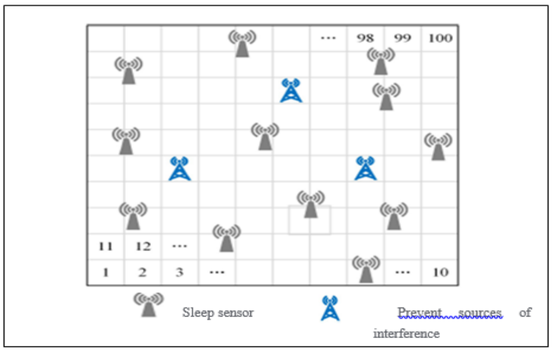

Figure 2 Compressed sensing positioning scene diagrams

The position of the interference source is uncertain and can be randomly distributed in any grid, and its work is described by a sparse vector t:

$t = [0,1,0, \cdots ,0,1,0, \cdots ,0]$ (1)

If ti=1, it means that there is an interference source in the i-th grid; otherwise, it does not exist. If there are R sensor nodes in the positioning area to collect positioning information, the positioning equation is as follows:

$zR = \mathbf{\Psi} R\times M\ TM + nR$ (2)

Among them, zR represents the sum of the RSS of all interference sources collected by the eth sensor node; Ψ is the perception dictionary, which is used to describe the relationship between the position of the interference source and the RSS; The RSS[14 - 19] of a sensor node is expressed as follows:

$\mathbf{\Psi} rm = Qm\ (, Km\ )$ (3)

Among them, Qm is the transmission power of the interference source located in the nth grid; Tr and Km are the coordinates of the rth sensor node and the nth interference source, respectively; g represents the relationship between the interference source and the sensor node. $\mathbf{\Psi} rm$ is affected by the influence of the transmitting power of the interference source and its distance from the sensor node. Once the position vector s is obtained, it can correspond to the coordinates of the interference source.

2.2 Sensor wake-up mechanism design

The introduction of the sensor wake-up mechanism under the CS framework has the following advantages: 1) Periodically wakes up the sensor nodes, which can save energy and prolong the service life of the network; 2) wake up different sensor nodes, which can collect more and more helpful positioning information; 3)

) to achieve positioning under the CS framework, which can make the number of wireless links awakened each time as small as possible.

At this time, the design of the wake-up strategy can be modeled as the construction of the observation matrix, let l=1,2,., M is the sampling time, then:

$$z_N^{(l)} = \Phi_{N\times R}^{(l)} \Phi_{R\times M}^{(l)} T_M + n_M^{(l)} = B_{N\times M}^{(l)} T_M + n_M^{(l)} \quad (4)$$

Among them, B(l), z(l) and m(l) are the perception matrix, measurement vector and noise vector at the lth sampling, respectively; here, it is assumed that the number of wireless links awakened each time is the same; TM represents the position of the interference source Φ(l) is the sampling matrix of the lth time, and only one element in each row is 1, indicating the wireless link index of the lth wake-up.

The design of the wireless link wake-up strategy is embodied in the compressed sensing positioning model, which is to design the observation matrix Φ, and the position of its non-zero element represents the wireless link to be awakened. This paper develops a random wake-up strategy, the non-zero elements in the observation matrix ΦS. The position of the 0 pieces is randomly generated, and there is only 1 in each row.

2.3 Establishment of positioning model under the wake-up mechanism

The intelligent interference source affects the communication by changing the power, so the perception dictionary Φ(l) in the CS model cannot be established. To solve this problem, a reference power Q0 is introduced. If the power of the interference source at the lth sampling time is Ql, the positioning model can be expressed as follows:

$(l) = (l)(l) = C(l)x(l), m = 1,2, \cdots , M$ (5)

Among them, $z(l)$, $B(l)$ and $T(l)$ are the measurement vector, perception matrix and position vector at the lth sampling, respectively. The establishment of $B(l)$ is shown in formula (3), and it needs to know the power Pl

of the interference

source. Still, it cannot be realized when the power of the interference source changes, so the reference transmits power is introduced, then:

$$y_m^{(l)} = \sum_{n=1}^{N} Q_n^{(l)} g(T_m, V_n^{(l)}) = \sum_{n=1}^{N} x_n^{(l)} Q_{n0}^{(l)} g(T_m, V_n^{(l)}) = \sum_{n=1}^{N} x_n^{(l)} F_{mn}^{(l)} \quad (6)$$

Among them, $Q_n(l)$ and $Q_{n0}(l)$ are the interference source's reference power located in the nth grid at the lth sampling moment. E is the

power corresponding to the reference power P(l) n0 Perception dictionary. At this time, the position vector $x^{(l)}$ is defined as follows:

$$Q_n(l) = x_n(l)Q_{n0}(l) \quad (7)$$

Although the elements of x(l) are not either 0 or 1, the index of the non-zero elements can indicate the target position. For example, if $x(l) \neq 0$, there is no

interference source in the nth grid.

Problem (5) involves the reconstruction of multiple measurement vectors. However, traditional numerous measurement vectors (Multiple Measurement Vectors, MMV) generally require the perception matrix to be consistent, so it is difficult to solve the above problems. Based on this, this paper introduces the BCS theory and explores the interference. In addition, the change law of source power is used to improve the positioning accuracy, which can solve the reconstruction problem when the perception matrix and the position vector are inconsistent.

III.SIMULATION VERIFICATION

The intelligent interference source location algorithm Wake-VBEM proposed in this paper is verified in Matlab. The 12m×12m square area is divided into N = 144 guards and Q = 144 sensor nodes deployed. K intelligent interference sources are randomly distributed, and each time, the number of awakened sensor nodes is

M. The noise is described by the signal-to-noise ratio (Sig-nal-to-NoiseRatio, SNR).

To measure the positioning performance of the algorithm, the average positioning error ErrL is defined as:

$$\mathrm{ErrM} = \frac{1}{L \cdot R} \sum_{l=1}^{L} \sum_{r=1}^{R} \sqrt{(y_l^t - \hat{y}_l^t)^2 + (z_l^t - \hat{z}_l^t)^2} \quad (8)$$

Among them, (y_l^t, z_l^t) and $(\hat{y}_l^t, \hat{z}_l^t)$ are the actual and estimated coordinates of

the k-th interference source in the n-th simulation, respectively. R and L are the total numbers of simulations and targets, respectively. The power change of the interference source can be regarded as a Gaussian process; the lth target power

$Q(l)$ changes at the lth sampling moment as follows [25-30]:

$$Q_k(l) = Q_k(l-1) + (1 - r)Q_0 + w(l) \quad (9)$$

Among them, $Q_0(l) \sim (\,, \sigma_q k)$ and $\sigma_q k$ is the variance of the power fluctuation of the kth interference source, and the parameter $w(l) \sim \mathcal{N}(0, (1 - s^2))$.r is used to describe the relationship between power changes. When the sampling interval is minimal, s is close to 1 and decreases with increasing sampling time. This model can set the power changes between different interference sources to be independent of each other, which is in line with the actual situation. Assuming four interference sources, the reference powers are 100w, 800w, 900w, and 1100w, respectively. When the correlation is s=0.5, the power changes of different interference sources are shown in Figure 3. The power changes of interference sources are inconsistent simultaneously at other sampling ties and other interference sources. Therefore, the power changes are a unpredictable. It can be seen that the proposed interference source change model can effectively simulate the actual power change. Thus, the performance of the algorithm is verified based on this model.

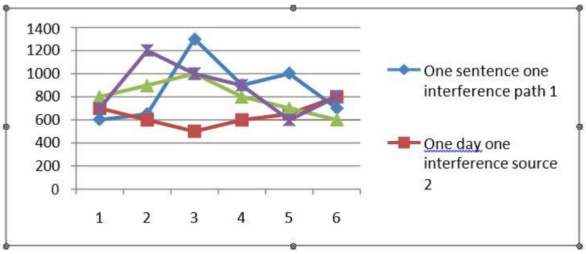

Figure 3 Schematic diagram of power variation of different interference sources

First, test the positioning performance of the algorithm under different sampling lengths M. Assuming that the number of sensor nodes awakened each time is N = 14 and SNR = 30dB when the number of interference sources L = 3, the ErrM of the algorithm under different sampling lengths is shown in Figure

4.SVM-VBEM and MMV-VBEM are single measurement vectors and VBEM algorithms that do not consider the law of power variation, respectively, and are used to compare with the proposed Wake-VBEM algorithm. As the sampling length M increases, the ErrM of both MMV-VBEM and Wake-VBEM algorithms decreases because M the addition of MMV can provide more positioning information. At the same time, SVM-VBEM only processes a single measurement vector, which cannot improve positioning accuracy. In addition, the MMV-VBEM algorithm does not consider the power variation of the interference source, its positioning error is significant, and the change of ErrM with M is small while Wake-VBEM, The ErrM of the algorithm decreases rapidly with the increase of

M, showing its superior positioning performance. To balance the positioning accuracy and algorithm complexity, M=2 in the following simulation.

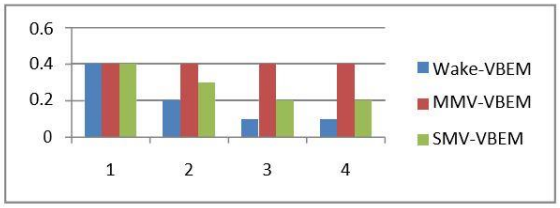

Figure 4 Effect of sampling length on localization performance

Secondly, the influence of the number of different interference sources on the proposed Wake-VBEM algorithm is tested. Let N = 14 and SNR = 30dB. When M

= 2, the average positioning error of different algorithms is shown in Fig. 5. It can be seen that the increase in the number of targets leads to the vector scarcity decreases, which affects the reconstruction accuracy, so the ErrM of all algorithms gradually increases. The proposed Wake-VBEM algorithm considers the power variation law of the interference source, and its positioning error is the smallest.

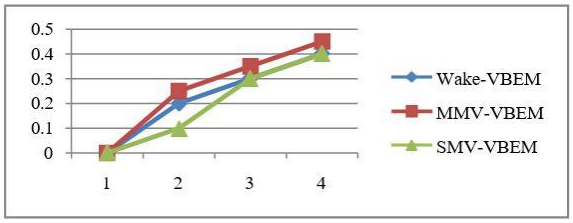

Figure 5 The effect of the number of targets on localization performance

Then, test the positioning performance of the algorithm under different sensor wake-up numbers. Let L=3, SNR=25dB and M=2, the change of ErrM of different algorithms with M is shown in Figure 6. Increasing M can obtain more positioning information, which helps to improve positioning accuracy. It can be seen that the ErrM of the three algorithms decreases with the increase in the number of wake- up sensors, and the ErrM of the proposed Wake-VBEM algorithm is the lowest.

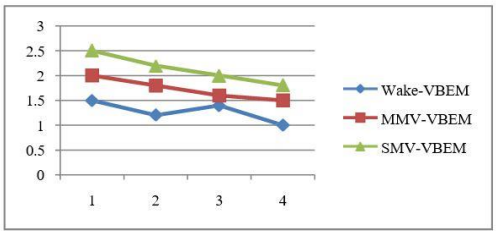

Figure 6 The influence of the number of awakened sensor nodes on the positioning

Finally, the anti-noise performance of the algorithm is tested. Let N = 14, L = 3 and M = 2, and the change of ErrM with noise is shown in Figure 7. As the SNR gradually increases, the ErrM of all algorithms decreases slowly. However, regardless of the SNR However, the ErrM of the proposed Wake-VBEM algorithm is always the lowest. In addition, when SNR=30dB, the ErrM of the proposed algorithm gradually begins to converge, reflecting the algorithm's good anti-noise performance.

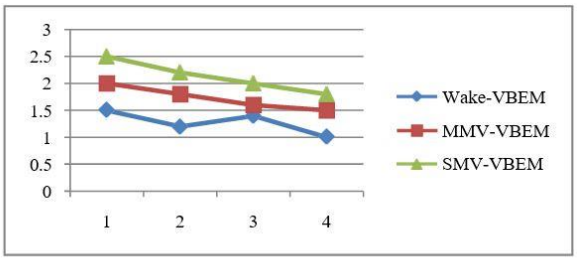

Figure 7 The impact of noise on positioning performance

Conclusion to solve the problem of positioning failure caused by the power change of intelligent interference sources, an energy-saving algorithm Wake- VBEM under the sensor wake-up mechanism is proposed. First, the random wake- up strategy is modeled as the design of the observation matrix under the CS framework. Then, the reference power is introduced. Based on the BCS theory and BCS theory; the positioning problem is modeled as a block sparse reconstruction problem. Finally, a reconstruction algorithm is designed under the VBEM framework, and the reconstruction accuracy is improved by exploring the power variation law of the interference source. Under the condition of unknown and changing source power, multiple interference source positioning can be realized, and the network's effective utilization can be improved simultaneously.

A Research On Use Of Manet For Wireless Device

Sapna K. Titare, Neehal B. Jiwane, Lowlesh N. Yadav,Vijay M. Rakhade

Shri Sai College of Engineering and Technology, Bhadrawati, Maharashtra, India

Abstract – **With the fast improvement of wireless gadgets a MANET got here into existence. A MANET which is also referred to as cellular advert hoc network which connect cellular gadgets wirelessly. it is a self-organizing community which does now not have any framework. consequently it's far self-governing device. each device in MANET is loose to transport in any direction dynamically so that it will proportion information between devices or nodes of network. MANET has no any administrator node which is chargeable for controlling different nodes, each and each node of MANET is behave as router and host itself and shape their own network. diverse routing protocol is chargeable for routing in MANET. This paper introduces, routing protocol, benefits, problems, programs, traits of MANET.**

Keywords: hoc network, , characteristics, challenges, applications

I. INTRODUCTION

Manage the spinned words as you want.. With the speedy boom of era devices of communication has drastic exchange in statistics society. In early era human beings used stressed out devices with the intention to talk with each different. however now because of strengthen era we replaced stressed out gadgets with the wi-fi devices like pc, cellular telephones, Bluetooth and so on. wi-fi network haven't any. of nodes which help in speaking over wireless medium with none centralized gadget. The mobile devices are of two kinds. First category of cell gadgets comes underneath the category which has their specific framework. And the second one does no longer have any framework. as a result, this form of category is known as ad hoc network. wherein each tool is capable of shifting and able to connect dynamically and these networks have now not any proper of access factor which is preset. each and each node is behaving as host or router and might ship information packets to other nodes.The movement of nodes is random, that's why an ad-hoc network works between the taking part nodes, causing random modifications within the network. As MANETs are a class of wi-fi networks, wireless users can form the community dynamically and do no longer want any infrastructural setups . A stressed business enterprise involves base stations, passages, and doorways. distant frameworks are related thru constant switches, middle factors, and switches, though, in an impromptu organization the place of switches, facilities, and switches is probably transportable. At a kingdom of time, the quantity of switches can develop or decrease. Likewise, the publications may also range in an impromptu employer. a versatile impromptu agency (MANET) is a shape far flung particularly appointed organisation that includes an collection of remote devices known as transportable hubs sometimes known as mobiles related by using faraway connections

II. ROUTING PROTOCOL

Protocol is a fixed of rules therefore routing protocol is a hard and fast of rules that's responsible for sending and receiving packets form one host to another. there may be various routing protocol for MANET.

a) Reactive protocol:

Those styles of protocol are labored most effective on every occasion they're inquiring for to do so. this is why those are also referred to as on-demand protocol. And these styles of protocols discover their course on every occasion there may be any order is soliciting for sending or receiving packets and for this reason it much less the overhead of routing desk and it do not any routing inform to shop.

b) Proactive Protocol:

it's miles exceptional from reactive protocol as it retains the routing facts of community. hence, it is also referred to as desk-driven routing it maintains and produce updated the network facts sporadically. however it faces the community in big community due to the fact large community it's far hard to preserve the information of every and every node. This form of protocol has greater overhead as compared to reactive.

c) Hybrid Routing Protocol:

This protocol is intervening between reactive and proactive. It overcomes all the shortcoming of reactive and proactive protocol.

III. Characteristics

a. Autonoums:

Ad hoc network can automatically tie to various nodes so that it will percentage data.

b. No frame work:

NO FRAMEWORK ad hoc network is unfastened from any precise framework. There isn't always any define structure outline for advert hoc community. for this reason it is less luxurious and extra vigorous.

c. Multi Hop Routing:

In advert hoc network every and each node behave as router and host each node behave as router and host itself and it disperse facts among various nodes. because of multi hop facts is broadcast easily

d. Dynamic:

DYNAMIC In advert hoc community every and every tool is impartial of working and transferring dynamically in any route.

e. Scalability of Network:

SCALABILITY OF network: when variety of users extended advert hoc community can work continuously with none stoppage in cutting-edge activity. four. programs .

IV. APPLICATION

i.Military Battle field:

that is most extensively used era used by military squaddies that allows you to store and maintain facts.

ii. Local level:

nearby stage: advert hoc network can robotically join multimedia community to disperse data among various nodes.

iii. Commercial sector:

three commercial quarter: ad hoc community is likewise beneficial in commercial sector for emergency operations like flood, fireplace, catastrophe and many others.

iv. Personal Area network:

non-public region network; With advert hoc network one could easily disperse information among wireless gadgets located in private location network.

v. Data Mining:

nformation MINING: ad hoc network is also beneficial in information mining to acquire knowledge or facts that allows you to find records.

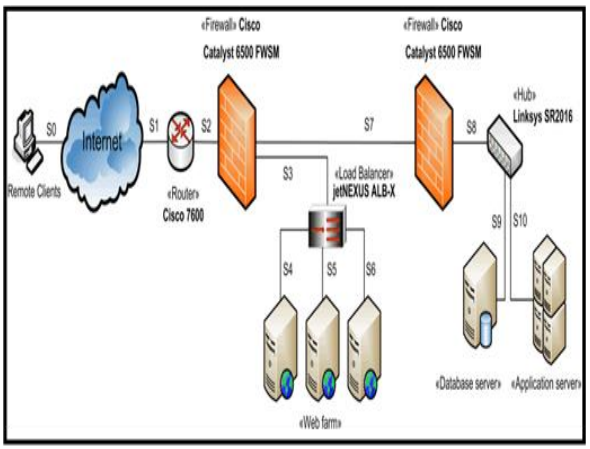

Fig:1 – Application of Network

V. ISSUES IN MANET

Troubles IN MANET As there are many blessings of advert hoc network this is dynamic and automatically connect to cell nodes through wi-fi network and it do not have any infrastructure and centralized node. There are certain problems in advert hoc network.

a) Security

safety: wireless network are much less proper than wired network

b) Routing

Routing is one of the first-rate challenges in MANET because advert hoc network trade network topology constantly some of the node

c) Quality of services

best OF carrier: QOS is likewise a massive defy in MANET is swiftly change it create an difficulty in MANET

d) MultiCasting

MULTICASTING: multicasting is a property wherein statistics is unfold to a collection of vacation spot.

Types of Manet:

MANETs have similarly been divided into 3 different sorts:

A. Vehicular ad-hoc wireless community (VANET) VANET, brief for Vehicular advert-hoc network, is one of the subclasses of MANETs. it's miles a unique class of wi-fi advert-hoc community with high mobility nodes and topology with a faster price of change. VANETs uses moving vehicles as nodes and create a network round them. each car inside the VANETs range will become a node, which in turn allows them to connect with every other ad create a network .

Despite the fact that motors inside a selected variety can create a connection with every different. As motors drop out of the community, due to increasing distance, other cars can be part of in connecting them to every other and making a mobile wi-fi network. those networks do not have infrastructural guide and depend totally on the cars to create a community and offer a network's functionalities

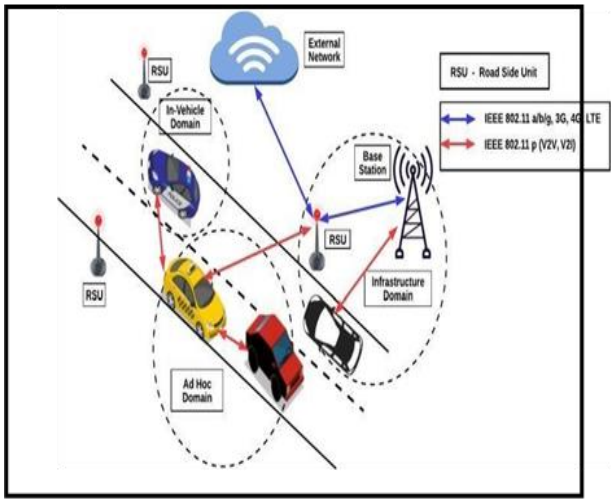

Fig:2 : Vehicular AD-HOC wireless network

B. Net-based cell advert-hoc community (IMANET)

MANETs linking mobile nodes with net-gateway nodes are referred to as net- primarily based cell ad-hoc

Networks (IMANET). With this type of community, regular routing algorithms do now not practice directly. As MANETS do not need any infrastructural support to function, these kind of networks work quality in which no fixed infrastructure exists. Hussain et al. (2020), UW magazine of computer technology.

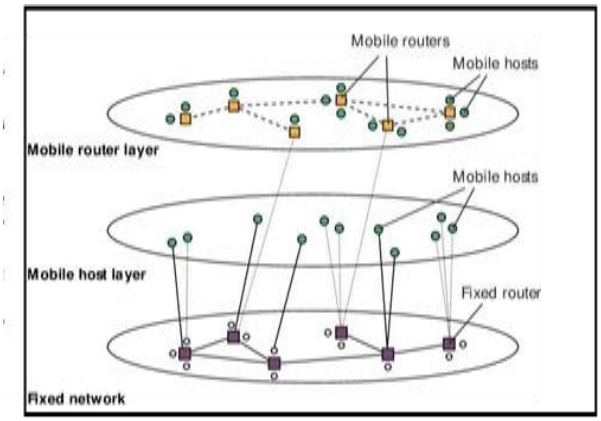

Fig:3: Internet based mobile Ad-Hoc Networks

C. clever Vehicular advert-hoc community (InVANET)

Artificial intelligence designed to prevent any kind of injuries of vehicles for diverse motives including drunken using, collisions, and so on. is referred to as clever Vehicular advert-hoc network (InVANET). Many advert-hoc networking technology combine VANET for handy, precise, and effective communique between vehicles. InVANET allows in defining safety measures in motors and also for better conversation among automobiles.

VI. METHODOLOGY

There are exceptional methodologies to design and classify routing protocols for MANET. for instance, changing of routing information, when and the way it exchanges and the way these routes are computed? some class of MANET protocols is listed underneath:

pro-active (desk pushed) Routing

This routing protocol maintains a listing of destinations and routes by way of dispensing routing tables everywhere in the community. There are some disadvantages of using this protocol the principle one is that those protocols require information maintenance and are gradual while reacting on restructuring. The maximum commonplace protocols underneath this are:

- Dynamic vacation spot-Sequenced Distance-Vector Routing Protocol (DSDV)
- wireless Routing Protocol (WRP)
- Fisheye country Routing

Reactive (On-demand) Routing

In these protocols, routes are observed on demand which is achieved by means of flooding the consecutive requests of packets. The disadvantage of these algorithms is that high latency time in locating routes and an excessive amount of flooding of the network can result in a clog in the network. it's also called on-call for routing. the primary Protocols are:

- Dynamic source Routing Protocol (DSRP)
- advert-Hoc On-call for Distance Vector Routing Protocols (AODV)
- Temporally Ordered Routing set of rules (TORA)

VII. Acknowledgement

I would like to expand gratitude to project guide Prof. Vijay.M.Rakhde who guided by providing the valuable suggestion in numerous way on this project which gave us the inspiration to improve our self independency. Secondly I would like to express my gratitude toward the project mentor Prof. B.Deharkar who help in finalizing the work done within the limited time period, I would also like to express heartfelt thanks to Head Of Department Lovelesh Yadav who has given us a platform where we can work on developing the projects and demonstrate the practical applications.

VIII. Conclusion

This paper offers review approximately cellular ad hoc community which is largely a community which does no longer have any framework and it's miles self-organizing. This paper efficiently explains the characteristics, issues and demanding situations, packages, routing protocol. MANET may be very boost and essential generation in nowadays's existence. we will easily speak with one another while not having stressed devices and irrespective of where they may be placed. however due to open nature of MANET there are also a few protection problems and attacks are possible in MANET. numerous assaults like denial of service, replay, Trojan house etc.

Cloud Computing and Cloud Computing Technologies: A-Review

Pooja Raju Katore , Ashish B. Deharkar, Neehal B. Jiwane Vijay M. Rakhade ,Lawlesh N. Yadav

Shri Sai College of Engineering & Technology, Bhadrawati, India

Abstract – **Cloud computing play a big role in today business environment. It provides on-demand services via the internet, to computing resources applications, servers data storage, development tools, networking capabilities, and more hosted at a remote data center managed by a cloud services provider. The cloud services provider makes these resources available for a monthly subscription fee or bills them according to usage.. Here we give what really cloud computing is and it's various computing technologies and their characteristics**

Keywords: Cloud computing, cloud services provider, Architecture, computing technologies, characteristics

I. INTRODUCTION

Cloud computing defines using resources remotely rather than locally. Today cloud computing play an important role in business applications. Cloud computing remove the headaches of managing hardware and software for the users, it is the responsibility of cloud provider for managing all these. Cloud computing is an internet based computing where different services are provided to customers with the help of internet.

The two most important component of cloud architecture is the front end and the back end. The front end is the computer user and the application that is used to access the cloud via a user interface such as web browser. The back end is the cloud itself that include servers and cloud storage devices.

II. CLOUD COMPUTING TECHNOLOGIES

A. Client-Server Computing

In client-server computing the system is parts into two entities. The First one is the server that gives resources or services and second one is the client that uses the resources or services provided by the server.

In this computing client sends request to the server through computer network. The server assign resources with the client but client do not share any of its resources. e.g. E-mail and World Wide Web.

The various characteristics of client-server computing are:-

- Client-Server Computing uses local processing power-the power of desktop platform. It changes the way enterprise accesses and uses data. In this loom, there is no restriction on data access i.e. all company staff can access data and they are also involved in various decision making process.
- Client-Server computing is open systems. It means you can configure your systems that include software or hardware from various vendors as long as they follow a common standard. Due to this feature company can make systems that include cost effective software and hardware to accomplish a particular task.
- Client-Server computing using the concept of modularity in which we combine software and hardware of different features together as a whole. These software and hardware components are actually modular in nature. Modularity allows the system to expand and modernize to meet requirements and needs as the company grows.

B. Cluster Computing

A cluster computing is a type of computing in which group of computers are linked together to perform various tasks so that user of the system thinks that it can work on single system. Cluster computing take an advantage of parallel or distributed computer system for linking of two or more computers into the network.

The various characteristics of cluster computing are:

- The processing power of cluster computer is same as a mainframe computer.
- Cluster computing has typically low cost, high bandwidth and low latency.
- Parallel applications designed to run on it.
- Gives the impression of a single powerful computer
- Generally cost effective compared to single computers of comparable speed and availability
- Deployed to improve performance and availability over that of a single computer

C. Peer-to-Peer Computing

A peer-to-peer (P2P) computing is a distributed type of computing in which each computer is connected to other computer in the network. The computer in the network can act as both client and server for the other computers in the network, allowing shared access to various resources such as files, peripherals, and sensors without the need for a central server. Each peer called computer in the network makes their resources available to other peers in the network without the need of centralized control.

The various characteristics of Peer-to-peer computing are:

- No centralized control.
- Clients are also servers and routers.
- Nodes contribute content, storage, memory, CPU.
- Nodes are autonomous.
- Ad-hoc Nature.

- Limited Capacity and Reliability of Peers.
- Scalability

D. Ubiquitous Computing

Ubiquitous computing also known as pervasive computing is an advanced computing concept where computing is made to appear everywhere and anywhere. Ubiquitous computing can occur using any device, in any location, and in any format. Pervasive computing makes devices smart by using sensor network.

The various characteristics of Peer-to-peer computing are:

- Permanency: The information always remains their and can only be removed if the learners want to remove it.
- Accessibility: The information is always available whenever the learners need to use it.
- Immediacy: The information can be retrieved immediately by the learners.
- Invisibility: Computing can be performed by Invisible Intelligent Devices - Wearable Computing Devices.
- Adaptation: Adapting to Device Type, Time, Location, Temperature, Weather, etc.

E. Grid Computing

Grid computing is types of distributed computing in which the resources of different computers in the network are used to solve a big task that require large number of CPU cycle and huge amount of data [3]. Grid computing is a computer network in which each computer's resources like processing power, memory and data storage are shared with every other computer in the system. O grid computing turn a computer network into a powerful supercomputer.

Grids provide protocols and services at five different layers as shown in Fig 5.

- Fabric layer: - It deal with resource management. The different resources in this layer are computer, storage system and networks, code repository, etc.
- Connectivity layer: - The connectivity layer deal with security i.e. it defines communication and authentication protocols for secure network transactions.
- Resource layer: - It provides access to resources by defining different protocols for monitoring, accounting and payment of sharing operations on individual resources.
- Collective layer: - It controls the interaction between different types of resources.
- Application layer: - Application layer rely on lower layers for grid to run which comprises user applications that operate within virtual organization Environments.

The various characteristics of Grid computing are:-

- Large scale: The resources in the grid range from few to millions.
- Geographical distribution: The resources in the grid may be located at distant places.
- Resource sharing: The shareable resources in a grid belong to many different organizations.
- Multiple administrations: In grid resources are shared from different organization. Each organization maintains their own security and administrative policies for their owned resources which result in challenging security problem for different policies.
- Resource coordination: In a grid resources must be coordinated.
- Grid cannot be built by one or by a single resource. One can be a part of grid.

III. CONCLUSION

Cloud computing is a new technology in today's environment Cloud is widely used in today's business environment. This paper discussed what actually cloud computing is and different cloud computing technologies with their characteristics. In spite of various challenges like performance, security cloud computing gaining more importance especially in enterprises.

Future Farms - Small & Smart: A Review

Anam Khan
Thakur College of Engineering & Technology Mumbai, India
anam.khan@tcetmumbai.in

***Abstract*— Agriculture being backbone of any country nearly about 60 of our country's population works in husbandry or the primary sector. It contributes further to our country's GDP. It employs the maturity of India's population. The internet of things exploration presents a frame in which growers may gain expansive information on the soil, crops growing in specific areas, and agrarian yield and productivity. By exercising resource optimization and smart planning, this technology- grounded agricultural practices will help growers in making wise agrarian opinions. The development of IOT grounded intelligent Smart Farming using smart bias is changing the agricultural product by not only adding the quality and yield but also to make farming cost effective. These practices of smart agriculture is to get live data like temperature, soil humidity and moisture to cover the girding terrain. All of this is fulfilled with the use of temperature, moisture, and humidity detectors. This paper briefly studies the need, advancement and compass of smart agrarian practices.**

Keywords— Drones, Organic Cultivation, Cloud Storage, Precision Agriculture, Robots.

I. INTRODUCTION

The agriculture sector forms only about 18 percent of India's GDP despite employing nearly 65 percent of the total pool. Despite significant enhancement in food grain product, there are several challenges to attack as the government aims to increase agrarian product as a share of GDP. Farming in India is largely dependent on nature, but climate and global warming issues make tilling changeable. The need of the hour is to educate growers in the use of ultramodern technology and innovative approaches to increase productivity and raise profitability. Natural imbalance is visible in pollution, soil declination, wildlife population decline, and a mortal- created differences of foliage and fauna.

It's reasonable to assume that mortal population growth will continue and place lesser demands on the Agri- ecosystem. therefore, technology has and will continue to play a major part in Farming and sustainable development going forward.

Technology has a major part in agriculture and agricultural practices; and with the arrival of digital technology, the compass has widened.

Innovation in agriculture is leading an elaboration in agrarian practices, thereby reducing losses and adding effectiveness.

Use of digital and logical tools is driving nonstop enhancement in farming, and the trend is then to stay, performing in perfecting crop yields and helping to increase the income of the agro community. This is

Figure 1: Digitalized farming

appreciatively impacting growers. Experimenters and masterminds around the globe are proposing different styles and infrastructures and grounded on that suggestinga variety of outfit to cover and cost the information regarding crop status during different stages, considering multitudinous crop and field types. Fastening on the request demand, numerous leading manufactures are furnishing a range of detectors, unmanned upstanding vehicles(UAVs), robots, communication bias, and other heavy ministry to deliver the tasted data. In addition, colorful commissions, food and agriculture associations, and government bodies are developing polices and guidelines to observe and regulate the use of these technologies in order to maintain food and terrain safety.

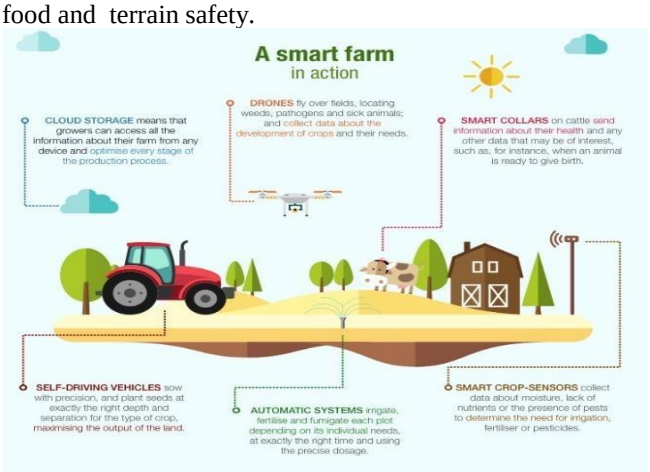

Figure 2: Future farms and work process

II. LITERATURE SURVEY

This research article provides a complete insight of internet of things on building the applications of precision agriculture. Various cost effective[1] smart technological adaptations in the agriculture sector are analyzed towards the upgradation of the traditional approach and the lifestyle of the farmers. Major agriculture applications like environment and soil monitoring, smart irrigation system, utilization of intelligent drones in the agriculture field, smart robot integration for various automated works in agriculture field are also discussed in this research article. It highlighted the advantages and limitations of an IoT based smart precision agriculture that can be further enhanced by researchers in the future.

Drones, also called Unmanned Aerial Vehicles(UAV), have witnessed a remarkable development in recent decades. In agriculture, they've changed agricultural practices by offering growers substantial cost savings, increased functional effectiveness[2], and better profitability. Over the once decades, the content of agrarian drones has attracted remarkable academic attention. We thus conduct a comprehensive review grounded on bibliometrics to epitomize and structure being academic literature and reveal current exploration trends and hotspots.

We apply bibliometric ways and dissect the literature girding agrarian drones to epitomize and assess former exploration. Our analysis indicates that remote seeing, perfection husbandry, deep literacy, machine literacy, and the Internet of effects are critical motifs related to agrarian drones. Theco-citation analysis reveals six broad exploration clusters in the literature. This study is one of the first attempts to epitomize drone exploration in agriculture and suggest unborn exploration directions.

This paper is considering all the aspects and highlighted the role of various technologies, especially IoT, in order to make the agriculture smarter and more efficient to meet future expectations. For this purpose, wireless sensors, UAVs, Cloud-computing, communication technologies are discussed thoroughly. Furthermore, a detailed study on recent research efforts is provided. In addition, various IoT-based architectures and platforms are provided with respect to agriculture applications. A summary[3] of current challenges facing the industry and future expectations are listed to provide guidance to researchers and engineers.

On the basis of all these facts, it can be concluded that every inch of land that is used for farming is vital to maximize crop production. And hence , to utilize the farmland effectively, the use of sustainable IoT-based sensors and communication technologies is not optional—it is necessary.

In Africa most of the farm houses are using a steady sub-division of their land for farming that draws the attention towards small-scale farming. Small-scale farmers[4] are poised to be significant economic drivers in developing countries in Africa. Hence, it clearly indicates the potential in smart farming applications. This research is aimed to provide appropriate farming practices information through co-designing an Agricultural Management Application that would maximize small-scale farmer's crop production. Reviewing relevant literature and applying an experimental design approach, an Agricultural Management Application was developed in this research. The results of the study proved satisfactory as the application developed was found useful and informative by local farmers. Because only a few crops are listed on the application currently in use, it is further recommended that more crops can be added to this mobile application. This will help farmers to expand their scope of participation and the use of the application.

Food security is in threat because of population growth and traditional agriculture is no longer adequate. Agriculture being one of the main foundations of a developed economy today. In recent years, agriculture sector is revolutionized and automatized. The precision agriculture is most advanced aspect of automation of agriculture. It has become essential due to the potentials and applications Including smart irrigation, agricultural robotics, remote sensing, and mapping. Agricultural robotics has made farming easier and more efficient and has come to the aid of farmers.

Usage of drones in smart farming[5]not only makes farming more accurate but also can help people farm smarter. Amongst all the drones in agricultural drones, the performance of spraying drones is very impressive and reliable. In this paper , the pros and cons of the spraying drone will be investigated. They are fast and use a low amount of water and have a few more advantages. There are a few drawbacks like battery efficiency. It can be concluded that spraying drones are a good solution to spray the crop fields.

III. TECHNIQUES USED IN SMART FARMING

Precision farming: It is a technique where inputs are utilized in precise amounts to get increased average yields, on the basis of traditional cultivation techniques. Small field size is one of the major problems in India. In the country More than 58 per cent of operational holdings have a size of less than one hectare (ha).

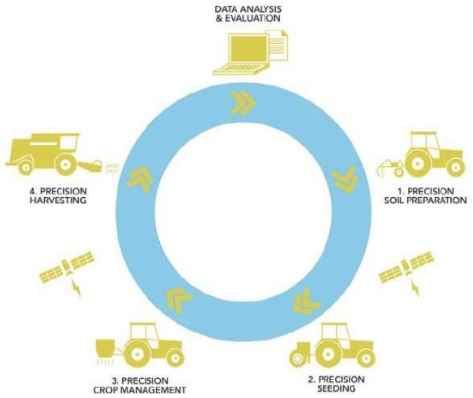

Figure 3[6]: Steps in Precision Agriculture

Precision agriculture involves the following four basic processes to effectively monitor, tracking the growth of

crop as well as the environment in nurturing the quality crop from the seeding stage onwards.

1. Environment and soil fertility monitoring
2. Effective smart irrigation
3. Smart drones for field monitoring
4. Utilization of robots in farming field

Drone in Agriculture: Drones are completely changing the whole process of cultivation and harvesting around the world. According to Industry estimates the use of drones could increase crops yields by 15 to 20 per cent. 100 Kisan Drones in different cities to spray pesticides on farmsacross India has already flagged off by the government.

Drones are part of day today life on many farms. They also make agricultural sustainable – and as an added bonus, they are helping to save deer as well along with overflying fields and monitoring crops. Every year, when fields are mowed and end up caught in the machinery countless young deer are overlooked. Drones help prevent this by spotting the animals from the air before beginning of the work.

Digital Agriculture: Use of digital technology to integrate agro-production from the paddock to the consumer. These techniques can provide the agricultural industry with tools and related information to make more informed decisions and improve productivity.

Farmers will be behaving more smartly with smart devices in their hands and would be able to be more aware and connected with different stakeholders.

Figure 4: Statistics of smart systems utilization across globe

Using smart farming applications, it provides a way for farmers to monitor their crops and animals via their smartphone. Depending on the software, statistics can also be looked upon.

Automation in Agriculture: Latest farming tools and automation in agriculture will smooth the production cycle and make it more efficient.

The mechanization of farms is an approach that has provided great benefits to farmers across the world and the same will be true for India.

In major commercial crop and animal value chains, autonomous and semi-autonomous farm robots will substitute labour intensive human tasks and drudgery.

Figure 5: Statistics of smart systems utilization across globe

Organic Farming will Prosper: In the coming decade, organic agriculture will prosper in India and will contribute to feeding 1.6 billion people.

Agriculture must have sustainable intensity and diversity, giving priority to organic farming, to sustain growing demand and supply . High consumption of high-value food and cash crops, and demand for bio-energy will create a favorable business environment by activating policies for high-value organic agriculture.

In the organic farming practices, a major breakthrough is required. Use of pesticide and modern fertilizer are bringing various health hazards. Plant and food quality is being in a state of degradation day by day. Personal or home farming practices are to be promoted and supported in various manners.

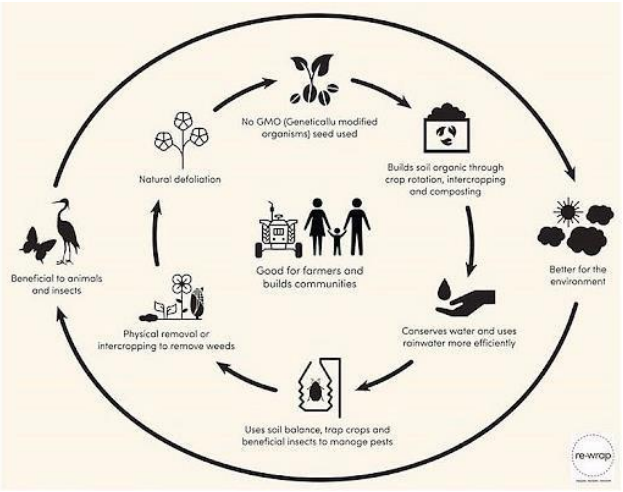

Figure 6: Working of Organic Farming

Hydroponics and aquaponics systems are pointing to success of the technology adoption in the organic farming culture. Possibilities in assisted large farmlands also need to be confronted through agricultural technologies. World watch institute, a global environmental institution explains prominent agricultural researchers, experts and scientists believe in the organic farming in near future still has the potency to feed the whole world. Smart farm lands and organic indoor farms have lot to do and succeed to every corner of the world.

IV. RECENT TRENDS

Block chain and the IoT:

Industry experts are certain that intelligent agricultural technologies is going to play an important role in near future, particularly the Internet of Things (IoT).

The ability of machines of communicating with each other is a must for cases such as precision farming – the precise cultivation of arable land – and smart greenhouses, because that is the only way to use collected data on climatic conditions, soil properties, etc. in order to make sure the ideal environment for the plants being grown and cultivated.

For example, If the plants are too dry specific sensors in the greenhouse detect them and they can notify the watering system immediately, which then gives water to the plants.

However, many smart farming models draw on the interaction between the Internet of Things and blockchain technologies, apart from solely relying on IoT.

These eventually creates a secure environment for storing and processing data, which actually makes it easier for farmers to use data-driven innovations in smart farming. The sensors built using IoT in an intelligent greenhouse can then operate as a private local blockchain, for example, which can be controlled centrally by its owner.

Indoors Organic Farm Systems:

Modern indoor farms are soilless and hydroponic or aeroponics. Aeroponics use nutrient rich mist as the growing medium. These farms are generally vertical farms. Vertical farm cultivates tray of setups arranged one over the other in vertical manner utilizing the indoor space to its maximum with minimum effort of arranging the growing systems.

World's largest indoor farm is a vertical indoor farm in New Jersey. These indoor farms apparently have 1 acre space for cultivation.

The System Includes[7]:-

Light weight cloth or clay pellet hydroponic/aeroponic grow medium trays.

LED lightings over each tray and programmable logic controls for lighting time, wavelength and amount of light.

Figure 7: Setup for Indoor Organic Farm

Tray sensors are used for measuring O2 and CO2 levels, nutrients like nitrogen, potassium and phosphorus, temperature and humidity. Grow medium helps in providing nutrient to water or air recycling and distribution systems.

V. CONCLUSION

As a result of growing population, growing average income and globalisation effects in India demand for volume, quality and nutritional food, and variety of food has also increased. Hence, pressure on dwindling available cultivable land to produce further volume, variety and quality of food will keep on adding.

Although the constraints in agriculture make the productivity and return complex but still a high untapped eventuality is there in India's farming sector. sweats are being made to convert all the challenges in husbandry into openings and this process is the future of husbandry.

While prognostications can exfoliate light on the future, we're still not there. A whole new generation of farmers, who aren't yet born, will be tilling mid-century, and much will be between now and also that we cannot prognosticate. But if the history and present are a indication to the future, Indian farmers will continue to seek better ways to produce crops by embracing invention. Issues similar as social-equity, gender- equivalency, and environmental justice will remain the critical pillars of agrarian and societal progress, and India must make giant hops in the coming times.

Abstract – **Point cloud data, which retains more 3D spatial geometric information, has emerged as one of the core data formats for describing 3D models with the rapid growth of 3D acquisition technologies. However, the majority of deep learning network topologies used in 3D point cloud model segmentation studies rely on expensive labelled high-quality training data. A weakly supervised learning-based method for collaborative and consistent segmentation of 3D point cloud model clusters is presented to address the issue of using training samples with a small number of labeled points to achieve collaborative segmentation of 3D model clusters. Initially, the K-nearest neighbor technique is used to create the local neighborhood graph between the points. The point cloud model's component features are then extracted using the local convolution approach, and a matrix of related components is created. The network weights are then refined using energy function back propagation to produce results for model cluster consistency segmentation. The experimental findings indicate that the algorithm's segmentation accuracy on the public dataset ShapeNet Parts is 85.0%. Furthermore, when the number of training sample labels is lowered to 10%, this algorithm can still yield segmentation results comparable to or superior to those of supervised learning approaches. In addition, segmentation accuracy is considerably enhanced compared to current weakly supervised mainstream techniques.**

Keywords: **Machine Learning, Cloud computing, Clustering, Segmentation, Supervised Learning, K-nearest neighbour;**

I. INTRODUCTION

Three-dimensional models become a new generation of digital multimedia after audio data, two- dimensional images and videos. Compared with traditional multimedia data, 3D models have attracted extensive attention from industry and academia because of their strong sense of reality, which is more in line with people's intuitive understanding of nature. With the wide application of technologies such as information technology industry, data-driven and deep learning in computer vision and computer graphics, 3D model segmentation has made remarkable progress. The segmentation of 3D models is a basic problem in the field of 3D model analysis. It divides the 3D model into several meaningful, connected and independent semantic components according to the geometric and topological characteristics of the 3D model [1] to help The understanding and analysis of 3D models is the research field of computer graphics important question to study.

The widespread use of laser scanning and other 3D sensing technologies in recent years has led to the development of 3D point clouds, which are now the standard format for representing 3D geometric data [2] and are being used extensively in a variety of industries, including autonomous vehicles, virtual reality, 3D city modeling, and more. Some deep learning methods have begun to try to analyze and process point cloud data. Literature [3] proposes that the PointCNN network model can directly apply the convolutional neural network structure to unordered point cloud data, avoiding the change of features with the order of input points, and enhancing the network's ability to process the model. Literature [4] proposed a deep learning network framework PointNet that can directly classify and segment point clouds. Considering the sparsity of the point cloud, the point cloud is not converted into multi-view or voxel grid, so that more 3D feature information can be preserved and better segmentation results are achieved. Literature [5] proposes a multi-feature fusion 3D point cloud model segmentation method, which learns the implicit relationship between global single-point features and local geometric features by constructing an attention fusion layer to fully mine the fine-grained geometric features of the model to obtain better model segmentation results. At present, most of the 3D point cloud model segmentation methods based on deep learning rely on labeled training data set, which limits the promotion of such methods.

Literature [6] learns the potential common features of the model from the labeled data set, so as to perform the collaborative analysis of the model. Therefore, if the number of labeled data sets is large enough, supervised algorithms can achieve ideal segmentation results. However, obtaining high-quality labeled data is time-consuming and expensive. On the contrary, the literature [7] proposes an unsupervised co-segmentation method to segment the input model into patches, and then classify similar patches by subspace clustering. Although unsupervised 3D model segmentation algorithms can utilize unlabeled data to achieve collaborative segmentation of 3D models, this segmentation algorithm comes at the cost of reducing the segmentation accuracy. Combined with the characteristics of point cloud data, this paper proposes a weakly supervised learning clusters based model for segmentation of 3D point cloud. In the feature extraction process, the use of local convolution operations can better correlate feature information between points and improve the network's ability to identify and segment point cloud models. Since similar models have similar feature information, similar component features can be represented by similar component matrices. When the network is learning, multiple models of the same type can be learned

collaboratively. In addition, the deep learning network is guided by the energy function, and the network parameters are optimized through backpropagation, so as to achieve consistent segmentation of point cloud model clusters. The main innovations and contributions of the algorithm are: (1) The neighborhood of the subset is chosen in the sampled point set before sampling, and the information of the discarded point can be incorporated into the related point to make up for the sampling loss.

In the neighborhood of , the feature information of more points is retained while reducing the computational complexity of the network. (2) Using the weakly supervised learning method for 3D point cloud model segmentation can reduce the dependence on high- quality labeled data sets in the network training phase. This method only needs to mark a small number of points in the training phase to achieve and supervise methods comparable to segmentation results.

1.2 3D Point Cloud Model Segmentation and Feature Extraction

The 3D point cloud model is composed of a series of point sets with geometric information. The essence of its segmentation is to classify the point sets point by point, aiming to classify the points of the same category into the corresponding parts to obtain the model segmentation results. Therefore, this paper proposes to use the local convolution method and construct a local neighborhood map to solve the above problems, and use a small amount of labeled data for training through the weak supervision method, which improves the universality and segmentation effect of the network architecture.

1.2.1 Construct the local neighborhood map of the point cloud model

The 3D point cloud model is a collection of 3D coordinate information of a group of unordered points. However, each point does not exist independently, and there is similar geometric information between adjacent points. Therefore, establishing the correlation between points can be more accurate. To characterize the local feature information of the 3D model well, Figure 1 shows the construction process of the neighborhood graph of the point. Define a point set as

$\{pi = xi, yi, zi)|i = 1,2, \dots, n\}$, where pi is any point in the point cloud, represented by the coordinates (xi, yi, zi) corresponding to the point , with pi as the center point, use the Knearest neighbor (KNN) method to establish a local directed graph G, which is composed of a vertex set V and an edge set E, defined as follows:

$$\begin{cases} G = (VE) \\ V = \{P_i|1,2,\cdots,n\} \\ E = \{e_i = (e_{i1}, e_{i2}, \dots, e_{ik})|i = 1,2,\cdots,n\} \\ e_{ij} = p_{ij} - p_i \end{cases} \quad \dots\dots\dots(1)$$

In the formula, ei is the ith directed edge set, and eij represents the directed edge from the adjacent point pij to the central point pi.

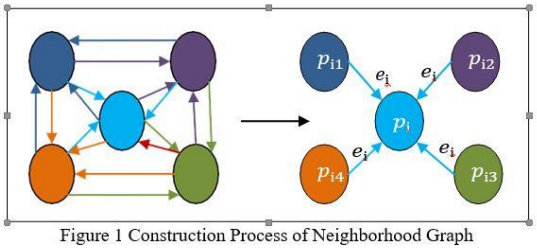

Figure 1 Construction Process of Neighborhood Graph

1.2.2 Local convolution operation to extract features

The local convolution operation is used to extract the features of the center point and the edge vectors between the center point and the K nearest neighbor points. Since the point cloud model is a set of unordered point sets, the maximum pooling operation is adopted. This method is not affected by the order of neighboring points and can extract the most important features of all edge vectors. Define the same feature extraction function fe for all points, then input a local neighborhood map whose center point is pi to get the output local feature li, the formula is as follows:

$$li = fe(G(pi, ei)) = \max\{h(pi, ei1), h(pi, ei2), \cdots, h(pi, eik)\} \dots (2)$$

Where $h(pi, eij)$ is the hidden feature vector between the center point pi and an edge vector eij. The output local feature li takes the maximum value { } of the hidden feature vector.

For the segmentation task, it is necessary to concatenate the global features and the extracted local features point by point, and use a neural network to output a prediction score for each point. The local convolution operation method is represented in the Eqn. (3).

$$p'i = h(pi, eij) = h(pi, ei1) \quad h(pi, ei2) \quad \cdots \quad h(pi, eik) \dots\dots(3)$$

In the formula, $p'i$ represents the updated point feature, which associates the own feature of each point with the corresponding neighbor point, and □ represents as pooling operation or summation. In summary, local convolution creates a new set of points with new dimensional characteristics linked to the local features by first applying a multi-layer perceptron to each point and its accompanying neighbourhood to record a local receptive field. The local convolution process is shown in Figure 2.

The local convolution operation mainly generates the edge features, which are used to represent the mapping between each point and its neighbors. This convolution method has two advantages: (1) KNN Graph can better extract point local information while maintaining the invariance of the arrangement, and improve the segmentation effect of the point cloud model;

(2) after multi-layer iteration it is then able to better capture potentially distant similar features.

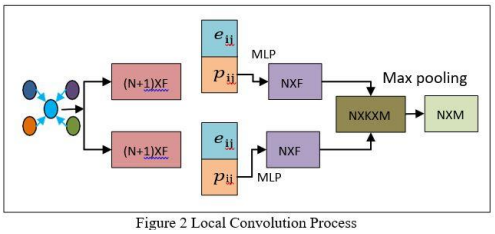

Figure 2 Local Convolution Process

1.3 Experimental results and analysis

The experimental are performed in the Intel Core i9 9900k CPU and NVIDIA Rtx 2080Ti GPU (11 GB video memory) processor, with CUDA 9.0, the GPU accelerated library is cudnn 7.0. To implemented proposed deep learning model the Keras and Tensorflow framework have been used.

a. Data Set

In order to compare with other algorithms, this paper uses the ShapeNetParts [27] dataset, which contains 16881 3D models, 16 categories, and a total of 50 labeled parts. Most models are labeled with 2 to 5 Parts, and labels are annotated on the sampling points of the 3D model.

b. Parameter Setting and Performance Evaluation

To improve the segmentation performance of the model, 2048 points are uniformly sampled from the model surface for training and testing experiments. In the experiment, adaptive moment estimation (Adam) is used to optimize the neural network model. The initial learning rate is set to 0.003. Momentum is set to 0.8 to prevent the network from falling into local optimum when updating parameters. In order to prevent inconsistent data distribution in the middle layer of the network during training, a batch normalization layer (batch normalization) is inserted before each input layer of the network, and the exponential decay coefficient of batch normalization is set to 0.5, so that the loss function can be quickly convergence. In this experiment, when the batch size is set to 32, the impact on the gradient of the network is minimal.

c.Evaluation Criteria

The intersection over union (IoU) on the point set is the metric that is used to evaluate how accurately the 3D point cloud model segments data. IoU is mainly used to compute the ratio between the intersection and union of two data point sets: true segmentation and predicted segmentation by model. The IOU formula is as follows:

$$IoU = \frac{TP}{T + P - TP} \quad \ldots\ldots\ldots (8)$$

In the formula, TP represents the true sample size; T represents the real true sample size; P

represents the predicted true sample size.It is required to incorporate the mean intersection over union (mIoU) for measurement after getting the IoU value for each type of model in order to assess the segmentation effect of the network on the entire model cluster. The formula is as follows:

$$mIoU = \frac{1}{m}\sum_{i=0}^{m}\frac{TP}{T + \sum_{i=0}^{m}(P - TP)} \quad \ldots\ldots\ldots (9)$$

In the formula, m represents the number of categories of the 3D model, and the larger the value of mIoU, the closer the real value is to the test value, so that the effect of model segmentation is better. In the ShapeNet Parts data set, since the number of models of different categories is different, it is necessary to continue to evaluate the segmentation accuracy from a quantitative perspective, so the part averagedIoU (pIoU) is introduced for further comparison. The formula is as follows:

$$pIoU = \frac{1}{\sum_{i=0}^{m}\sum_{i=0}^{m}TP} \times \sum_{i=0}^{m}\frac{TP\sum_{i=0}^{m}T}{\sum_{i=0}^{m}T + \sum_{i=0}^{m}(P - TP)} \quad \ldots\ldots\ldots (10)$$

This formula represents the weighted summation of the IoU of each class according to the frequency of each type of model. In this experiment, the frequency is the number of each type of model. The higher the pIoU value, the higher the segmentation accuracy.

d. Analysis of Results

The collaborative segmentation effect of the algorithm on the 3D point cloud model cluster is as follows: Where point clouds of different colors represent different model segmentation parts. It can be seen that the colors of the same parts corresponding to each type of model are consistent, which better reflects the consistency of the collaborative segmentation of the 3D model clusters. Table 1 and figure 3 shows the comparison of the algorithm in this paper with the algorithms in literature [4], literature [21,23], literature [26] and literature [28] on the ShapeNet dataset. The algorithm in this paper adopts a weak supervision strategy, and establishes a local neighborhood map of points through the KNN method to better correlate information between sampling points. When only one point is marked for each component in the model, it can already obtain competitive As a result, when 10% of the points are marked, the mIoU value increases by 0.012 and the pIoU value increases by 0.014 compared with the algorithm in [4]. In addition, the algorithm in this paper uses an energy function back propagation iteration to generate the consistent segmentation results of the model. Compared with the recursive proximity search strategy adopted in the literature [28], the mIoU value is increased by 0.042, and the pIoU value is increased by 0.027. Since the algorithm in this paper adopts a weakly supervised learning strategy and experiments with a small amount of labeled data, the segmentation accuracy is slightly lower than the methods in [21] and [26]. However, compared with the weak supervision strategy adopted in literature [22] and literature [23], the mIoU value increased by 0.007 and 0.017, and the pIoU value increased by 0.001 and 0.004, respectively.

Table 1 Comparison of segmentation performance with existing method

Algorithm	mIU	pIoU
PointNet	82.5	85.4
PointNet++	83.7	87.3
DGCNN	84.4	87.6
KD-Net	79.3	84.8
Capsule-Net	82.7	86.3
BAE-NET	80.8	86.2
Our Algorith (1 Point)	76.7	77.2
Our Algorithm (10% Points)	83.5	87.2

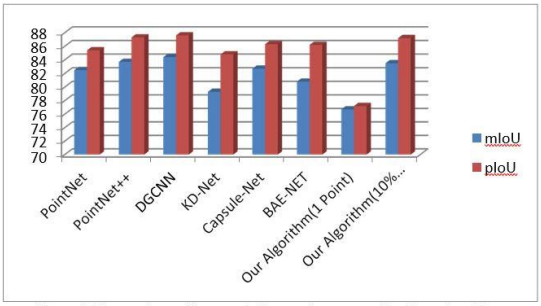

Figure 3 Comparison of segmentation performance of various algorithm

This study further compares the segmentation performance in terms of mIoU and pIoU of various algorithms. Literature [4], Literature [21], Literature [26] and Literature [28] all adopt the supervised strategy, while the literature [22], Literature [23] and the algorithm in this paper adopt the weak supervision strategy. When each part of the model is when marking a sampling point, compared with the supervised strategy in [28], the weak supervision strategy in this paper has a certain improvement in the segmentation accuracy of some models, among which the accuracy of the hat model (cap) and the cup model (mug) are respectively improved. 0.049 and 0.036. When the marked sampling points in the training samples are increased to 10%, the segmentation accuracy of various models is comparable to the segmentation results of the supervised strategy in the comparative literature, and the segmentation effect of some models is even better than the supervised learning method. Compared with literature [28], the segmentation accuracy of the car model (car) and the rocket model (rocket) has improved most significantly, increasing by 0.075 and 0.101, respectively. Literature [26] uses the edge

convolution method to correlate the features between point cloud model points. When segmenting a model with a large number of training samples, the segmentation result is better than other algorithms, such as airplane model (airplane), chair model (chair) and Guitar model (guitar). Compared with literature [26], the segmentation accuracy of the algorithm in this paper is reduced by 0.005, 0.011 and 0.006 in the three types of models of airplane (airplane), chair (chair) and guitar (guitar), but in the car model (car), knife model (knife model).), the rocket model (rocket) and the table model (table) have higher segmentation accuracy than the literature [26] algorithm by 0.007, 0.003, 0.022 and 0.009, respectively. Literature [22] uses the attention mechanism driven by dynamic routing to effectively extract local feature information, so that it has a high segmentation accuracy for small parts of the model. For example, the segmentation accuracy of the motorcycle model motorbike is 0.044 higher than that of the algorithm in this paper. Literature [23] adopts a branch auto-encoder, and each branch learns a component feature of the input model separately, without model cluster consistency optimization, and the classification accuracy of the model with a small number of input sets is low. For example, the segmentation accuracy of the algorithm in the bag model (bag), earphone model (earphone) and rocket model (rocket) is higher than that of the algorithm in [23] by 0.099, 0.069 and 0.048, respectively. The experimental results show that compared with the supervised algorithm, the weak supervision strategy in this paper can still obtain competitive results when dividing various models when the number of marked points is reduced to 10%. Compared with the weak supervision method using different strategies In contrast, the main advantage of the algorithm in this paper is to constrain the consistency of model segmentation results by constructing component feature matrices, and to achieve label prediction for unlabeled points with a label propagation strategy under weaker supervision, which can complete collaborative segmentation tasks while further improving the segmentation accuracy. Therefore, the advantages of the weak supervision strategy are also reflected in the algorithm of this paper.

The role of each module of this network architecture is very important. In order to better analyze the impact of each module of the network on the results, the segmentation accuracy comparison of the ablation experiment is shown in Table 2. It can be seen that: (1) the local convolution module has the greatest impact on network performance. After removing the local convolution module, the segmentation result mIoU is reduced to 56.3%. After the final after far-point sampling, local convolution can characterize the spatial relationship between each sampling point and its neighbors to make up for the feature information lost in the sampling process. (2) The impact of removing the energy function on the segmentation results is inferior to (1), which proves that this module can effectively implement back propagation learning, and constrain the consistency of the segmentation results with the feature matrix. (3) After replacing the farthest point sampling with random sampling, the segmentation accuracy rate has declined, because this sampling method cannot have a good coverage of the sampling space, which is not conducive to the subsequent extraction of feature information. The results of ablation experiments show that the components of the network constructed in this paper are effective and can complement each other to achieve the best performance.

The three labeling techniques were tested in the experiment to confirm that the weakly supervised sample labeling strategy used by the algorithm in this paper had certain advantages. The comparative findings are

displayed in figure 4 for each labeling strategy. 100% training samples (samples) and the quantity of labeled points (Pts) included in each sample serve to define the labeling approach. The experimental results show that as the marked points of the training samples are reduced from 100% to 10%, the mIoU value of the segmentation result is reduced from 83.93% to 82.98%, and the pIoU value is reduced from 86.80% to 86.18%, which are respectively reduced by 0.49 percentage points and 0.1 points. As a result, it is evident from the experimental findings that the segmentation accuracy of the algorithm in this study does not significantly change when the number of markers is decreased (from 100% to 10%), which effectively verifies that the algorithm in this paper is less dependent on the number of markers. The reduction of marked points has strong robustness and weak supervision, which saves time- consuming and laborious manual marking costs.

Table 2 Verify Effectiveness of Model Components with different ablated experiments

Replace with random sampling	Local Conv	Energy Function	mIoU %
Yes	Yes	Yes	71,2
Yes	Yes	Yes	56.3
Yes	Yes	Yes	67.1
Yes	Yes	Yes	**81.6**

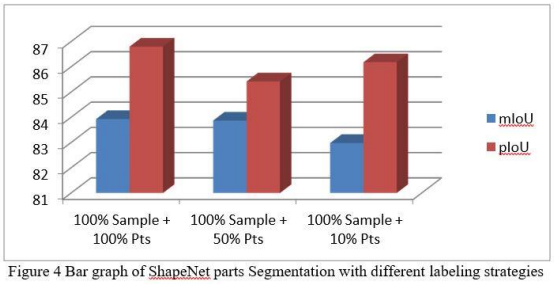

Figure 4 Bar graph of ShapeNet parts Segmentation with different labeling strategies

1.4 Conclusion

This study presented the proposed a co-segmentation model based on weakly supervised learning, aiming for addressing the co-segmentation problem of 3D point cloud models with a small amount of labeled data. First, use the farthest point sampling method to sample the original point cloud, and establish a local neighborhood map of the point through the KNN algorithm to associate the information between points, so as to better characterize the local characteristics of the model. Then, model features are extracted using local convolution methods to generate feature descriptors corresponding to each part of the model. Finally, by constructing the component feature matrix, the consistent segmentation results of the model clusters are obtained through the energy function backpropagation iteration in the deep learning network. Experiments were carried out on the ShapeNet Parts dataset. Compared with supervised methods such as literature [4] and literature [26], the deep learning network proposed in this paper only needs a small number of marked points to effectively achieve point cloud model segmentation. When it is reduced to 10%, the results comparable to the supervised algorithm can be achieved, and compared with the weakly supervised methods in the literature [22] and literature [23], the algorithm in this paper achieves better segmentation under weaker supervision result. However, the algorithm in this paper also has limitations: on the one hand, the algorithm has a clear neighbor relationship for each point in LocalConv, so the network calculation complexity is greater, and the efficiency will decrease when processing large-scale point cloud data; on the other hand, Since the algorithm in this paper adopts a weak supervision strategy, it has obvious advantages in terms of data set requirements, which makes the network

more universal. However, compared with the fully supervised algorithm, the segmentation results of some models have obvious gaps. These are issues that require further research in the future.

Machine Learning Based Detection Of Depression And Anixiety Using Voice Recognition

Pratiksha Deshmukh, Dr.Harshali Patil
Thakur College of Engineering & Technology, Mumbai, India
pratikshajd@gmail.com, harshali.patil@tcetmumbai.in

Abstract – **A more objective assessment is required to assist patients in receiving a speedier and more accurate diagnosis of depression. A significant number of people suffering from depressive illnesses are not diagnosed correctly. Despite the fact that the actual predictive value of speech traits has not been studied, it is clinically simple to collect data on them, and their link with depression has been researched. Hence, it is unknown how much a person's voice traits affect their ability to be diagnosed with depression generally. Every person has anxiety at some point in their lives. The word "anxiety" is frequently used in everyday speech to describe the unpleasant feelings that accompany tension or fear. Computers can prepare data for factual study using machine learning techniques in order to reach a certain range of performances. It encourages the use of computer frameworks to automate decision-making based on data inputs while creating the models for the test data. A paradigm for forecasting anxiety and sadness is presented in this article. This framework receives a set of voice data as input. To remove data noise and make the input data set consistent, this data set has undergone preprocessing. The input data set is then subjected to different machine learning methods such as Nave Bayes, Random Forest, and SVM. Data classification is carried out. The classification results of several methods are compared**

I. INTRODUCTION

Everyone [1] experiences anxiety at some point in their lives. The word "anxiety" is frequently used in everyday speech to describe the unpleasant and uncomfortable feelings that people experience when faced with stressful or frightening situations. A wide range of things might make someone anxious. The majority of the time, though, stress is to blame. Anxiety brought on by stress is the most frequent cause of treatment requests among college students. One in eight undergraduate students who have stress-related problems in college seek therapy. Anxiety is defined as an underlying fear brought on by a compelling urge to commit. It is a group of symptoms brought on by inadequate adjustment to the stresses and demands of life. One of the most frequent problems college students deal with is anxiety. Some people could feel overwhelmed by the added demands that come with moving to a new location, being far from family, and the need to perform well in school. Anxiety disorders are among the most frequent and widespread mental ailments. Anxiety disorders are characterised by differences in physiology, thought, behaviour, and emotion. College students may exhibit them in a variety of ways, such as adjustment problems, anxiety tests, social phobia, and anxiety disorders brought on by drugs. [2] [3]

The signs and symptoms of anxiety [4] [5] can include problems with the mind, the body, or the environment. Many symptoms of anxiety include excessive worrying, fear, agitation, overly emotional reactions, and negative thoughts. While they are anxious, some people appear calm, but their minds are always racing. This negatively affects their quality of life. Chest tightness, a racing or hammering heart, and a pit in the stomach are common symptoms of anxiety. Some people get headaches, sweat, and even the urge to urinate when they are anxious. The signs of anxiety include worry, panic, losing focus during an exam, feeling helpless while executing activities, and losing interest in a challenging subject.Depression [6] affects a person's thoughts, actions, feelings, and fitness and is characterised by a low mood and aversion to activity. Anxious, reluctant, helpless, unworthy, guilty, irritated, or restless feelings are common among depressed people. Individuals could stop finding pleasure in formerly enjoyable activities, experience excessive or loss of hunger, struggle to concentrate, remember details, make decisions, or even consider suicide. College may be difficult for students, and depression is common. University students frequently experience depression, and campus life can be demanding.

II. RELATED WORKS

Millions of people experience depression, a powerful sense of helplessness, gloom, and unhappiness [7]. It's more than just a "black mood"; it's a persistent, uncontrollable feeling that makes it difficult to go about daily tasks. By 2023, depression is expected to overtake all other causes of death as the leading cause of death.

There are different levels of depression [8], ranging from general to clinical. It's common to experience depression. Mood disturbances are the most overt of the symptoms, which appear in the four fundamental domains of human functioning: emotional, cognitive, physical, and behavioural. Changes in food or weight, disturbed sleep, psychosis, diminished energy, feelings of guilt, disorganised thinking, difficulty concentrating, trouble making decisions, persistent death thoughts, and thoughts of harming oneself are all common signs of depression. Depression has been related to a range of harmful health outcomes, such as impaired recovery and diminished immune function.An area of information technology that departs from conventional computer methods is machine learning [9] [10]. According to conventional wisdom, algorithms are collections of explicitly designed instructions that a

computer uses to find or fix a problem. Machine learning techniques enable computers to prepare data inputs for factual inquiry in a particular field. It promotes the development of computer frameworks for test data models to enable automated decision-making based on data.There are many algorithms on social media to recognize depression and bullying, as the basic requirement is to interpret textual data as we want it to be. Nevertheless, accurate algorithms begin as their building block from the Support Vector Machine, Random Forest, Navie Base theorem. The field of machine learning is constantly evolving. Supervised training and uncontrolled learning are two essential types. approaches for machine learning. Similar to this, decision-making, deep learning, and the closest K- algorithm are typical algorithmic strategies in machine learning. Examine the most popular programming languages for machine learning by outlining some of its advantages and disadvantages. In addition, biases like this are avoided throughout the development of machine learning algorithms.

III. VOICE RECOGNITION

Voice recognition is another way to detect depression and anxiety using machine learning. Voice analysis can reveal subtle changes in pitch, tone, and other speech patterns that can indicate depression and anxiety. Some researchers have used machine learning algorithms to analyze voice recordings and identify patterns associated with depression and anxiety.There are several ways to use voice recognition to detect depression and anxiety. One approach is to use a machine learning algorithm to analyze speech features, such as pitch, tone, and speaking rate. The algorithm can be trained on a dataset of speech recordings from people with and without depression and anxiety. Once the algorithm is trained, it can be used to analyze new speech recordings and determine whether the person is experiencing depression or anxiety.Another approach is to use voice recognition to detect specific vocal biomarkers that are associated with depression and anxiety. Researchers have identified several biomarkers, such as the rate of speech, pauses, and variations in pitch, that can be used to identify depression and anxiety. Machine learning algorithms can be trained to detect these biomarkers and use them to predict depression and anxiety in new voice recordings.Overall, voice recognition is a promising approach to detecting depression and anxiety using machine learning. a study published in the Journal of Affective Disorders found that machine learning algorithms were able to accurately distinguish between the speech of people with depression and those without depression. The algorithms analyzed features such as pitch, tone, and pauses in speech to make their predictions.Another study published in the Journal of Medical Internet Research used a mobile app to collect voice samples from people with depression and anxiety. The app analyzed the samples using machine learning algorithms and was able to accurately detect depression and anxiety in the participants.

IV. DEPRESSION DETECTION USING VOICE RECOGNITION SURVEY

There have been several studies that have explored the use of voice recognition and machine learning for the detection of depression. Here are some examples of literature in this area:"Depression Detection by Fusing Vocal and Linguistic Features Using Deep Learning" by F. Alam, et al. (2021): This study used a deep learning approach to analyze both vocal and linguistic features of speech to detect depression. The researchers collected speech samples from 62 participants and used a combination of acoustic and linguistic features to train their model. The results showed that the model achieved an accuracy of 83.87% in detecting depression. Depression Detection from Speech using Deep Learning and Hand-Crafted Features" by S. Lee, et al. (2018): In this study, the researchers collected speech samples from 142 participants with and without depression. They used both deep learning and hand-crafted features to train their model, and achieved an accuracy of 86% in detecting depression."Detecting Depression with Audio and Textual Features" by S. Soleymani, et al. (2017): This study used a combination of audio and textual features to detect depression. The researchers collected speech samples and written responses from participants and used machine learning algorithms to analyze the data. The results showed that the model achieved an accuracy of 73.9% in detecting depression."Depression Detection via Harvesting Social Media: A Multimodal Approach" by M. Li, et al. (2019): This study used both text and voice data from social media to detect depression. The researchers used a combination of natural language processing and machine learning algorithms to analyze the data. The results showed that the model achieved an accuracy of 82% in detecting depression. These studies suggest that voice recognition and machine learning can be effective tools for detecting depression, and that a multimodal approach that combines vocal and linguistic features may lead to higher accuracy in detection.

V. MACHINE LEARNING USE IN HEALTH CARE DOMAIN

Machine learning has the potential to revolutionize healthcare by improving the accuracy and efficiency of diagnosis, treatment, and disease prevention. Here are some ways in which machine learning is being used in healthcare:Medical image analysis: Machine learning algorithms can be trained to analyze medical images, such as MRI scans and X-rays, to help diagnose diseases and conditions. For example, machine learning models have been developed to identify cancerous cells in medical images, reducing the need for invasive procedures.Electronic health records analysis: Machine learning can be used to analyze patient data in electronic health records (EHRs) to identify patterns and trends that can help with diagnosis and treatment. For example, machine learning algorithms can be used to identify patients who are at risk of developing certain diseases,

allowing for earlier intervention and better outcomes.Personalized medicine: Machine learning can be used to develop personalized treatment plans for patients based on their individual characteristics, such as genetics and medical history. This can lead to more effective treatments and better outcomes.

Drug discovery: Machine learning can be used to help identify new drugs and treatments by analyzing large amounts of data and identifying patterns and relationships. This can help accelerate the drug discovery process and lead to more effective treatments for diseases.

Health monitoring: Machine learning can be used to analyze data from wearable devices, such as fitness trackers and smartwatches, to monitor health and detect early warning signs of disease. This can help individuals take proactive steps to improve their health and prevent disease.

Overall, machine learning has the potential to transform healthcare by improving diagnosis, treatment, and disease prevention. However, there are also challenges associated with implementing machine learning in healthcare, such as data privacy and security concerns, and the need for regulatory oversight. As such, continued research and development are needed to fully realize the potential of machine learning in healthcare.

VI. MACHINE LEARNING FOR DEPRESSION AND ANXIETY DETECTION

Machine learning has shown promising results in the detection, diagnosis, and treatment of depression. Here are some ways in which machine learning is being used for depression and anxiety:

1.Detection: Machine learning algorithms can be trained on various types of data, such as speech, text, and physiological signals, to detect patterns that are associated with depression and anxiety. These patterns can then be used to develop diagnostic tools that can help identify individuals who may be at risk for depression.

2.Diagnosis: Machine learning can be used to analyze patient data, such as medical history and symptoms, to help clinicians make more accurate diagnoses. For example, a machine learning model can be trained on patient data to predict the likelihood of a patient having depression, which can help guide the diagnostic process.

3.Treatment: Machine learning can be used to personalize treatment plans for individuals with depression and anxiety. By analyzing patient data, such as medical history, symptoms, and treatment outcomes, machine learning algorithms can identify patterns that are associated with successful treatment. This information can then be used to develop personalized treatment plans for individuals with depression.

4.Early intervention: Machine learning can be used to identify individuals who are at risk for depression before they develop the disorder. By analyzing data from multiple sources, such as social media activity, physical activity, and sleep patterns, machine learning algorithms can identify patterns that are associated with depression and anxiety risk. This information can then be used to develop early intervention strategies to prevent the onset of depression.

Overall, machine learning has the potential to improve the detection, diagnosis, and treatment of depression, and has the potential to lead to better outcomes for individuals with depression.

VII. MACHINE LEARNING TECHNIQUES

Real values (housing costs, number of calls, total sales etc.) are measured depending on variable via a linear regression (s). In this connection, the relationship between independent and dependent variables is formed using the best possible line. This best fit line is called a regression line and the linear equation $Y= a*X + b$ is shown. This is known to be the Y-regression line on X and there is another X- regression line, and it is represented by $X = c*Y + d$. The best way to understand linear regression is to recall your child's experience. Allow us to declare that we want a fourth-grade youngster to instruct understudies in his class by growing weight requests without asking them their loads! What can we anticipate the child doing? He/she would almost definitely look (outwardly dissect) people's stature and job and mastermind them using a combination of these distinct factors. In fact, this is linear regression! The child has truly comprehended that height and construct would be related to the burden by a relationship that resembles the equation above. [11] The closest neighbour method of regression and classification can both be used with a pattern recognition model. The nearest k is a positive, ordinarily very small number that is occasionally abbreviated as k-NN. The k nearest training examples will be the inspection or regression inside the space. The main goal of classifying k-NN is: The class membership is a result of this role. This produces a new object in the class with the greatest number of its closest neighbours. The object's closest neighbour determines its classification if $k = 1$. [12] Decision trees should appear to or offer advice on making decisions and should refer to options. In machine learning and data mining, decision trees are employed as a prediction model. These models present data in order to let users decide what the data's objective value is. Creating a model that forecasts the estimation of an objective based on input data is the aim of decision tree learning.

The Support Vector Machine is a binary linear, non-probabilistic classification technique. The data is categorised into one or more target groups using a training model that is created. Points are used to represent the data objects in space. The objects of various categories are separated by a clear gap, which spreads its breadth. Which side of the gap the new instances are on determines the target classes for them. The support vector machine can also do non-linear classification when the input datasets are not labelled. The support vector machine uses unsupervised learning to categorise data because there are no goal classes to which the examples can be allocated. Once clusters have been created, additional instances are added based on functions. The author describes a potent non-linear support vector machine-based model-based recommendation system. The most popular approach for

working with unlabeled data is non-linear support vector machine approaches, which are employed in a wide range of industrial applications. [15]

In his paper, author [16] presented Random Forest as an ensemble learning technique for classification and regression operations. During the training phase, it produces a large number of decision trees and predicts the outcomes of the individual trees using regression techniques. It has a low variance and quickly links the many aspects of the supplied data for prediction. The reason behind this methodology's initial lack of enthusiasm is because random forest classification techniques are difficult to understand.The goal of machine learning is to simulate the conversion of light and sound into vision and hearing in the human brain. The machine learning engineering system is composed of many layers of a hardware-built neural artificial network and is powered by biological neural networks.One layer's contribution to the progressive layer is the outcome. Both unsupervised and supervised machine learning methods can be used to classify data.

Machine Learning Based Framework for Anxiety and Depression Prediction:

Figure following depicts a framework for predicting anxiety and sadness. As input to this framework, there is a set of voice data. There are 600 records in the input data set. 340 records are connected to depression sufferers, while the remaining 260 records are related to normal persons. This data set has been preprocessed in order to eliminate noise from the data and make the input data set consistent. The input data set is then subjected to different machine learning methods such as Nave Bayes, Random Forest, and SVM. Data classification is carried out. The classification results of several methods are compared. Table 1 displays these findings.

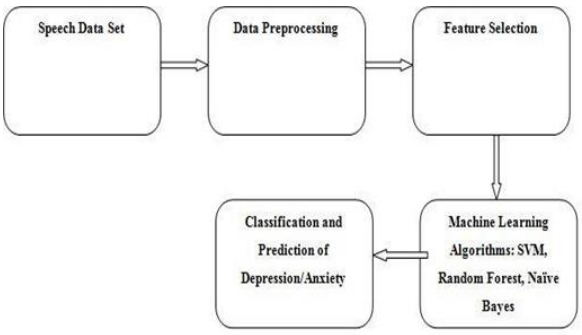

Fig.1: A Framework to Predict Depression/Anxiety

A. Data Cleaning

Data cleansing is an essential tool for data and NLP research. Text cleanup removes stop words (words that don't affect the model very much). These are usually pronouns, conjunctions, and so on. In addition, code cleanup in NLP removes unique characters such as @, #, and trailing characters. Stemming translates the same term as a word with a specific root, so the model is applied in all cases where similar words are used, and it works better and minimizes problems.

B. Tokenization and Sequence Padding

Tokenization is a greater state-of-the-art shape of statistics control that could fit and change exceptional textual content files. It can be the proper alternative for big projects. The Tokenizer ought to be constructed to suit both uncooked textual content or encoded textual content files in an integer. Next is sequencing and collection padding in which we remodel the tokens into sequences used for a sequential pattern.These sequences change in duration, so we pad positive sequences to get all of the statements or sequences to a popular length.

C. Naïve Bayes Classifier

Naïve Bayes classifiers are highly used for text based classification. It is a probabilistic learning model that applies Bayes Theorem [7].

The dataset is first subjected to the pre-processing stage. Pre-processing consists of following steps:

1. Tokenization: This process splits the given text into relevant tokens like characters, words, phrases etc., Here word –level tokenization is used [7].

2. Bag-of-words: Bow counts the number of times a particular token appears in the given text. To achieve this a class called Count Victories from scikit-learn is used.[7]

Naive Bayes Classifier is another machine learning algorithm that can be used for depression detection. Here are the general steps you can take to use Naive Bayes Classifier for depression detection:

Data collection: Collect data on individuals with and without depression. This data can include a variety of features such as demographic information, medical history, and psychological assessments.

Data preparation: Clean and preprocess the data. This may involve handling missing values, normalizing the data, and feature engineering.

Split the data into training and testing sets: Use a portion of the data to train the Naive Bayes Classifier and another portion to test the performance of the model.

Feature selection: Use feature selection techniques to identify the most relevant features for depression detection.Train the Naive Bayes Classifier: Train the Naive Bayes Classifier on the training data, using the selected features. Naive Bayes assumes that all features are independent, and calculates the conditional probability of each feature given the class label.Test the Naive Bayes Classifier: Test the performance of the trained Naive Bayes Classifier on the testing data. Use appropriate evaluation metrics, such as accuracy, precision, recall, and F1-score, to assess the performance of the model. Iterate and refine: Analyze the performance of the Naive Bayes Classifier and refine the model as necessary, including adjusting hyperparameters such as smoothing factor.Overall, Naive Bayes Classifier is a relatively simple algorithm that can be effective for depression detection, especially when the number of features is large. However, like any machine learning

algorithm, it is important to carefully consider the data and features used in the model, as well as to seek input from mental health professionals when interpreting the results.

D. Support vector Machine (SVM)

SVM is a supervised learning model that emphasizes two different classes in a higher dimension. You can customize multiple features while balancing good performance. SVMs are especially famous for their powerful features.We are working on real-world data, including definitive rationale and its insensitivity to high-dimensional data. SVM is an algorithm with some marked training examples. SVM training algorithms are potential hyperplanes, Divide the case into two classes. Escalate the distance between shared hyperplanes.

Support Vector Machines (SVMs) are a type of supervised machine learning algorithm that can be used for classification tasks, including depression detection. Here are the general steps you can take to use SVM for depression detection:

Data collection: Collect data on individuals with and without depression. This data can include a variety of features such as demographic information, medical history, and psychological assessments.

Data preparation: Clean and preprocess the data. This may involve handling missing values, normalizing the data, and feature engineering.

Split the data into training and testing sets: Use a portion of the data to train the SVM and another portion to test the performance of the model.

Feature selection: Use feature selection techniques to identify the most relevant features for depression detection. Train the Random Forest model: Train the Random Forest model on the training data, using the selected features. Random Forest is an ensemble learning method that constructs a multitude of decision trees at training time and outputs the class that is the mode of the classes of the individual trees.

Train the SVM: Train the SVM on the training data, using the selected features and an appropriate kernel function. The kernel function maps the data into a higher-dimensional space to allow for better separation between the classes.

Test the SVM: Test the performance of the trained SVM on the testing data. Use appropriate evaluation metrics, such as accuracy, precision, recall, and F1-score, to assess the performance of the model.

Iterate and refine: Analyze the performance of the SVM and refine the model as necessary, including adjusting hyperparameters such as the kernel function and regularization parameter.

Overall, SVMs can be a powerful tool for depression detection when used appropriately. However, it is important to note that depression is a complex and multifaceted condition, and SVMs may not be effective in all cases. It is important to carefully consider the data and features used in the model, as well as to seek input from mental health professionals when interpreting the results.

Training example is closest to the hyperplane. SVM is predictive Determines to which side of the hyperplane the object is tilted. The linear classifier relies on the inner product between vectors [20] (support vector ai and test tuple aT):

$$\boldsymbol{K(ai, aj) = ai\ Taj}$$

If each data point is mapped into high-dimensional space via some transformation Φ: a → φ(a), the inner product becomes

$$\boldsymbol{K(ai, aj) = \varphi(ai)T\varphi(aj)}$$

A kernel function corresponds to an inner product in some expanded feature space. A common kernel function is the radial basis function (infinite-dimensional space):

$$\boldsymbol{(ai, aj) = (-|ai - aj\|2/2\sigma 2)}$$

Although SVM can tolerate the data outlier, it is computationally inefficient and sensitive to the Kernel.

A. Random Forest

In Random Forest Algorithm, the dataset is divided into several individual trees and forms a class with similar functionalities. Then from the different classes, the final class is selected by voting the majority. The main advantage of any decision tree-based algorithm like Random Forest is the clear and understandable prediction rules that may be generated from the training dataset. Random Forest is a machine learning algorithm that can also be used for depression detection. Here are the general steps you can take to use Random Forest for depression detection:

Data collection: Collect data on individuals with and without depression. This data can include a variety of features such as demographic information, medical history, and psychological assessments.

Data preparation: Clean and preprocess the data. This may involve handling missing values, normalizing the data, and feature engineering.

Split the data into training and testing sets: Use a portion of the data to train the Random Forest model and another portion to test the performance of the model.

Feature selection: Use feature selection techniques to identify the most relevant features for depression detection.

VIII. RESULTS

By training the naïve bayes classifiers, SVM and Random Forest on depression and harassment datasets and visualized the results. The results are as follows.

Table 1 gives accuracies for depression prediction:

Model	Test Accuracy
Naïve Bayes	67%
SVM	90%
Random Forest	69%

Table 1: Model Accuracy on depression dataset

Thus the SVM model performs best out of all the three models

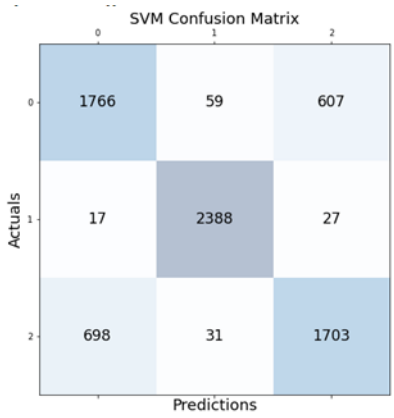

Figure 2 SVM Confusion Matrix

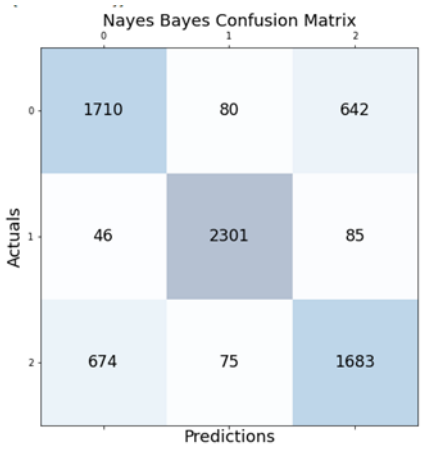

Figure 3 Naive Bayes Confusion Matrix

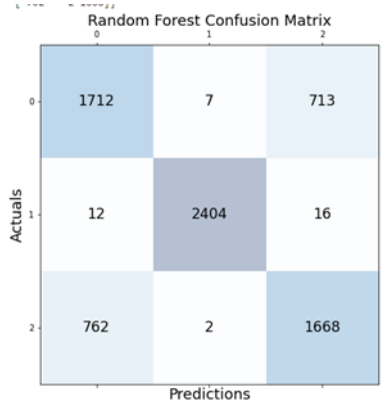

Figure 4 Random Forest Confusion Matrix

IX. CONCLUSION

Everybody has anxiety at some point in their lives. The word "anxiety" is frequently used in everyday speech to describe the unpleasant and uncomfortable feelings that people experience when faced with stressful or frightening situations. Computers can use machine learning techniques to prepare on data inputs for factual enquiry and deliver findings that fall within a specific range. In order to automate decision-making based on data inputs, it encourages computer frameworks to develop models for test data.

A paradigm for forecasting anxiety and sadness is presented in this article. This framework receives a set of voice data as input. To remove data noise and make the input data set consistent, this data set has undergone preprocessing. After that, various machine learning techniques including Nave Bayes, Random Forest, and SVM are applied to the input data set. There is data classification. The classification outcomes of several approaches are contrasted.

X. ACKNOWLEDGMENT

The authors express their gratitude for the support given by their college, Faculty of Computer Engineering, for their continuous encouragement.

Restaurant Table Booking Application

Mr.Aaryan Saygaonkar,Mr.Hariom Soni,Mr.Kartik Shah,Mr.Arjun Gujar,Ms.Maitri Vaghasiya,Ms.Niki Modi
Thakur College of Engineering & Technology,Mumbai, India
niki.modi@thakureducation.org

Abstract: With the rate at which humanity is progressing in various fields, new inventions have changed the field again and again. In this changing world, one industry that has kept adapting to the changing technology while keeping its original essence intact is the food industry. People have been fond of the concept of delicious dishes whether they were cooked at home or bought from outside. On average, 163 million people visit restaurants each week to satisfy their hunger. Post-pandemic people have become accustomed to the tradition of online delivery of food items through various mobile applications. People can roam outside and visit places they were restricted to visit before and revisit the old customs they used to follow. One such custom would be calling a restaurant to reserve tables or visiting a restaurant and waiting in queue till a table frees up for you to sit. In the modern age of mobile and web applications where there is an app for almost every service. We would like to preach the idea of booking or reserving restaurant tables through a mobile application. An application that works similarly to booking tickets for movies, trains, or flights but is focused on satisfying your hunger. We present such an application to solve all these hunger pangs and be different from just ordering food online.

Keywords - Restaurant, Manager, Customer, Application, seat booking, Reservations, Mobile Application, food, Table booking

I. INTRODUCTION

Restaurants have been around for a while satisfying the hunger of people and the desire for good food around the world. The purpose of visiting a restaurant has ranged from trying new food to being one of the events for an outing. Such plans brought with them a huge crowd of people visiting restaurants on a daily basis. Situations started arising where there were no tables available at a restaurant and people had to wait in long queues before getting a chance to satisfy their hunger.

The first act of reserving tables at a restaurant was somewhere around in the mid-20th century. The process of reserving a table was instructing the manager or the personnel in charge about when they would want the table to be free for their visit and which table they would like to be seated at. This process has evolved over time, where tables at a restaurant are booked by calling the restaurant and making your desired reservation.

There are several problems with this method of reserving tables. When almost every type of industry has a mobile application for conducting many of its functions. A mobile application for solving the problem of restaurant reservations has been proposed. The application will be designed for hassle-free table booking at a restaurant.

Manual booking done by the customer can be efficiently managed through the application. Customers have to decide their restaurant of interest. The application allows the customer to book their table online, based on their desired number of guests and availability at that time. [4][5].The admin can efficiently manage the bookings according to the schedule of the customers.

II. LITERATURE SURVEY

In the past few years, it is experienced that customers are desirous to find a handy application for reservation of tables and menus or any other services to avoid physically walking to the hotel or contacting by call or reserving through a middleman. Therefore it is aimed to develop an application for table reservation and online menu booking. The growth of mobile and wireless technology is making a large impact on our lives in the present condition as compared to previously. [1]

Nowadays people are looking for an application that satisfies their needs even more precisely. Even the

restaurant industries are looking for any mobile application that enhances the dining experience as well as increases the profit which in turn is not only an advantage for restaurant industries but also for the customers to choose the restaurant of their desired choice and location.[5][7]

This application will save time, cash, and paper by converting the manual reservation system to an automated system.[5] Running a restaurant means spending 100% of your time focusing on one metric — the number of customers visiting your restaurant. Between making sure your front-of-house and back-of-house are operating harmoniously, you are often left with no time to focus on increasing this number. [7]

Increasing restaurant reservations is not as difficult as you think. There are a number of quick changes you can make at your restaurant to start tapping into missed bookings. Some methods are easier than others, but all will increase restaurant reservations.

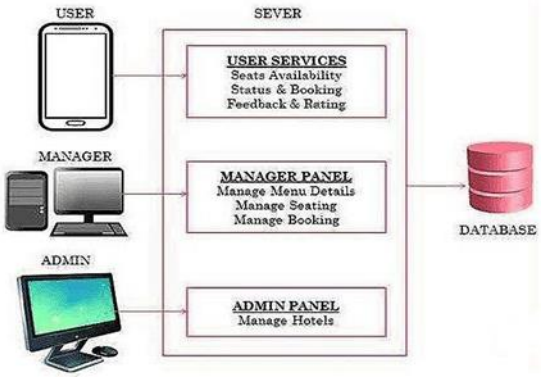

Fig. 1. - Restaurant Management System

The above figure shows a framework overview of the proposed restaurant seat booking application. This framework gives online menu requesting and reservation-making capacities and a menu suggestion benefit. The proposed restaurant seat booking application enables immediate identify customers via GPS-based location and

then actively recommends the most appropriate menus for customers according to their consumption records. For new clients, the administration staff gives proposals in light of feast ubiquity and afterward makes clients' inclinations to store in the back-end database; to infer items preferred by customers or items close to those preferred items based on customers' preference data stored in the system. [2]

Below, is certain reasons support how old fashion reservation system is losing customers:

1. Guests aren't able to check table availability online and make bookings

If you require guests to call, email, or fill out a form to make a booking, you are already missing out on a large number of restaurant reservations. The extra effort involved in the

process is often enough to turn customers away in favor of an easier booking process.

With more than 25% of people making reservations exclusively online, it is a channel that you can't afford to ignore. Online reservation systems allow your guests to choose their preferred date, view available times, and reserve a spot, without the need to make a call or send an email. By partnering with an online reservation system you remove the main barrier to entry preventing potential guests from visiting your restaurant.

2. Double booking without a table management system can sometimes get out of hand

Selling your tables through various channels (website and phone) tends to get messy without an online reservation system. Every time a booking comes through, your reservation team will have to manually update booking information to get an idea of how many tables you have left. This is not only a headache but also a source of potentially lost revenue for your restaurant. Using a table management system gives you the information you need to double-book tables.

3. Communication with guests is broken

When a guest makes a reservation at your restaurant, there are certain forms of communication they should receive. These include booking confirmations, reminders, and a message sent after their visit requesting feedback. Smaller restaurants have no way of automating this process without the help of services, such as a reservation system. Their best bet is to try and find free templates online that lack personalization and require each message to be sent manually. Having these messages sent automatically not only makes it easier for the restaurant staff but also increases customer confidence and helps cut down on no-shows. [3][6]

III. OBJECTIVE

To make an online restaurant table booking system +++that will recommend a table to book before visiting the restaurant according to their requirement. The Online Restaurant Management System is made to offer both the restaurant and the consumer a service facility. The employees of a restaurant can use this software to handle patrons and orders, and make it simple for them to locate open tables or nearby orders. The services include management of online ordering for food, management of customer and waiter information, and management of menu information.[8][10]

Customers can examine menu details using this software and reserve orders for a given time. On the management side, the staff is also permitted to change menu details, price, chef assignments, store details pertaining to requested orders, etc. Therefore, the goal is to provide a user-friendly interface that can track all of the customers' orders.

IV. EXISTING SYSTEM

In the manual system, everything depends upon the waiter and the diary. Also, there is no automated system for keeping the records in the restaurant.[9] The consumer must make a phone reservation to make a reservation for food in a typical online restaurant management system. In the unlikely event that the phone connects, the customer will request a contemporary menu, discuss the menu items they want, and place their purchase. They will also need to submit some of these identity details. It takes 5-8 minutes to finish this process. In addition, the employees at the restaurant must physically record each reservation on paper and place an order on the line with a special priority based on price and timing. The chef is then given a specific order to complete. [12][13][14]

Therefore, this takes a lot of time and paperwork. Therefore, a system that can oversee the restaurant's daily operations and automate all the procedures is required in order to save paperwork and save time.

Problems of Existing System:-

a. No computer-based data.

b. Loss of time, cash, and paper.

V. PROPOSED SYSTEM

In the proposed system, we provide customers to book restaurant tables according to their requirements of the number of seats and time. We have developed an application for the same which is currently operable for four restaurant chains. The application also provides the menu and restaurant details about its timings. Seats can be chosen according to the liking and comfort of the user. The new online restaurant management system is built on a website that logs customer orders online; however, consumers must first register with the system in order to use this feature. The user must enter his email address or User ID, password, and preferred time for order delivery upon login. The customer can view the menu page with the items specified for the appropriate time after successfully logging in. He or she can use the menu to browse the available items based on pricing and food category, and then place an order for food. On the management side, the employee must first login before the rights are set based on their classification. The notification of the order or reservation will be sent to Manager. The manager will then have the duty to manage all the orders and reservations. The managers will have access to editing menus in case it has been changed. If the employee is a chef, you are only permitted to change the order item's status to reflect the menu items that he has

produced. The administrator has the authority to update the website as needed, including adding or removing menu items. You may see a list of menu items, reservations, messages, and contact details right away on the homepage.[15][16][17]

VI. METHODOLOGY

Customer Registration Module

Customer details and other information specific to that customer are included in the customer registration module. After that, a database is used to store all of this data.

Administrator Module

The online restaurant management system's menu management information system is accessible to the admin. The menu, orders, and client profile are all editable by him.[5]

Customer Online Ordering and Reservation Module

To place an order for meals or reserve a table, a form must be filled out on the customer's online ordering and reservation module.

Menu Module

The management of the food that the restaurant prepares for clients is under the purview of the menu module. Customers can examine the menu and make reservations for orders in this module.

General Report Module

The system offers a way to create reports. The following will be in the report:

1. Reports on customer orders and reservation tables

2. Information about customers and servers.

As a result, the design is intended to benefit both the patron and the restaurant manager, particularly with regard to online ordering and table reservations.[10]

Features of a Restaurant Table Booking System:

User-Friendly Interface: The user interface (UI) of the app or website for the restaurant table reservation system is the first thing you need to keep in mind. The app should be simple to operate. Do not attempt to make it mysterious. Try to keep things as simple as you can. The app should be simple to use so that users can quickly reserve a table for themselves. The restaurant's information must all be simple to find. Don't try to complicate matters; instead, keep it straightforward and honest.[8]

Easy to understand Calendar: You must maintain things more understandable and straightforward, as we just suggested. Any system for online restaurant reservations must include a straightforward calendar. When it comes to dealing with online reservations for restaurant tables, a correctly kept calendar is essential. It can lead to anarchy and be a major system failure if not organized.

Customers ought to have explicit access to the reservation calendars. If not, customers would have numerous issues, such as multiple bookings and incorrect table reservations. We are confident that you do not want your customers to experience any of these issues.

A Visually Appealing Menu: According to Grubhub, adding images to your restaurant's menu will boost sales by 30%. If a customer sees images of the dining area and the dishes you are serving, they are more inclined to browse your entire website. Your sales will quickly soar if your app, website, or online restaurant reservation system offers a visually appealing menu.[6][7] Additionally, studies reveal that more than 85% of patrons visit a new restaurant after viewing photos of the menu items. To get customers to your restaurant, try to organize a professional photo shoot for the advertisements of your distinctive meals.

VII. USER INTERFACE DESIGN

Project Architecture Algorithm: The application consists of various screen layouts which are redirected from one screen page to another. Below is the separately mentioned UI screen for our application.

1. Splash Screen

2. Menu Page

a. List of different cuisines

b. List of different dishes

3. List of Branches

4. Seat Layout of a Branch

a. Seat Booking Form

5. Feedback Form

a. Contact Information

All of these pages were finalized after seeing what a customer ideally is looking for when browsing through the best dine-in restaurants. The interactivity for the user is also enhanced so they do not feel static and the application can actually make them stick to it and enjoy the whole process right from the thought of using it. For a dynamic experience, some fun activities still can be embedded to make the user visit again while ordering the food. Usually, customers ought to skip sometimes in a hurry to enjoy the whole vivid variety of restaurants in their locality and they tend to miss out on the best offers also if any restaurant has. To avoid this problem, the best-suited environment is to have a rating visible to the customer itself when they look over the restaurants. It is nearly possible, that by the brand name or misconceptions of some top-notch restaurant name or by chefs, customers feel they can visit the dine-in without even hesitating, still, there can be a lot better options for them to look for after reviews of people available on the application.

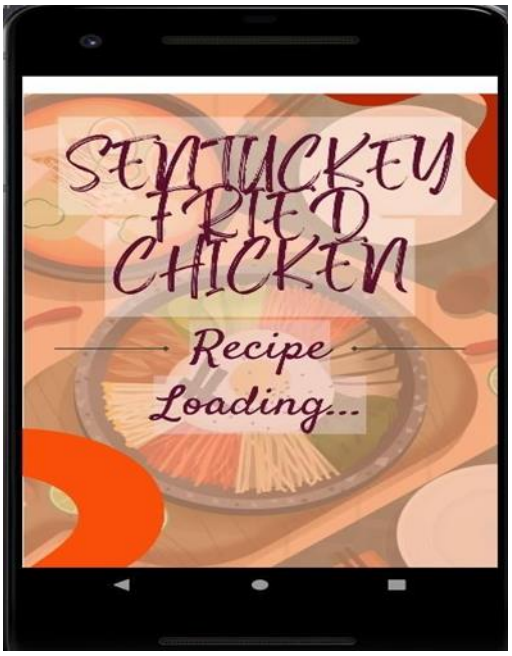

Fig. 2. - Splash Screen

The splash screen is the first Landing UI whenever a user interacts with the application. The User experience is more emphasized so as to make more interactivity and screen timeout is more.

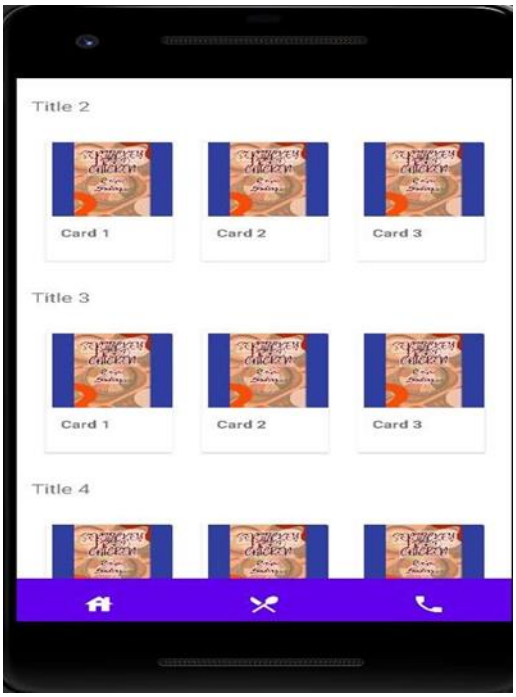

Fig. 3. - Menu Page

The menu page is the main UI wherein users can customize their order purchase. The screen adjustment is relatively compact and easy to scroll and look for the best-fitted dish to order for.

Fig. 4. - List of Branches

This page is choosing the right location near to your vicinity area, so as to visit the right location in nearest destination restaurant possible. This allows users to choose a particular area based on their choice.

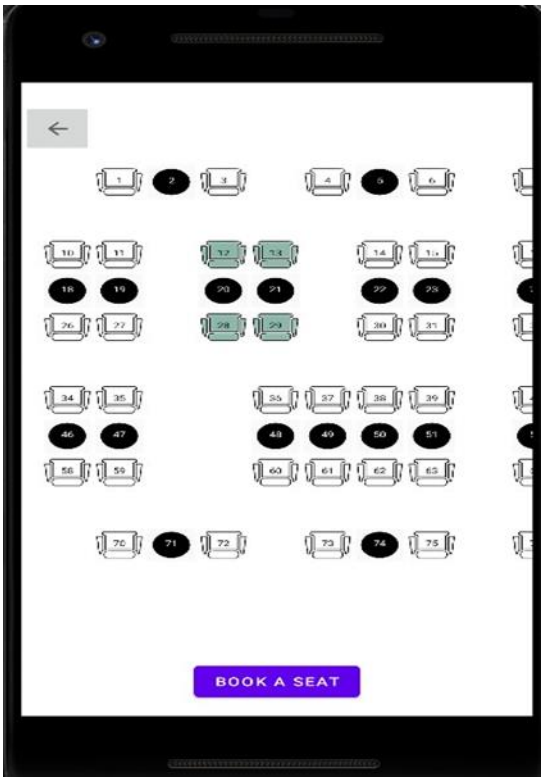

Fig. 5. - Seat Layout

Many customers do not have a good experience or a comfortable sitting area given a hasty place full of crowd. This page defines available chairs and tables placed over the whole dining area and allows the customer to sit according to their convenience. The user can select as well as deselect here.

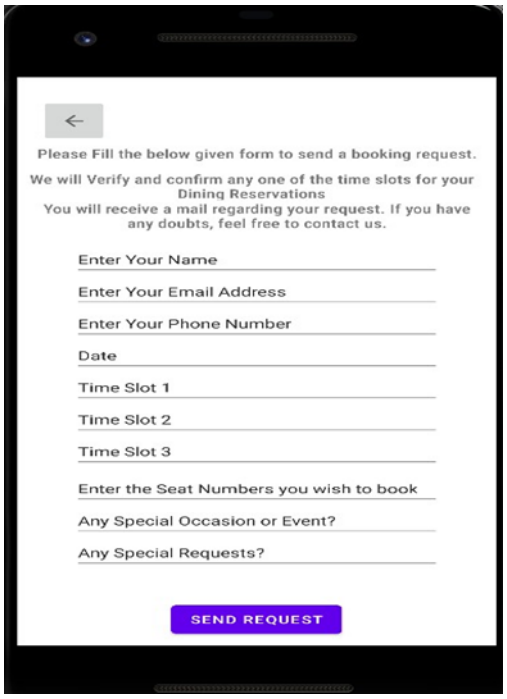

Fig. 6. - Seat Booking Form

The seat booking form asks users for their identity for official registers.

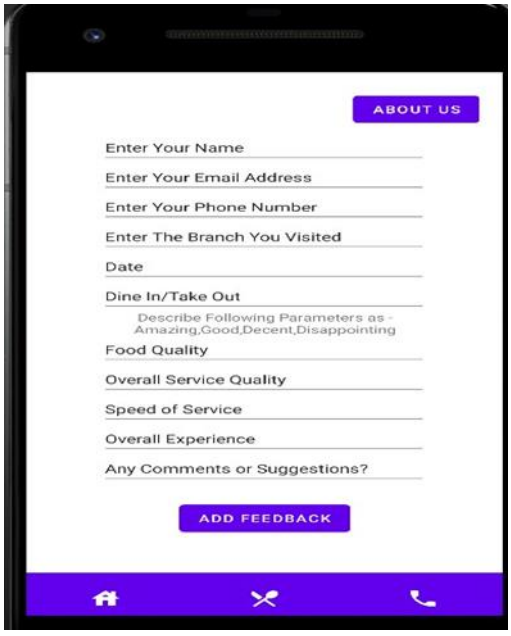

Fig. 7. - Feedback Form

The feedback form asks for rating and customer's experience. The UX of the page is designed to give the best possible experience.

Fig. 8. - Contact Information

The contact information page stores the contact details of the registrants with all the people who visited along and stores the same in the backend database for official purposes.

Building a restaurant reservation system is a wise investment in the current economic climate, and it is probably the hospitality sector's future after the epidemic. Although they appear to be straightforward, there is a tonne of room for improvement and the development of truly original systems.

VIII. CONCLUSION

The restaurant reservation app offers customers a variety of options that guarantee a superior eating experience compared to conventional techniques. With mobile applications, everything has grown easier in our digital age.

With the ability to create Android and iOS apps, USM is the top mobile app development business in the USA and India. To convert your concepts into mobile applications, get in touch with us. The concept is built around an Android application that customers may use to reserve the desired table and menu from a restaurant at their convenience. Previously, table reservations were made manually, a practice that is gradually coming to an end in well-known restaurants. However, these days, consumers are entering the digital era of restaurant reservations, and vendors are considering using a digital method of booking. Everything in a manual system is dependent on the waiter and the booking notebook; there is no automated mechanism in place to maintain the records. The overall goal is to create a reservation system for tables and menu items to help staff members with simple problems with the current manual reservation method.

Taking time and money as examples. Modern society favors high-tech services, particularly those provided online. [18][19]

In order to assist restaurant owners in automating their business operations, the project has been built skillfully.

[20] Customers have the option to reserve a table, a menu, or both via the suggested reservation system, depending on their convenience. The customer must pay 50% of the total price when ordering from the menu. If the customer is running late, they can cancel the reservation and reserve a table for the next available time window, but they must do so 30 minutes before the time slot they had chosen or their advance payment won't be refunded.[7]

IX. ACKNOWLEDGEMENT

A sincere thanks to Ms, Niki Modi, and Dr. R. R. Sedamkar for briefly explain about Mobile Computing and Android Components. We would also like to thank our batchmates who patiently solved our queries and took part in the discussion for the betterment of the Project. With the help of many resources compiled together, we finally made an Application that defined our potential of understanding Android Components.

Facial Emotion Recognition for Feedback using Convolutional Neural Networks

Mr.Prerak Khandelwal,Mr.Aaryan Pimple,Mr.Devang Punatar,Mrs.Ashwini Patil
Thakur College of Engineering and Technology,Mumbai, India
itsprerak@gmail.com,aaryanpimple99@gmail.com,iamdevangpunatar@gmail.com,ashwini.patil@thakureducation.org

Abstract— **This study provides an overview of the phases, methodologies, and datasets used in modern Facial Emotion Recognition (FER). FER has been known for decades and is an important topic in computer vision and machine learning. By using convolutional neural networks to recognize facial expressions, we can gain valuable insights into the emotional states of people and provide better services, such as personalized healthcare, improved customer service and more effective marketing. Automated FER can be used in a variety of settings including healthcare, education, criminal investigation, and Human Robot Interface (HRI). A comparative study showing the performance and conclusions of each model is summarized. The aim of this study is to use several models like Resnet50, VGG16, Mobilenet and also our developed CNN architecture that can be integrated in systems, for different purposes like getting feedback on products or services or in other systems like virtual Learning can be integrated platform. Finally, facial emotion recognition using convolutional neural networks can help to reduce bias in decision-making processes, as it can provide an unbiased assessment of a person's emotional state.**

Keywords— CNN, Facial Expression Recognition, Facial Feature Extraction, Expression Classification.

I. INTRODUCTION

In today's world, facial expression identification has become a critical issue in a variety of applications. In recent years, many studies have been conducted on facial emotion recognition. The goal of facial emotion detection is to use specific facial images to help determine the state of human emotions (e.g., neutral, happy, sad, surprise, fear, anger, disgust, contempt). The goal of facial emotion identification is to accurately and automatically detect facial emotion states. As a result, it can be difficult to determine the similarity of the same emotional state in different people, since they can show the same emotional state in different ways. For example, the expression may change depending on the person's mood, skin color, age, and environment. Each studyuses a different abbreviation for Facial Emotion Recognition (FER), such as B. Facial Emotion Recognition or Facial Expression Recognition. In this article, the abbreviation FERstands for Facial Emotion Recognition.

As indicated in Figure 1, FER is divided into three primary stages: Face detection, feature extraction, and emotion classification are the three steps. A picture of a face is identified in the first step, which is a preprocessing stage, and facial components of the face are detected from the region. Eyes, eyebrows, nose, and mouth are examples of face components. The second step involves extracting informative traits from various areas of the face. A classifier must be trained before being used to produce labels for the Emotions using the training data in the final stage.

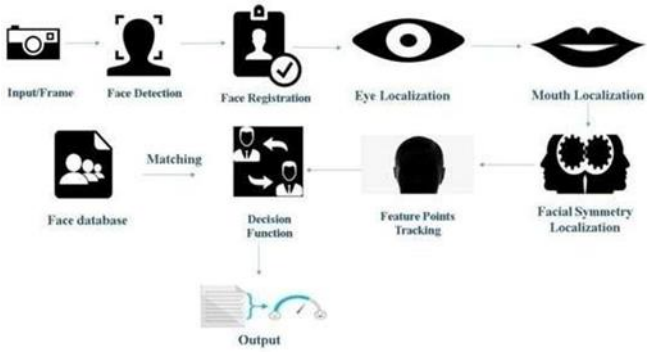

Fig.1. Flowchart

Regarding feature extraction, another technique for facial expression analysis (FACs) is Facial Action Coding System [1]. Ekman [2] popularized this concept as a facial coding system to classify emotions based on movements of specific facial muscles. Various Action Units (AUs) are used to categorize facial activities and AU collections are used to

categorize emotions [3]. Deep learning is a type of machinelearning that can be used to recognize emotions and analyze facial expressions. Deep learning, on the other hand, isaffected by data size, which could impact performance [1]. This model is specifically designed for sequence predictionwith:

II. LITERATURE REVIEW

One of the papers proposed a model to solve the problems of emotion recognition based on facial recognition in virtual learning environments [4], and the efficiency and accuracy are considered at the same time. Using HAAR Cascades to detect eyes and mouth and identify all kinds of emotion through the neural network method, the combination of efficiency and accuracy is achieved. It can be applied to real distance education. The application of emotion recognition invirtual learning environments is a much-researched topic. In addition to the change of uncertainty factors makes teachers and students face pattern is more complex, so the emotion recognition in the online learning network application mode is a very challenging topic. the subject requires further research. Since this research does not involve the illumination and pose of the image, it is uncertain how much these factors influence facial expressions and thus the final emotion recognition. All of these issues need to be explored in future research and validated by experiments. To make the theory and technology of emotion recognition fully meet the practical requirement, there are suggesting that the comprehensive application of image processing, pattern recognition, computer vision and neural networks, psychology, cognitive science, and integrates with other biometric authentication methods and methods of human- computer interaction perception based on the in-

depth and meticulous research work.

Another method for Facial Emotion Recognition through 3 steps - Face Detection, Feature Extraction and Emotion Classification [5]. Face Detection deals with geometric and appearance features and can be done by Haar Classifiers, Adaptive skin color, Adaboost Contour Points. Feature Extraction to get features for better emotion recognition can be done through LBP, LDA, Fisher Face method, PCA, CNN, etc. Emotion classification is to give emotion label to each data point by using features and models like hidden Markov, Neural Network, SVM, Bayesian, etc. A deeper insight into different research papers and their accuracies are also given, where SoftMax Classifier gives best result.

The FER may improve the interaction between Human Robot Interface in near future. This research could also involve the process of improving performance of emotion classification models, through addition of layers as well as doing cross validation on dataset. An ensemble of different classification models can be used which may give an even better performance for dataset. This hasn't been explored.

For emotion recognition based on the Perspective of Computer Simulation, there can be two parts, image extraction through online learning platforms and performing FER (Feature Extraction Recognition) using a deep learning model, CNN (Convolutional Neural Network) to analyze students' emotions according to their facial expressions from the perspective of computer simulation [6]. The preprocessing includes face detection, alignment, rotation, and resize, according to the different elements in the original images. The facial expression recognition algorithm trained by the standard facial expression database is employed to detect the faces and classify the facial expressions in terms of anger, disgust, fear, happiness, sadness, surprise, contempt, and neutral.

Lastly, the histogram of probability distribution about the expression is plotted and provided for the tutor so that the teaching plan can be adjusted timely. The proposed method is unable to provide satisfactory results when facing problems, such as backlight, shadows, and facial incompleteness, caused by complex environments. The testing of various other deep learning models which could have provided better results.

Another research gives a study about 2 datasets, namely CK+ and FER datasets and gives a comparison between the performance of Resnet50 model which is deep residual neural network and the convolutional neural network [7]. A 50-layer architecture is implemented for datasets having images of seven types of emotions. The findings are that Resnet50 model gives a better performance with an accuracy of 88.3% and 81% for CK+ and FER dataset respectively, while the convolutional neural network gives an accuracy of 67% and 64%. With the increase of depth and using identity shortcut connections better feature learning can be achieved ultimately delivering a high- performance network. An ensemble of different classification models can be used which may give an even better performance for dataset. This has not been explored. Moreover, there is a lack of the testing of various other deep learning models which could have provided better results.

It has been examined how human emotion, which is often expressed by face expression, could be recognized using computer vision [8]. The study is performed by analyzing journals and researches related to this topic, ranging from psychological to technological journals. Several algorithms and techniques have been reviewed, and at the end of this paper, a summary of recommendation for performing facial emotion recognition based on the reviews of the techniques/methods is given.

TABLE I. LITERATURE SURVEY

Paper Name	Advantages	Gaps Identified
Emotion Recognition of Students Based on Facial Expressions in Online Education Based on the Perspective	1. This paper examines how image extraction through online learning platforms and a deeplearning model, CNN, can be used to analyzestudents' facial expressions in computersimulations. 2. A facial expression recognition algorithm trained by a standard facial expression database is used to classify emotions such asanger, disgust, fear, happiness, sadness, surprise, contempt and neutral.	1) The proposed method is unable to provide satisfactory results when facing problems, such as backlight, shadows, and facial incompleteness, caused by complex environments. 2) This research lacks the testing of various other deep learning models which could have provided better results.
Deep Residual Learning for Facial Emotion Recognition	1. The paper compares the performance of a Resnet50 model, a 50-layer deep residual neural network, and a convolutional neural network on two datasets, the CK+ and FER datasets.	1) An ensemble of different classification models can be used which may give an even better performance for dataset. This hasn't been explored.

	2. It is suggested that an increase in depth and use of identity shortcut connections can lead to better feature learning and a higherperforming network.	2) This research lacks the testing of various other deep learning models which could have provided better results.
Facial Emot ionRecognition UsingComputer Vision	1. This paper examines how computer vision can be used to recognize human emotion expressed through facial expression. 2. Six papers are discussed, and the algorithms and tools used for facial emotion recognitionare explored, including SVM, Adaboost, neural networks (CNN, CNNLSTM, k-NN, MLP), Bayesian networks (Naive-Bayes andGaussian-TAN), VGG_S, Microsoft Kinect 3D, and SURF.	1) Larger amount of training data is required. 2) Convolution Neural Network does not encode the position and orientation of the object.
		3) Inability to be spatially invariant to theinput data.

After a careful analysis as shown below, it can be seen that the prime requirement of clients is to express proper unambiguous meaning of images and that will perhaps help intellectually impaired people. This analysis is done after observing responses to a survey created by us and floated among college students and elders.

TABLE II. REQUIREMENT ANALYSIS

DESCRIPTION	CRITICALITY LEVEL
Identifying features from image	5
Removing image face ambiguity	4
Accurately predicting emotionfrom face image	3
Aiding nonverbal communication through emotions known throughfacial expression	4

III. METHODOLOGY

1. Dataset:

The dataset has been taken from Kaggle and consists of 48x48 grayscale images, The faces have been automatically registered so that the face is more or less centred and occupies about the same amount of space in each image. This data is in the form of a CSV file, having the following columns:

- Emotions: This consists of an index given to each of the emotions expressed in corresponding images. There are 7 unique emotions, namely Angry (0), Disgust (1), Fear (2), Happy (3), Sad (4), Surprise (5), Neutral (6).
- Pixels: This consists of an array of 2304 pixel values in each row, which is a our pixel matrix of 48x48 dimensions. These can together be plotted to get our digital image. Thisformat helps in storage optimization.
- Usage: This tells whether the row (image) should be used for training or validation.

Moreover, our dataset consists of 35887 rows or images in total.

	emotion	pixels	Usage
0	0	70 80 82 72 58 58 60 63 54 58 60 48 89 115 121...	Training
1	0	151 150 147 155 148 133 111 140 170 174 182 15...	Training
2	2	231 212 156 164 174 138 161 173 182 200 106 38...	Training
3	4	24 32 36 30 32 23 19 20 30 41 21 22 32 34 21 1...	Training
4	6	4 0 0 0 0 0 0 0 0 0 0 0 0 3 15 23 28 48 50 58 84...	Training

Fig.2. Dataset

2. Pre-processing:

The next step is to make sure our data is ready for deep learning process, so that it can be used meaningfully. As seenin figure 2, the emotions like 3: Happy, 4: Sad and 6: Neutral occur majority of times in our dataset, while the emotion of disgust occurs extremely less.

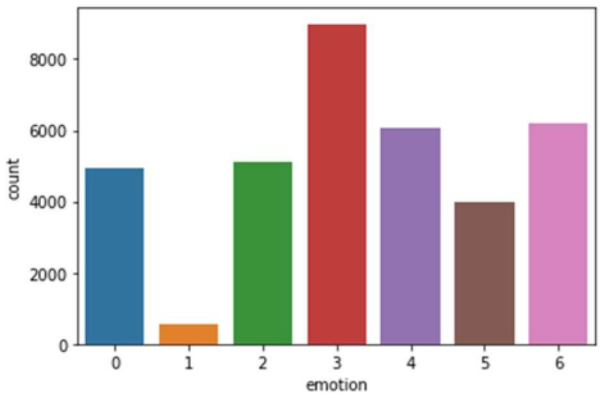

Fig.3. Count plot of emotions

We do not want this imbalance and thus, we remove the disgust emotion instances from our data. The number of rows becomes 35340, which is not a major change compared to ourentire dataset.

To make our data compatible for our neural networks, a NumPy array to represent the data is created of size, (35340, 48, 48, 1). Our data is split into training and validation set, inthe ratio, 90:10, as shown in figure 3.

```
X_train, X_valid, y_train, y_valid = train_test_split(img_array, img_labels,
                                                      shuffle=True, stratify=img_labels,
                                                      test_size=0.1, random_state=42)
X_train.shape, X_valid.shape, y_train.shape, y_valid.shape
((31806, 48, 48, 1), (3534, 48, 48, 1), (31806, 6), (3534, 6))

print(X_train.shape)
(31806, 48, 48, 1)
```

Fig 4. Splitting data

The pixel values in our independent variable X are divided by 255 to normalize them, since pixel values range from 0 to 255.

3. Selecting Parameters:

Several parameters or conditions need to be selected under which our deep learning model can work.

- Callbacks: Two callbacks called early stopping and Reduce LR on Plateau are applied. The idea of early stopping is very simple[9]. The model tries to work on the loss function for training data, by tuning the parameters. Early stopping keeps a track of the enhancement of performance for validation data, and in case there is no significant improvement with respect to training performance, it stops running to reduce computation. This way it prevents overfitting as well. Reduce LR on plateau also reduces the learning rate in case the improvement seen for a fixed number of epochs is less.

```
early_stopping = EarlyStopping(
    monitor='val_accuracy',
    min_delta=0.00005,
    patience=11,
    verbose=1,
    restore_best_weights=True,
)
```

```
lr_scheduler = ReduceLROnPlateau(
    monitor='val_accuracy',
    factor=0.5,
    patience=7,
    min_lr=1e-7,
    verbose=1,
)
```

Fig 5. Callbacks

- ‘Image Data Generator: When our data does not consist of good amount of variation, we use this tool to create variations in our data. This can be done through horizontal flip, width shift, height shift, zooming, rotation etc.

```
train_datagen = ImageDataGenerator(
    rotation_range=15,
    width_shift_range=0.15,
    height_shift_range=0.15,
    shear_range=0.15,
    zoom_range=0.15,
    horizontal_flip=True,
)
train_datagen.fit(X_train)
```

Fig 6. Image Data Generator

- Batch size and epoch: The batch size is the number of rows or instances considered for training during each epoch. Wehave chosen to divide our data in batch size of 32. The epoch is segment of data being trained in one pass. We have 100 epochs (can be pre-empted by early stopping).

4. Applying models:

Deep Learning models are then applied on our dataset, whichrun for multiple epochs. Each of these models have their own unique architectures, and thus produce varying results.

However, the general terminologies of layers used in Convolutional neural networks are given below:

A CNN contains several layers that are designed to recognizesimpler patterns (lines, curves, and so on) first. Patterns that are more complex follow (faces, objects, etc.).

- Convolution Layer – The kernel slides across the image matrix and dot multiplication are done to get a value as elements for the resultant output matrix.

- Pooling Layer – This helps in reducing the spatial size of the representation by deriving a summary statistic of the nearby outputs.

- Fully Connected Layer – In this, the input image from the previous layers is flattened and fed to the FC layer.

- Dropout – Usually, when all the features are connected to the FC layer, it can lead to overfitting in the training dataset. To overcome this problem, a suppression layer is used where some neurons are removed from the neural network during training

- Activation Function – It adds non-linearity to the network. There are several commonly used activation functions like the ReLU, Softmax, tanH and therefore the Sigmoid functions.

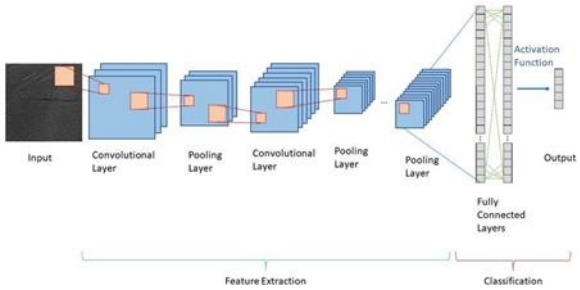

Fig 7. Convolutional Neural Network

Model 1: VGG16

VGG 16 was proposed in 2014 by Karen Simonyan and Andrew Zisserman from the Visual Geometry Group Lab at Oxford University in the work "Very Deep Convolutional Networks for Large-Scale Image Recognition" [10]. This model won 1st and 2nd place in the above categories in the 2014 ILSVRC Challenge.

The architecture of VGG is given in the figure. The idea behind the uniform use of 3 x 3 filters distinguishes the VGG. Two consecutive 3 x 3 filters give an effective receptive fieldof 5 x 5. Likewise, three 3 x 3 filters give a receptive field of7 x 7. In this way a combination of several 3 x 3 filters can enter a receptive area of greater Size. Although VGG has its own advantages, it faces the problem of exploding gradients. An error gradient is the direction and magnitude calculated during training of a neural network used to update the network weights in the right direction and by the right amount, yielding very large slopes. These in turn result in large updates to the network weights and in turn an unstable network.

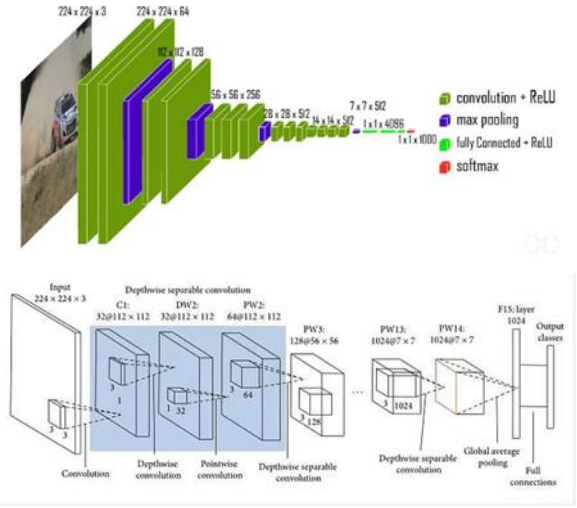

Fig 8. VGG16 architecture map

Model 2: Resnet50

ResNet, which was proposed in 2015 by researchers at Microsoft Research, introduced a new architecture called Residual Network[11]. To solve the vanishing/exploding gradient problem, this architecture introduced the concept called residual blocks. In this network we use a technique called skip connections. The jump connection connects activations of one layer to other layers by skipping some layers in between. This forms a remainder block. Resnets are made by stacking these leftover blocks together.

The approach behind this network is that instead of layers learning the underlying map, we allow the network to adapt the residual map. So instead of saying H(x), initial mapping,let the network fit,

F(x) := H(x) - x which gives H(x) := F(x) + x

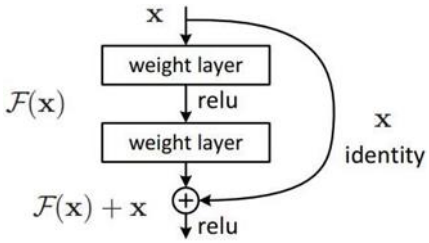

Fig 9. Skip Connections

The benefit of adding this type of skip connection is that regularization skips a layer that degrades the performance ofthe architecture. So this leads to training a very deep neural network without the problems caused by vanishing/exploding gradients. The authors of the paper experimented with 100- 1000 slices of the CIFAR-10 dataset.

Model 3: Mobilenet

Mobilenet is a model that performs the same convolution as CNN to filter images, but in a different way than the previousCNN[12]. It uses the idea of depth convolution and point convolution, which is different from normal convolution as done by normal CNNs. This increases the efficiency of CNNin predicting images and hence it can compete in the mobile systems as well. Because these types of convolutions greatlydecrease the comparison and recognition time, they provide a better answer in a very short time and hence we use them as our image recognition model.

Fig 10. Mobilenet architecture

Model 4: Self designed Deep CNN

A deep neural network (DNN) is an ANN with multiple hidden layers between the input and output layers. Similar to flat ANNs, DNNs can model complex nonlinear relationships. Computers have proven to be good at performing repetitive calculations and following detailed instructions, but not so good at recognizing complex patterns.

When there is the problem of recognizing simple patterns, a support vector machine or a logistic regression classifier can do the job well, but when the complexity of the patterns increases, there is no other way but to go for deep neural networks. Therefore, shallow neural networks fail for complex patterns like a human face and have no alternative but to go for deep neural networks with more layers. The deepwebs can do their job by breaking down the complex patterns into simpler ones. For example a human face; A deep mesh would use edges to detect parts like lips, nose, eyes, ears, etc.and then reassemble them to form a human face.

As you can see in the figure, the architecture starts with a convolution layer, batch normalization, max pooling and dropout. These sets of layers are repeated three times. The flatten and dense layers with softmax

function are used at theend to predict the emotion as the output.

Model: "DCNN"

Layer (type)	Output Shape	Param #
conv2d_1 (Conv2D)	(None, 48, 48, 64)	1664

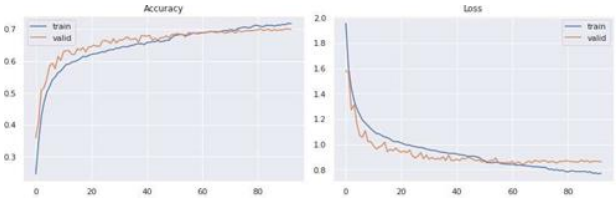
Fig 11. Deep CNN architecture

5. Integrating with system:

A separate system can be created, using Django, HTML/CSS,which can get user input as multiple images or live pictures. These can be processed using our best model, and then can help in predicting the emotion of the collective data. This can be very useful to get feedback through visual data of faces of users for any system, providing any product or service.



- Self designed Deep CNN:

It ran for 93 epochs, before stopping early. As we can see, it worked better than the other models, through gradual increase in both Training and validation accuracy.

- VGG16:

IV. RESULT AND DISCUSSION:

It ran for only 13 epochs before stopping early. As we can see, this model suffers from the same accuracy and no improvement through the epochs. Thus, not a fit one for ourdataset.

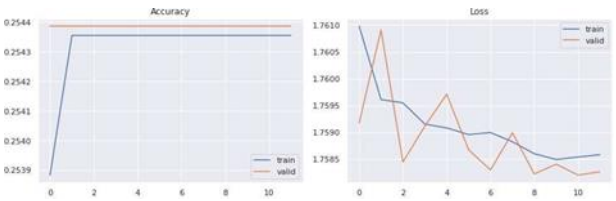


Fig 12. Plot of History - Epochs for VGG16

- Resnet50:

Similar to VGG16, It ran for only 13 epochs before stopping early. There are minor fluctuations in accuracy and loss, but still it does not show any major improvementsthrough the epochs.

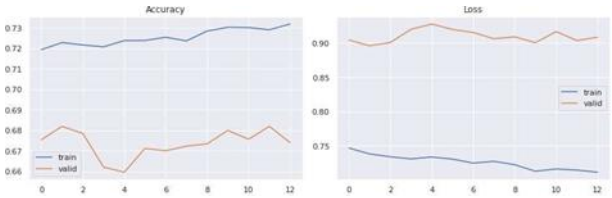

Fig 13. Plot of History - Epochs for Resnet50

- MobileNet

It ran for about 89 epochs. As compared to others, it is a computationally less expensive model, and still was able to show gradual improvement in performance through running on epochs.

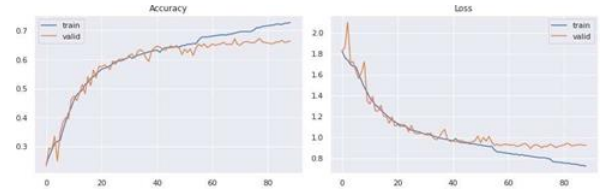

Fig 14. Plot of History - Epochs for MobileNet

Fig 15. Plot of History - Epochs for Self designed Deep CNN

In the table we can see how our Deep CNN is giving the bestvalidation accuracy of 69.92%, with Resnet50 close behind with 67.40% accuracy. MobileNet also managed to give accuracy of 66.38%. VGG16 gave the least performance with 25.44% accuracy. Further work can also be done, to improvethese models.

TABLE III. Performance of all models

Models	Training accuracy	Validation accuracy
VGG16	25.44	25.44
Resnet50	73.18	67.4
Mobilenet	72.74	66.38
Deep CNN	71.68	69.92

V. CONCLUSION

The development of a facial emotion recognition system hasthe potential to revolutionize the way people interact with computers, as well as help us better understand the emotions of those around us. This system can use machine learning and facial recognition technology to accurately detect and categorize the emotions of people in an image or video. Withthis, the system can then be used to improve user interfaces for computers, as well as helping people to better understandthe emotions of those

around them. The system also has potential use in the medical and psychological fields, as it can be used to diagnose and track mental health issues. Overall, facial emotion recognition systems can be used to benefit people in many different ways and can help us to better understand the emotions of those around us.

VI. FUTURE SCOPE

The future scope of a facial emotion recognition system for the feedback system could include the ability to identify and respond to multiple emotions and facial expressions at the same time. This could be used to provide more nuanced and accurate feedback, as well as to gain a better understanding of how people are responding to different stimuli. Additionally, the system could be used to predict future behaviors and reactions, allowing for more targeted marketing and customer service initiatives. Another potential use case could be to identify emotionally charged conversations in customer service environments and automatically redirect them to a more suitable representative. Finally, the system could be used to provide real-time feedback on user engagement, allowing for more efficient and effective user experience design.

Development of Web Educational ERP System using Modern Tool

Vishal Pandey Harsh Keniel , Sagar Pachare , Dr. R R Sedamkar
Thakur College of Engineering & Technology,Kandivali (East), Mumbai.
vishalpandey917@gmail.com, harshkeniel123@gmail.com, spachare91@gmail.com,rr.sedamkar@thakureducation.org

Abstract— **College ERP system provides a simple interface for maintenance of different students, departments, faculties and other information. It also provides a way to share projects and have peer learning through blogs. Our college ERP system has all the information about the students, teachers, events, departments and other respected information. The system allows the admin to add students, faculties and any other events. Our system allows a faculty to enter or input student's attendance into the database and also give assignments which can later be viewed by students and faculties. The students can view his/her attendance through a separate student login and also add their projects onto the system. The system provides a blog/discussion section where students can post their doubts/queries which can be resolved by their peers or faculties. This will help improve peer learning and get students to share their knowledge.**

Keywords: - Project, Blog, College, Database, Faculty, Peer, Students, ERP

I.INTRODUCTION

Existing ERP systems are not enough to meet the current needs of students. Students and faculties are dependent on multiple platforms like classroom, teams etc. We feel there is a need for such a platform which can benefitstudents as well as teachers. So we have decided to develop a system which aims to improve the current system and add more functionalities. Our system provides platforms for teachers to manage assignments. We aim to improve the task of managing attendance for students. Furthermore, we have decided to add a project section in our system so thatstudents can easily get information about different ongoing projects or previously done projects through this. With addition of this section students will get exposure to the project world and will get connected with their colleagues . Furthermore, there will be a blog/discussion section on which students can put their various doubts and other peers can give solutions to that.

II.LITERATURE SURVEY

Enterprise Resource Planning (ERP) college web application is the one kind of web application which integrates all the modules and functionalities of a college system on a single system that can be handled by the administrative head and accessed by the students and faculties with valid user id and password [1].

Over the last 10-15 years, organizations have been in growing numbers, turning to ERP (Enterprise Resource Planning) systems to consolidate their information technology infrastructure, streamline business processes, and help them become more efficient and effective. The ERP software market has been very lucrative for both software developers as well as consultant firms. These systems are very large and complex, and as such, often require expert assistance for successful implementation [2]. Indeed, existing ERP research has neglected the higher education sector worldwide, even though most universities have implemented or are in the process of implementing an ERP system [3].

As we know, a college has different information sections, such as branches, courses, fees, students etc. The main goal of the entire system is to provide a user-friendly interface and give an ease of access to various information about college on an online platform. The College ERP system brings all the details of the college to an online portal which is updated by admin only and can be accessed by the students and faculties. Only a person having administrative access is enough to maintain all the reports and records of the system. The most important thing is that our system reduces human work and can also provide security as per requirements.

Table1.:Comparative Study

Sr No	Gaps	Finding
In [7]	Most of the companies faced various technical issue and finding experts to resolve the issue was a difficult task. Organizations were resistant to change as per needs.	Universities with the successful ERP implementation was able to adapt its social structure to the new technology. While other case studies have provided insight into why ERP projects fail or succeed.
In [8]	Systems were not scalable and resistant to change as data grows Server crashes and database server failure.	User friendly which covers the holistic needs of the entire schools and college and allows the administrators to register the daily required information of Students, Teachers & office staff.
In [6]	Maintaining huge data was aproblem with manual system No efficient way to manage redundant data, difficulty inupdating data, etc.	The results shows that the fundamental problem in maintaining and managing the time table and the daily schedule of the system was overcome.

In [9]	Many processes were repetitive and needed to enter data manually. There was no transparency whether the data is safe or not.	The present research paper is the outcome of the pilot study of the use of ERP system in the college administration and in depth study can be undertaken in future to understand the details of ERP system, its uses and limitations.
In [10]	Administration faced problem in maintaining and managing work for daily schedule and time table. Lack of proper infrastructure. Different data managementprocesses were in isolation & cannot interact with eachother.	The fundamental problem in maintaining and managing the work by the admin is overcome. By using this web-based application the amount of time consumption is reduced and also the manual calculations are omitted, the reports can be obtained whenever on demand by the user.

used to make important decisions. Taking this into consideration, we made a questionnaire which covered questions regarding the current ERP system, why there is a need for new features ,etc.

1. Following questions were included in survey:
2. Do you think the existing ERP system of college is sufficient to meet different requirements?
3. Do you feel that there is a need to improve the existing ERP system and more useful functionality to it?
4. We all know that managing attendance during an online lecture is a tedious task for teachers. Do you think it would be useful if this process could be done easily?
5. How useful would it be if we could have a Platform for uploading our assignments on the ERP system only so that we do not need to use different platforms?
6. Do you think there is a need for any platform which will help connect students of the same college irrespective of the year they are studying?
7. In our academic career we work on different projects, but did you ever feel that there could be some platform through which we can get help on projects from others or know what are different projects going or completed by students in our college? (getting info of all projects at the same place)
8. We are also planning to add a Discussion Forum section to our web app so that students can interact,ask their queries or share some valuable information with others. Do you think it will be useful?

Below are responses for some of the questions which we asked in the survey:

III.PROBLEM STATEMENT

The work proposed in this paper addresses the followingissues:

1. To provide facility for managing assignments in anERP system.
2. To allow the students to push their projects into theERP system and manage them.
3. Students will get exposure to the project world andwill get connected with their colleagues.

IV.DATA COLLECTION AND VISUALIZATION

Survey is very important when we are doing research. Surveys can help gauge the representativeness of individual view and experiences.When done well, surveys provide hard numbers on people's opinions and behaviors that can be

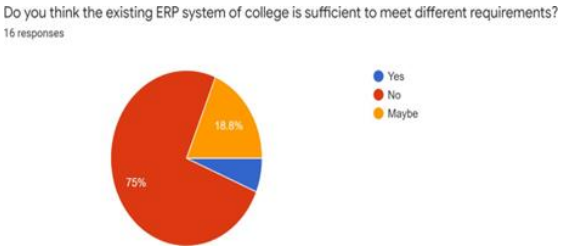

Figure 1.:Responses for question 1

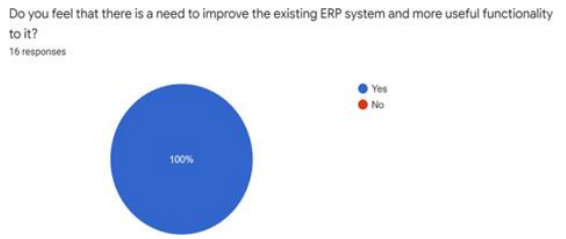

Figure 2.:Responses for question 2

Figure 3.:Responses for question 4

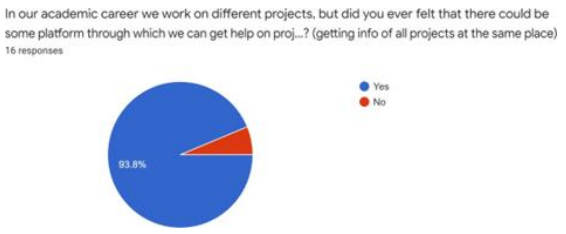

Figure 4.:Responses for question 6

Figure 5.:Responses for question 7

V.PROPOSED SYSTEM

So we have proposed an Advanced ERP system which will add extra functionality to existing systems and aims to improve existing systems. Some features are:

1. Our project provides a platform for teachers to manage assignments.

2. Students can easily get information about different ongoing projects or previously done projects.

3. Students can easily get connected with other students in the college.

4. Also students can get answers for their queries which can be answered by other students through the blog/discussion section.

Users:

1. Admin: The admin has entire rights to the working system. Admin is the one who handles the admission, Employee registrations, Academics flow. At the start he enters the appointed staff of the assigned department. Then the classes are installed

and the appointed staff is assigned to the respective classes. Once the teachers are allotted then the student registration process begins. All these functions are handled by the admin only. This access is not allowed for the other users. Admin is responsible for the accountability of the college. Heis the one who maintains all the accounts of the assigned staff and registered students.

2. Staff / Teachers: The Faculty members are installed by the admin and the login information is generated by the system. The faculty has the entire rights to handle the data of their subjects for their respective classes. Faculty members are given entire rights to give the information and can also upload the note and assignments for their specific subject. Faculty can also access the blog and project section and act as moderator wherever required he/she can take down any post which seems irrelevant.

3. Students: The newly admitted students are entered in the system by the admin. When the student gets admitted the user-id and password is generated by the system. The students get access to his/her profile, college events, college routine and other information having student access. Students can also access the blog and project section.

Core Modules:

1. ERP

a. Fees

b. Assignment

c. Attendance

d. Syllabus/portion

e. Subject

f. Feedback

2. Project

a. Explore (View projects posted by otherstudents)

b. Add Project (Domain, title, etc)

3. Blog/ Discussion

Figure 6.:Flow chart for our proposed system

We also made a prototype for the project section. Below aresome wireframes we built for the same.

VI RESULT AND DISCUSSION

To make the proposed solution accessible to people, all the above-mentioned components are modularized and connected to each other in backend by referring to the system design created and serving it as an Application Programming Interface (API). To make this service accessible a web-app has been developed.

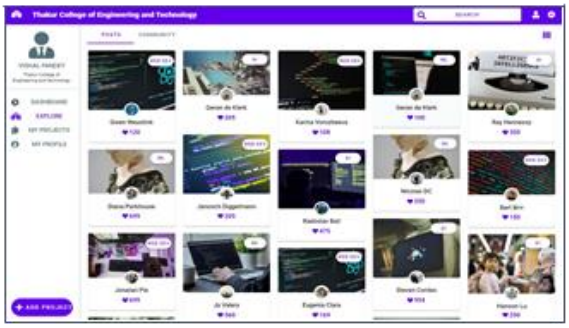

Figure 7.:Explore Page UI

Figure 8.:My Projects UI

Figure 9.:Posts UI

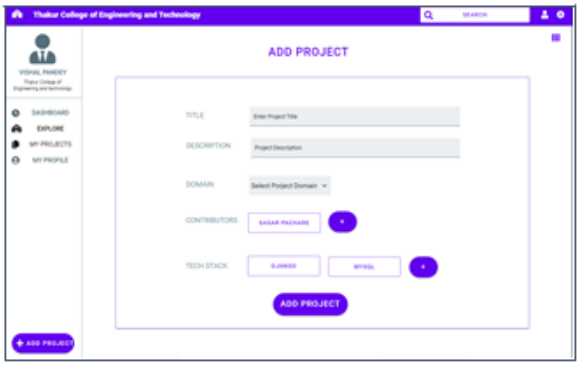

Figure 10.:Add Project UI

1. Server-Side Development

For developing the backend logic, we have used JavaScript programming language with libraries like Node.js and Express.js. Its flexibility in organizing the project structure as per our preference and the ability to write async code makes it a better choice than other frameworks. As an outcome, our proposed solution can be served on a server and can be accessed by calling the API.

2. Client-Side Development

To make our solution to general public, a Web-App needs to be developed which connects to the API developed. The web-app is written in HTML5, CSS & JavaScript using React.js Framework. This level of the architecture is what the user will interact with to access the features of our application.

3. Database Tier

Our Database Tier (Model) will be hosting PostgreSQL. This is where we will store all of the crucial data our application needs to function.

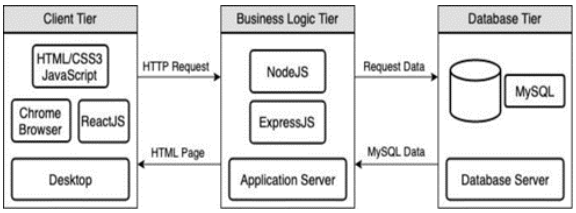

Figure 11.:Client-Server Architecture

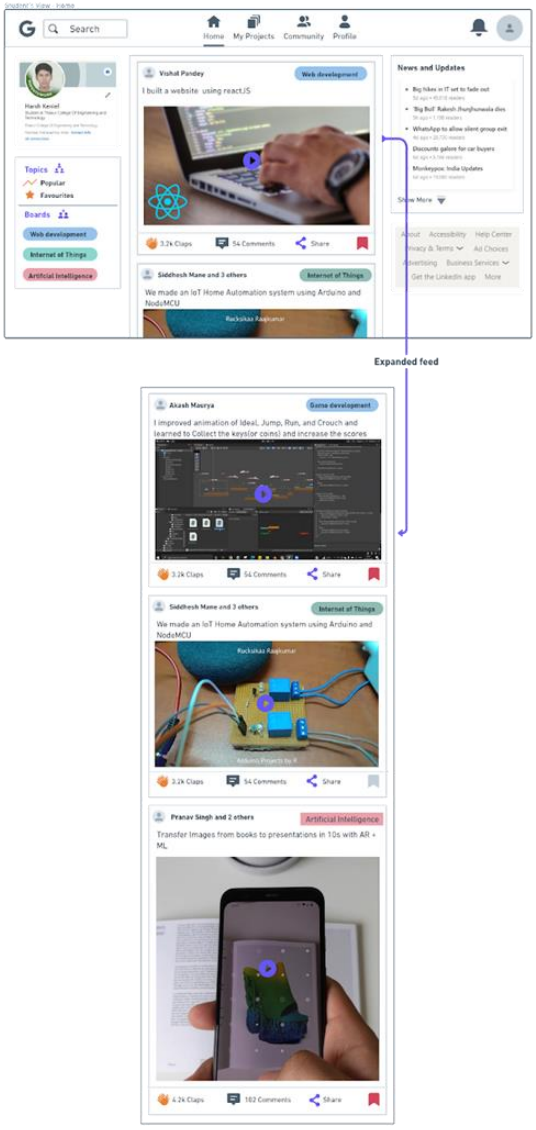
Therefore, by leveraging Client-Server Architecture, we served our proposed solution as a web-app.

Below is the project feed section of our Project Module as you can see the application will allow the students to put their projects onto the platform and view them as a feed just like in LinkedIn, this allows the students to view each other's projects and learn from them.



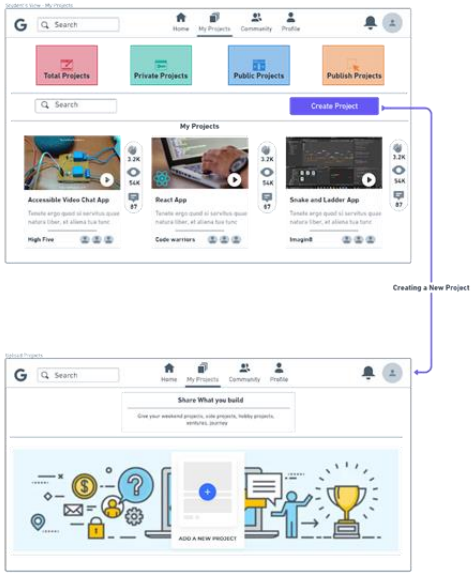


Figure 12.:Project Feed

This is the project panel where students can see their projects which they have created onto the platform and also create new projects using the create project button

Figure 12.:Project Panel

VII CONCLUSION

The benefits of a properly selected and implemented ERP system can be significant. The future of successful ERP implementation does not rely on further improvements of technology, but on bringing people and business up to speed on the appropriate use of ERP technology to fit their defined business needs and objectives [4]. ERP systems are rapidly beginning to embrace the demands forthcoming for e-commerce applications such as online billing and payment, e-procurement, etc. The data warehouse and data retrieval tools are maturing and will play a more important role in the future [5]. Hence, every educational institute should use ERP for proper planning, management and to improve quality.

Abstract—**New shopping methods with various attributes compared with traditional internet shopping can improve the administrations of business websites or E-commerce systems. The utilization of internet shopping has been developing significantly over some time. Augmented reality (AR) may assume the most significant job in improving the method of web-based shopping. The advancement of new AR innovation can be made valuable if it can imitate the highlights that have made web-based shopping the most favorable shopping source in present times. The execution of AR shopping is changing internet business by helping the web retailers to decrease the developing expense of profits and furnishing their clients with all the more captivating and advantageous approach to shop through their gadgets. Imaginative AR arrangements permit clients to envision their item continuously, from the comfort of their place. And it may play a major role in the industrial revolution with a specialization area.**

Keywords—Augmented Reality, AR kit SDKs, E- commerce, Industrial revolution.

I. INTRODUCTION

E-commerce is a boom in the modern business. E-commerce means electronic commerce. E-commerce (Electronic commerce) involves buying and selling of goods and services, or the transmitting of funds or data, over an electronic network, predominantly the Internet. E-commerce (Electronic commerce) is a paradigm shift influencing both marketers and the customers. Rather e-commerce is more than just another way to boost the existing business practices

E-commerce provides an easy way to sell products to a large customer base. However, there is a lot of competition among multiple e-commerce sites.

There is a fundamental disconnect between the wealth of digital data available to us and the physical world in which we apply it. While reality is three- dimensional, the rich data we now have to inform our decisions and actions remains trapped on two- dimensional pages and screens. This gulf between the real and digital worlds limits our ability to take advantage of the torrent of information and insights produced by billions of smart, connected products (SCPs) worldwide.

Augmented reality, a set of technologies that superimposes digital data and images on the physical world, promises to close this gap and release untapped and uniquely human capabilities[1].

Augmented Reality (AR) exhibits the mix of innovations that empower to join the PC created content with a live video display in real-time[2]. Augmented Reality is the combination of virtual and real worlds, enclosing the real world with computer- generated virtual objects in real-time. As per one of the most ordinarily acknowledged definitions, AR is supposed to be an innovative technique having three key prerequisites: a combination of the real and virtual article/objects in a real environment, adjusting real and virtual article/objects with each other, and real-time interaction. On account of versatile AR, innovation includes the expansion of advanced components to this present reality through a cell phone camera[3]. AR was perceived as a rising innovative technology of 2007, and with today's smartphone and AR programs, we are starting to get a handle on this astoundingly new and invigorating kind of human-PC collaboration. An AR framework is officially characterized as an application that satisfies the accompanying three properties, to be specific, (a) ready to mix genuine and virtual substance in a genuine climate, (b) is continuous and intuitive, and(c) can enlist virtual substance in a 3D climate. An AR framework is officially characterized as an application that satisfies the accompanying three properties, to be specific, (a) combination of virtual and real substance in a real world, (b) is realistic & intuitive, and (c) can enlist virtual substance in 3D environment[4].

II. LITERATURE REVIEW

In this [5] paper Leading e-commerce providers have built large and complicated systems to provide countrywide or even worldwide services. However, there have been few substantive studies on e-commerce systems in the real world. In this paper, we investigate the systems of Tmall and JD, the top- two most popular e-commerce websites in China, with a measurement approach but Limited to Specific Region, also only mobile application user traffic was considered

While this [6] paper The faster speed of 5G networks and high-resolution screens of 5G-enabled devices might lead to a higher degree of customer willingness to engage in e-commerce activities, more time spent on e-commerce websites, and more purchases online. The features of 5G can also lead to a higher degree of effectiveness of e-commerce vendors' activities such as online advertising. However adaption of 5G network and stable release will take time.

In this [7] paper BDA capabilities are used in e-commerce activities as a key growth

direction to increase vendors' evenues and attract customers. Based on the importance of analyzing big data and its advantages to e-commerce operations, this paper aims to study the values of implementing BDA in e-commerce to both vendors and consumers although Lack of solution on how to implement the solution

where market does not has much consumers.

Here [8] The research proposes and tests the technology adoption model of AR, which can serve as an initial step in the direction of efficacious embracing of AR by e-commerce firms. In contrast to earlier research on technology adoption conducted from the customer perspective establishing the usefulness and ease of use of the new technological system, this article highlights the key factors influencing the adoption intention of AR. The measurement model validation established the robustness of the proposed model still Exploring factors affecting AR adoption from an organizational viewpoint is a fairly new area in IS research & AR technology, upcoming revisions may discover additional factors to improve the capability of the model.

Lastly in this paper [9] The objective of this study is to examine whether the hypothesized features of MAR applications and their relationship with

persuasion dimensions leading towards purchasing intention would be supported by the data. Except for informativeness, the relationship of real-time interactivity, entertainment, and irritation with cognition and affection persuasion dimensions is supported by the data. The only limitation is the generalizability of the results is limited since the collected student data from a convenience sample may not be representative of all users

III. USABILITY STUDY

A usability study was conducted to compare our enhanced AR e-commerce system with a traditional e-commerce system. To avoid web page design bias, two web pages were designed using the same design template, which included a word description of the product and a visualization of the product. The only difference between the two types of e-commerce systems was in the visualization component[10].

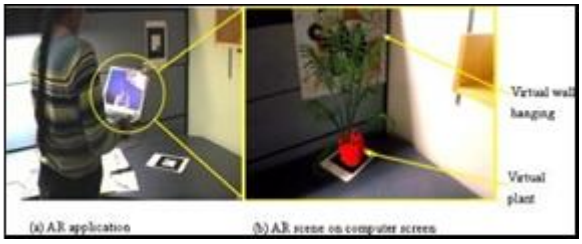

Fig 1: AR Demonstration

For visualization, traditional e-commerce web pages typically use several static 2D pictures of a product, viewed from different perspectives. Our AR- enhanced ecommerce website uses ActiveX controls for visualization. Users only need to click one button, and then the system will download 3D models in real time and activate the AR visualization capability [11, 12]. System users can visually bring products into their actual physical environments, as shown in Fig. 3. To control for interaction bias during the usability study, users were only asked to use the visualization capabilities of the systems, rather than the entire menu system, which was developed.

IV. SURVEY ANALYSIS

Survey analysis refers to the process of analyzing your results from customer (and other) surveys. Data on its own means nothing without proper analysis. Thus, we need to make sure out survey analysis produces meaningful results that help make decisions that ultimately improve the business. A quantitative analyst's main task is to present a given hypothetical situation in terms of numerical values. Quantitative analysis helps in evaluating performance, assessing financial instruments, and making predictions. Below is the Quantitative Analysis of thesurvey carried out.

Q1. How often do you use e-commerce applications[13]?

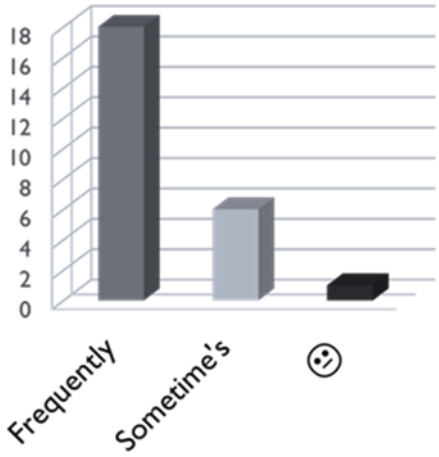

Fig 2: Use of E-commerce

Q2. Concern about data privacy ?

Fig 3: Data Privacy concern

Q3. Major concern related to user experience while using an E-commerce Application[14] ?

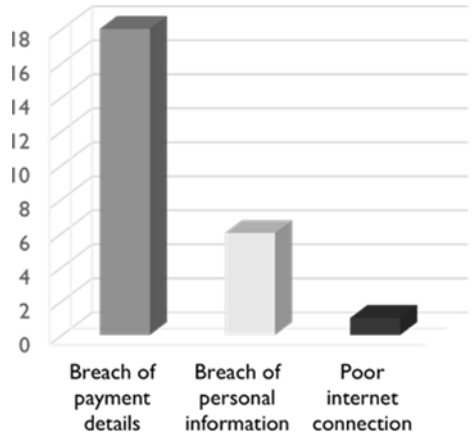

Fig 4: Major Concern in E-commerce

Q4. Have you used AR in any of the e-commerce applications[15]?

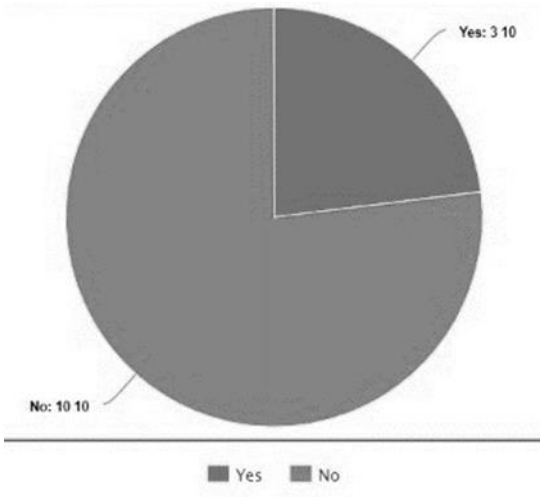

Fig 5: AR Usability

V. TOOLS & TECHNOLOGY

Blender-3D: It is an open-source 3D creation suite which is available free of cost and supporting the integrity of the 3D pipeline—demonstrating (modeling), fixing, animation, simulation, delivering compositing, and movement tracking video altering and game creation[11].

Unity-3D: It is a cross-platform 3D game-engine created by Unity technology Co. Ltd. It can superpose the virtual onto reality and acknowledges human-computerized collaboration with some Augmented Reality tools. It permits Vuforia SDK augmentation modules to distinguish and follow under the relating ports and makes AR applications and games.

ARToolKit for Android: ARCore is Google's platform for building augmented reality experiences. Using different APIs, ARCore enables your phone to sense its environment, understand the world and interact with information. ARCore uses three key capabilities to integrate virtual content with the real world as seen through your phone's camera: Motion tracking, Environmental understanding & Light estimation [16].

VI. PROPOSED WORK

From the above analysis and research, we are aiming to build a solution which will solve the aforementioned problem. Our proposed solution consists of many components which contribute to form a service. Following figure demonstrates the flow chart and different components that will be required to build such a solution [17].

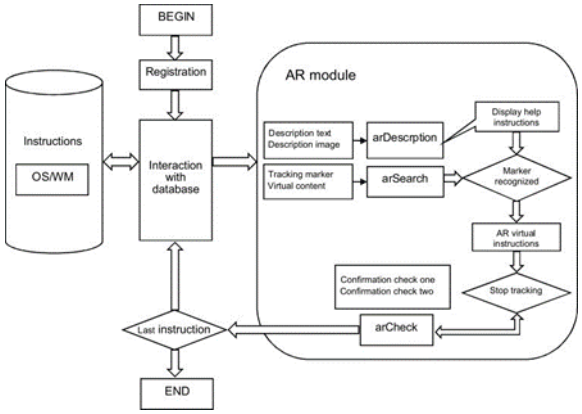

Fig 5: Architecture of System

The Body Measurement feature has a goal to offer the user the most accurate virtual fitting of the body. This AR solution is a better way to measure the fitting of the user which is revolutionary in eCommerce.

AR user manual demonstrates the process of reading a manual of appliances in an interactive way with a step-by-step virtual guide. Users without any hassles using smart devices can easily go through the details of the product. It also reduces the time and the fear of unknown risks while going through the manual of any appliances.

Cosmetics and beauty brands are hopping on the AR train to success. It makes sense: Seeing an eyeshadow applied to your face often looks vastly different from how it appears in the online product photo of the compact.

VII. APPLICATION

Virtual try-on solutions: "It looked great on the mannequin." -Everybody, at least once, after trying a new clothing item on for the first time and realizing it doesn't suit you at all. The fear of that very outcome can reduce conversion rates. Shoppers want to really know what they're getting and take every precaution for it to be what they want. And if they do take the chance to buy and it doesn't work out, your return rates will go up [18,19].

Fig 6: Brands using AR

Retail and Wholesale: Ecommerce has numerous

applications in this sector. E-retailing is basically a B2C, and in some cases, a B2B sale of goods and services through online stores designed using virtual shopping carts and electronic catalogs. A subset of retail ecommerce is m-commerce, or mobile commerce, wherein a consumer purchases goods and services using their mobile device through the mobile optimized site of the retailer.

Digital Advertising: Online advertising uses the internet to deliver promotional material to consumers, it involves a publisher, and an advertiser. The advertiser provides the ads, and the publisher integrates ads into online content. Often there are creative agencies which create the ad and even help in the placement. Different types of ads include banner ads, social media ads, search engine marketing, retargeting, pop-up ads, and so on.

VIII. RESULT & DISCUSSION

The execution of the item/ Product with Augmented reality in e-commerce permits a client to review items or experience administrations by the reasonable appearance of the item in their daily life before purchasing. Implementation of this paper can assemble an innovative promoting effort to catch the client s consideration and impact, attitude, and behavior. This can assemble attention to mark credits and offer clients the opportunity to essentially encounter the advantage of those characteristics for themselves. Clients cannot just shop for an item/product online through genuine interfaces but also attempt the item. Retailers can conquer physical restrictions and offer admittance to each item includes, eventually bringing more clients into the selling funnel for higher transformation.

IX. CONCLUSION

By utilizing augmented reality precisely, clients can be propelled to select the correct choice for buying items/products. This is advantageous to the retailer to persuade their intended interest group besides clients will have the option to get extensive data like surveys, and related items. All the more critically, AR specifically, can provide clients to in- store shopping experience, paying little heed to their zone service can superimpose 3D objects in various spaces, permitting customers to interfacing with advanced delivery to their own place with consolation.In this domain of the present scenario of more products, shorter runs immensely accelerate the variation in products, and enhance the business rivalry. Resilience in the application of above-mentioned AR- based marketing method lies in its ability to impart an intelligent fast and effective decision-making thought process in the mind of application user who may not be even technically sound about the usage of the product and its relations with other elements in its vicinity after being procured. In the future, a dynamic framework consisting of various stakeholders such as a user with an E-commerce interface who may be or even can be a potential customer, various professionals, and concerned entrepreneurs related with various domains ranging from logistic and supply chain to manufacturing [20, 21], R&D, customer support can be proposed and can be simulated tohypothetical conditions and responses given by them can be recorded and studied for various desired objectives.

X. ACKNOWLEDGMENT

This paper and the research behind it would not have been possible without the exceptional support of our guide, Dr. Harshali Patil. Her enthusiasm, knowledge and exacting attention to detail have been an inspiration and kept our work on track.

Foodera (Self Ordering System For Restaurant)

Aroma Sinha,Pallavi Vishwakarma,Abhishek Kumar Yadav ,Dr. Prachi Janrao

Thakur college of Engineering & Technology Mumbai, India

askurkure123@gmail.com,pallavivishwakarma999@gmail.com,abhishekh.y10@gmail.com,prachi.janrao@thakureducation.org

Abstract—**In the today's era, technologies are increasing daily with new features in the respective sections. Even in the age of technology, the traditional pen paper method is followed by many restaurants for receiving the orders, which in turn wastes a huge amount of time of both, the restaurant and the customer. Various earlier efforts were done to bring the technology in the field of food servingindustries. After analyzing them we have a proposed a system which improves efficiency and accuracy for restaurants by saving time, eliminating human errors, getting customers feedback. This system will remove manual order placing system which includes interaction with waiters, it contains digital menu where people can digitally place there order directly to the chef and from there the process can be managed.**

Keywords—Digital menu, Android application, Order management, Menu management.

I. INTRODUCTION

As the technology is increasing day by day the Standard of living has also been developed. By using of technology our life becomes easier and convenient and almost every field technology has developed. In adopting new technology, the food industry still lags behind as compare to other technology especially automation in different processes. After so many years restaurants and hotels still follow manual process of paper and pen system due to which table turnover process has become solve as everyone knows thatin the foodservice industry, table turnover is tough to optimize. As a restaurant owner, you want to turn tables as frequently as possible and serve the maximum number of guests. There are quite a lot of ways your restaurant can maximize table turnover, from updating your dining room to preparing certain menu items in advance but all this have some constraints and also this system requires a lot of manpower and it istime consuming. Sometimes due to increase waiting time customer tend to leave the restaurant and also due to lack of waiter's patience of a eating and hangout place and results in clutter. This system provides a solution to all this problem as nowadays everybody is on their phone and want every work to be done by there mobile phone so we proposing an application through which they can order their food without even contacting the waiter just by the help of their mobile phone. It increases the user experience while ordering food as it provides visual representation of the item and can also decide their order by others feedback as well.

II. LITERATURE SURVEY

There are number of research papers which uses these technologies introduced in market to automate this system such as:

A. Robots as waiters

This system includes robots in the place of waiters to take orders it provided contactless services which is very much needed in this covid situation and also attracted customers but it has the same disadvantage as seen with waiters such as lack of robots, process becomes solve, maintenance and installation of robot is very costly and cannot be afforded by small restaurants, order get changed, customization not possible etc.

B. Converting table into screen

This process included converting the table into the screen in this when a customer wants to order something he just simply click on their touch screen table and can place the order from their itself but this system also had drawback as installation is costly and it required proper maintenance and since it is a restaurant, table damage is common and dueto which it damage the screen placed on table as well.

C. Computer based ordering

In this process the customer goes to the cashier place the order do the payment and then wait for their order to get ready, but this system fails during rush hours since there is abig line to place the order and it takes time for a person to decide their order it increases the waiting time for others as well and also if a customer needs to order something new heneeds to go again to the cashier and do the same process again.

We have a conducted a survey in the form of multiple choice to find out what is the expectation of the customer

with this type of application and whether they are going towilling to accept this type of technology in future.

The following are the questions asked in the survey:

- Age Group

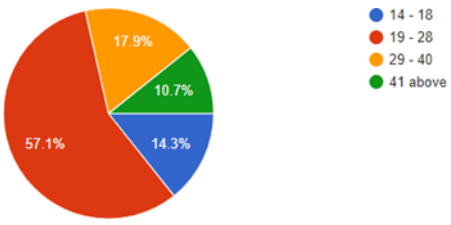

Fig. 1

- How frequently do you visit restaurants?

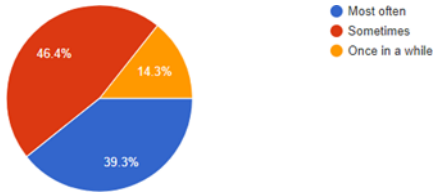

Fig. 2

- Do you hesitate to interact with waiter?

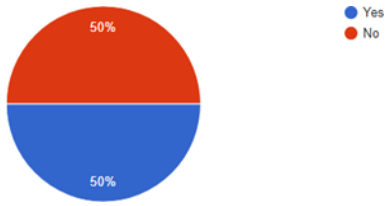

Fig. 3

- Have you ever experienced long waiting time forordering food?

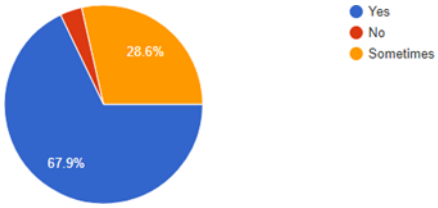

Fig. 4

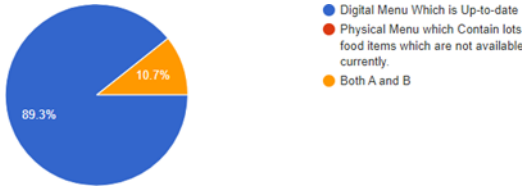
- How would you like to place an order at restaurants?



-

Fig. 5

- Would you like to use an automated system forordering food at restaurants?

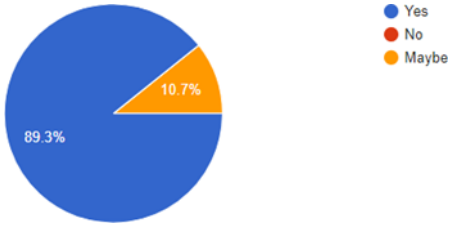


Fig. 6

- Would you like to know the quality of ingredients and calories intake of a food item before ordering?

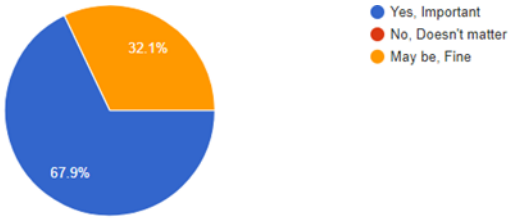

Fig. 7

- Have you ever experienced issues regarding onlinepayment at restaurants?

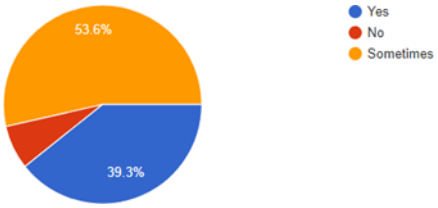

Fig. 8

- What do you think about future of self-orderingsystem at restaurants in India?

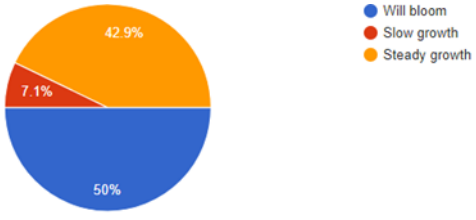

Fig. 9

III. PROBLEM STATEMENT

As the technology is increasing but still in restaurant, we use the same old-fashioned way of ordering food were waiter write the orders from customers, takes these orders to the kitchen, updates them in records, delivers the ordered of food items at the

exact table and then makes the bill and as we all know It doesn't matter where your table is within a restaurant, you can never find a waiter when you want your bill or when you want to order another drink.

Key issues

- In this Covid situation people wants contactlessservice.
- Fewer Staff increases waiting time for orderingfood.
- While ordering large amount of food in restaurants people don't have an idea of bill amount which can create problem at the end.
- Introverts' interaction problem with waiters.
- Getting orders wrong mistake is a classic.
- customized orders are often neglected by waiters.
- Allergic/Vegan etc. people face problems while ordering food because waiters don't know the exact ingredients in the food.

IV. METHODOLOGY

This project proposes a solution to design a self-ordering system named as foodera using an android application for ordering the food. This system works when a user scans the QR code placed on the table and download the application and after login he will be able to see the digital menu and through that he can place the order and can also see the description, calories, ingredients and can choose the best dish by seeing ratings and feedback and if he wants, he can customize it as well once the order is decided customer needs to pay to place the order once the payment is not done E-Bill will get generated.

Fig. 10 System Architecture

The process begins with the arrival of the customers. If there are available seats, the waiter will assist the customers to the available table. But if not, the customer will have to wait until seats become available. When seated, waiter will hand the menu and ask for their orders The customers will then choose their orders from the menu and the waiter will give them to the kitchen staff and to the cashier, so that the cashier will be able to initially process the customer's bill. The kitchen staff will prepare the orders that the waiter will serve. Once finished, the customer will ask for the bill from the waiter, and the waiter will get it form the cashier. After receiving the bill, the customer will then pay the bill.

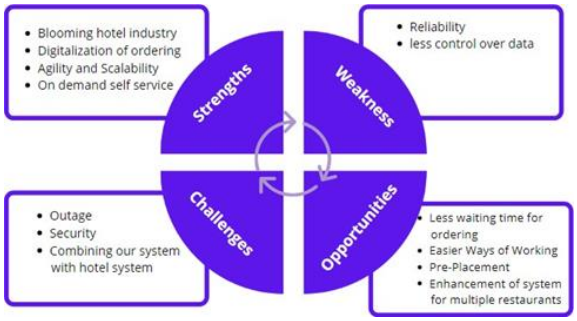

Fig. 11 SWOC Model

Upon sending of customer orders, the kitchen staff can be notified by the system as to the table number, order quality and descriptions. Once the orders are completed, the kitchen staff will notify the waiter thru the app. Payment Module The customer may use the app in viewing his bill for payment. The cashier can print an Official Receipt if the customer wants a copy. Below is the screenshot of the Payment Module.

The results show some areas for improvement in the quality of their service and Responsiveness maybe considered as critical factor.

Failure Points	Issue	Dimension
1. Wait for available seat	Customer sometimes has towait before being seated	Responsiveness
2. Ask for Menu	Waiter is unable to respond promptly	Responsiveness Empathy
3. Delivery of order	Waiter sometimes is unable to deliver the correct order	Reliability
4. Ask for bill	Waiter is unable to respond promptly	Responsiveness Empathy
5. Wait for bill	Processing of bill takes time	Responsiveness
6. Receive receipt and change	Waiter is unable to give receipt and change right away Processing of customer's payment takes time	Responsiveness

Table no: 1 Failure Points of the Restaurant's

V. RESULT AND DISCUSIION

This system has developed a user friendly which can be used by anyone very sufficiently. The customer will scan the QR Code which is placed on the table. Then the customer will be redirected to

the ordering site and may choose the order from the menu. The menu indicates the quantity of the customer's order and the customer must click the "add to cart" option to complete the order. The app will show if the order is successfully added to the cart. If thenotification of the successful ordering does not pop up, then the order is not added to the cart. When the customer accesses their cart, it will show the summary of their order. When a customer is ready to submit order, he then clicks "Submit Additional Order". System will ask for confirmation (Figure 4) since customer is not allowed to cancel their order once submitted. These orders will be received by kitchen staff.

Fig. 26 Revenue Analysis

VI. FUTURE SCOPE

This proposed system can be enhanced in future by introducing new features such as multiple restaurant access can be done with the help of single application, table booking, hall booking can also be added in this application. We can also include in this application to order a foodbefore reaching restaurant to save time.

VII. CONCLUSION

This proposed system the potential to attract customers to the restaurant and changing their dining experience in efficient way, even will help in completing the dream of digital INDIA. It will help to ease this process and will make the restaurant task much easier and more efficient. With reduction of man-power required for order taking it is not going to

be cost efficient for restaurant but it will also increase their efficiency in table turnover and they can take serve more customer in less time. The researchers recommend setting an ordering system containing delivery option to cater to increasing demand. Customers prefer their food being delivered to avoid travelling and falling in long queues. There should also be a function to monitor inventories to avoid over/under stock. The researchers also recommend a function that can monitor the employees' payroll and tips. This function will definitely help to automate the manual recording of payroll every month. This can lessen the errors and make sure that the recording and computation of absences and leaves can be easily generated. On the tips, since the restaurant has a centralized tipping policy, this function will help compute the tips based on the days and time they work to have a fair division of tips. Moreover, for further improvements, data visualization techniques to allow analysts to more easily derive insights about data and make wise decisions must be incorporated [20]. Thus, charts/ graphs about fast selling or slow moving items,

VIII. ACKNOWLEDGEMENT

We gratefully acknowledge the support, guidance, and encouragement of my Dissertation Guide Associate Professor Dr. Prachi Janrao ma'am for this novel work.

Design and Development of Vendor based E-commerceapplication with predictive data analytics

Khan Mohammed Aamir,Deepak Pandey,Rohan Pardeshi,Vidyadhari Singh
Thakur College of Engineering and Technology,Mumbai, India
1032190164@tcetmumbai.in,deepakp9757@gmail.com,rohanpardeshi412@gmail.com,Vidyadhari.rks@thakureducation.org

Abstract— **With the substantial increase in electronic commerce, companies are looking for technological advancements and innovative ways to manage the vast amount of data generated and to extract meaningful insights from it for better decision-making. Predictive analytics has been recognized as a key aspect in business decision-making and a potential driver of strategic decisions. Despite this recognition, many e-commerce businesses have yet to fully integrate analytical capabilities into their processes. This paper highlights the significance and role of using predictive analytics models in our e-commerce project. These tools have become crucial for gaining valuable knowledge for decision-making through their ability to make predictions and through various applications used by global e-commerce firms. The paper accomplishes its goal by constructing a predictive analytics model for sales forecasting in our e-commerce project and analyzing an online transaction dataset. The results from the model are presented, and insights extracted from the prediction model are discussed.**

Keywords—Generative Predictive analytics; Predictive models; Online Transactions; e-commerce; Search Behavior, Conversion Rate, Computational Models

I.INTRODUCTION

The electronic commerce industry is experiencing rapid growth worldwide, with retail e-commerce sales reaching 3.53 trillion US dollars in 2019 and projected to reach 6.54 trillion US dollars in 2022 [2]. This growth is attributed to the recognition of e-commerce as a critical tool for competitiveness in the global market, enabled by technological advancements in internet technology [3]. E- commerce provides companies with strategic planning, customer services, cost reduction, and the ability to enhance productivity and efficiency, leading to prosperity and growth and creating new market opportunities [4]. As a result, companies are incorporating the latest technological advancements into their e-commerce processes to stay ahead in the industry. Our solution facilitates this by translating audio and synthesizing the translation in the speaker's voice and lip movements, making it appear as if the speaker is speaking the translated words. Predictive analytics is a rapidly growing and crucial application of technology in the big data field, and it is becoming the cornerstone of all business decision-making [6]. Predictive analytics

is a type of data analytics used to forecast future outcomes by analyzing historical data to uncover patterns and relationships [7]. It uses statistical algorithms and machine learning techniques [7]. A report [8] estimated that the global market for predictive analytics would grow at a compound annual growth rate (CAGR) of around 25% from $1.7 billion in 2013 to $5.24 billion in 2018 and projected to reach approximately $10.95 billion by 2022. This suggests that more and more organizations are turning to predictive analytics to gain a competitive advantage [8].

Predictive analytics is also used to predict future outcomes by analyzing historical data and making better preventive decisions. The application of predictive analytics models uses machine learning to analyze customer reviews, click-through actions, preferences, and past purchase history to improve sales prospects and understand the reasons for customer churn in real-time [9]. Retailers around the world are also using predictive analytics for price optimization, merchandise planning, and evaluating the effectiveness of promotional events to determine the most appropriate offers for consumers [10].

II LITERATURE SURVEY

In Over the past couple of years, there have been several studies in business analytics that have utilized machine-learning models to predict customer purchase behavior [11]. These studies include da Silva's (2014) research, which created four machine- learning models on a clickstream dataset, Fernandes' (2015) study, which built a sequence model to predict real-time purchase likelihood, and Vieira's (2016) use of deep learning algorithms to analyze purchase behavior. These studies have made important contributions to the field of business analytics by applying machine-learning techniques [12] and demonstrating the potential of using these techniques to better understand customer interactions with e- commerce websites.

However, due to limitations in the available data, these studies have used limited, aggregate-level features such as the number of page views for a customer over the past week [13, 14]. This results in less detailed insights and makes it harder to translate the findings into practical actions for e-commerce websites.

A. Predictive Analytics:

Predictive analytics is a form of data analysis that utilizes forecasting, regression analysis, pattern matching, multivariate statistics, and predictive modeling to determine the likelihood of future events [15]. Kopp [16] defines it as a method for identifying an event before it occurs using big data. The applications of predictive analytics are based on advanced data mining, machine learning, artificial intelligence (AI), and deep learning algorithms [17, 18]. It has a long history in computer science and information

systems, and has been demonstrated to be effective in a range of domains, including sales forecasting, strategic sales management [20, 19], recommender systems [21], and fraud detection [22]. Predictive analytics models are built using quantitative techniques, usually machine learning algorithms, to construct predictive models [23]. It is an integral part of business intelligence [24] and decision support systems.

B. Predictive Models Techniques

• Classification: Classification models answer questions that require a yes or no response (e.g., "Is this customer about to churn?" or "Is this a fraudulent transaction?") by providing broad analysis and guiding a decisive variable (target or class). The construction of the model is based on decisive or numerical variables (predictors or attributes) [25].

• Clustering: Clustering is an unsupervised machine learning method that sorts data into separate groups, each containing similar attributes [26]. This process helps to uncover unknown relationships in a dataset, such as using a cluster model to separate customers into similar groups based on common characteristics and develop strategies for each group on a larger scale [27].

• Association Rules: Association rules are a rule-based machine learning method used to find important associations in observations [30]. It means finding all item sets that have support greater than the minimum support and then using large item sets to generate rules with confidence greater than the minimum confidence [31].

III. Survey Analysis

Survey analysis involves reviewing and examining the outcomes of customer surveys (and others) to extract meaningful insights that can be used to make informed business decisions. The process of analyzing survey results is crucial as raw data alone is meaningless without proper interpretation

Q1. How often do you use e-commerce applications?

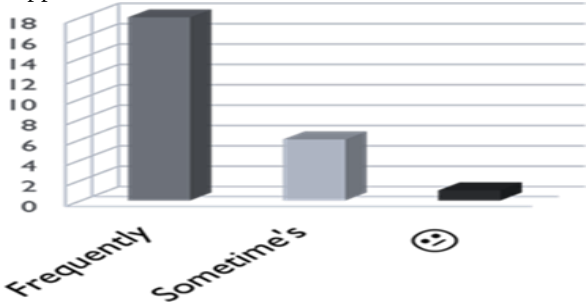

Fig 2 Use of E-commerce

Q2. Major concern related to user experience while using an E- commerce Application?

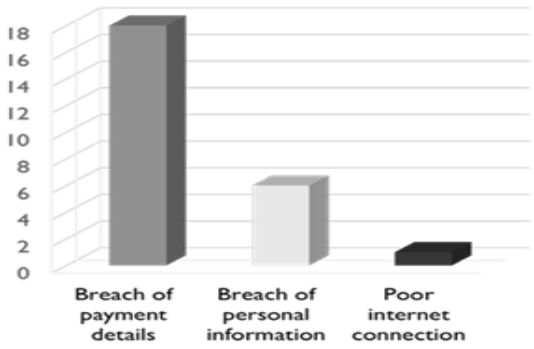

Fig 3 Concerns about data privacy

Q3. What big data analytics tools eCommerce firms prefer?

I. Proposed Work

We are creating a full-fledged cross platform application, where admin of the application can add products which vendors can sell, and users(consumers) can buy. ChkOUT will be a platform where user can buy product & vendors list their Product It will Consist of 3 Interfaces:

• Mobile App: for User to Buy Listed Products.
• Web Application: for Vendor Registration & Product Listing
• Web Application: For admin for Moderation and Verification of Vendors, Listing Products & Manage Users.

This app will be very much user friendly with great User Experience. Sellers must register themselves to the app and list their products on vendor registration page which on after verification fromadmin will be updated on app. Guest user can view products without any registration but have to register in order to make anypurchase.

As we know that there going to be a lot of data for this project as we discuss in the introduction and literature review. So, we are going to use these for predictive analysis. This will be going to help Vendor as well company to manage their product inventory and making

profit from the collect data. Now, the detailed information is disused in the next section Methodology.

II. METHODOLOGY

1. For making website and mobile application:

Sequence Diagram & Flowchart: Using the Unified Modeling Language (UML), a sequence diagram depicts the flow of messages that are delivered and received by objects during an interaction. A sequence diagram is a collection of objects represented by lifelines and the messages they exchange throughout an interaction. Here, wecan see all of the system interactions and system reactions.

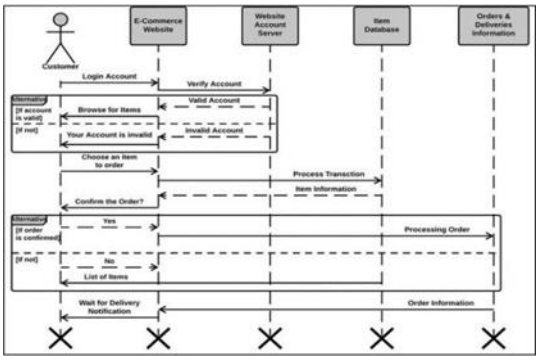

Fig 4: Sequence diagram

• Architecture Diagram: A software system's physical implementation of its component parts is mapped out visually in an architectural diagram. It displays the connections, restrictions, and limits between each piece as well as the overall structure of the software system.

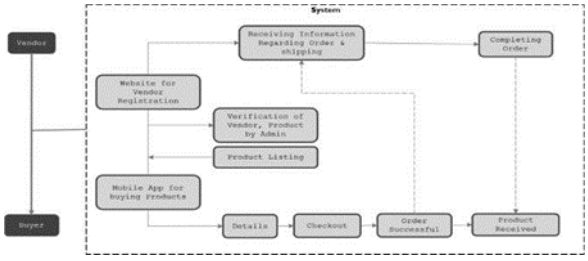

Fig 5: Sequence diagram

2. Data analytics

In this part, we provide examples of the framework for predictive modelling in detail as it relates to the problem at hand. The six steps of the predictive analytics process are depicted in figure 6. The problem is characterized in the first stage (the identification of the issue) using the model's suggested results, objectives, scope, and deliverables. The subsequent step (the gathering and preparing of the data) involves gathering and analyzing data from numerous sources. The third phase, analysis (data analysis and model creation), calls for pre-processing techniques including data cleansing, transformation, and modelling to ensure that meaningful data is retrieved for future processing. Use statistical models to confirm the primary hypothesis after that. The following stage (placement, monitoring, and management of the Predictive modelling is the process of predicting the future. After implementation, results can be used to inform daily decision-making. The model is monitored at the final stage to make sure it is producing the desired results.

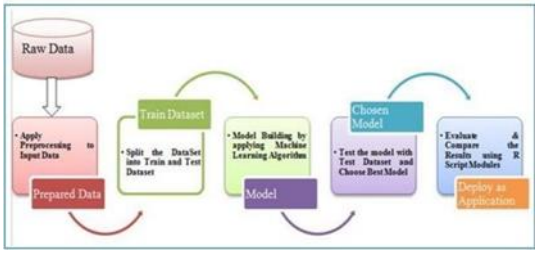

Fig 6: Predictive modeling framework

VI. IMPLEMENTATION DETAILS

To make the proposed solution accessible to people, all the above-mentioned components are modularized and connectedto each other in backend by referring to the system design created and serve it as an Application Programming Interface (API). To make this service accessible a web-app has been developed.

• Server-Side: Development For developing thebackend logic we have used Node js , Express js, and MySQL database. Its flexibility in organizing the project structure as per our preference and the ability to write async code makes it a better choice than other frameworks. As an outcome, our proposed solution can be served on a server and can be accessed by calling the API.

• Client-Side: Development To make our solution to general public, a Web-App needs to be developed which connects to the API developed. The web-app is developed using front-end technologies like HTML5, CSS, JavaScript & React js. The designing part is handled using HTML and CSS and JavaScript is added to provide various functionalities to make user experience better. The Mobile application is created using Flutter with Blocstate management.

• Data Analytics: For predictive analytics Power Bi, Tableau, Machine Learning algorithms and Deep learning are used for better prediction and clustering of the customer into different groups or chunks.

VII. SYSTEM DESIGN

• Data Flow Diagram

Level 0 DFD is often referred to as a context diagram. It offers a broad overview of the entire system or process under or being modelled. In what is meant to be an overview view, the system is shown as a single, high-level process along with its connections to external entities.

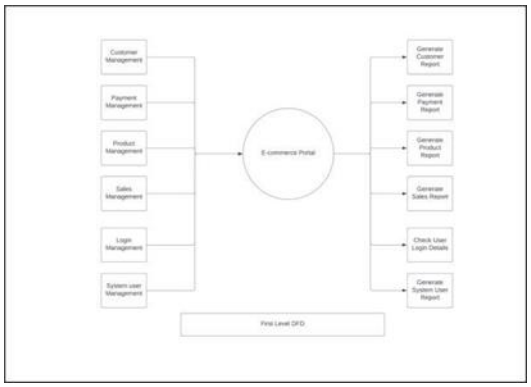

Fig 7: 0 Level DFD

Compared to a context diagram, as per fig 8: Level 1 DFDs go into more detail while still giving a general picture. In level 1 DFD, the single process node from the context diagram is broken up into sub-processes. As more processes are implemented, the diagram will need more data flows and data stores to connect them.

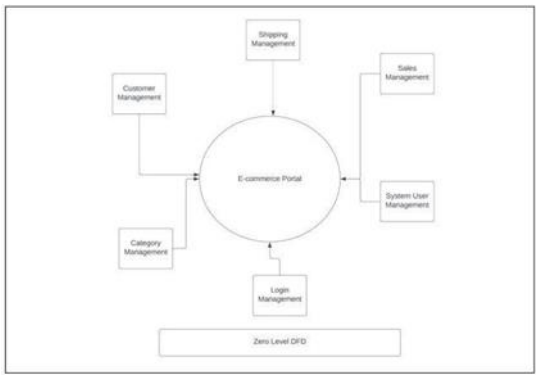

Fig 8: 1 Level DFD

This level two data flow diagram (DFD), in fig 9 template can map out information flow, visualize an entire system, and be shared with your stakeholders.

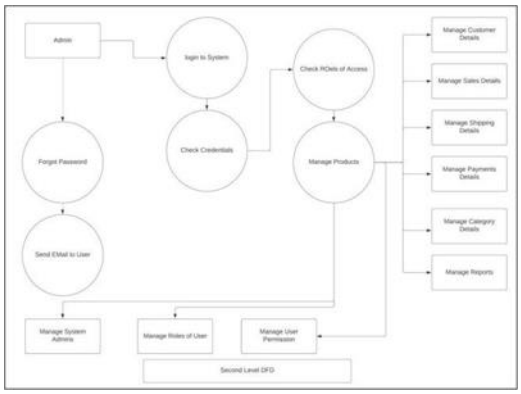

Fig 9: 2 Level DFD

VIII. APPLICATIONS

As we know e-commerce for electronics and many items

are huge in future and today itself.

1.This E-commerce project will help many small and new vendors to expand their business online.

2.This project going to target the electronics market, so using this project will boost all the electronics seller to sell their product online with ease.

3.As we are also providing the predictive analytics that will going to help the predict customer behavior in future and help to make future discussion for making higher conversion rate and make higher profit.

IX RESULT AND DISCUSSION

This study set out to shed light on the value and function of applying predictive analytics models in e-commerce projects, where these tools have grown to be essential tools for gathering crucial information for better decision-making. Predictive analytics was applied to an online transaction dataset gathered through an e-commerce company for predicting product category sales in order to achieve this goal, and the dataset has been studied.

The predictive model was then created to demonstrate how it may be utilized to gather important information. In order to provide adaptive decisions, predictive modelling is essential, and businesses today must use the most cutting-edge analytics to compete. Such models could be useful for the ecommerce firms to make high operational efficiency, improve customer satisfaction, and robust revenue and profit levels.

Only 71,159 (4.9%) of the 1,530,738 transaction records are conversion cases; the rest are non-conversion records. The outcomes of the model construction as well as the descriptive statistics are both presented below.

Results of the random forest model the 15 predictor variables and one target binary variable with two levels were included in the RF creation process (buying and not buying). We used the R package caret to carry out the RF model's tuning and training. The only variable that has to be changed is the number of variables chosen at random at each split, or mtry.

Mtry	Accuracy	Accuracy SD
1	0.6805	0.0050
2	0.6998	0.0049
3	**0.7008**	**0.0049**
4	0.6998	0.0048

Fig 10: Accuracy for Random forest

Results of the logistic regression model: The logistic regression method was used to build the second model. The VIF (Variance Inflation Factor) and the LASSO approach were both utilized to choose variables to minimize the problem of variable multicollinearity because the 15 predictors are potentially correlated.

Performance:

Classifiers	Accuracy	Sensitivity	Specificity
Random Forest	0.76	0.73	0.82
Logistic Regression	0.61	0.61	0.60

Fig 11: Comparison for random forest and Logistic regression

	Random Forest		Logistic Regression	
Prediction	Actual (Reference)		Actual (Reference)	
	True (buy)	False (not buy)	True (buy)	False (not buy)
True (buy)	135,621	50,614	93,402	59,990
False (not buy)	24,373	109,397	65,805	100,014

Fig 12: confusion matrix for Random Forest and Logistic regression

IX. CONCLUSION

The transition required today from business to become data- driven, evidence-based organizations is mandatory due to the global boom of big data in all facets of the business world. Big Data has brought about a fundamental change in how firms are set up and managed. Therefore, the use and deployment of data analytics tools is seen as an essential component of the decision-making processes in all businesses, but particularly in ecommerce firms.

In order to demonstrate the value and impact of using one of the data analytics models in this e-commerce project, a predictive model example for a dataset of online transactions is described in this paper. The huge volume of data being produced enables e- commerce businesses to make quick decisions that can help save money and improve operations.

For example, by analyzing big data, including customer online behavior, purchases, and product searches, it is possible to better understand consumer behavior and preferences. Few studies have been able to conclusively link search activity with conversion decisions, despite the substantial body of literature on various elements of search behavior in the context of e-commerce. In this study, we built a random forest prediction model using 15 search behavior factors. The model's online conversion forecast accuracy was 76%. The RF model also offered a rank of variables according to their significance in the model's development. As a consequence, whereas devices, query length, hour of the day, and query position do not significantly influence the prediction model, page and session dwell duration, user type, click entropy, and click position are the most crucial variables. The work has a number of restrictions. The way server log analysis is done is one of its main limitations.

Due to the queries that are stored on the local system or proxy servers, the logged data does not accurately reflect user behavior. Additionally, the session-level analysis depends on the accurate identification of the session borders, which is difficult without programs that keep track of the start and finish times of sessions.

Abstract: **The stock market has abundant opportunities. The satisfaction of keeping a stock with conviction and seeing it grow to multiple-bagger status is unmatched. However, because of how complex the stock market has become, it is likely to not get lucrative results if we try manual trading to gain profits. Also managing all the trading accounts is difficult and time- consuming as information available for analysis is enormous. The recent development in trading strategies allows the use of algorithms to buy/sell the stocks automatically. This automation can improve the trader time management and efficiency. This paper proposes real-time trading strategies on broad range of stock markets by closely monitoring the trade results and news in real-time to detect patterns that can enable stock prices to go up or down. The proposed system in this research paper is an algorithmic trading web application that has the potential to make rapid, data-driven trading decisions, reduce emotions and biases and increase efficiency and automation in the trading process. Algorithmic trading web application can also help traders to manage their risks more effectively, and to diversify their portfolios across multiple assets and strategies.**

Keywords: financial, algorithmic trading, research, technology, efficiency, stock market, algorithms, automation.

I. INTRODUCTION

Artificial intelligence is now more important to human life than ever before. According to University of Georgia research, people trust computers more than people. Both stock market investors and traders may envision how technology is a part of everyday life for trading. Algorithmic trading, commonly referred to as "Algo trading," enables investors and traders to transact on the stock market by employing automated procedures. In 2008, algorithmic trading was introduced to India, but very few individuals were aware of it. It was created to automatically carry out numerous market trades at precise timing and speed, which is impossible for people to perform.

The history of algorithmic trading dates to the late 1970s, when computers first started to be used in the financial markets. The first use of algorithms in trading was for simple execution of trades, such as routing orders to market centres to achieve best execution. Over time, algorithms became increasingly sophisticated, incorporating more advanced mathematical models and artificial intelligence techniques. In the 1990s, electronic trading systems became more prevalent, leading to a growing use of algorithms for a wider range of trading strategies.

The development of the internet also made it possible for traders to access real-time market data and execute trades from anywhere in the world.

The early 2000s saw the rapid growth of high-frequency trading (HFT), which uses algorithms to make rapid trades based on minute-by-minute market movements. HFT quickly became a dominant force in the financial markets, accounting for a significant portion of all trading volume. Today, algorithmic trading is a key part of the financial industry, and its use continues to expand as technology improves and new trading strategies are developed. Despite some concerns about fairness and stability in the financial markets, algorithmic trading remains a popular and influential tool in the world of finance.

The ability to create automation in some stages of the trading process greatly improves the reaction time of a trader, by processing and incorporating the information as it arrives and managing a growing number of accounts. This can increase the trader efficiency and profit margin. In the new electronic market, algorithmic trading is an essential tool for the trader and is widely used. In 2014 first quarter, algorithmic trading was responsible for 17 to 25% of the total market volume per month.

Currently all the major companies in investment banking offer algorithmic services packages to their clients. The algorithms can be categorized according to their function in the following manner:

- Impact-Driven - Minimize the impact of the trade on the market. Orders with big quantities can have a negative impact on the market, as its required quantity can be larger than the number of orders offered at a certain price level, causing the order to “walk on book” and be fulfilled at increasingly worst market prices.
- Cost-Driven - The objective of cost driven algorithms is to reduce the general cost of trading. They must take into consideration all factors that can influence the cost. Similar to the impact-driven algorithms, they must take into consideration market impact, but not to the point of avoiding it in its totality.

The concept of the proposed paper is to define and implement a real-time algorithmic trading system using trading APIs and web technology. Users can perform algorithmic trading methods, keep an eye on their trades and portfolios, and access real-time market data and statistics with this web application. The web application app provides access to the powerful tool of algorithmic trading in a simple way that is understandable to all.

II. LITERATURE SURVEY

In this paper [1], the author reviewed the most advanced techniques to forecast financial asset trends and answer

the question of whether those techniques can be used to successfully trade the complex financial markets. The systems use deep learning (DL) and machine learning (ML) protocols to investigate phenomena and non-obvious relationships that affect the likelihood of successful trading. Their forecasts are based on linear or nonlinear algorithms that are frequently supplemented with sentiment analysis or pattern identification from social media investors.

In this paper [2], the author's research aims the creation of an algorithmic trading approach that will automatically trade user strategies alongside its own algorithms for intraday trading based on various market conditions and user approach, and throughout the day invest and trade with continuous modifications to ensure the best returns for day traders and investors.

In this paper [3], the author proposes a novel DRL trading policy so as to maximise the resulting Sharpe ratio performance indicator on a broad range of stock markets. The training of the resulting reinforcement learning (RL) agent is entirely based on the generation of artificial trajectories from a limited set of stock market historical data. In order to objectively assess the performance of trading strategies, the research paper also proposes a novel, more rigorous performance assessment methodology.

This paper [4] identifies the most preferred platform for Algo-trading and challenges encountered by the investors adopting these strategies. Finally, the study arrives at a meaningful conclusion and provides scope for further research in this area of study.

In this paper [5] discuss about Algorithmic Trading and trading strategies with Quantopian platform, to create intelligent trading algorithms as well as back testing them to see how they would perform on historical data. The set of trading algorithms example includes strategies and how would it be helpful for all the others and how we can utilize these strategies in real live trading to make profit and most important to understand the market data.

This research paper [6] talks about how algorithmic trading works using Artificial intelligence technology and discusses the top five trading strategies adopted in algorithmic trading and the key advantages of implementing them. This research paper also emphasizes on evaluating the critical differences between discretionary trading and algorithmic trading and why traditional traders should consider switching to algorithmic trading platforms.

This paper [7] presents a rule-based trading approach for algo trading by incorporating the concepts of Elliott waves. The study consists of three phases. In the first phase, we select a technical indicator.

In the second phase, we define the rules for conducting trade using the selected technical indicator. In the third phase we analyse the trend using Elliot waves. The study is aimed at adoption, deployment, and development of analgorithmic trading system.

This paper [8] is an exploration of the application of algorithmic techniques at a retail investor's scale. Using simple quality and value factor models to machine learning techniques like Random Forest and AdaBoost, we have explored if a retail investor can participate in the capital markets and earn better returns than by investing in ETFs. Given that factor investing and various rules-based strategies have previously been studied in academia, we fill the gap in the literature by providing our own approach as well as testing performance across two geographical regions. The empirical analysis performed in this thesis suggests smart beta algorithmic trading or AI based strategies outperform on risk adjusted basis. We therefore conclude that retail investor can leverage on algorithmic techniques and AI based strategies such as smart beta or factor investing to create medium to long term trading models.

III. PROBLEM STATEMENT

Traders are looking to improve their performance and manage risk in today's complex and fast-paced financial markets. With continued advancements in technology and new trading strategies being developed, automated tradingis likely to play an increasingly important role in the financial industry in the years to come.

The objective of our system is to obtain understanding of how the financial market operates and to develop a functioning prototype of an algorithmic trading, taking into account its already created infrastructure. We learn the fundamentals of the financial market, then implement the most popular trading algorithms while leaving some room for modification based on our analysis of our clients' demands and most desired features. Understanding a system's inner workings is crucial in order to deal with technology that is directly tied to the financial market.

The work proposed in this paper addresses the following issues:

- In today's era of digitization, staying updated with financial trends is a necessity for businesses to both outsmart the competition and achieve desired business growth.
- Machine learning-enabled technologies can give advanced market insights, algorithmic trading models allow trading companies to make better trading decisions by closely monitoring the trade results and news in real-time to detect patterns that can enable stock prices to go up or down.
- Our application will provide an ecosystem for financial monitoring, smart investment predictions, financialadvisory and algorithmic trading.

IV. METHODOLOGY

The proposed system is a software platform that allows traders to execute trades based on mathematical algorithms and models. The algorithms analyse market data, such as prices, volumes, and economic indicators,

and use that information to make automated trading decisions. The web application provides traders with a user-friendly interface for defining their trading objectives and constraints, as well as for testing and implementing their algorithmic trading strategies. The algorithms can be programmed to execute trades automatically, or they can provide signals that the trader can use to execute trades manually.

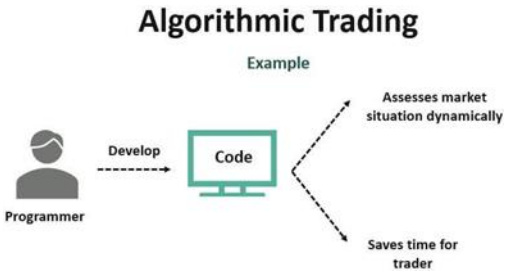

Figure 1. Algorithmic Trading Overview

Overall, our system provides traders with a powerful tool for making informed investment decisions and maximizing returns, while reducing the risks associated with manual trading. In the next section the building blocks of our trading system will be defined.

A. Define trading objectives and constraints.

The first step in developing an algorithmic trading strategy is to define the trading objectives and constraints. This includes determining the type of assets to be traded, the desired risk/return profile, and any other constraints such as maximum trade frequency or position size.

B. Data collection and preparation

In order to make informed trading decisions, the next step is to collect and prepare the relevant market data. This includes historical price data, economic indicators, news events, and other relevant data. Free information sources, Google and Yahoo both provide stock data. The disadvantage of using the python package yfinance to download historical stock prices from yahoo finance is that it only offers historical data—not real-time data.

Paid APIs (application programme interfaces) as Zerodha's kite Connect, FXCM Forex trading, Market Stack, EOD Historical Data, Alpha Vantage, IEX Cloud App, Tiingo, Intrinio, Quandl, and Polygon can be used for real-time data. The data is cleaned, transformed, and transformed into a usable format for further analysis. Our system makes use of FXCM forex trading API and Alpha Vantage API.

Figure 2. Historical trading data of IBM stock

C. Algorithm development:

The next step is to develop the algorithmic trading strategy. This involves the use of various mathematical models and algorithms, such as regression analysis, decision trees, and machine learning algorithms. The strategy is based on the objectives and constraints defined in step one and is tested using historical data to ensure that it meets the desired risk/return profile.

Technical Indicators

Technical indicators are mathematical calculations based on the price and/or volume of an asset and are used to provide traders with information about market trends, potential buy and sell signals, and other aspects of market behaviour. Technical indicators are widely used in algorithmic trading, as they help traders to identify trends, make informed investment decisions, and manage risk. Our system uses multiple technical indicators in combination, to gain a more comprehensive understanding of market conditions and to generate more accurate trading signals. Some of the most common technical indicators used in algorithmic trading include:

- MACD (Moving Average Convergence Divergence):

The MACD is a trend-following momentum indicator that is calculated by subtracting the 26-period exponential moving average from the 12-period exponential moving average.

$$\text{MACD} = \text{12-Period EMA} - \text{26-Period EMA}$$

Algorithm:

Step 0: Input the current year.

Step 1: take the historical data of price for 6 values say onJan 1st, March 1st, May 1st, July 1st, Sept 1st, November1st.

Step 2: Calculate the moving average value of the above databy using the above-mentioned formula.

Step 3: Repeat the above steps for the previous 5 years from the current year.

Step 4: Plot the MA values in graph using Visual Prolog Features

- RSI (Relative Strength Index)

The Relative Strength Index (RSI) is a momentum oscillator that measures the strength of an asset's price action. The RSI is calculated by comparing the magnitude of an asset's recent gains to the magnitude of its recent losses over a specified number of periods, typically 14periods. The RSI ranges from 0 to 100, with values above 70 indicating that the asset is overbought, and values below30 indicating that the asset is oversold.

$$RSI_{\text{step one}} = 100 - \left[\frac{100}{1+\frac{\text{Average gain}}{\text{Average loss}}}\right]$$

$$RSI_{\text{step two}} = 100 - \left[\frac{100}{1+\frac{(\text{Previous Average Gain}\times 13)+\text{Current Gain}}{-((\text{Previous Average Loss}\times 13)+\text{Current Loss})}}\right]$$

- OBV (On Balance Volume)

The On-Balance Volume (OBV) is a momentum indicator that uses volume data to predict changes in an asset's price. The OBV is calculated by adding the volume of an asset on up days (when the price increases) and subtracting the volume on down days (when the price decreases). The basic idea behind the OBV is that an increase in volume usually precedes a change in price. If the OBV is rising while the price of an asset is also rising, this is considereda bullish signal, as it suggests that buying pressure is increasing and that prices are likely to continue to rise. Conversely, if the OBV is falling while the price is also falling, this is considered a bearish signal, as it suggests that selling pressure is increasing and that prices are likely to continue to fall.

$$OBV = OBV_{prev} + \begin{cases} volume, & if close > close_{prev} \\ 0, & if close = close_{prev} \\ -volume, & if close < close_{prev} \end{cases}$$

D. Backtesting

Before implementing the algorithmic trading strategy in a live environment, it is important to backtest the strategy using historical data to ensure that it performs as expected. This involves simulating trades using the algorithm and comparing the results to actual market data. Any issues or problems with the strategy can be identified and addressed during this stage. Backtesting is the process of testing a trading strategy using historical market data to evaluate its performance. The purpose of backtesting is to simulate the performance of a trading strategy over a specified time period, and to determine how well the strategy would have performed if it had been in use during that time. During backtesting, the trading strategy is applied to historical market data, and trades are executed according to the rules defined by the strategy. The performance of the strategy is then evaluated based on metrics such as profitability, risk-adjusted return, and maximum drawdown.

Backtesting is an important step in the development of an algorithmic trading strategy, as it allows traders to evaluate the effectiveness of the strategy and to identify any weaknesses or limitations before implementing it in a live trading environment. By conducting backtesting, traders can avoid costly mistakes and ensure that their strategies arerobust and effective. Overall, backtesting is a critical component of algorithmic trading and helps traders to refine and improve their strategies, reduce risk, and maximize returns.

We backtested the momentum trading strategy using MACD technical indicator on various stocks such as Apple, Amazon, Cisco, Facebook, Microsoft, Qualcomm, Intel, Verizon and plotted their returns, Sharpe ratio and Max Drawdown.

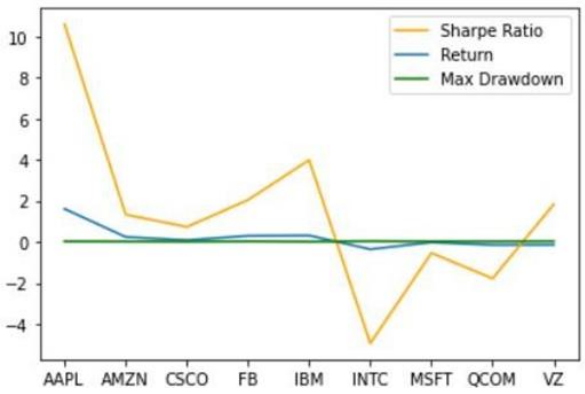

Figure 3. Sharpe Ratio, Returns and Max Drawdown of stocks after trading

E. Implementation:

Once the algorithmic trading strategy has been tested and refined, it can be implemented in the web application. The implementation should be automated and incorporate riskmanagement features to ensure that trades are executed in line with the trader's objectives and constraints. The trading data is passed through the gateway to the respective systems as shown in Figure (4) below usually this process will be deployed in the cloud.

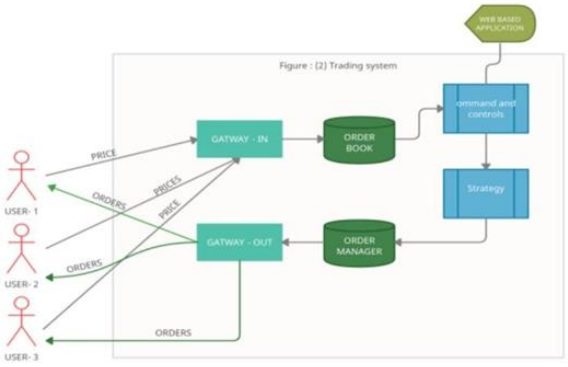

Figure 4. Trading system design

Design and development of an application for financial recommendations and algorithmic trading

G. Snapshots:

Fig 5 illustrates the flowchart of the algorithmic trading process to be integrated into the web application. After identifying the trading strategy, the next step is to translate it into code. This involves writing algorithms that will execute the strategy, taking into account various market conditions and parameters. We implemented the trading algorithms using Python as programming language.

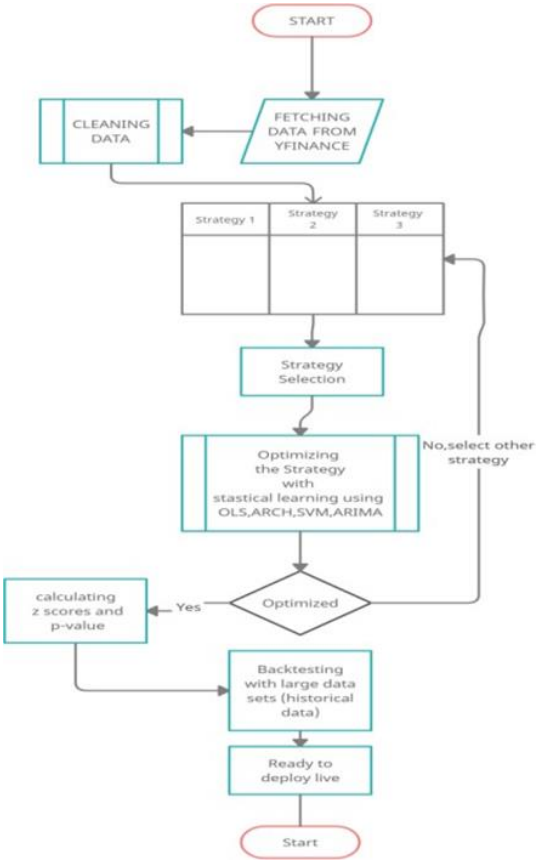

Figure 5. Algo-Trading Flowchart

F. Monitoring and maintenance:

The final step is to monitor the performance of the algorithmic trading strategy and make any necessary updates or adjustments to ensure that it continues to meet the trader's objectives and constraints. Monitoring includes the ongoing analysis of algorithmic trading systems to identify potential issues or areas for improvement. This can involve the use of backtesting and real-time simulations to evaluate the performance of the algorithms, and to identify any errors or potential areas for optimization. Maintenance involves the regular updating and improvement of algorithmic trading systems. This can involve fixing bugs or addressing other technical issues, as well as making updates to the algorithms or software programs to improve their performance. Maintenance is also an important component of risk management, as it helps to ensure that algorithmic trading systems are operating in a stable and secure manner.

Figure 6. Algo-Trading Homepage

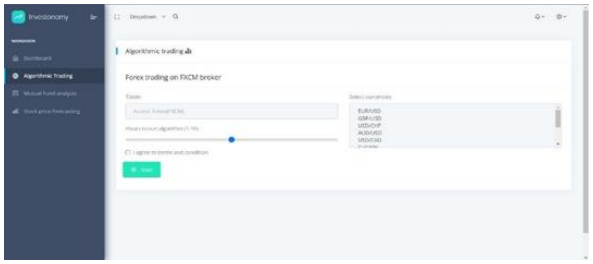

Figure 7. Algorithmic trading page

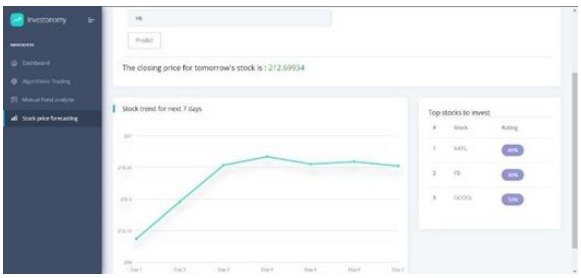

Figure 8. Stock market analysis

V. CONCLUSION

In conclusion, algorithmic trading has revolutionized the financial markets by introducing a more systematic and efficient approach to trading. With the use of advanced algorithms and technology, algorithmic trading has been able to achieve faster and more accurate decision-making, leading to improved trading performance. However, the increased use of algorithmic trading also raises concerns about fairness, transparency, and stability in the financial markets. To ensure that algorithmic trading continues to benefit the financial markets, it is important to continue to monitor and regulate the use of these algorithms.

Our system allows users to access and execute algorithmic trading strategies using our website. Our web application includes features such as real-time market data, portfolio management, and the ability to place trades based on algorithmic signals.

Users can also typically set up alerts and notifications, monitor their trades and portfolios, and access various analytics and reports. It provides traders with the ability to make informed trading decisions on-the-go, without needing to be tied to a desktop computer. By leveraging

thepower of algorithms and web technology, traders can potentially improve their trading performance and make more informed investment decisions.

Entertainment Assistant for the Digital Inclusion of Elderly People

Hrishikesh Joshi,Aryan Kawli,Kartik Kounder,Dr. Rekha Sharma
Thakur College of Engineering and Technology Mumbai, India
hrishikeshjoshi2801@gmail.com,apkawli2510@gmail.com,kartikkounder@gmail.com,rekha.sharma@thakureducation.org.

Abstract—**Nowadays, there are many social media platforms like Instagram, Facebook, Telegram, and many more for social connection. The aged people who are not adaptive to the Technologies face a lot of difficulties to engage. Which leads to stress, anxiety,depression, and many more. To Overcome this problem,this paper discusses an application that is quite useful tointeract with elderly people this application provides a user interface for elderly people to engage and listen to avariety of stories, music, and for other entertainment purposes. They will also have an audio chatbot. This machine learning-based chatbot, created with the help of Rasa and AimyBox, will enable user voice commands. The user interface, created for the android platform, is so friendly that it is very easy to operate. We have also created a section for storytelling which will help the users reminisce. Our application is useful for the entertainment of old people as well as for helping them cope with their day-to-day needs. The solution discussedin this paper also contains features like reminders, chatting platforms, etc., which will improve the users' lives.**

Keywords—machine learning, natural language processing, natural language understanding, digital assistant, entertainment, reminiscing

I. INTRODUCTION

Old people have a lot of free time and comparatively fewer activities to do. Not being able to utilize this

extra time properly may cause anxiety or depression in them. Depression is a major mental health problem, which is yet to be recognized as an important public health challenge. About 322 million people are affected by depression worldwide [1]. Depression is the singlelargest contributor to global disability (7.5%, 2015) anda major contributor to suicides (~ 800,000 annually) [2]. In India, elderly persons (60 years and above) constitute 8.6% of the total population (India Census 2011), which is projected to reach 19% by 2050 [3]. Thus, depression among the elderly population is likely to be a major cause of disease burden in the future. Theelder people need to socialize with people of their ownage to cope with these problems [3]. Connecting to other people is one of the basic needs of these people. This is psychologically beneficial, as it boosts stable emotions and minimizes depression and loneliness. Older adults tend to be in a better place emotionally if they can remain active in familiar communities in meaningful ways. Thus, entertainment and communication are the key points.

A few kinds of research were studied to know the current situation in the field. In all the research done till now, the aspect of creating better conversation has beengiven more importance than entertaining the users. Sometimes, only conversations aren't enough to makea person stay away from boredom and loneliness. Also,

there are some existing applications in this field, but they lack some or other things every time. All the solutions focus on one problem at a time. There is no such solution where all the functionalities are combined together.

In this paper, we are going to integrate various functionalities helpful to the elderly, with the help of a voice assistant. For this, we are going to use theAndroid platform to build all the required functionalities such as storytelling, joke platform, chat rooms, reminder application, etc. When the user speaks the waking keyword, the assistant will start listening. Then, the assistant will convert the speech to text form,for further processing. From this input, the assistant will find the intention of the user, such as if the user wants to record a story, or he wants to hear a joke, etc.This will be done using various NLP and NLU techniques provided by RASA. Then, the assistant willgive a command back to the system, which is called intent in Android terms. Using this intent, the application will perform whatever was requested by the user.

The following sections of this paper will thoroughly discuss the problem statement of the paper, all the researched literature, including the papers studied and

the existing applications analyzed, give a brief explanation of the working of the application proposedin this paper.

II. PROBLEM STATEMENT

Depression and anxiety have become a major problemin the society especially among elderly people. Senior citizens are most vulnerable because of issues related to loneliness and boredom. To help them, we need a system which is easy to use and provides to the need of their entertainment and a basic form of communication.

Reminiscing is very important to reduce loneliness and depression. With the generation gap and less communication among family members, reminiscing has become more and more difficult for elderly people.Thus, we need an application which may help them reminisce.

III. LITERATURE SURVEY:

For this paper, we referred to some research papers about digital solutions for the problems of elderly people. Most of the papers proposed AI-basedconversational agents. These papers with their work and identified gaps are discussed in the table below:

TABLE 1: LITERATURE SURVEY

SN	Year	Title of paperand Name of author	Work Done	Results	Gaps Identified/Future scope
1	2021	Conversational Agents for Elderly Interaction [1]	Study different conversational chatbots for the elderly to find answers to 5 research questions related to the topic.	(1) Most used input type is speech (2) The main engagement strategyused is personalizing	(1) limited dialogue leads to a decrease in acceptance and satisfaction by the users (2) Only conversations provided, no further usage
2	2021	Entertainment chatbot for the Digital Inclusion of Elderly People Without Abstraction Capabilities. [2]	Designed an entertainment chatbot for elderlypeople with a newsservice as a base. Used face recognition to improve user experience.	(1) Users would getthe latest news. (2) Users mood dependent responseswere given by the chatbot	(1) confused users were particularly baffled by chatbot interruptions when they paused for too long. (2) No much functionality above entertainment and news service.
3	2021	Assistive technology for elderly people:State of the artreview and future research agenda. [3]	This study aims to analyze the progressof academic research in assistivetechnology for the elderly in the past two decades using a systematic literature review.	(1) Assistive technology researchhas accelerated in recent years, especially in regionsthat have aging issues. (2) Though some of the latest technologies like IoT, AR, VR, and AI have been used to implement AT, there is still scope for leveraging themto personalize users' experience. .	(1) The social significance factor needs more attentionand holistic outcome-based technology implementation and evaluation to be considered. (2) The ethical implications of technology used for elderly assistance needto be analyzed as it has animpact on human values.
4	2017	A Context- Aware Platformfor ComprehensiveCare of ElderlyPeople:	This paper presentsthe architecture thatwill take SAFER (“Smart Assistance platform For Elderly care”). The	Many elderly peoplewere made to use the app developed and following suggestions receivedfrom them:	(1) There are different systems that focus on the care of the elderly, each of them provides aspecific service, which contributes to their

		Proposed Architecture.[4]	objective of this platform is providing, in an integrated way, a setof smart services that improve the quality of life and social integration ofelderlies.	• To use large lettersto read the messageswithout effort. • To employ friendly colors to take care eyesight. • To locate the application buttonsin the center of the screen. • To follow the less number of steps to get a result. • To make clear and precise recommendations.	care. The most optimal option would be to integrate in a single platform several intelligent services that contribute to their physical and social care. In this platform several options must beoffered so that the elderly can lead a more independent life.
5	2013	Context-Aware Elderly Entertainment Support SystemIn Assisted Living Environment. [5]	This paper proposesa novel context- aware elderly entertainment support system. It focuses on the design of this system by identifying its requirements from the perspective of the elderly and caregivers.	Issues discussed: (1) Contextawareness (2) Entertainment media recommendation (3) Rule definition (4) Media rendering	(1) The expected involvement of a "caregiver" in the system context that hasboth advantages and disadvantages.

The survey showed that all the efforts have been doneon better conversations. The aspect of creating better conversation has been given more importance than entertaining the users. Sometimes, only conversations aren't enough to make a person stay away from boredom and loneliness. Thus, the major and common gap identified in all the above papers is that they don'tconsider the overall entertainment, and focus only on conversations. The purpose of this paper is to bridge this gap, and provider a one complete package application for the entertainment of the elderly.

We also studied some existing applications which are very useful to people in the age group. These applications were majorly focused on the entertainment and healthcare of the elders. Some of them, which arerelevant to the proposed solution are listed in the tablebelow:

TABLE 2: GAP ANALYSIS

SN	Name of Application	Work Done (Hardware/Software) (Structure) (Method/algorithm)	Results	Gaps Identified/ Future scope
1	Pill ReminderPro	Keeps track of medication. Sends reminders every day about which medications to take and when. Also, an option for selecting days of the week for certain medicines which areto be taken weekly.	Easy to schedule medications daily or weekly. Notifications do not require any typeof connection.	User Interface is not readable for older adults.Could be betteroperable with a voice-activated assistant. Only one feature, i.e.,reminder
2	Audible	Provides Audiobooks and podcasts tolisten to. Elders can enjoy listening tothe stories for hours. Can be used withAlexa, to enable voice commands.	Voice commands makeit very much user- friendly, especially forelder people. A huge number of audiobooks and podcasts are available.	Recording audiobooks is not feasible forall users. Only one feature, i.e.,audiobooks
3	Kindle	Provides a huge number of books and eBooks. Very efficient readability. Can be used with Audible to sync audiobooks with eBooks.	Good interface, readable to elders. Theoption to enable audiobooks through audible makes it even more satisfying for elders.	Writing a book on kindle is notan easy process.Only one feature, i.e., eBooks
4	LibriVox	One platform to download/listen tomany audiobooks/stories.	A large number of audiobooks are available, categorizedby genres and authors.	Interface is not friendly for older adults. Only one feature, i.e.,audiobooks.
5	Pillboxie	Keeps track of medication for you andyour family. Detailed GUI. One can save information for multiple patientsin the family as well.	Supports multiple patients. Interesting andengaging GUI.	Not operable for older adults.Only one feature, i.e., reminder

The above survey showed that there are many solutions provided for older adults, but they lack some or other things every time. Also, all the solutions focus on one problem at a time. There is no such solution where allthe functionalities are combined together. Some of those have voice assistants, but others need to be operated manually, which is a little difficult for the agegroup we are targeting. This paper gives the solution toall these gaps in the existing system. With the voice assistant and all the features combined, it is a single platform where all entertainment will be given to the elderly.

IV. METHODOLOGY

Taking all the existing systems and previous work into consideration, and identifying the gaps these projects had left, we have proposed a solution that will help keep the elders entertained and thus reduce manypsychological and emotional problems of the older adults.

As discussed above, the existing solutions lack integration of many functionalities. The proposed solution is to combine all the functionalities that are useful for older adults into one single application and empower that application with a voice assistant.

We conducted a survey, asking people whether eldersin their house would prefer using a voice-controlled application or a UI-controlled one, and the results showed us most of the elders would prefer a voice-controlled application.

The proposed application will have various features that are helpful for the elders. These features are listedbelow:

A. Story Feature

During the survey and research, we found out thatelderly

people like to indulge in past stories of themselves and other people. Hence we decided toinclude a story-telling feature wherein the users can share their own stories and see other people'sstories, the visibility of these stories will be similarto the posts we see on social media. The extra features planned along with story-telling is to likeposts, audio feature, favorite a post, share a post, comment on a post, etc. With the power of digitalassistant, posting and reading/listening stories willbe very easy for the users.

B. Reminders:

Frequent reminders setting will help the users to be able to set reminders about the tasks that they intend to carry out. This feature will help add-on the list of basic features that the app will provide.

Task-management and scheduling will become easier for the user once this feature is integrated instead of installing another application that fits this very purpose.

C. Joke platform:

Funny posts in the form of jokes provide thenecessary humour and entertainment necessary for the application to cater to the user's needs at the time of use of the application in a better way. These jokes will usually be auto-generated with the help of a joke-generator functionality in the back-end of the application. The users might alsobe provided to contribute with their own funny jokes in a separate panel in the jokes section itself.These joke will be added in the list of jokes that other people can view along with credits to the original author. This will increase engagement along with facilitating entertainment.

D. Chat room:

Users will be able to chat with one another about the topics they want to, and share posts using the app itself instead of sharing them on third-party

applications like WhatsApp or any other chatting applications. Multiple users can also create chat groups to chat with multiple usersat the same time. This feature will enable the users to create chat rooms, where other online users mayjoin in to have a nice chit-chat. A user can create achat room by specifying a topic for the discussion,and all the other interested users can join it. Also,a link to join a particular chat room can be sharedacross any other social media as well.

E. Music:

The users in our target age group, are generally interested in devotional songs and bhajans.Considering this fact, a customized musing feature will be provided in this application. Even if a useris not into bhajans, the obvious choices of peoplein the age group, such as old melody songs will beconsidered while creating this functionality.

All these features, combined with the digital assistant,will provide the best possible solution to the problemsof older adults.

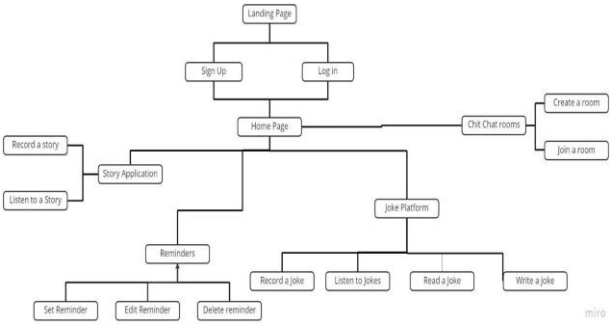

Figure 1: Block Diagram for the Application

The following platforms are used to develop the voice assistant:

A. RASA:

Rasa is an open-source conversational AI platformthat enables programmers to construct and

implement unique conversational AI systems, such as chatbots and voice assistants. Rasa offers libraries and tools for creating, testing, and deploying conversational models. It also supportsa variety of messaging services, including well- known ones like Facebook Messenger and Slack,as well as bespoke API interfaces.

With Rasa, programmers can build conversationalmodels that comprehend inputs in natural language, retrieve pertinent data, and offer suitable replies depending on the circumstances. Rasa trains its conversational models using machine learning methods and offers tools for monitoring and assessing the models' performance over time.

B. AimyBox:

AimyBox is a platform for building AI-powered voice assistants that gives programmers the resources and tools they need to make unique voice assistants. AimyBox interacts with well- known speech-to-text and text-to-speech engines, like Google Cloud Speech-to-Text and Amazon Polly, and enables developers to create voice-enabled applications for a variety of platforms, including Android, iOS, and Raspberry Pi.

AimyBox offers a complete set of tools for creating voice assistants, including an intent recognition system, a dialogue manager, and a voice assistant API. The dialogue manager offersa practical way to monitor and control the flow ofthe discussion, and the API makes it simple for developers to include the voice assistant into their apps. The voice assistant can comprehend user requests thanks to the intent recognition algorithm and produce pertinent responses based on theconversation's context.

As shown in Figure 2, the input from user, which is in speech form, is converted into text, and fed to the dialogue API. This API is created with RASA. It findsout the intent and sends it back to the application. The application will know which action to perform throughthis intent. Also, the API will send a response, which will be converted to speech form, and returned to the user. This whole process is controlled by AimyBox. AimyBox

basically allows the integration of RASA with the Android application.

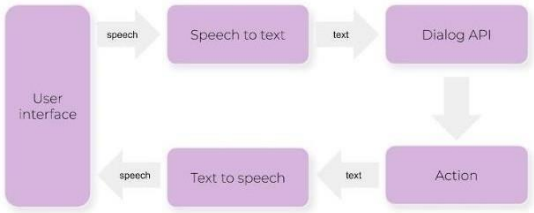

Figure 2: General flow of the application [13]

The Prototype of the UI of the proposed solution is given below:

Figure 3: landing page

Figure 4: log in page

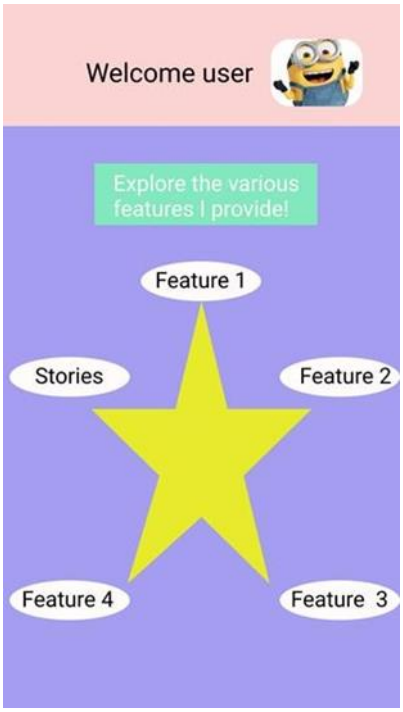

Figure 5: Home page

Figure 6: Stories home

Figure 7: Read a story

Figure 8: Record a story

V. RESULTS AND CONCLUSION:

This paper reviewed papers and articles about mental health of senior citizens. From this literature review, itwas found that the main reason for damaged mental health, depression and dementia is loneliness and lack of socialization. Reminiscing, that is, recalling and/or sharing happy past memories and experiences, can helpa lot to reduce the effects of loneliness.

This paper was ideated by keeping the social aspect in mind. The objective is to make elderly people feel comfortable around digital gadgets, and while doing so, keep them entertained and taken their care of as well. The paper will also help them reminisce over past memories. Reminiscence is proven to be very effective against loneliness and depression, especially in old agepeople. Also, this paper will help them socialize through the chat rooms. This, combined with the easeof use provided by the voice assistant, and many otherfeatures, will be very helpful to the elders.

With The help of this paper:

a. Older people will have a means of entertainment.

b. Through this entertainment, they will be introduced to new technology.

c. They will be included in the new digital era.

d. Reminiscing will help improve their condition a lot

e. Social involvement of the old people will increase.

f. Healthcare will be improved.

g. The solution shall be useful in addressing the

problem of loneliness for the elderly generation.

h. The story feature can help the elders reminisce about their past, which is proven to help overcome loneliness and depression in elders.

i. The reminder function will help improve their overall health by not letting them miss any medication.

j. The chat function will help them socialize, which is another method to avoid loneliness.

Furniture E-Commerce Portal With Augmented Reality

Adarsha Devadiga, Arjav Desai

arjav973@gmail.com, devadigaadarsha@gmail.com

Abstract: **The administration of corporate websites or e-commerce systems can be improved by new buying behaviors that combine cutting-edge features with customary online shopping. This paper is a combined epitome of the widest optional invention corridor that depends on AR partnerships and avoids the use of physical commerce with the product. The use of online shopping has evolved dramatically over time. Augmented reality (AR) may play a major role in enhancing the web-based purchasing system, particularly for furniture and bulky items. The development of new AR innovations can become valuable if they can replicate the features that have made online shopping the most preferred purchasing source in the present. With the help of Google's AR Core or Apple's AR Kit SDKs, AR can operate in a system. Before displaying anything through the augmented view so that the user can see it in their actual spaces, it is simple to create a 3D model. Deliveries of 3D models are made using a game engine and AR SDKs in the consumer device, which is managed by numerous systems built in an IDE. By assisting online merchants in reducing gain expense and providing their customers with all the more profitable and witty ways to purchase through their widgets, AR shopping is revolutionizing the online retail industry. Imaginative AR setups allow users to continuously daydream about their things from the comfort of their home. It may also be a crucial factor in the artificial revolution in industries where physical presence is a huge barrier. The most typical use of augmented reality (AR) is e-businesses using mobile/web cameras to display their products (clothes, accessories) as a 3D protuberance in a virtual changing room. However, we attempted to address the issue of purchasing heavy and bulky goods in large quantities, which buyers typically deny, claiming they only trust physical retail outlets where they can see the furniture's size. Through augmented reality, we usually allow the viewer to experience the entire product in their own house, choose their own specifications, and then place an order, which boosts the order rate and the viewer's level of trust. Overall, the study's findings demonstrate that the AR e-commerce system can aid customers in forming more informed judgements.**

Keywords: Augmented Reality, AR kit SDKs, E-commerce, Google AR core.

I. Problem Definition/ Objective

Although the introduction of e-commerce in this modern period has undoubtedly streamlined the consumer experience, some things, such as furniture, interiors, clothing, etc., don't truly provide the customer a realistic idea of how it will actually look in a particularsetting. This has an effect on the sales of these goods and hinders the expansion of this industry.

As a result, we came up with the concept to apply augmented reality in the furniture ecommerce industryto help customers see the furniture in their homes before making a purchase and improve their decision-making.In this way, they can simulate the physical presence ofan object, like a sofa, on their phones.

II. Introduction

The use of augmented reality (AR) to overlay computer- generated images in the actual environment is beneficial. The representation technique can be consolidated in AR and used in a variety of applications. For representation connectivity in a device, a vision- based AR framework was introduced. AR also facilitates perception of undetectable concepts or events by superimposing virtual items or data over real-world objects or circumstances.

Entrepreneurs are experimenting with new marketing strategies in today's concept of staying current, one of which is augmented reality (AR). It is a real-time, direct or indirect view of an actual, physical environment, with computer-generated sensory input like music, video, graphics, or GPS data enhancing its aspects. As a result, technology works through improving how one now perceives reality. Typically, augmentation takes place in real-time, within a semantic context, and withthe user's surroundings. Advanced augmented reality (AR) technology makes it possible to incorporate computer vision and object recognition, for example, and makes the information about the user's immediate surroundings dynamic and digitally manipulable. On top of the real world, artificial information can be superimposed about the surroundings and its inhabitants. Research investigates the use of computer-

generated imagery in real-time video broadcasts to improve the view of the outside environment.

Customers who shop online get an immersive experience thanks to the usage of augmented reality in ecommerce web design, which enables them to interact with products in real time while staying in their own area. AR fills the gap that shoppers see between in- person and online buying experiences. Due to the Covid-19 pandemic's restrictions on retail businesses' opening hours, which prevent customers from physically handling things in stores, there is a gap thathas become even wider.

With the aid of a variety of technological advancements, augmented reality (AR) enables the real-time fusion ofcontent developed on a PC with a

live visual display. The real world is surrounded by computer-generated virtual things in augmented reality, which combines the virtual and real worlds. According to one of the most commonly accepted definitions, augmented reality (AR) is a cutting-edge approach that requires three essential elements: combining real and virtual items in a real environment, altering real and virtual items with one another, and real-time interaction.

In order to be considered an AR framework, an application must meet the following three criteria: (a) be able to combine real and virtual content in a real environment; (b) be continuous and intuitive; and (c) be able to incorporate virtual content in a 3D environment. An application that satisfies the following three qualities, specifically (a) the combination of virtual and real substance in the actual world, (b) is realistic & intuitive, and (c) may enlist virtual substance in 3D environment, is formally classified as an AR framework.

III. LITERATURE SURVEY

The car sector was the first to use the term augmented reality in advertising. By combining augmented reality with it, e-commerce can undergo a significant transformation. 77% of consumers prefer to utilize augmented reality (AR) technology to preview products and product variations including color, size, style, and differences. AR marketing and advertising is a major concept that integrates computerized (digital) data or objects into the subject's perception of the real world, frequently in collaboration with other media, to uncover, communicate, or exhibit consumer benefits to achieve hierarchical aims. In 2015, the market worth of augmented reality was 640.4 million, and by 2020, it must generate $120 billion in revenue. In that sense, enterprises and customers are embracing AR to a great extent. AR is used in a wide range of industries, including manufacturing, correspondence, healthcare, retail, transportation, the military, education, gaming,

and online commerce. This evaluation is based on the use of augmented reality in online commerce, taking into account how well this remarkable innovation can simulate an in-store purchasing experience. The tool can modulate 3D objects in many locations, enabling users to interact with ease and sophisticated delivery to their own location. Companies like IKEA and converse are using augmented reality to let customers gradually visualize household items in their homes using mobile applications. The apparent benefit and satisfying experience of the buyer can be attributed to the growth in the development of AR apps.

When it comes to implementing augmented reality (AR) technology in online businesses, Ecommerce companies must enhance their mechanical proficiency by developing 3D object models using 3D modelling software and programming tools, as well as having a strong innovative team.

AR marketing and advertising is a major concept that integrates computerized (digital) data or objects into the subject's perception of the real world, frequently in collaboration with other media, to uncover, communicate, or exhibit consumer benefits to achieve hierarchical aims.

This project was necessary for us to create in order to get around the difficulty of seeing actual furniture items through online shopping. This will undoubtedly increase sales of these difficult-to-see objects that can be seen through AUGMENTED REALITY. In the next ten years, the e-commerce industry is expected to rise by over 600 billion dollars. The furniture industry is a big part of this and might make a significant contribution in the years to come if AR is used now. We, the computer engineering students, have the desire and capacity to create this app and successfully combine the thriving e-commerce sector with the AR vision technology. Additionally, large corporations like IKEA and Urban Ladder have begun to consider it and have begun integrating their platforms with AR vision for a better customer experience and ultimately greater sales.

Sr.No.	Year	Author	Title	Objective		Gaps
1.	2021 (Jan)	Navneet Garg, Ankita Parek, Ajinkya Lale	Evolution in E-Commerce with Augmented reality	According to this study, new online purchasing strategies with different benefits from traditional online shopping can enhance the management of corporate websites.		It is quite expensive to use it on a daily basis, and small enterprises would have less access to it. Since AR is now fairly expensive, it is still challenging to implement on a large scale from the perspective of ecommerce.
2.	2008 (Oct)	Yuzhu Lu, Shana Smith	Augmented Reality E-Commerce: How the Technology Benefits People's Lives	The goal of the study paper is to create a specialized real-time multi-platform chat application that natives may use to share information and converse more quicklyand easily.		The approach to the problem is quite generalized as no key differentiating featurehas been introduced to encourage large-scale adoptability of the productand is limited to a few selected subset of users. Thus is difficult to translate into a profitable business model.
3.	2021	Indira Amaris	Consumers Perceptions and attributes on Augmented Reality in Online Retail.	The purpose of this research is to comprehend how consumers view augmented reality and determine whether or not the retail sector will actually gain from it.		This solution's limitation to just private networks and smaller sample size is a disadvantage. Additionally, the paper's qualitative structure seems to rule out any pragmatism in its solution.
4.	2019	Mehmet Karakus Aaron Clark	Augmented Reality In Education: A Bibliometric study.	This study examines how augmented reality technology can be used in the education industry, such as in mechanical engineering or MBBS.		The paper suggests good options to integrate AR into the education sector. However for the retail or business point of view it doesn't give a detailed idea on exploring the market size or making a business out of it.
5.	2007	Yuzhu Luand Shana Smith	Augmented Reality: E-commerce assistant.	This article offers ideasfor how to create an augmented reality application that might serve as a consumer's e-commerce helper. It provides information on a variety of complex problems that this assistant can help the user address.		The proposed paper is excellent for creating applications, but imposing it on a retail website will take away access to the main augmented reality function and may overwhelm consumerswith technology.

IV. IMPORTANT FINDINGS.

give them power over digital aspects in their physicalenvironment.

According to a Google consumer AR poll, 66% of respondents are interested in utilizing augmented reality to assist them with their purchases. High return rates are one of the major issues facing online shops as consumers continue to prioritize online purchasing. AR gives customers the exceptional chance to try before they purchase since it offers an immersive experience with 3D visuals, virtual try-ons, and product demos. Due to the ability of customers to make an informed purchase, which will ultimately result in a decrease in return rates, augmented reality technology helps to battle high return rates. The use of augmented reality technology fosters greater consumer involvement with online retailers, which may ultimately lead to higher conversion rates.

Before making a purchase, a customer can evaluate

goods or services based on the reasonable look of the item in their daily lives thanks to augmented reality implementation in e-commerce. Through legitimate web interfaces, customers can do more than just browse products; they can also test them out. Retailers may overcome physical limitations and provide access to each item's components, thereby bringing more customers into the sales funnel for higher conversion. "See It In Your Space" and "Try Before You Buy" Online buyers love augmented reality because it allowsthem to see how the goods will look before they buy. AR is used by furniture and home décor companies to show buyers how various things will look in their homes.

Brands increase customer confidence by making online products "physical," which in turn lowers return rates. Sales are increased because customers are more inclined to click "add to cart." They are less likely to send things back, saving businesses money on shipping, restocking, and repackaging expenses. Both the company's bottomline and their customers' delight are winners. The interactive nature of augmented reality in e-commerce enhances the purchasing experience. Customers feel more a part of your brand and the product when you

V. Conclusion

Around the world, e-commerce is expected to expand rapidly. The potential for augmented reality to surpassthe search engine in e-commerce is great. Using augmented reality, customers can be encouraged to make the best decision while purchasing goods. Additionally, customers will have the ability to obtain in-depth information like surveys and related things, which is useful to the merchant in terms of persuadingtheir target interest group.

By superimposing 3D things in various locations, augmented reality (AR) can give customers an in-store buying experience while allowing them to comfortably interface with enhanced delivery to their own location. Even defining top-down manufacturing policy as a heuristic about future customer wants might benefit from the beneficial feedback provided by data collected from the implementation of AR approaches in marketing.

VI. ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance and encouragement of my Dissertation Guide Associate Professor Mr. Vikas Singh for this novel work.

Abstract-- **Our proposed system is an onlinefood ordering system that enables ease for the customers. It overcomes the dangers of the conventional queueing system. Our proposed system is a medium to reserve online meals problem loose from restaurants in addition to messcarrier. This device improves the approach of taking the order from purchaser. The web meals ordering device units up a meals menu on-line andclients can without difficulty place the order as according to their desire. Also with a meals menu, customers can without problems tune the orders. This system furthermore allows a feedback tool wherein the user can give the feedback, ratings about the orders also, the proposed system can recommend accommodations, meals, primarily based at the ratings given by way of the consumer,the resort workforce will be knowledgeable for the enhancements together with the quality. The charge may be made online or pay-on-delivery machine. For extra secured ordering separate debts are maintained for each user by supplying them an identification and a password.**

Keywords— Automated Food Ordering System, Dynamic Database Management, Route Optimization

I. INTRODUCTION

The online food ordering system sets up a food menu online and customers can easily place the order as per they like. Additionally with a meals menu, online clients can without difficulty locate the orders. The management maintains customers database and improve food delivery service. The restaurant management structures motivates us to expand the machine. There are numerous facilities furnished so

that the user of the system gets service successfully. Additionally, the machine considers eating places as well as mess facility to the customers. Again, the idea comes that mainly mess customers are character who are shifted for diverse reason in new cities. So, they're interrelated. Growing use of smart telephones is also taken into consideration as a motivation, so that any customers of this system get all provider on single click on. Another motivation can be considered as the device could be designed to avoid customers doing deadly mistakes, users can exchange their personal profile, users can book their meals items through customers can offer feedback and recommendations and might supply rankings, it's going to give appropriate feedbacks to restaurants / mess carrierproviders. Due to lack of a full fledge application that can fulfil the customer requirements by providing himfood from restaurants as well as from mess service, there is a need for the system. This proposed gadget may be used by the folks that keep moving from citiesto cites. As nicely because it can be useful for the students studying in different towns. The proposedsystem will provide the flexibility to the customers/users to reserve from both eating places or mess. It will also provide Recommendations to the customers from the restaurants/mess owners uploadedon a daily basis. In the proposed system, there might be no issue on the amount of order the purchaser wants. Also, same application can be used as a Startup Business for the developers. It'll provide real time clients remarks and rankings at the side of the remarksto the restaurants/mess owner. It offers appropriate feedbacks to customers, so if there is any error took place, then there can be a remarks conversation towards customers. The proposed system is designed to keep away from users doing fatal errors and inappropriate action. Scope of proposed gadget is

justifiable because in massive quantity peoples are transferring to one-of-a-kind cities so extensive varietyof humans can make a use of proposed system. The system/interface will take input from the user. The primary attributes so that it will supply input to the dataset are:. Name, cope with, email-identity, cell no, different non-public related values, and so forth. The output will include consumer/purchaser's order, invoice, remarks and fee alternatives. First of all there might be 10 to 12 eating places and mess offerings considered internal 2 to 3 regions. The reason why to choose this venture is the concept in the back of mission this is to solve problem of humans which they're facing after they shift to specific city. The device isn't always simplest for consumer however additionally for company who gives meals provider. This system is for making green communique among consumer and producer of the food system if you wantto then results in the suitable and powerful system.

The online food ordering system sets up a food menu online and customers can easily place the order as per they like. Also, the online clients can without problems locate their orders. The management keeps consumer's database and improve food delivery carrier. This system furthermore allows a feedback tool wherein theuser can give the feedback, ratings about the orders also, the proposed system can recommend accommodations, meals, primarily based at the ratingsgiven by way of the consumer, the resort workforce will be knowledgeable for the enhancements together with the quality. The price may be made online or coins or pay-on-delivery machine. For extra secured ordering separate debts are maintained for each user by supplying them an identification and a password.

II. LITERATURE REVIEW

In [1] an automated food ordering system is proposed which will keep track of user orders smartly. Basically, they implemented a meals ordering system for specific form of restaurants wherein person will make order or make custom meals via one click handiest. By way of android application for tablets pcs this system was carried out. The front end was developed using html, css, javascript, reactjs and at thebackend mysql database was used.

In [2] patron using the smart device is taken into consideration as a simple assumption for the device. While the patron approach to the eating place, the saved order may be confirmed with the aid of touching the telephone. The listing of selected preordered items will be proven at the kitchen screen, and when confirmed, order slip will be published for further order processing. The solution gives smooth and

convenient manner to select pre-order transaction form clients.

In [3] there has been an try and layout and implementation of virtual dining in eating places the usage of android technology. This system was a simple dynamic database software system which fetches all statistics from a centralized database. Efficiency and accuracy of restaurants as well as human errors were improved by this user-friendly application. Earlier drawbacks of automated food ordering structures had been triumph over with the aid of this system and it requires a onetime funding for devices.

In [4] an application of integration of hotel management structures with the aid of web services era is offered. Ordering System Kitchen Order Ticket (KOT), Billing System, Customer Relationship Management system (CRM) are held together by the Digital Hotel Management. Add or expand of hotel software system in any size of hotel chains environment was possible with this solution.

In [5] research work aims to design and develop a wireless food ordering system in the restaurant. Technical operations of Wireless Ordering System (WOS) including systems architecture, function, limitations and recommendations were presented in this system. It was believed that with the increasing use of handheld device such as pdas in restaurants, pervasive application will become an important tool for restaurants to improve the management aspect by minimizing human errors and by providing higher quality customer service.

In [6] along side customer feedback for a restaurant a layout and execution of wi-fi meals ordering system became done. It enables restaurant owners to setup the device in wi-fi surroundings and update menu shows without problems. Smart phone has been integrated in the customizable wireless food ordering system with real-time customer feedback implementation to facilitate real-time communication between restaurant owners and customers.

In Paper [7], the purpose of this study was to investigate the factors that influence the attitude of internet users towards online food ordering in Turkey among university students. A Technology Acceptance Model (TAM) developed by Davis in 1986 was used to study adoption of Web environment for food ordering. Trust, innovativeness and outside affects are added to the model as primary factors at the side of tam.

In Paper [8], the research work aims to automate the food ordering process in restaurant and also improve the dining experience of customers. Design implementation of food ordering system for restaurants were discuss in this paper. This system, implements wi-fi facts get right of entry to to servers. The android application on user's mobile will have all of the menu information. Kitchen and cashier gets the order details from the patron mobile wirelessly. These order details are updated within the important database. The eating place proprietor can control the menu adjustments effortlessly.

In paper [9], this research works on efforts taken by eating places owners also to undertake facts and communique technologies such as PDA, wireless lan, pricey multi-contact screens and so on. To decorate dining experience. This paper highlights a number of the limitations of the traditional paper primarily based and pda-based food ordering software and proposed the low-value contact display primarily based eating place control gadget using an android cellphone or tablet as an answer.

III. USABILITY STUDY

Shortest path algorithms are mainly separated into two wide groups. The first group is called the single source shortest path (SSSP). Purpose of SSSP is to find out the distinguished from the single supply vertex to all different vertices. The second group is called all pair shortest path (APSP) and the purpose of this path is to dig out the smallest path among all sets of vertices shown in the graph [20]. The calculation of this smallest path could be exact or roundabout solution. The use of the best algorithm is depending on the features and requirements of the program. Like, the purpose of the shortest path algorithm is to generate the quick reply even in the existence of a huge input graph. From between these two algorithms, Dijkstra and Bellman's ford depend to get the fast and efficiently smallest path between two vertices. Java languages are used to find the shortest path along with requirements. The name of the program is mentioned as shortest path optimization system and to elaborate its functions from the Unified Modelling Language (UML) class diagram java language is used.

This Section discusses the results obtained after running the simulation of the two algorithms. Foralgorithms of Dijkstra and Bellman-Ford, they areused for finding the solution for single destination and single source with single pair of the shortest path problem. For Bellman-Ford algorithm, it works well with negative edges and is capable of detecting anegative edge cycle in a graph. However, for Dijkstra algorithm, it works well with positive weights in a

directed or undirected graph. The performance of the Bellman-Ford algorithm is most effective when the graph has a small number of nodes, while Dijkstra's algorithm can work better when the graph has a large number of nodes. The results for the running time are shown in Table

No. of nodes	Dijkstra (in ms)	Bellman-Ford (in ms)
5	1351	513
10	3724	756
50	2072	9577

Table 1:Time count of Dijkstra & Bellman-ford

Based from Table 4, for Bellman-Ford algorithm, when the number of nodes is small, the running time is better than Dijkstra algorithm. However, Dijkstra algorithm has better running time when the number of nodes is larger. Our results are same to other researchpapers. For example, in [21], the authors showed that Dijkstra is most effective for a massive variety of nodes. In [23], for higher number of nodes, the Dijkstra's algorithm is better and efficient. Also, in [], Dijkstra's algorithm emerged to produce shorter time in both small and big graphs. Dijkstra's algorithm takesa time on a graph with edges E and vertices V can be represented using the Big-O notation as a function of

|E| and |V|. Dijkstra's algorithm takes time 0(|E|+|V|Log|V|). And the time taken by the algorithmof Bellman-Ford is O (| V | ·| E |) as shown in Table 5. Based on the time complexity, we can conclude that Bellman-Ford algorithm takes more time than Dijkstra algorithm.

For example, an individual wants to calculate the shortest distance between the source, A, and the destination, D, while calculating a sub path which is also the shortest path between its source and destination. Let's see here how Dijkstra's algorithm works; It works on the fact that any sub path, let say a sub path B to D of the shortest path between vertices A and D is also the shortest path between vertices B and D, i.e., each sub path is the shortest path. Here, Dijkstra's algorithm uses this property in the reverse direction, that means, while determining distance, we overestimate the distance of each vertex from the starting vertex then inspect each node and itsneighbours for detecting the shortest sub path to those neighbours. This way the algorithm deploys a greedy approach by searching for the next plausible solution and expects that the end result would be theappropriate solution for the entire problem.

IV. PROPOSED WORK

To overcome the limitations of above system, an Online Food Ordering System based on Route Optimization is proposed. To develop a reliable, convenient and accurate Food Ordering System is considered as a general Objective of the study. To develop a system that will surely satisfied the customer service will be considered as an objective. One of the Objective is to design a system that is able to accommodate huge amount of orders at a time and automatically compute the bill. To evaluate its performance and acceptability in terms of security, user-friendliness, accuracy and reliability is an important objective. To improve the communication between the client and customers is one of the objective. The figure.1 represents the simple system architecture of the proposed system.

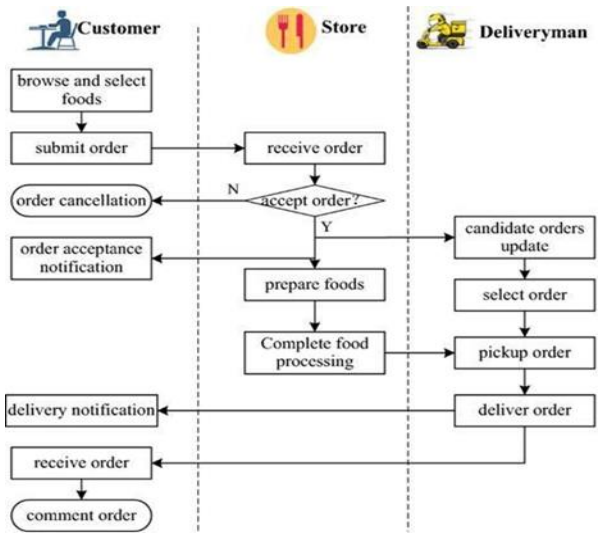

Fig 7: System Architecture

The architectural design consists of 3 main users: - Service Consumer, Owner of Mess/Restaurant, and Employee of mess. When a person shifted to newcity he has to find source for hygienic and quality food,so he/she will search and select restaurant or home- based food service based on his category and as well as service that is veg or non-veg.

Here the main function is, in what pattern user will search the service so for that purpose a part of Dijkstra's algorithm allows us to find the shortest pathbetween any two vertices of a graph.

It differs from the minimum spanning tree because the shortest distance between two vertices might not include all the vertices of the graph.

How Dijkstra's Algorithm works

Dijkstra's Algorithm works on the basis that any subpath B -> D of the shortest path A -> D between vertices A and D is also the shortest path between vertices B and D.

Djikstra used this property in the opposite direction i.ewe overestimate the distance of each vertex from the starting vertex. Then we visit each node and its neighbors to find the shortest subpath to those neighbors.

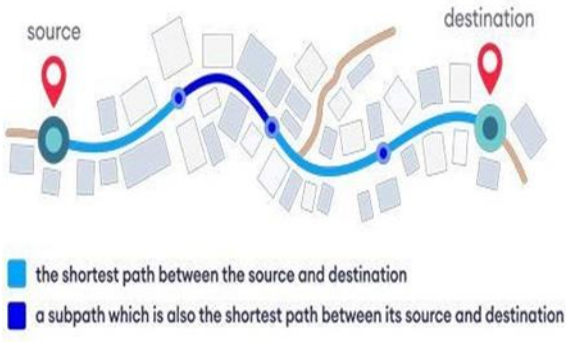

Fig 8: Dijkstra's Algorithm Example

The algorithm uses a greedy approach in the sense that we find the next best solution hoping that the end result is the best solution for the whole problem.

Dijkstra's Algorithm Applications

- To find the shortest path
- In social networking applications
- In a telephone network
- To find the locations in the map

Another example would be that the firefighter department wants to develop a system that finds the shortest distance between the closest firefighter department and the house being burnt to avoid the extra delay. Or logistics companies want to develop a system that finds the shortest distance between the warehouse and destinations to avoid extra spending and time.

V. RESULT & DISCUSSION

This paper presented the comparative analysis in termof shortest path optimization between two algorithms. The two algorithms are compared which are Dijkstra and Bellman-Ford algorithms to conclude which of them is more efficient for finding the shortest path between two vertices. Our results show that the Dijkstra algorithm is much faster than the algorithm of the Bellman ford and commonly used in real-time applications. Many researches have discussed shortest path algorithms to solve the shortest path problem in

these applications. In this study, a very popular algorithms called Dijkstra algorithm and Bellman-Ford algorithm are used to make a comparison between them on the basis of complexity and performance in terms of shortest path optimization. Our results show that Dijkstra is better than the BellmanFord interms of execution time and more efficient for solving the shortest path issue, but the algorithm of Dijkstra work with non-negative edge weights.

VI. CONCLUSION

Therefore, conclusion of the proposed system is based on user's need and is user centered. The system is developed in considering all issues related to all user which are included in this system. Wide range of people can use this if they know how to operate android smart phone. Various issues related to Mess/Tiffin Service will be solved by providing them a full-fledged system.

Thus, implementation of Online Food Ordering system using route optimization is done to help and solve one of the important problems of people.[15]

Design of CRMSOFT: A Customer Relationship Management System using Analytical tools.

Aniket Vishwakarma, Riya Vishwakarma, Ujwal Yadav, Rekha Sharma

Thakur College of Engineering &Technology, Mumbai, India

Abstract- **A CRM (Customer Relationship Management) system is a software solution that helps organizations manage customer interactions and data throughout the customer lifecycle with its ability to provide services such as sales, inventory management, employee tracking, workflow management, report generation, and file storage. CRM system designs were created in order to satisfy businesses and/or customers by developing new CRM business models. Moreover, one of CRM's biggest challenges is keeping up with a manufacturing sector that has been rapidly moving from a product-centric to a customer-centric focus. In this paper, we present our work focusing on the CRM implementation challenges from four different perspectives: sales, user interface, forecasting, and inventory. Considering these perspectives in CRM implementation projects, organizations can realize several benefits, such as reducing costs and saving time or extra effort.**

Keywords: Customer Relationship Management, CRM, Analytical CRM, Inventory System, Sales, Billing System

I. INTRODUCTION

Customer Relationship Management (CRM) is not a clear concept according to Pohludka and Štverková [1]. CRM "refers to a strategy, a set of tactics, and a technology that has become indispensable in the modern economy" [2]. CRM is a wide concept [1] that initially focused on keeping customer loyalty [3] and developing strong customers' relationships. However, this side of CRM represents, today, only the tip of the iceberg. CRM has been gaining interest from scholars [4];

[6] because of its multidisciplinary role in "marketing, operations, sales, customer service, R&D and IT" [7]. CRM grew into a field that interrelates people, processes, and significantly more technology [9], but why? "Since CRM uses IT as an enabler, the importance of its implementation has been revealed by different authors in both academia and industry".[14] Hence, technology makes CRM an interesting topic [7] to explore because of its advances in CRM systems [10]

A CRM system is an information system (IS) aiming to develop and leverage customer relationships digitally [11]. A CRM system can have different goals like providing digitalized customer support or generating sales, for instance [12]. "CRM and its system are gaining increasing interest from smaller businesses" [13]. However, literature express a gap of knowledge, having mainly examined the implementation of CRM systems for large companies [7] without testing these ones on small companies. Small companies lack research on implementing CRM systems fitting their organizational size.

The motivation behind CRM System is to provide a software that organizations use to manage day-to-day business activities by providing services such as billing system, inventory management system, order system, payment gateway, employee tracking system, workflow management, report generation, file storage. It also includes enterprise performance management, software that helps plan, budget, predict, and report on an organization's financial results.

Plenty of companies struggle with a legacy system which may once have done the job but is now woefully inadequate to do the job of the modern CRM System. Eventually you'll find that this is no longer sustainable, whether through lack of vendor support, a knowledge gap created when users leave or just plain old lack of functionality stopping you from getting any meaningful information. Furthermore, the humble spreadsheet might once have been a fantastic resource to store your data and even provide some basic analysis of that data but it's long been surpassed by CRM system. Multiple spreadsheets in companies are still a common occurrence but as your company has grown, you've probably got too much information to be handled by your existing spreadsheets alone. Do you really want to add yet another spreadsheet to your mix? A CRM system replaces spreadsheets whilst bringing together all your data and giving you real time answers. In today's accountable society, many jobs require accurate traceability.

Problem definition

The problem that needs to be solved is the lack of a comprehensive CRM system that can effectively manage different aspects of a business such as billing, inventory, payments, reports, and orders. Many businesses struggle to manage these areas efficiently due to the absence of an integrated system that can address all these functions. This leads to challenges such as delayed payments, inaccurate billing, inefficient inventory management, and delayed order processing. To overcome these challenges, the proposed solution is to design a CRM system that leverages analytical tools to address these issues effectively. The system should provide a comprehensive view of customer interactions, streamline billing and payment processing, enable efficient inventory management, generate timely reports, and automate the order processing system. By providing an integrated platform, businesses can streamline their operations, reduce costs, and enhance customer satisfaction

bjective of the project

1. Increasing the customer base - CRMSOFT is a whole system where everything is provided in an

organized manner. The customer base increases due to the high-quality of services being provided to them. It helps in interacting with the customers in a better manner.

2. Insights in real time - This system keeps you updated in real time which helps in a faster decision-making process. None of the things need to be maintained manually. The data can be accessed needless of time zones and places.
3. Offers complete mobility – You can access it anytime, anywhere regardless of the devices. Mobility will also help in expanding your business. It will also help the business to run in an efficiently.
4. Cost management - This one source is accurate, in real-time and helps in reducing the operation costs. If the right solution is selected by user and the right vendor too who are able to meet user needs then user are bound to see a powerful ROI.
5. Security - One should be not worrying about their data once you have it in CRMSOFT. This new system will help you in improving the accuracy, consistency and the security of the data with the help of the built-in resources and the firewalls. The restrictions of data will be enhanced by managers of the solution so that the software can be as secured as you want it to be.

The software is majorly segregated into different modules like customer management, transaction management, product management, report generation, inventory management etc. Till date one of the major algorithms used for inventory management are XYZ analysis, ABC analysis etc. The proposed software is intended to implement both the algorithms to extract the benefits of both the existing algorithms.

ABC analysis is an inventory management technique that determines the value of inventory items based on their importance to the business. ABC ranks items on demand, cost and risk data, and inventory mangers group items into classes based on those criteria. While XYZ analysis is a way to classify inventory items according to the variability of their demand or derived/forecasted consumption. XYZ analysis can be used to plan material requirements and inventory levels so that waste, production delays, or excessive inventory levels can be avoided.[7]

Another important module of CRM system that defines the key and important feature of the software is sales forecasting. The major algorithms used till date are ARIMA, SARIMA, SARIMAX, VARMAX etc.

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts associated with vector autoregressive moving-average processes with exogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated to each other, they are also correlated to each other's past values. The VARMAX procedure can be used to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables). The VARMAX procedure enables you to model the dynamic relationship both between the dependent variables and also between the dependent and independent variables.[8]

II. LITERATURE SURVEY

The candidate papers are selected based on title and abstract searches related CRM and its equivalent, model or architecture or framework and personalization. The selected articles are based on background search. Every component, tools and techniques most commonly used by previous researchers will be done ranking process, to see which is the most widely used or proposed. Based on these findings, the authors will further study and be considered as the basic platform for proposing or developing a new, personalize Customer relation management. Finally, this literary study will be able to answer research questions related to common components, tools and techniques to build a personalized CRM System.[5]

i) Title: Design and implementation of bank CRM system based on decision tree algorithm

This paper realizes in-depth analysis and mining of customer data information through data mining and other methods, and transforms customer data information into customer knowledge model. Help bank decision makers make better decisions and help banks to have more advantages in the process of market competition. This paper considers the development status of the bank, summarizes the existing customer data information through the decision tree algorithm, and realizes the design of the bank customer relationship management system based on data mining technology. The system implements customer-centric, collates and summarizes existing customer information, and transforms the mined business data into customer knowledge and models. This paper realizes that when the user implements a series of system operations, the required data information can be obtained conveniently and quickly. Moreover, by implementing the establishment of a decision tree, the intelligent technology implements the division of the acquired customer information on a percentage basis. In this way, from the user's point of view, it is closer to the user's way of thinking, which helps to improve user satisfaction.

1. System login interface

When the user opens the system, the first interface that comes out is the system login interface, so the login interface must give the customer a good impression. The requirements for the login interface are very convenient to operate, and the interface should be simple and clear.

2. Custom Management Analysis

The purpose of the system customer management module

is to provide users with uniform and complete customer information. Through this module, users can easily understand all customer information. This will help users to provide products and services to customers in a targeted

manner and maintain good customer relationships.

3. Customer statistical analysis

In the CRM system, the bank practitioners are required to use the data analysis in the system to classify the customers, and according to the data, the customers are classified according to the level to understand their risk values and which financial products are suitable for them in the daily business process, to improve the bank's profits.

4. Analysis of system test results

In the process of system testing, based on the customer information data, through the implementation of specific functional tests, and then the data information is stored in the server. when there are 1 million data traffic, the processing performance of the system is relatively stable, especially the way the system uses data mining technology to display and analyze.[16]

ii) Title: Web Based Customer Relationship Management Application for Helping Sales Analysis on Bike Manufacturer

This application is able to support the performance of sales representatives to conduct business processes, because the sales representative can maintain relationships with their customers. Sales representative can store their data safely and regularly so they can get the latest information and accurate report about the customer and company. This application comprises 5 sub-systems:

1. Data setting

This sub-system manages the spread of news and files to sales representatives, sales managers, and customers.

2. Dealer information settings

This sub-system collects data for new customer. After collected the customer data, the customer can be sales lead.

3. Leads and opportunity determination

In this sub-system there are several stages to determine customer position.

4. Sales tasking

In reaching on their targets, sales representative must do some tasks to manage and this sub-system help sales representative to know and doing their task.

5. Dealer visit

6. This sub-system collects date and time dealer visited by sales-representative.

Sales representative can store their data safely and regularly so they can get the latest information and accurate report about the customer and company. Based on questionnaire that has been distributed, it can be concluded that the system can help the sales agent for daily process, it is supported by the user's opinion both in the ease of application use, design and suitability needs. For the next step need to add live chat to help sales representative communicate with their sales manager or their customer. [17]

iii) Title: Sales Forecasting Using Deep Neural Network and SHAP techniques

They propose a multi-layer neural networks algorithm to forecast the sales in the next 28 days of Walmart. they introduce experimental results and utilize RSSM as the

evaluating metrics, and our NN model has a better approximation than the SVM algorithm and linear Regression. and evaluate the contribution of the features in model to the results, by using SHAP to get the SHAP summary plot. It was able to forecast the summary by using the SHAP Summary plot and it forecast the which product is have most important and the higher demands.

They introduce our NN sales forecasting model. Neural networks are series of algorithms that endeavor to recognize underlying relationships in a set of data through a process that mimics the way the human brain operates. And the neural networks of simple processing elements operating on their local data and communicating with other elements. There exist many types of neural network,but the basic principles are similar. Each neuron in the network need to receive input signal, to process them and to send an output signal. Because of the limited information provided by the dataset, a neural network should be a good choice as it can auto select the hidden features and fit the data accordingly. The common simple multi-layer neural networks should be sufficient enough to output one value for each input feature. They used it to predict the sales in the next 28 days. [18]

iv) Title: Implementation of Improved Billing System

In this paper, There is a total of 8 steps involved in the implementation of this billing system. First, they have created a layout of the system using Tkinter. Then, the store's database is created using SQLite. Connection between database and the GUI is created using Python and also cart module is created where products are added using Python. A module is created to generate the bill. "pyzbar" is used to create bar code reader (decoder) module and "QRcode" is used to create the QR code generator module. Android studio is used to create QR code scanner application for android devices.

This project was about improving the existing billing system by making it digitalized. A better way of billing system was implemented. Instead of a printed bill, the customer obtained a digital copy of it, which reduced the wastage of paper. This also helped the seller to save the cost of buying paper. The bill was first stored in the

seller's system in an organized manner. After that, a QR code was generated, and this QR code could be scanned by the customer and be transferred to their device. This also ensured the customer wouldn't lose their bill. This project was implemented to make the process of billing more efficient.[19]

v) Title: A NOVEL FUZZY MCDM MODEL FOR INVENTORY MANAGEMENT IN ORDER TO INCREASE BUSINESS EFFICIENCY

In this paper, two novel integrated fuzzy inventory management models have been developed in order to achieve a more rationalized and economical business. Based on the reports of marketing logistics subsystems and the organization of warehousing systems, multi-phase models of sorting and inventory management have been formed, taking into account the multi-criteria function. Based on the following criteria: quantity, unit price, annual procurement costs and demand, the classification of inventory has been performed primarily with the novel integrated fuzzy FUCOM – fuzzy EDAS model. The developed integrated model has shown exceptional characteristics for solving the problem of inventory classification and management. In this particular case, the classification of inventory into groups A, B and C has been performed in a range according to the following restrictions: group A all values >= 1.00, group B >= 0.50 < 1.00, group C < 0.50. In addition, it has been developed a novel fuzzy FUCOM – ABC model that can be used to sort inventory for all multi-parameter inputs. The greatest contributions of the research are the newly developed fuzzy models that provide a better insight into inventories, which is causally related to the cost function of the entire company. The developed integrated models have been verified through a comparative analysis with traditional ABC analysis approaches, taking into account the single-criterion function since they showed significantly better performance. total number of steps in the proposed methodology is four, consisting of several activities each, which makes a total of 11 activities. The following section of the describes in detail all the steps with the presented methods that are applied.

The first step – defining inputs

The second step – data collection and processing

The third step – forming and application of integrated fuzzy MCDM (Multi-Criteria Decision-Making model.

The fourth step – results and sensitivity analysi - ABC analysis, Comparison analysis [15]

Table 1 Summary Table

r.No.	Work Done	Result	Future Scope
	This paper realizes in-depth analysis and mining of customer data information through data mining and other methods, and transforms customer data information into customer knowledge model. This paper considers the development status of the bank, summarizes the existing customer data information through the decision tree algorithm, and realizes the design of the bank customer relationship management system based on data mining technology. The system implements customer-centric, collates and summarizes existing customer information, and trans- forms the mined business data into customer knowledge and models.	The most important details in this text are the system login interface, Customer Management Analysis, Customer Statistical Analysis, and Analysis of System Test Results. The login interface must be convenient to operate, clear, and provide users with uniform and complete customer information. Customer statistical analysis is used to classify customers according to their risk values and which financial products are suitable for them. Analysis of system test results is done based on customer information data, and the processing performance of the system is stable when there are 1 million data traffic.	Only 2 algorithms discussed, more algorithms need to be discussed along with their efficiency in detail under different circumstances and operating capabilities
	This application comprises 5 sub-systems: • Data setting • Dealer information settings • Leads and opportunity determination • Sales tasking • Dealer visit	This application is able to support the performance of sales representatives to conduct business processes, because the sales representative can maintain relationships with their customers. Sales representative can store their data safely and regularly so they can get the latest information and accurate report about the customer and company	It doesn't include customization to satisfy the particular business model also system is not able to predict the which SKU will work better for the future

	They propose a multi-layer neural networks algorithm to forecast the sales in the next 28 days of Walmart. they introduce experimental results and utilize RSSM as the evaluating metrics, and our NN model has a better approximation than the SVM algorithm and linear Regression. and evaluate the contribution of the features in model to the results, by using SHAP to get the SHAP summary plot	It was able to forecast the summary by using the SHAP Summary plot and it forecast the which product is have most important and the higher demands.	The model need improvement to improve the prediction effect, and we need to apply different algorithm to this model to overcomes other sales problems.
	The 8 steps involved in the implementation of this billing system include creating a layout using Tkinter, creating a database using SQLite, creating a connection between database and GUI, creating a cart module, creating a module to generate the bill, creating bar code	This project was implemented to improve the existing billing system by making it digitalized. Instead of a printed bill, customers obtained a digital copy of it, reducing the wastage of paper and saving the seller money. The bill was stored in the seller's system and a QR code was generated	A simple payment model using basic cryptocurrency features can be proposed to reduce costs and guarantee integrity and nonrepudiation of electronic payments.
	reader (decoder) and QR code generator modules, and creating a QR code scanner application for android devices.	to be scanned by the customer and transferred to their device, ensuring they wouldn't lose their bill.	
5	The proposed methodology consists of four steps: defining inputs, data collection and processing, forming and applying MCDM, results and sensitivity analysis, and ABC analysis.	Two novel integrated fuzzy inventory management models have been developed to achieve a more rationalized and economical business. Based on the reports of marketing logistics subsystems and the organization of warehousing systems, multi-phase models of sorting and inventory management have been formed. The classification of inventory has been performed with the novel integrated fuzzy FUCOM – fuzzy EDAS model.	Fuzzy MCDM models, ABC, and XYZ analysis can be used to create a universal fuzzy MCDM model for a larger number of companies, create inventory management policies, and combine them for precise inventory management.

III. TOOLS & TECHNOLOGY

Table 2 Tools & Technology

Software	
Programming Languages	JavaScript, Python
Operating Systems	Windows Operating System
Databases	Mongo dB, S3bucket
Others Technologies	UML, Node, React, RE-React, Visual Studio 2008, Postman,
Web Server	Apache

The software is majorly segregated into different modules like customer management, transaction management, product management, report generation, inventory management etc. Till date one of the major algorithms used for inventory management are XYZ analysis, ABC analysis etc. The proposed software is intended to implement both the algorithms to extract the benefits of both the existing algorithms.

Table 3 Combined Analysis of ABC-XYZ

	A	B	C
X	High value percentage Continuous Demand High Predictive value	Average value percentage Continuous Demand High Predictive value	Low value percentage Continuous Demand High Predictive value
Y	High value percentage Fluctuating Demand Average Predictive value	Average value percentage Fluctuating Demand Average Predictive value	Low value percentage Fluctuating Demand Average Predictive value
Z	High value percentage Irregular Demand Low Predictive value	Average value percentage Irregular Demand Low Predictive value	Low value percentage Irregular Demand Low Predictive value

IV METHODOLOGY

The proposed software deals with integrating the features of existing CRM system with the benefits and features of enterprise resource management. Also, the software is intended to add value to the data that it collects in the form sales, finance inventory report by performing various algorithms on it and help in providing the future insights that may help to increase and scale the business and profit of the company. The techniques and methodology used for collection of data will be secondary sources and all quantitative method for the research will be used to finish the study which is related to the initiatives regarding development and learning effectiveness. Quantitative method also aids for collection of data for verifying the hypothesis.

ABC analysis is an inventory management technique that determines the value of inventory items based on their importance to the business. ABC ranks items on demand, cost and risk data, and inventory mangers group items into classes based on those criteria. While XYZ analysis is a way to classify inventory items according to the variability of their demand or derived/forecasted consumption. XYZ analysis can be used to plan material requirements and inventory levels so that waste, production delays, or excessive inventory levels can be avoided.[15]

Another important module of CRM system that defines the key and important feature of the software is sales forecasting. The major algorithms used till date are ARIMA, SARIMA, SARIMAX, VARMAX etc.

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts associated with vector autoregressive moving-

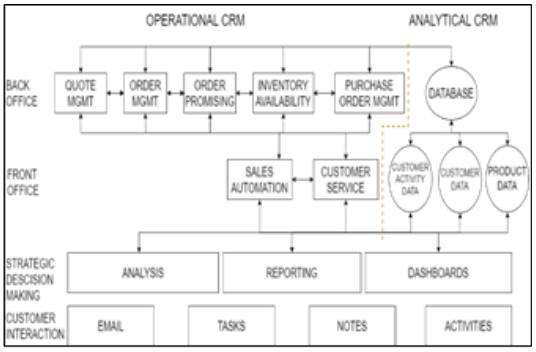

Figure 1 Flow Diagram of CRMSOFT

average processes with exogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated to each other, they are also correlated to each other's past values. The VARMAX procedure can be used to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables).

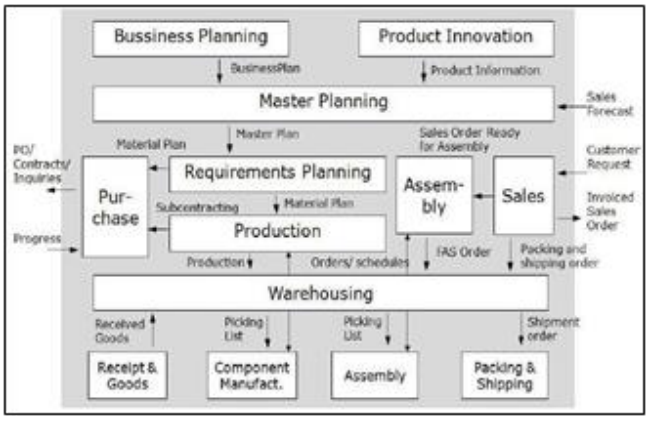

Figure 2 Functional Model of CRMSOFT

The VARMAX procedure enables you to model the dynamic relationship both between the dependent variables and also between the dependent and independent variables.

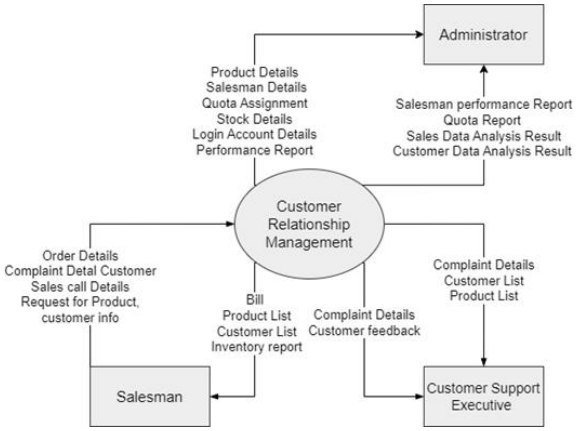

Figure 3 Structural Diagram of CRMSOFT

V RESULT & DISCUSSION

Having a centralized system and database for all of your business-critical data means that everyone in the business has access to the same key information, which is the same no matter which department is looking at it. You also have the opportunity to integrate your software with other systems like Customer Relationship Management (CRM) to ensure that data is up-to-date, relevant and consistent across all systems. It can also be managed and controlled using group policy, which not only makes the whole thing more secure, but ensures that all users are getting a consistent experience and access to the data and tools they need to do their job. By reducing the need for manual data entry and re-entry, CRMSOFT removes the risk of human error, and can help you facilitate and collect infinitely more accurate data that can be accessed in real-time. This allows you to perform more accurate reporting, as well as forecasting, enabling you to make better business decisions. As systems become more user-friendly, it also becomes easier for both management and end-users to generate their own highly accurate reports and forecasts, without the need for IT or business analysis resource. From an operations perspective, manufacturers, in particular, will

begin to become more reliant on Internet of Things (IOT) devices and applications to collect data and run certain parts of their processes. High levels of accuracy will be key to a successful and streamlined process. In operations, real-time data from this software can help management make reactive decisions around labour and machinery utilization, allowing for quick and easy improvements to be made and problems to be solved. This results in better lead times and lower costs per unit.

V CONCLUSION

In this paper we have discussed the importance of CRM system can be used to automate tedious, repetitive and manually completed tasks. With time-consuming tasks taken care of, your workforce can focus on more on the activities that will have the most impact on business success. No more jumping between different programs. With information stored in one centralized location, your operations can move faster and with more efficiency. With all of your applications easily accessible from one spot, you can plan, execute, and analyse in one cloud- based system to drive profitability and productivity across your business. This new system will help you in improving the accuracy, consistency and the security of the data with the help of the built-in resources and the firewalls. The restrictions of data will be enhanced by managers of the solution so that the software can be as secured as you want it to be.

VI FUTURE RESEARCH

The business functions of start-up companies, especially the SMEs and MSMEs, are initially processed and streamlined manually using basic digital systems. The day-to-day activity of these trading entities is managed directly by its owner(s) or under their direct supervision. As the business takes shape and expands in terms of clientele, revenue, expenditure, manpower, technology, production capacity, logistics, geographical presence, etc, it becomes difficult to contain the management of the business within the scope of simple digital solutions and manual supervision. This is where the need arises for an efficient software like CRMSOFT. It also interlinks each department with the other so that necessary information could be accessed for making the right business decisions and for efficiently accomplishing all business functions. It rules out data misinterpretations and communication gaps by storing all business data in a common repository and by granting role- specific access to uniform data for all authorized personnel. Internet-powered remote access to business empowers business stakeholders to do business in real-time at any time and from anywhere, even while on the move. These faculties empower business decision-makers and managers to make data-driven, precise and profitable decisions. By deploying a world-class digital system like CRMSOFT, businesses can integrate disparate entities, eliminate wastage and redundant activities, maximize utilization of resources, optimize

productivity, empower business stakeholders to make timely correct decisions, ensure absolute statutory compliance, always be in real-time touch with the business irrespective of time and space, and increase User Experience as well as Customer Experience.

College Enquiry Chat Bot

Sangita Mahto, Neehal Jiwane, Ashish.B.Deharkar, Vijay M. Rakhade , Lawlesh N. Yadav
Shri Sai college of Engineering &Technology,Bhadrawati, Maharashtra, India.

Abstract-: **Chat bots are the knowledgeable systems that understands and responds to the question asked by users in their own language. Chat bot responds in voice communication a touch like however a person's move with each other. throughout Institute's tutorial Admission procedure there is a massive queue at the enquiry window. Students simply have to be compelled to add question range to the chatbot and it can answer to student question. A login and register system webpages can also be additional inside the system to forestall unknown users from gathering details. The user might offer their suggestions through the suggestion box. The system replies exploitation AN economical Graphical worm that suggests that as if a real person is interacting with the user. This Chatbot is usually a sort of service that is in a position to be your agent providing you enquiry data regarding faculty.**

- ***The college enquiry chatbot intends to contour the method of question resolution***
- ***The chatbot is supposed to make students feel as if they are speaking with college professionals, and their queries are answered through informal text.***
- ***The final goal of our web site is to save|to avoid wasting} lots of time and energy and additionally to be updated with faculty activities.***
- ***A login and register page is added inside the web site to prevent unknown users from gathering data.***
- ***In modern era, generation has keen interest in texting rather than using mails, participating them through chatbots are aiming to be a good alternative for our projected system.***

Keywords: Chat Bot, Virtual Assistant, College Enquiry, Web Application, Queries.

I.INTRODUCTION

Chat bots are sort of a virtual agents which might converse like humans' interaction. they're going to attempt to answer your queries or doubts through chatting medium as if human is interacting with you. This project deals with creation of a chatter bot will answer which may connected queries quickly as potential. As a undergraduate or unaware person we want basic information to know regarding college, this application will facilitate in providing such enquiry information through chatting medium. A chatbot is associate instance of emotional calculation system that mirrors human conversations to supply instructive, esteem based totally, andinformal organizations. This chatbot would be developed concerning college amenities, faculty and placement and their facilities. This project is mainly college, fee structure etc.

- Log out.

II. LITERATURE SURVEY

A chatbot is an instance of emotional calculation system that mirrors human conversations to grant instructive, esteem based and informal organizations. These type of chatbot provides answers to the queries of the students. Objective of the project is to develop a chatbot system which is able to establish answers related to user submitted queries. A database is developed, which can store knowledge relating to queries, answers, keywords, logs and feedback messages. A chatbot aims to form a language between every human and machine. The machine has been embedded data to identify the specializing in creating a chatbot to use by students to induce their queries responded simply from the faculty web site. Enquiry Chatbot has the potential to make friendly conversations respond the course and college details, supply the tutorial calendar, answer the usually asked queries and provides the timings, address, contacts and events data of the departments.

A. Aim

- This project aims to develop a enquiry Chabot that answers any queries post by students like college details, course-related queries, location of the school, fee structure etc.
- One among the prime goals of chatbots is to favor an intelligent human and build it tough for the receiver of the conversation to understand the important alongside aboard various architectonics and capabilities for his or her usage has wide fill out.

B. Objectives

- The main objective of the project is to develop associate rule which is able to be used to establish answer related to user submitted queries.
- The college enquiry chatbot intends to contour the method of question resolution
- The chatbot is supposed to make students feel as if they are speaking with college professionals, and their queries are answered through informal text.
- The final goal of our web site is to save|to avoid wasting} lots of time and energy and additionally to be updated with faculty activities.
- A login and register page is added inside the web site to prevent unknown users from gathering data.
- In modern era, generation has keen interest in texting rather than using mails, participating them through chatbots are aiming to be a good alternative for our projected system.

C. Features

- Login and Register page.
- About Us Page
- Suggestion Box
- Answers to users' queries
- Replies using an effective GUI
- Also answers queries post by students like college details, course-related questions, location of the

sentences and making a decision itself as response to answer a question. The user message i.e. question is hold on to the response principle. The information of chatbot are stored within the database. The development of Chatbot application in numerous programming language had been finished making a computer program to send input and receive response. Structured query language (SQL) for pattern matching had been used within the program.

II.METHODOLOGY

A. On-Line Enquiry

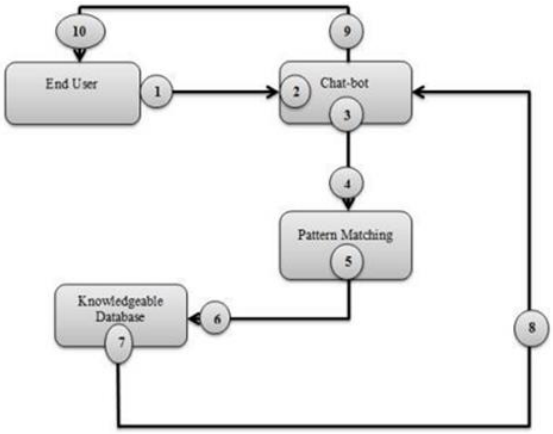
Students will enquire concerning facilities and question associated with exams, academics, fee structure, etc.

Students can even ask queries related to cultural and social activities carried out in the college.

B. On-Line Chatbot

The result may be showed to the user in the form of card format or in text format. The question are going to be answered on the basis of queries asked and also the response media created. Users that wish to enquire about the college at the time of admission or any competition held within the college will question to the chat-bot.

C. Given below is the system architecture of this chat-bot



The basic rule which will be enforced for operating of this planned system is as follows: Step 1: Start.

Step 2: Get the input question from the user. Step 3: The question is pre-processed.

Ste 4: Fetch the remaining keywords from the question.

Step 5: Match the fetched keywords with the keywords in knowledge base, and supply an acceptable response

Step 6: Further the database module is employed to call correct services using entity data to seek out correct information.

Step 7: The keywords are matched with the assistance of keyword matching algorithm. Step 8: It returns the question response to the chatbot.

Step 9: Chat-bot packages the info into correct response for display by the client. Step

10: Exit.

III.MODELING AND ANALYSIS

A. Problem Definition:

College Campuses are immense in terms of the area they cover. If a certain person has a question that he needs to enquire, he/she would need to visit varied departments gathering segments of the solution to the question he had. As we see, whenever admission days are nearer all college members strive their best to guide parents and students to induce into course they want. College Enquiry Chatbot will reduce half the work by giving students brief information concerning admission, courses, fees and lots of additional. All the queries by students will be answered through the chatbot.

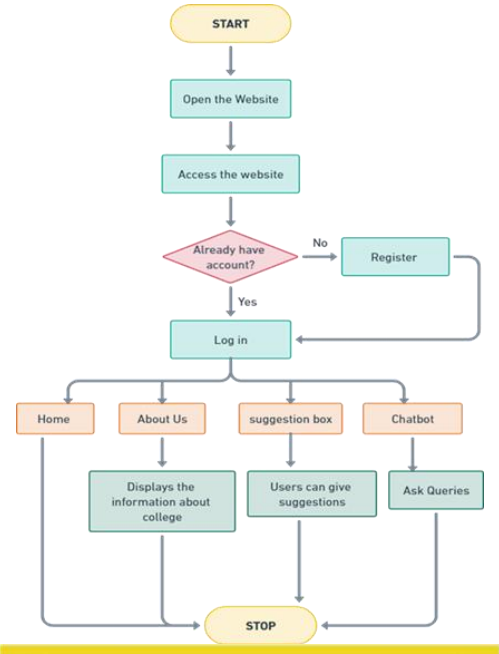
B. Framework used is chatbot:

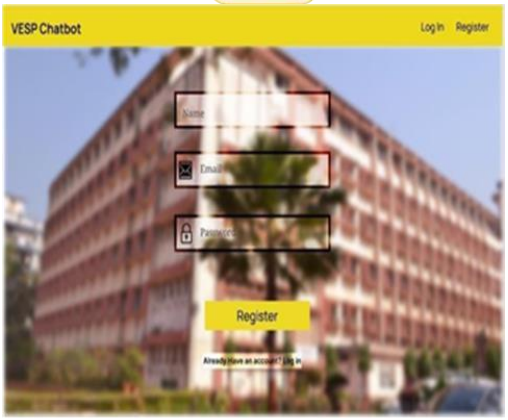
Flask:

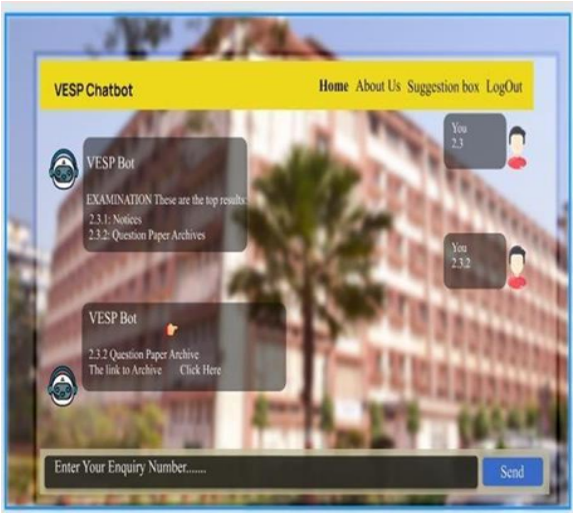
Flask may be a little and light-weight Python web framework that has helpful tools and options that build making web applications in Python easier. It offers developers flexibility and may be a additional accessible framework for new developers since you'll be able to build an online application quickly using solely one Python file.

Flask is known as a micro-framework as a result of it's light-weight and solely provides elements that are essential. It also provides the mandatory elements for web development like routing, request handling, sessions and so on. For the opposite functionalities like data handling, the developer will write a custom module or use an extension. This approach avoids unnecessary boilerplate code, that isn't even getting used.

C. Flowchart:







VI. CONCLUSION

Chat bot are often utilized by any college and Universities on their web site in order that external stakeholders will raise their queries anytime. And it'd be considerably effective to simplify the admission method additionally as this chatbot isn't solely providing college data. A database is developed to store all connected data's and to develop a web interface. The web interface developed had one component which is for the administrator. A information system was designed, that stores data relating to queries, answers, keywords, logsand feedback message. Chabot framework is carried out to satisfy scholarly requirements of the clients. Generating reaction from a Chabot is information based one. At the point once a user starts asking queries within the Chabot Graphical interface (GUI). The question is looked within the data base. On the off chance that the reaction is found within the data base it's shown to the client else the framework tells the administrator regarding the missing reaction within the data set and provides a predefined reaction to the user.

A Novel Survey on Artificial Intelligence in Cyber Security

Mrs.Pratibha Tambewagh , Dr. D. R. Ingle
BVIT, Kharghar, Navi Mumbai BVCOE, Kharghar, Navi Mumbai,
pratibha.tambewagh@bharatividyapeeth.edu, dayanand.ingale@bharatividyapeeth.edu

Abstract— **Artificial intelligence (AI) and Cyber security are closely related to each other. Today computers, mobiles and networks have reached every home. These tools are no longer just entertainment. Technology is becoming advanced day to day. Educated and un- educated people get benefit from these advanced technologies. Recently Government involved the topics of AI and Cyber Security in education curric- ulum. As technology develops, so do the users, cus- tomers, business advances and this is where cyber threats come in the picture. This paper elaborates Cyber Security and need of Artificial Intelligence for cyber security. The role of AI become important for cyber security viz. Application security, Net- work security, Device security, Information secu- rity, Cloud security, IoT security.AI has the ability to potentially detect misleading information. AI can be used as a tool to mitigate breaches on the cyber space and it can be used by the nation for some good work**.

Keywords-Artificial Intelligence (AI), Cyber Security, machine learning (ML), Cyber-attacks, Internet of Things (IoT), Denial of Service (DoS), Cyber Physical Systems (CPS).

I. INTRODUCTION

Artificial Intelligence means -the way in which computers can be made to copy the way humans think. Cyber security is the practice of defending computers, servers, mobile devices, electronic systems, networks, and data from malicious attacks. The task of detecting attacks and intrusions using systems is becoming increasingly difficult. Cyber security is an important component of national security. Information is unavoidable when it comes to Nation security. A major res- ervoir of information is social media. Identifying threats may require some sophisticated techniques. This information is given by gullible people through social media like twitter, Facebook, etc. In this case, the ad- vantage of the attackers is to target someone, defame them, and gain money. Only Artificial Intelligence in action can protect a nation from an attacker. Cyber at- tackers are benefited by anonymous providing infor- mation to the media, free speech, talking to unknown people on social media and giving confidential infor- mation. Some people are making money by spreading fake news and the security of the country is deteriorat- ing [1].

II. LITERATURE SURVEY

The biggest cyber security threats are Phishing, Ransomware, Botnet, DoS attack, social engineering attack, Cryptocurrency hijacking. These attacks are done for fraud, exploitation, extortion, causing disrepute and for personal revenge. To survive from the above attacks, we need AI with modern technology. AI is capable to protect against such attacks. AI is revolutionizing the role of information. Its experiment could help un- ravel the complexities of cyber space.Even in medical applications, we can design and implement the cyber security with the help of AI. In this, AI plays an important role in finding vulnerabilities in the applications. A public auditing scheme can be developed in health systems by tooling AI [2]. It enables the modern paradigm to make promising gains in the health sector. Trusted Auditing, information measurement, cyber physical devices/systems (CPS), Internet of Things (IoT) can be leveraged at the end user. Medical-CPS have maintained the reliable relation between data owner and proxy authorizer.AI provides strong computation process on cloud server. It provides better authorization, data management and trusted auditors. These systems provide guarantee to se- cure the data in place of the owners only. It also pro- vides patient secrete information anonymity and confi- dentiality.

Cyber attacks are increasing with the devel- oping technology and attackers are also upgrading their targets. It is necessary to know the cyber threat to understand the attacker characteristics. For this it is necessary to gather detailed information about the attack. The more information we get, the faster we can take protective measures against it. A country like USA has developed such AI mechanisms that integrate intelligence of cyber threat and develop the cyber security taking into account advanced threats. It is possible to improve and upgrade the existing cyber security by col- lecting information about cyber incidents, malwares.

In 2020, the fight against covid-19 disease was going on all over the world, the government of each country was preparing plans through consulting their doctors and experts. At that time, most of the countries collected patient's information to predict the possible development pattern. Healthcare sector is a more vulnerable target than any other for attackers and at the same time it is easy target. Hackers steal patient's data

from healthcare. Hackers know that if patient data or healthcare systems are compromised, they can demand large ransoms. AI system can be used to protect against such ransomware attacks. Cyber security should be implemented using AI, deep learning technology.

Today billions of people in the world are con- nected to each other using social media such as Twitter and Facebook. Many organizations are also connected among themselves through social media. Cyber attackers collect maximum information from social media and carry out cyber-attacks. Cyber attackers manipulate the information to spread rumors about diseases, ex- pose people's privacy, spread violence among various group of people. This can be controlled by using AI and social media systems can be kept safe.

Of course, every device that improves human life includes more computer systems. The production of digital data has also been done a lot. Managing this data in a smart manner has also become essential. The old data processing method recommendations are very ex- pensive and somewhat risky. AI, block chain, deep learning and machine learning techniques enable detection and mitigation of anomalies in DOS attacks, double spend attacks, malware and advanced persistent threats. They all have a high degree of accuracy [3]. Security challenges and attacker's motives (financial gain, anonymity and isolation attacks) get categorized in AI system. AI system includes various aspects of information such as integration, transaction, classification, anomaly detection and privacy protection.

The maritime industry has seen a lot of growth and financial gains over the past few decades. However, the introduction of serious and potentially new types of threats has a significant impact on the mar- itime industry. Hence, there is a need to develop effec- tive, preventive and corrective tools and techniques to address cyber security threats [4]. IoT devices, sensors and some modern devices are used in the ship. AI can be used for cyber risk, potential threat reduction and for severity determination. Despite the advancements in field sensors, communication, navigation technology along with rapid technological advancements, new avenues for cyber-attacks have opened up. A ship lacks technical persons to handle an attacking scenario during a crisis, so we can use AI systems. It has cyber security characteristics to deal with cyber-attacks.

Internet usage is increasing day by day. AI can detect new attacks faster than humans. AI is ready to save companies from intrusion. Many companies have implemented AI related applications. It has been tested and found to be effective in combating cyber-at- tacks. AI algorithms are also needed to fight crime [5]. Cybercriminals are also stealing intellectual property using computer systems. The possibility of AI-automation can include data protection and instant protection. Many elements of AI are important for cyber defense. One of them is detection capability. There are also some AI programs available to detect specific steps and be- haviors. AI systems can monitor any system 24 x 7. Therefore it is considered very effective detection sys- tem. This factor has led many organizations to imple- ment AI-based security. Detection, prediction and re- sponse time skills of threats are the main features of AI.

Internet connectivity and intelligence devices provide improved services to humans. However human are facing technical challenges. Cyber security, privacy resistance and physical security are aspects used in IoT. It is necessary to protect the tools from vandalism and theft [6]. Many aspects can also be provided by AI for IoT security such as antitheft, communication circuits, sensing devices, biometrics, current plan analyzer, tracking methods, etc.

Artificial intelligence is increasingly used in cyber security applications. AI is capable of intrusion detection, malware detection, spam filtering, detection of cyber-attacks and threats, and avenues for defense. Where cyber-attacks become more varied and complex there is the trust of human users on the AI model.[7] The next generation will surely understand every model made on the basis of AI. Therefore, there is a need to focus on literature, research and applications of AI in cyber security.

Fiber optic network is considered a very im- portant part of the world's telecommunication compa- nies. Fiber optic network is spread all over the world. Actuators are used to operate intelligent devices in a small part of the world. During the covid-19 pandemic, all the companies asked their employees to work from home using the public internet. Such networks are vulnerable so this can easily be done by a DOS attack by an attacker [8]. But AI and machine learning have created algorithms that can detect DoS attacks quickly and efficiently.

The Industrial Internet of Things(I-IoT), a network which connects wireless devices using a sys- tem that bring people physically together to improve productivity and performance of industrial processes. In I-IoT there is a need to detect attacks accurately and quickly to avoid the sophisticated consequences that cyber-attacks can have [9]. Some algorithms are implemented in AI to detect such attacks. They include Decision Tree, Random Forest, Logistic Regression etc.

Cyber-attack is done by finding the vulnera- bility of any software. It is necessary to design detectors to eliminate their vulnerability. AI and deep learning are effective for this. AI is also perfect for digitization, literature review, availability of data center and many other such features [10]. AI can also suggest how to

classify which algorithms to use and when. Representation with the help of graphs is the need of the time. Also, we can make applications with the help of AI in embedded systems.

The rest of the paper is organized as follows: Section III deals with Methodology and Section IV deals conclude the result.

III. METHODOLOGY

Artificial intelligence (AI) - The study of computer sys- tems that attempt to model and apply the intelligence of the human mind.AI is a branch of science, borrowing characteristics from human intelligence and applying them as algorithms in a computer friendly way.

Machines are better than Humans in:

1. Alertness.
2. Speed and Power.
3. Sensor Detection outside Human range.
4. Routine work.
5. Computation.
6. Short term memory storage.
7. Simultaneous activities.

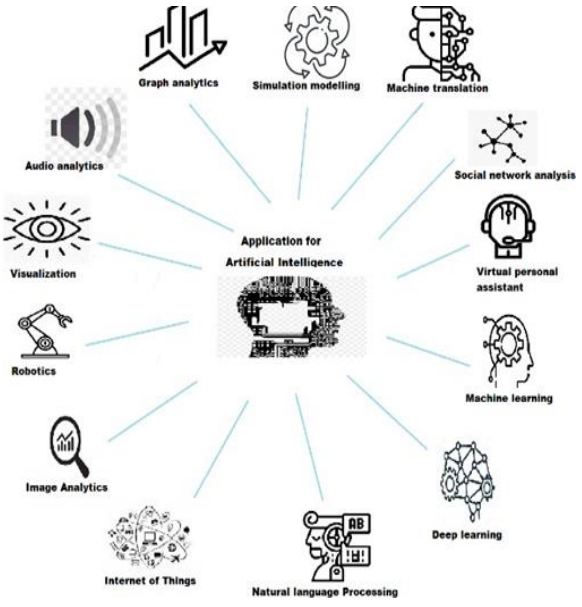

Fig.1 Applications for Artificial Intelligence

Fig.1 shows the applications of AI in differ- ent fields. Using the same applications, we can create many types of models for cyber security, which will be useful to humans in daily life. Some machine learning (ML) algorithms in cyber security are used to automat- ically respond to cyber threats. Various security tech- niques of threat intelligence are used for such security. "Machine learning is the process of mechanical learning which can take different forms with different characteristics and predictive abilities. The three machine learning types are supervised, unsupervised, and reinforcement learning." [12]

A) Supervised Learning:

"Supervised Learning is where a machine learns from training data, and maps out inputs and outputs, based on rules provided in said training data, and from inferred functions. In Supervised Learning, the dataset is labelled, wherein there is a target variable. The value of which the ML model learns to predict, using different algorithms. For instance, it may do this based on IP ad- dress location, frequency of web requests and so on. From this, an ML model can then predict if the IP was part of say a Distributed Denial-of-service (DDoS) at- tack, and more. To design any security model with ar- tificial intelligence and machine learning require Da- taset'' [13]. Dataset is nothing but collection of large data This data set is divided into two parts. One is the training data and the other is the testing data. The trained data is used to train the machine learning model and the testing data is used to check the accuracy of the learning model. The main goal is for the machine to ex- tract the information from the unlabelled data sets, that could aid performance and increase productivity.

B) Unsupervised Learning:

'In Unsupervised Learning, there is no labelled data, thereby, no prediction of a target variable. Unsupervised Learning tries to find interesting associations, or patterns, within a dataset. For instance, clustering can be applied in user analytics where application users can be grouped together. By doing this, it is possible to see what data should belong to a specific group, or not.

Machine learning is about developing patterns and manipulating those patterns with algorithms. In order to develop patterns, we need a lot of data that has complete, relevant and rich context. It is not just about the quantity of the data, but also the quality' [12].

C) Reinforcement learning:

'Reinforcement learning is a sub-branch of Machine Learning that trains a model to return an optimum solution for a problem by taking a sequence of decisions by itself' [12].

One simplified mechanism is derived phase wise to design cyber security. The phases are as follows:

1. Data Set:
   - Data collection from data source (Net- work activity, Database activity, Appli- cation activity, user activity.
   - Data identification.

2. Pre-processing:
   - Cleaning.
   - Data conversions.
   - Clear missing, duplicate values.
   - Visualization.
   - Feature engineering vectorization.
   - Encoding.
   - Normalization.
   - Feature extraction.
3. Sampling:
   - Training set. (Data preparation, model training)
   - Testing set. (Data preparation, model test)
4. Train Model:
   - Kernel function, Kernel scale.
   - Cross validation.
5. Model evaluation:
   - Accuracy.
   - Precision.
   - Recall.
   - Score.
6. Result:
   - Virtualization.
   - Production.
   - Required action by user.

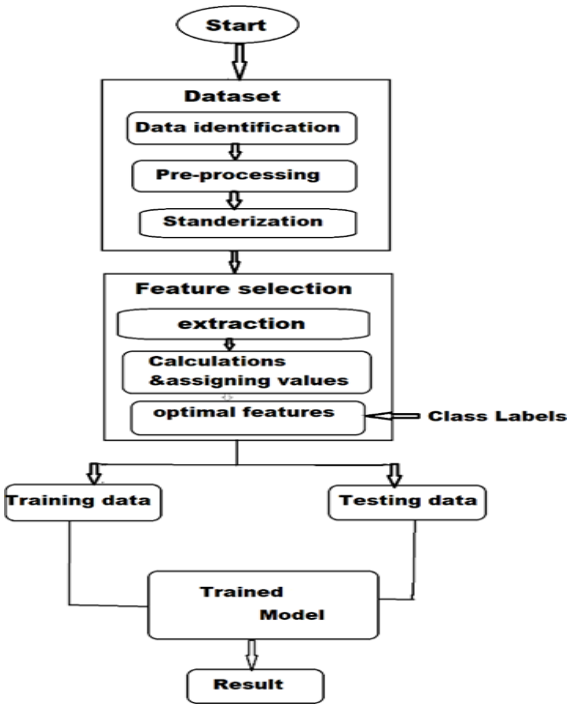

Fig. 2 Block diagram security mechanism with artifi- cial intelligence and machine learning

Table 1 shows different types of algorithms suggested to prevent various categories of attacks. These types of algorithms can be used to design security mechanism.

Table1. AI applications in defending mechanisms against different categories of cyber-attacks.

Cyber attack types	**Learning models (Techniques)**
Malware	• RF- Random Forest Algorithm • CNN-Convolutional Neural Networks • DT-Decision Tree Algorithm • GNB-Gaussian Naive Bayes Algorithm • SVM-Support Vector Machin Algorithm
Spam	• XGBoost-Extreme Gradient Boosting • NB and RF-Naive Bayes and Random Forest • RNN-Recurrent neural network • CNN-Convolutional Neural Networks
Botnet	• DBSCAN-Density based spatial clustering of applications with noise • LSTM-Long short-term memory • VAEs-A variational autoencoder • ML-Machin learning
Fraud	• GNN-Graph Neural Networks • LGB-Light Gradient Boosting • Transfer learning • Sequential modeling
Phishing	• Phishpedia-A Hybrid Deep Learning Based Approach to Visually Identify Phishing Webpages • NB and RF-Naive Bayes and Random Forest • SVM-Support Vector Machin Algorithm • MMHAM- Multi-modal hierarchical attention model
Network Intrusion	• Neural Network and attention • XGBoost-Extreme Gradient Boosting • BiLSTM- Bidirectional Long Short-Term Memory model • Stacked RF
Denial of Service	• XGBoost-Extreme Gradient Boosting • DNN-Deep neural networks • ML-Machin learning

IV. CONCLUSION

Using techniques such as artificial intelligence and machine learning, we may be able to develop analytical

methods. using AI deep learning technology, we can predict the possible development pattern in medical sector and can implement Cyber Security. We can make social media more secure by taking advantage of AI. CPS and IoT systems are made saturated with the help of AI. By using AI, we are able to control ransomware attacks.AI can be used in Enhancing Security and Pri- vacy in Smart Environments. Cyber risk can also be reduced with the help of AI in the Maritime Industry. AI and machine learning algorithms can detect DoS at- tacks and mitigate it. The future of AI will continue to grow due to the increased use of technology. AI can greatly improve our lives.

Medical Image Processing and Machine Learning: A Study

Hiral S. Padhariya,Shailesh Chaudhari
Veer Narmad South Gujarat University, Surat, India
hspadhariya@vnsgu.ac.in, sachaudhari@vnsgu.ac.in

***Abstract*— Machine Learning Field is rapidly growing field in the research sector since 2 decades and a growing field in medical imaging processing sector. So, to diagnose the diseases at the early stage machine learning provides the various techniques and algorithm such as supervised learning technique, unsupervised learning technique, Reinforcement learning technique, Active learning, Semi-supervised learning, Evolutionary learning and lastly deep learning. It enables machine to automatically learn data from the past experience and predict things without any need of being explicit programmed. First we need to provide input of the past data then trained the data using some sort of machine learning algorithm then building logical models and finally it provides output. The main aim of these survey paper is to give brief detail regarding how machine learning can be useful in the medical sector.**

Keywords—Machine Learning, Supervised learning, unsupervised learning, Active learning, Semi-supervised learning, K-Nearest Algorithm, Naive Baye's Algorithm, Random Forest Algorithm, K-Means Clustering.

I. INTRODUCTION

Machine Learning is field in the computer science and it is a branch of artificial intelligence. Before 40-50 years the machine learning concept was not in the way but now it has become need and a part of our daily life. In 1936 Alan Turing have gave a theory on how machine can execute somesort of the paper on "Computer Machinery and Intelligence".Today, when data are in the form of the image there are Machine Learning algorithm which interpret the images for further processing.Image Processing is a computer technology that is applied to the images for further processing, analyzing and get the meaningful information from them. Some of the steps involved are as follows:
Some of the data processing steps involved arerepresented as diagrammatic in Fig. 1.

1. Finding the Data
2. Importing Libraries
3. Importing Dataset
4. Find Missing Data
5. Encode Categorical Data
6. Splitting dataset into training and test set
7. Feature Scaling

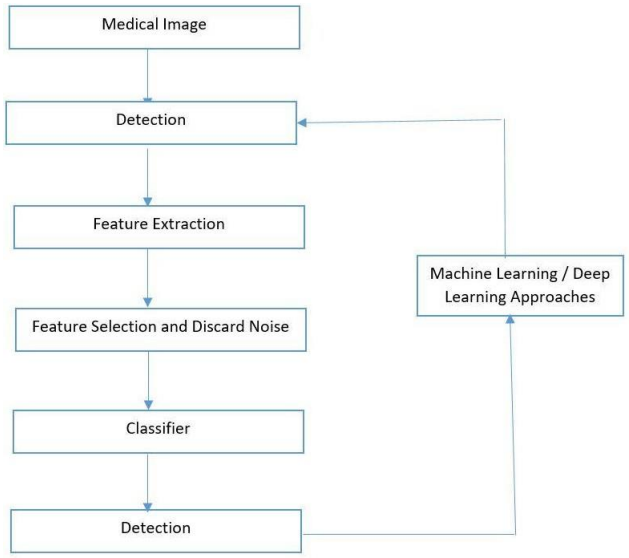

Fig. 1. Image data processing steps

The Life cycle of Machine Learning involves the phases as shown Fig. 2.

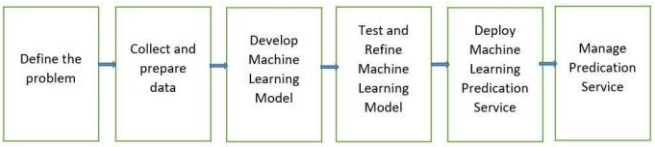

Fig. 2. Machine Learning life cycle

II. MACHINE LEARNING IN MEDICAL IMAGING:

As now a day's medical issues have become a common part of human life so identification of diseases at early stage it is too important so that precautions and care must be taken. For early detection of the diseases machine learning is a way which helps us by giving us various algorithm and to study specific diseases in medical imaging. As there are many

entities such as lesions in medical image which cannot be shown correctly using some mathematic solution [1].So in some recent years if we talk about the skin diseases it has become common in almost entire region of our world. One of the major skin diseases that is skin cancer is found to be deadliest disease in humans. As the skin cancer is found of 2 types that is Malignant Melanoma and Non- Melanoma.So; if we talk about the Malignant Melanoma it is found to be dangerous skin cancer and about 4% population is affected, while 75% death cases are noted by this skin cancer.So to prevent such type of diseases early detection and treatment must be provided to the patient. The presence of Melanocytes which is present in the body is the cause of Melanoma Diseases So; one of the way to examine structure of skin is dermoscopy and till now, the accuracy for detection of this skin cancer is 75%-85%. So some of the stages for dermoscopy image analysis system are as follows:

- Collecting dataset
- Hair Removal
- Shading Removal
- Glare Removal

Also, to identify and classify different data based on different classes; SVM algorithm is used which is a type of supervised learning algorithm (Fig. 3). The performance of these algorithm is very accurate even for small amount of data as compared with other classification algorithm.

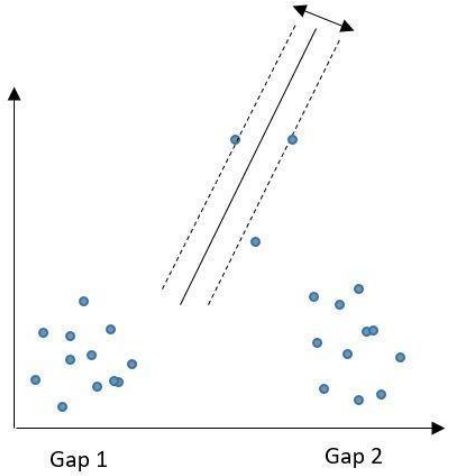

Fig. 3. SVM Classifier

Representation of Block Diagram of Medical image processing in machine learning is shown in Fig. 4.

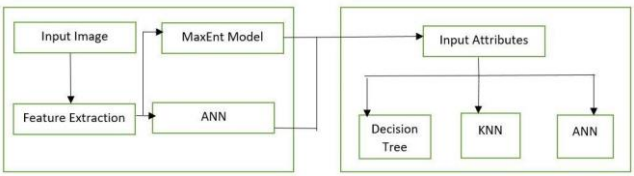

Fig. 4. Medical Image Processing

- Stage 1: Computer Vision: For identification of the skin diseases based on features extracted from the image by using the various image processing technique. The computer vision consists of two phases. In phase one image is taken from any smart devices or camera and some important features are extracted and in the next step the feature that we extracted in phase 1 helps us to identify the skin diseases by using various different model. Some features such as color of the infected area with respect to healthy skin, shape by using edge detection of infected area.

- Stage 2: Machine Learning: For detection and classification of the image various machine learning algorithm are used. The attributes are taken as input such as exocytosis, acanthosis after that it is trained using dataset and finally testing is done by the algorithm. Image processing are now a days have become advances in field such as instrumentation and diagnostics and most of these field are based on image processing. Machine Learning and artificial intelligence have been rapidly progress in the recent years. For supporting such activities as medical image processing, image fusion, image segmentation, retrieval of image analysis of the image. It helps doctor to assist diagnosing and prediction risk of the diseases at the early stage.

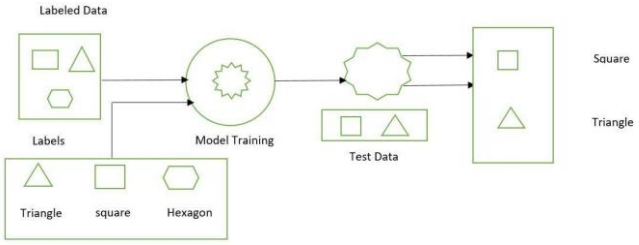
Some of the machine learning algorithm such as SVM, KNN, NN they are being limited in processing of image also some time consuming. So, if we talk about the other algorithm such as CNN, KNN in which raw data in fed, having automatic features which automatically learn rapidly.Although to identify the diseases or to detect the diseases based on CNN in medical image have been given significant accuracy, now a day there are new advancement in machine learning and one of the concept is of deep learning. Basically it is used for the recognition of various objects.Deep learning applied to medical imaging now it has become more popular technology in era of the digital world. Applying deep learning based algorithm to medical imaging have become a growing era. For the cancer detection and continuous monitoring of diseases deep learning is used.The detection of diabetic Retinopathy now a day to manage it manually it is too difficult and also it takes a lot of time. At the beginning of these diseases there are hardly no symptoms at the early stages which actually delay in the treatment. The automated detection of Diabetic Retinopathy provides better accuracy Deep learning also provides accurate result for cardiac imaging, some of the application CT and MRI scan are most of recent use technique of deep learning.So, In order to work with various machine learning algorithm machine Learning is divided as follows:

A. Supervised Machine Learning
B. Un-supervised Machine Learning
C. Semi-supervised Learning
D. Reinforcement Learning

A. Supervised Machine Learning:

It teaches the machine with the labelled data after that model make predictions and provide the output. Basically it helps us to solve real-world problem such as spam detection. Further, it is categorized into two types

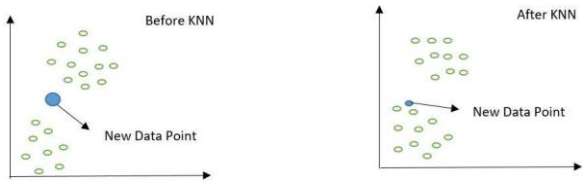
1. Regression
2. Classification



Some commonly used algorithm are:

1. Naïve Bayes
2. Linear Regression
3. Logistic Regression
4. K-Nearest Neighbor
5. Random Forest

K-Nearest Algorithm: KNN is a type of supervised learning algorithm and it is one of the simplest algorithm to implement. Based on the similarity of the new data and available data it classifies a new data point. This algorithm isalso called aa lazy algorithm because it does not directly learn from the training dataset but it stores data at time of classification and actions are performed on the dataset. Suppose we have two different categories named as category A and category B and a new data point X. so to identify that new point lies in which one of the category KNN algorithm can be used.KNN is useful where we want to recognize the patterns toclassify objects. As value of K generally depends on type of the problem. The most preferable value of K=5. By selectingthe multiple value of K it may lead to overfitting.



Steps involved for the KNN are as follows:

- Selecting number K of neighbors.
- Calculate Euclidean distance of K.
- Take nearest neighbor of K as per the Euclidean distance value.
- From the K neighbors, count number of data in each category.
- The number of neighbor which is maximum from given category assign new data point to that category.
- Model is ready to use.

A good example in real life scenario is for heart diseases prediction as in a normal routine life hear diseases is a common disease for death of humankind. According to report of US the death ratio is up to 35% so to avoid such type of issues quality and improvement should be done in the health sector. KNN is one of the frequently used algorithm in prediction of the diseases [4].

KNN and genetic algorithm helps us to improve the accuracy for the given diseases dataset. The algorithm make use of the two parts:

1. It deals with evaluating attributes using genetic search
2. Select the attributes with the high ranked
3. Applying KNN with genetic on subset of attributes which provides maximum accuracy.

Calculate the accuracy of classifier.

Naïve Bayes Algorithm: It is a supervised learning technique which is used for solving classification problems and it is based on Bayes theorem. generally, for text classification where we have a high amount of dataset and for building fast machine learning model that make quick prediction Naive Bayes is useful. It is a probabilistic algorithm which predicts on basis of probability of object.

Bayes theorem is called as Bayes Rule used to determine probability and formula for Bayes theorem is stated as

$$P(A|B) = P(B|A).\ P(A)/P(B)$$

Where, P(A|B) is posterior probability that is probability of A on Event B.

P(B|A) is likelihood probability which means probability of this hypothesis is true.

P(A) is prior probability where it observes evidence before hypothesis.

P(B) is Marginal probability

Some of the advantages of using Naïve Bayes is it is one of the fastest algorithm to predict dataset and also it can be used for multi-class classification.

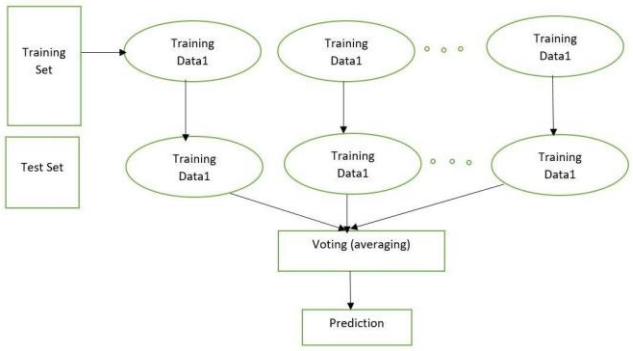
Applications where Naïve Bayes used is:

- Face Recognition: It is used for face recognition as it identifies the face based on features such as nose, mouth, eye, ear etc….
- Prediction of weather: As it is used to identify daily weather conditions.
- Medical sector: As based on patient's information on their medical history it is used to identify certaindiseases such as cancer, heart diseases etc…
- Classification of different news: Based on thesealgorithms whether news is political, educational oriented or world news and so on it helps to predict the news.

The real scenario in field of medical where this algorithm is useful to predict Hemoglobin protein sequences, so based on the protein sequence information which we are getting from the patient for getting better accuracy result these algorithm is used to classify normal and diseased proteins. The data which we are getting from the patient are patient id, patient name and protein sequence related information. After that it will be compared with the training data and classify accordingly. So the result which we get from these is by taking dataset size as 20 accuracy value is 85% and dataset size as 50 accuracy size is 84% [6].

Random Forest Algorithm: It is popular algorithm in machine learning which belongs to the supervised learning technique. This algorithm can be used for classification as well as for regression problems. It combines multiple classification for solving a complex problem to enhance the performance of a model.

Here, in this algorithm it does not rely on one of the decision tree, it takes predictions from multiple tree and based on majority it predicts the output. If tree leads to great number, then high accuracy it will show and it also prevents overfitting.



As random forest predict dataset based on the multiple trees, some predict correct output while some not. But all together predict the correct output. So, two assumptions for better performance are stated as

- Some actual value must be there in the feature variable of dataset.
- Prediction done from each tree should have very low correlations.

As this algorithm takes less training time compared to all other algorithm. The accuracy is high for the output which it predicts and even for the large amount of dataset it runs efficiently. Also, it can maintain the accuracy where at some point large amount of data is mining.

How actually Random Forest Works?

As the random forest works in a two-phase. In First phasewe create a random forest by combining multiple decision tree, and second is to make predictions for each single tree created in phase one.

Step 1: Selection of any random "K" data points from thegiven training set.

Step 2: Building the decision tree with the selected datapoints.

Step 3: Choosing number as N for the decision tree that we want to build.

Step 4: Processing same step 1 and step 2

Step 5: For new data points, finding the prediction for each decision tree and assigning new data point to the category with majority votes.

Some Real life applications of Random Forest Algorithm are:

1. Banking: generally, it helps to make a good decision whether to provide a customer should provide loan or not.
2. Health care: Here, based on the previous medical history patients are diagnose. Past records are viewed for proper dosage of patients.
3. Stock Market: For Financial analysts it is used to identify market for stocks and also enables them to remember the behavior of stock.
4. E-commerce: As based on the past consumption behavior it can predict the performance of customer.

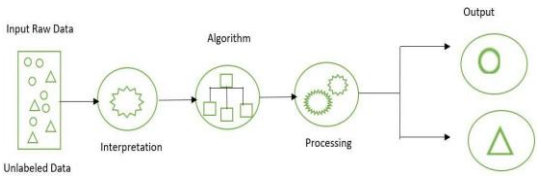
B. Un-supervised Ma

C. chine Learning:

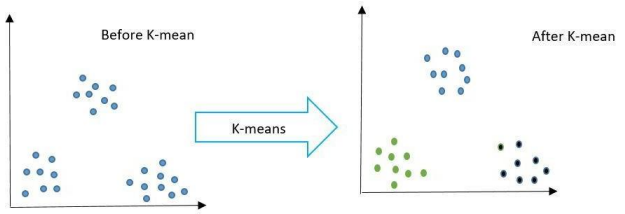
It is a type of Machine Learning in which model istrained with the unlabeled dataset. Here, these technique is used to find hidden pattern from the dataset and group together as per some similar data point.

Unsupervised learning is categorized into two types:

1. Clustering
2. Association



K-Means Clustering Algorithm: It is a type of unsupervised machine learning technique helps us to solve the clustering problems in machine learning. Generally, it groups the unlabeled dataset in multiple cluster. Here, K is the pre-defined cluster which is created in the process. Let's say if value of K=2, it has two clusters, and for value of K=3,there will be three clusters. It is called as centroid based algorithm, where every cluster is associated with the centroid.These algorithms minimize the sum of distance between data points and their corresponding clusters. As in the input it takes the unlabeled dataset and then divides into K-numb of clusters and these process is repeated until it does not findthe best clusters



How does K-means algorithm work?

Step 1: Select the value of K to decide the number of clusters.
Step 2: Solving random K Points.
Step 3: Assigning each data which is closest to centroid and which will form the pre-defined K clusters.
Step 4: Calculating new centroid and variance of each cluster.
Step 5: Repeating the step three, and reassign each data point to the new closest centroid of each cluster.
Step 6: If any reassignment occurs, then move to step-4 else go to finish.
Step 7: The model is ready to use.

How to choose value of K:

To find the value of K one of the method is elbow method it is one popular way to find the optimal number of clusters. The concept uses is **WCSS** which stands for **"Within cluster sum of square"** it is stated as:
WCSS=Σ pi in cluster 1 distance(pic1c1)^2 + Σ pi in cluster 2 distance(pic1c2)^2 + Σ pi in cluster 3 distance(pic1c3)^2

Here, Σ pi in cluster 1 distance(pic1c1)2 is the sum of square of distance between each data point and centroid within cluster 1 and also it is same for the other two terms.

For finding the optimal value this method uses some of the steps stated below as:

1. Execution of K-means clustering for a given dataset for different values of K (range: 1 to 10)
2. For every value of K, it calculates WCSS value.
3. Plotting the graph between number of cluster K and WCSS.
4. If the point which is plot looks like an arm, considered it as best value of K.

B. Semi-supervised Machine Learning: This Machine Learning Technique is the combination of the supervised and un-supervised learning techniques. It combines the algorithm with unlabeled dataset which is used in unsupervised learning and also make use of the labeled dataset similar to supervised learning technique. It improves the limitation of the supervised and unsupervised learning techniques.

C. Reinforcement Machine Learning: In this method it provides rewards for the good one and punishing for undesired ones, also rewards are gained through the experiences when it interacts with the environment.

III. CONCLUSION

As the need of machine learning skills are growing faster in few years. Currently machine learning is in use and they are in the learning process. The use of machine learning in the field of medical image processing plays important inferences for the medication. Along with this Deep Learningare also used in the identification of diseases. Along with thisbased on the different algorithms in machine learning techniques different algorithm such as KNN, Naïve Bayes which have been used for various detection of the diseases. Digital Image processing helps us to identify the image and based on the input data of the image various operations are performed on the image and finally it is trained with the model by applying various different machine learning technique. One of the deadest diseases such as skin cancer which now can be detected at the early stage using machine learning. Here, there are some algorithm listed for different diseases detection.

***Abstract*— Autonomous industries are Introduce, the capabilities in all aspects, are extensively and progressively life via Cyber-Physical Systems (CPSs). On the other hand, people are indispensable for completing activities that humans can only do (often called human-in-the-loop). By fusing people's knowledge and experience with machines' autonomy, human-in-the-loop solutions could deal with demanding jobs in chaotic settings. This article aims to assist designers in their analysis and creation of human-in-the-loop solutions by providing relevant methodologies and procedures. These fixes enhance the human experience, call for interactions that draw in the human, provide natural and intelligible cooperation, and stay out of the human's way. This article outlined the technical hurdles in creating person-in-the-loop CPSs and presented a methodology to aid designers in identifying and specifying how the human and the system should function together, emphasizing the control techniques and implementing the interactions. This method makes the process of designing solutions with humans involved easier. Since our approach frees subject matter experts from solution-focused work, use it early in the software development life cycle.**

Keywords—Cyber-Physical Systems, Human activity, human experience

I. INTRODUCTION:

Human behavior regarding technology systems, decision-making processes, and the boundaries between human and modelled automation control, as seen through the lenses of the research communities focusing on automation and job analysis, is underappreciated. Collaboration and symbiosis studies show how humans and machines might assist each other adapt and thrive in the workplace. Jobs that need specialised skills that machines cannot replicate are highlighted by the labour market when they emerge.

However, because of the immense complexity of CPS and the most recent progress of the supporting technologies, the present research needs to answer the emerging demands for work design better. Value creation in the workplace occurs primarily in the areas of (b) decision-making and (c)creative activity, (d)and (e)social behaviour, all of which pertain more to individuals' daily lives than to their specific occupations. These include, in combination with CPS technologies, a) collecting the talents and other characteristics of the employees and b) understanding and directing the interaction between workers and CPS technologies, which happens at multiple levels (f).

To consider the human role and lead its improvement in production systems, there needs to be more frameworks, methodologies, and instruments that go beyond the physical and procedural viewpoint of labour. Through maximising gains and fostering continuing expansion of this function, There is a need for innovative approaches to improve the design and assessment of work in production settings characterised by the inclusion of human workers and CPS.

II. PROPOSED METHODOLOGY- DESIGN WITH CORRELATED ANALYSIS:

In a greenfield setting, a new manufacturing system must be designed from the ground up; in a brownfield setting, alterations to the existing system and therefore need work design. Most people agree that humans play a pivotal part in production systems since they are the only ones to regulate the systems, deal with unexpected events, and develop adaptable solutions. However, when engineers and designers think about creative technological solutions, they tend to focus on the manufacturing phase and typical working circumstances, limiting their ability to appreciate the human element fully.

The suggested technique seeks to broaden the reach of analyses and designs of human labour by zeroing down on various scenarios that provide a clearer picture of the opportunities and obstacles associated with incorporating humans into cyber-physical production systems. Instances of breakdowns, product swaps, and identifying scheduling-impacting fluctuations are just a few examples.

The technique facilitates evaluations of human-systems combinations to guide design decisions, factoring in all relevant viewpoints and components within a holistic framework. More importantly, this method helps managers and engineers to explain their human resource strategy, cultivates a multi-perspective knowledge of employees' roles, and promotes early identification of any mismatch between top-level plans and technological progress in the factory.

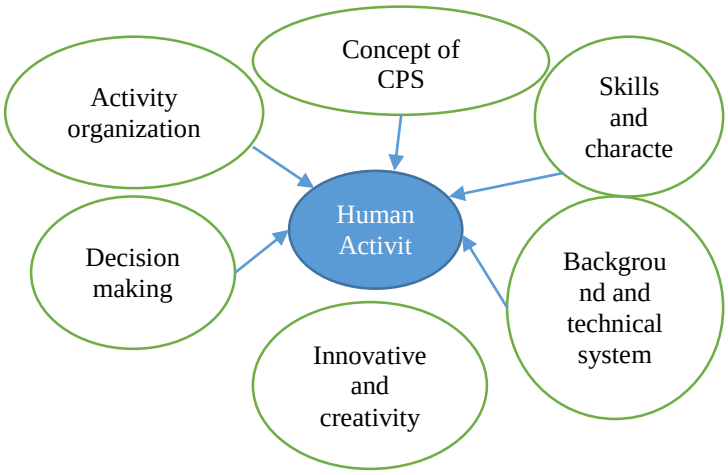

Fig. 1. Figure 1: Frame work

Analysis of the human and CPS components and how they relate to the activities is possible using the given paradigm. The division of the job into discrete blocks is defined uniformly from the four angles.

A. Activity organization:

CPS incorporates the idea of addressing problems on both a physical and a cyber or digital level. An extra holistic dimension, at which human and societal cycles emerge, is brought to light by the abstraction viewpoint. The term " abstraction " refers to the level of organization above which the action occurs, propagates, and has consequences. Using this viewpoint, we can determine which resources would be most helpful and what kinds of talents and abilities would be required. Consider the physical and cyber levels of CPS and the holistic level of human and social loops to determine the abstraction perspective. (Standard American Phrase) (AP) Physical - affecting the physical realm or physical processes (AC) The actions have an impact on the digitalized data, hence the term "cyber" or "digital" is used (AH) All-encompassing: affecting mental constructs.

B. Decision making:

Employees are being asked to take on more responsibility for making decisions and resolving issues. Human activities should be defined in terms of the stages that make up this process. A decision ladder and a job analysis use to break down the many steps of these tasks into three main phases: (DI) understanding the situation, (DII) analysing and making decisions, and (DIII) carrying out the plan.

Additionally, a specific section has been added to the process for handling reporting tasks, which are often overlooked in deliberation evaluations (DIV). Because of the employees' willingness to share their insights, experiences, and expertise with one another and with CPS, these gatherings are crucial. Finally, we have separated the non-productive steps into their own phase (D0). From the viewpoint of the people making the decisions, the following groups of actions have been established:

Diagnosis (DI)(situational awareness); Determination(DII) (analysis and choice making); Development (DIII) (task completion); Description (DIV) (reporting and explanation); and Other (D0) (non value added activities).

C. Innovative and creativity:

Jobs that need originality and imagination are rising in demand while those requiring repetitive activities are decreasing in value due to technological advancements. In this study, we base our categorizations of activities on the human performance models' categories of abilities, rules, and knowledge.

IL) Predicated on custom or established procedure (IM) rule-based and method-based systems rely on established, agreed-upon rules and procedures to solve problems. (IH) One who generates novel ideas and insights.

D. Background and technical system:

Lean Production Systems and the ideas of Socio-Technical Systems may come from different places of origin and perspectives. However, they share an appreciation for the importance of the human element in the workplace. Human interaction-based forms of e-employment are less likely to be mechanized. In this paper, we provide a scale to quantify the amount and quality of social contact, from "none" (no interactions) to "extreme" (benefiting the team's or community's overall social cohesiveness). As the name implies, the minor interaction level signifies the absence of any interactions.

In contrast, the highest level (interactional complexity to reach an understanding via mediated discussion and bargaining) represents the highest level of interaction. Activities have been categorised as follows from this viewpoint: (SL) no or poor social contact, (SM) negotiation/mediation, and (SH) strengthening social cohesiveness.

E. Skills and characteristics:

Employees need specific skills, talents, and knowledge to perform job duties. Several frameworks are available to assist with identifying these things, and each business may use unique descriptions. However, shared models are helpful since they allow for evaluation and cooperation amongst diverse institutions, programmes, and services. More than 900 industries have adopted the O*NET® Content Model1 as a standard. The Employment and Training Administration (ETA) of the United States Department of Labor also offers a relevant resource in the form of the Advanced Manufacturing Competency Model Clearinghouse. In addition, the human factor considers employees' demands for safety, health, and other factors. These may be short-term issues like stress or weariness or more long-term issues like old age or a disability.

In this effort, we focus first on representing the human factor by using the same skills, talents, and knowledge used by O*NET and ETA.

F. Concept of CPS:

The CPS subcomponent of this paradigm is laser-focused on helping people meet their basic requirements and participate in meaningful activities at work. While cyber physical systems' distributed design allows them to perform a wide range of functions in the background, we focus primarily on the service provided to the worker. CPS research is only getting started and that there are no excellent taxonomies for

these programs. We have used the following service categories as a point of departure for this study:
Alerting using an innovative dashboard's visual representation, or more generally,Assistance in making choicesThe Power of Working Together Socially The combination of Worker augmentation and Workplace learning Changes in the Workplace

Advice/Suggestions
Tablets and smartphones, HMDs and other wearables, desktop/HMI, specialized equipment like exoskeletons or collaborative robots, picking systems, put-by-light, etc. systems may use all to supply the services.
Engineers, operations managers, and others may benefit from the suggested technique. Designers of factories and workplaces at large, if they are designing a brand-new production process or preparing to implement minor modifications into a preexisting framework. Even though the theoretical road map described in Generalizability characterizes Figure 2; it becomes CPS-specific when used in the plan for analyzing and creating.
The Problem Setting is the first step on the journey, and it establishes the scope of the problem, the goals of the activity, and the direction in which it will integrate human and technical systems. At this stage, the designers must define the scope of their work, outlining the goals they want to accomplish and the range of possible design solutions. They may, for instance, weigh the possibility of incorporating a health monitoring system into a machine tool's design to keep tabs on its operational state to facilitate predictive maintenance. Evaluate whether or not available employees meet the position's skill requirements and ensure that employees' time is valued appropriately.
Scoping is the second step involving determining what will be measured and how. In the scenario above, designers are thinking about implementing a health monitoring system (TO BE) and want to evaluate it against the current system based on Periodic Maintenance (AS IS). Within this remit is the tagging of a critical scenario and highlighting crucial roles in the goals. The method may be a maintenance technician checking to see whether intervention in machine maintenance is required.
Modelling the workflow is encouraged during Analysis & Design. This workflow consists of a series of individual activities triggered by the scenario's events and involves the relevant roles for the design option. The characterization of each exercise uses the analysis and design framework, with particular emphasis on the perspectives most directly connected to the strategic goals. The beginning of our scenario may be the occurrence. When a maintenance intervention is imminent in the AS IS scenario, the maintenance technician contacts the production planner to discuss whether or not to halt operations. The production planner would account for the scheduled downtime for each machine. In the TO BE scenario, on the other hand, the maintenance technician can assess the plots and the health monitoring application to determine how much longer the system will last before failing and, as a result, whether maintenance adds intervention needs to the production schedule as a maintenance job.

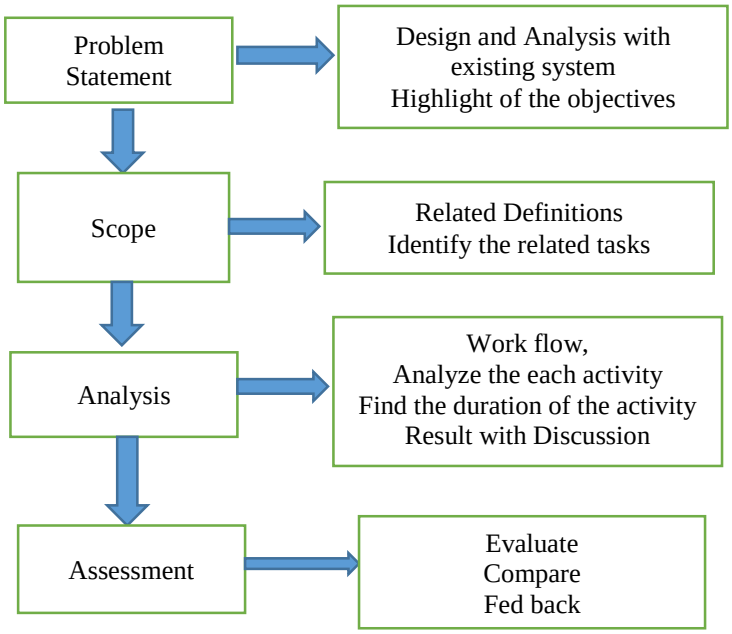

Fig. 2. Work flow

Modelling the workflow is encouraged during Analysis & Design. This workflow consists of a series of individual activities triggered by the scenario's events and involves the relevant roles for the design option. The characterization of each exercise uses the analysis and design framework, with particular emphasis on the perspectives most directly connected to the strategic goals. The beginning of our scenario may be the occurrence. When a maintenance intervention is imminent in the AS IS scenario, the maintenance technician contacts the production planner to discuss whether or not to halt operations. The production planner would account for the scheduled downtime for each machine. In the TO BE scenario, on the other hand, the maintenance technician can assess the plots and the health monitoring application to determine how much longer the system will last before failing and, as a result, whether maintenance adds intervention needs to the production schedule as a maintenance job.
The technique suggests adding quantitative data to the activity modelling, such as the probability of the event and each branch in a split workflow, as well as the time it takes to do an activity.
After the implementing method, a discrete event model will have been created that can be simulated to extract synthetic information about the progression of one or more scenarios to calculate, in a nutshell, how much time was spent on decision-making or utilizing a particular skill. The approach was developed primarily for quantitative data, although it may also infer using qualitative features. Down the case study, it may extract the maintenance technician's whole set of abilities by summarizing the activities throughout the entire process, allowing the technician to zero in on contacts with the production planner.
The systematic process ends with an assessment, where can contrast information about the reference option with the design choice (such as implementing a health monitoring system). May, for instance, include contrasting the two scenarios concerning the necessary expertise levels for

maintenance professionals. It would also emphasise a more streamlined procedure by eliminating the necessity for the repair specialist and the production planner to haggle. High-value activities, such as decision-making or execution, may be prioritised using the criteria and examples from the current capabilities. Hints and suggestions for the human and CPS elements of the design might come from this stage of the process. A skills gap may occur if the Maintenance Technician isn't well trained to analyse and understand the health Monitoring plots and decide on maintenance actions. To further improve the efficacy and efficiency of the operations, Might crate various hypotheses for providing CPS-based services, such as aiding in the forecast of the remaining time before failures.

III. CASE STUDY WITH INDUSTRIAL APPLICATION:

Two industrial use the cases to test the methodology, cosider with various design approaches. The fallowing Sections provide visual representations of the procedures followed and the outcomes.

A. Case-1: Compressor plant:

This facility is responsible for massively producing industrial compressors of the appropriate sizes. Job shop principles govern the production setup, with workers trained to handle specific processes and machines.

The service is preventative, reactive, and remedial. The operator's involvement is crucial in both circumstances since they must determine if the intervention is preventive or corrective. At the strategic level, we use Enterprise Resource Planning (ERP) software and a strict scheduling system. Must determine Scheduling changes on the production floor.

This application of the approach includes detailed annotations of each step:

1. To maximise human effort, we propose a solution consisting of a programme that will assist the operator in producing a pre-diagnosis in case of a breakdown rather than submitting a free-form ticket for maintenance intervention. As this phase progressed, it became clear that the Key Performance Indicator (KPI) to implement this goal may vary depending on the strategic focus of the individual business.
2. Targeting: the current state of use affairs (AS IS) as a baseline against which the design alternative will be evaluated. The operator and the maintenance technician's respective responsibilities in the event of machine failure have been singled out as the primary subject of this case study.
3. Figure 3 displays the simulated analysis and design process, including the sequence of design options and reference case operations.

Specifically, the human element has been defined in terms of skills, chosen from a pool of thirteen that are most applicable to the field of industry, as detailed in:

1) Teamwork is combining efforts with other people to achieve common goals.
2) Work is planned and prioritised so that time efficiently and tasks are completed.
3) The third category is "innovation and invention," which includes developing novel uses for existing processes and goods.
4) The fourth competency is solving issues and making sound decisions based on an understanding of STEM concepts.
5) Use equipment and tools properly, in line with all applicable policies and regulations
6) Look for ways to learn more about methods, equipment, and software that may simplify tasks and boost output.
7) Keep your tools, gadgets, and equipment up to date with regular maintenance
8) Recognize the origins of malfunctions and settle on a course of action
9). Perform maintenance problem diagnosis using standard operating methods
10) Examining, Checking, and Recording Data This includes data entry, transcription, recording, storage, and maintenance in textual or electronic/magnetic format.
11) The Eleventh Step: Use Data-Gathering and Observational Methods
12) Keep all necessary inspection reports, paperwork, and records
13) Other

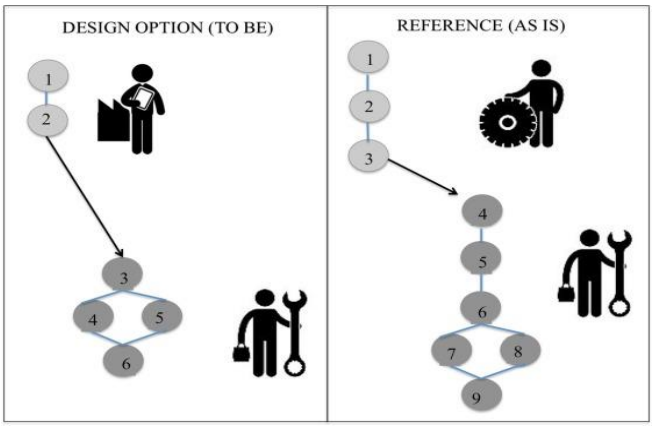

Fig. 3. Human activity flow chart

Using the analysis and design framework, we have described the tasks involved in the design alternative (TO BE) and the baseline (AS IS) workflows.

To evaluate the design alternative (TO BE), Compare the actions of the two active roles in the reference context (AS IS). There was an upsurge in the "Describe" IV activity from the operator. This change might be seen either as a potential loss of production or an opportunity for the operator's expertise to be transferred to the maintenance worker. Moreover, the operator must possess additional skills, specifically skill n.5, to use the option. By eliminating tasks like bookkeeping and reading service tickets to determine whether an inspection is necessary, maintenance technicians can devote more time to actual "fieldwork." Generally speaking, the design is a more efficient use of resources. Assessment phase results included the following recommendations for bolstering human activities.

1. Monitoring service that sends out alarms when certain conditions are met, such as when the temperature, vibrations, or energy usage go beyond a user-defined threshold.
2. In the event of a machine problem, this service application may help the operator inspect the machine and contribute their observations and expertise to the data from the sensors and the machine records to assist in a diagnosis.
3. Service that alerts the technician to potential problems before they occur and offers advice on how to proceed (dynamic interactive troubleshooting guide);
4. Intelligent decision support system (service) to help maintenance technicians decide what kind of intervention is needed.

IV. DISCUSSION:

Two industrial cases have been used to demonstrate how the proposed methodology can be used by manufacturing companies to address work organisation in the context of technological shifts during the design phase. When alternative approaches can be explored, and early feedback on technical projects can be gathered, analysed, and, if feasible, incorporated into the final blueprints.

Based on the examples provided, it is clear that this technique may be used to encompass a variety of approaches to and considerations for human labour, all of which can be described in terms of KPIs that reflect the enterprise's direction. Some key performance indicators (KPIs) are calculated based on the categories used to classify the activities concerning one or more employees and situations. Key performance indicators include the share of time spent on exercise, the percentage of time spent on non-value-added activities, the share of time spent on activities involving high or moderate social interaction, and the allocation of time spent on activities involving high or medium innovation. There are additional key performance indicators that highlight the importance of people. In this context, one example is the number of necessary talents for a specific position. Businesses make their human resource strategy clear by setting goals to improve or improve upon individual indicators and then including these results in evaluating design alternatives. Although these KPIs alone cannot provide a complete picture of a design's human resources consequences, they may help decision-makers become more aware of those implications as they weigh various design alternatives. However, there is some ambiguity in the assessment because stakeholders were only partially involved, there needed to be more expertise with these sorts of concerns, and the primary emphasis was on technology.

Possible solutions were found by analysing the two application situations. Examples of services that might benefit from using CPS to aid and facilitate the human effort. In addition, by generalising from actual business examples Using extrapolations from existing research, we can determine the appropriate categories in light of the four views and the human component of Figure 1's analysis and design framework. This Product, The specifics of the actions that needed backing informed the consistent best practises for auxiliary services made possible by CPS.

V. CONCLUSION:

The importance of humans in the evolving manufacturing environment toward Industry 4.0 has been emphasised by policymakers, industrialists, consultants, and scholars. To maximise performance, manufacturing systems should consider both technical and human-centric factors, although this is seldom done. The suggested approach to modelling and evaluating human actions inside cyber-physical systems helps to close this knowledge gap. Industry examples demonstrate its potential use for evaluating and creating other designs. Improvements to the whole cyber-physical-social infrastructure may involve data gathered from industry applications. As a bonus, these suggestions have been generalised from the specific circumstances and augmented to provide a set of guidelines for labour planning.

Even though it has flaws, the current work offers a unique way to help humans design labour integrated into cyber-physical systems. It focuses on strategic perspectives for human roles in how technology interacts with people.

Abstract— **Using a variety of sensors, automatic activity recognition systems can continuously monitor a wide variety of physiological signals from sensors con- nected to the user or the user's surroundings. When applied to healthcare, this can greatly benefit areas like automated and intelligent monitoring of everyday ac- tivities for the elderly. This article represents a novel approach to analysing the data using Artificial intelligence. The data was collected from the smartphone's internal sensors using the feature ranking algorithm. These sensors collect data regarding human activities. Classify the collected information using random for- ests, ensemble learning, and lazy learning techniques. The suggested method may lead to intelligent and autonomous real-time development, as shown by extensive tests utilising a public database1 of human activity using smartphone inertial sen- sors. Human activity tracking for use in eHealth situations, including the elderly, the handicapped, and other populations with unique healthcare requirements..**

I. INTRODUCTION

Most app developers and smartphone owners have helped propel the mobile application (app) ecosystem to the forefront of global economic growth. According to recent sta- tistics, the most downloaded apps in 2022 by users will be according to their require- ments. Studies show that although internet users are increasingly dependent on smart mobile devices (such as smartphones and tablets) for their day-to-day activities and demands, they may not always be aware of or able to influence the processing of per- sonal data using these tools. Moreover, it is frequently difficult to analyse apps' privacy and security features because of the complexity involved in understanding how they function because of their dynamic environment, reuse of software libraries, and inter- action with other networks and systems. Inadequate data protection and security proce- dures are often the result of app developers' lack of awareness, expertise, or understand- ing of how to properly arrange for and engineer privacy and security needs into their products, rather than any deliberate neglect of such standards.

The General Data Protection Regulation governs the collection, storage, and disclosure of personal information using applications (EU)

The present Data Protection Directive 95/46/EC [2] is being replaced by a new one that is immediately applicable in all Member States. While The General Data Protection Regulation (GDPR) strengthens the privacy and security guarantees estab- lished by the Data Protection Directive. offers supplementary safeguards that give users more say over their private information, is extremely difficult to do on a mobile device or the internet5 . Beyond the requirements of GDPR, this also applies to The EU's Di- rective on Privacy and Electronic Communications also has implications for mobile applications. Transmissions EU Directive 2002/58/EC (ePrivacy) [3] are being revised at the moment and compliant with the General Data Protection Regulation. In January this year, the European Commission proposed a new ePrivacy Regulation. Commission and is being discussed at the moment in the European Parliament and the Council. Ees- sential safeguards for users' personal information in mobile applications, including pro- cedures for ensuring the anonymity of users' data and the prevention of data breaches exchange of messages and information, installation of apps and files (cookies) on end- user gadgets and rules governing tracking's effect on users' privacy preferences.

Combining these numbers with the blurring of barriers between personal and company-owned mobile devices, it's clear that mobile app analysis is becoming more vital for businesses. In reality, these applications may expose sensitive information about workers, which cybercriminals might use for social engineering, the practice of tricking people into giving up sensitive information to steal it, or even for exfiltrating data or installing malware (malware). Companies are right to be wary of the ever-ex- panding cyber threat environment, which now includes mobile apps, due to the sensi- tivity of the data they collect from their customers (personally identifiable information, or PII). The term "mobile device management" refers to a method businesses use to deploy and control mobile devices like smartphones and tablets. Rules and an applica- tion make up this framework usually, with the latter used to manage policies that limit an employee's access to install mobile apps and enforce security measures. These reg- ulations are implemented to prevent unauthorised access to sensitive information, such as financial records, social security numbers, and intellectual property, and to ensure that malware is updated and cannot compromise systems (IP). An incident responder or mobile device manager

may remotely erase all data on a lost or stolen employee's mobile device.

II EXPERIMENTAL VALIDATION WITH ACTIVITY RECOGNITION PROCESS:

We utilized a public activity recognition (AR) database1 for experimental validation of our method. This Thirty people between the ages of 18 and 50 have provided labelled data for this database. Every single individual performed. Wearing a smartphone belt case while doing six things, including but not limited to: walking on level surfaces, climbing stairs, swimming, playing a video game, and playing a board game sitting, standing, and lying down, as well as walking up and down stairs. In this case, we uti- lized a smartphone to sensor package with 3-axis linear acceleration measuring accel- erometer and angular velocity measuring gyroscope angular velocity, both at a fixed rate of 50Hz, which is more than enough for recording human motion. The two com- ponents of the database are the raw sensor data that has not been processed and the collection of features data that is processed extracted.

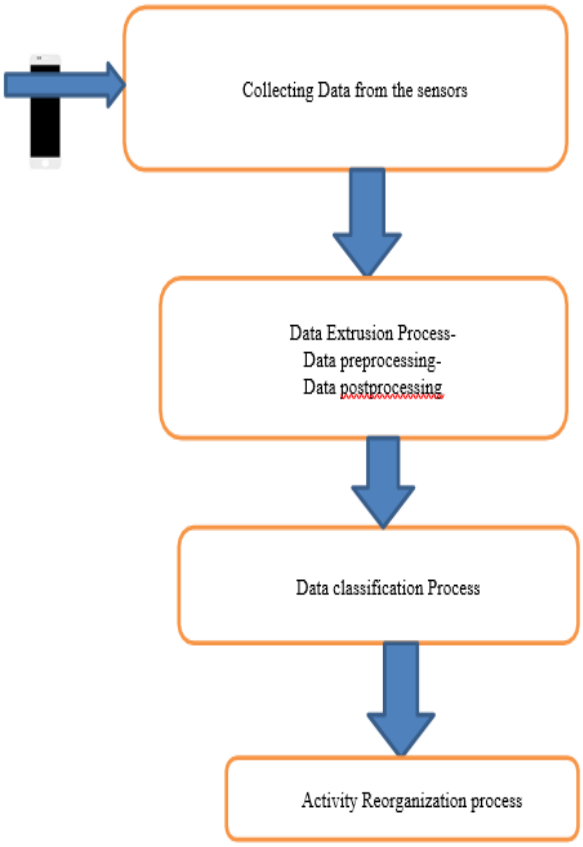

Figure 1: Frame work- Activity reorganization in step by step

At first, 2.56-second fixed-width sliding windows with 50% overlap were used to sam- ple the noise filters of the raw data. There are 17 parameters, that may be extracted from the time- and frequency-domain analysis of accelerometer data.

Another data set has 2.32-second-long vectors with 552 features apiece. Each vector stores information about the interval, including the average, maximum, lowest acceleration and angular velocity along all three axes and other, more advanced features like the Fourier, transform and autoregressive coefficients. We utilised this dataset to test our activity recognition method's efficacy. Figure 1 depicts the block diagram for this dataset's processing. The preceding section will go on to discuss the relevant con- text.

III MOTIVATION OF THE RESEARCH WORK:

There are several benefits of using cell phones for automated activity identifi- cation, including the convenience of the device's mobility and the absence of the need for bulky, unpleasant permanent equipment.

Other well-established methods of activity identification include body sensor networks and dedicated hardware configurations. For example, While such sophisti- cated setups may improve the effectiveness of activity detection, it is unreasonable to expect individuals to wear them regularly in most residential settings due to the effort, time, and convenience involved in doing so. Smartphones have a leg up on the compe- tition for activity detection because of their portability, simplicity of use, and the ability to utilise the phone's many sensors. Smartphone sensor outputs need the development of practical machine learning and data mining technologies for automated and intelli- gent activity detection. While several machine learning approaches are developed, the best algorithm for recognising mobile phone activities remains unclear. It would be a massive boon to the eHealth field if automated activity identification systems could be constructed using the intelligent processing of numerous smartphone sensor character- istics. They focus on remote activity monitoring and recognition in the elderly and dis- ability care sectors.

This article compares the naive Bayes classifier and the unsupervised k-means cluster- ing method. The comparison for activity recognition on several novel machine learning and data mining approaches in smartphones, Adopting the random forests and random committees on the decision tree method. A publicly available smartphone activity iden- tification database 1 reveals that integrating machine learning and data mining signifi- cantly increases recognition performance over earlier smartphone-based activity detec- tion methods. I'll explain the machine learning methods that allowed a mobile app- based activity recognition system.

IV DATA MINING APPROACH TO CLASSIFY THE ACTIVITIES:

In the next stage, work will organize in the form of data mining. Initially, based on the ranking system

preprocessing is implemented. For preprocessing technique, Con- sider real-time smartphones (561 parts). In this case, the data is used to determine the relative value of various constituents, with less important ones being disregarded. In the setting of our very high-dimensional datasets, our attribute selection technique has performed exceptionally well, allowing us to employ almost half as many characteris- tics as before while maintaining the same level of recognition performance. A battery of tests was conducted using a range of feature rankings derived from an information- theory-based ranking technique. These varied from the use of a Naive Bayes classifier as a starting point to those of Decision Trees, Random Forests, Ensemble Learning , and Lazy Learning . Several different classifiers were evaluated for this work, and we offer summaries of each below.

IV.1 Bayesian Classifier:

This classifier uses Bayes' theorem at its core to make inferences based on probabilities. Naive Bayes, the most straightforward Bayesian approach, is explained as a specific example of an algorithm that requires no modification for continuous data. Since it is supervised learning and easily trained, it provides a valuable starting point for evaluat- ing other methods in terms of accuracy and generalization.

IV.2 K-Mean classifier approach:

In this case, the dataset may be unlabeled since clustering is an unsupervised learning technique. Instances are stored into two categories: those that are the same or connected and those that are distinct. K-Means is the most well-known and straightforward tech- nique for determining whether instances may classify based on some criteria. Because of its ease of use and the fact that it can process unlabeled data, it might serve as a benchmark against measuring the performance of other classifiers.

IV.3 Decision tree-classifier approach:

The dependent variable, or the desired outcome for a new sample, is calculated using a decision tree classifier based on predictive machine-learning algorithms. Here, the in- ternal nodes of the decision tree represent distinct qualities, and the branches between the nodes represent the range of values that each attribute may take in the data samples being analyzed. The terminal nodes further indicate the dependent variable's ultimate values (classification). In statistics, the word "dependent variable" refers to the variable whose value is being predicted; in this context, it is the attribute whose values are being anticipated. Consequently, the independent characteristics are the independent varia- bles in the dataset, contributing to predicting the dependent variable's value. The J48 Decision tree classifier employed in our tests has a straightforward algorithmic ap- proach. Whenever it has to categorize anything new, it must first generate a new deci- sion tree using the attribute values from the existing training data. Attributes that dif- ferentiate across samples are used to identify the next batch of items added to the train- ing set. This attribute gives us the most helpful data since it allows us to easily distin- guish between different occurrences of the data, which is essential for accurate catego- rization.

4.4 Random forecasting approach:

When it comes to ensemble learning techniques for classification and regression, Ran- dom Forests are a decision tree ensemble. Additionally, they may be seen as a kind of closest neighbor predictor, as they build many decision trees during training and use the class mean as their output. Random Forests is an ensemble of decision trees (a term used by Leo Breiman15). Through averaging and balancing the two extremes, Random Forests aim to mitigate bias and variation problems. In addition, there aren't many knobs and dials to fiddle with in a Random Forest; in most cases, you may get good results by just utilizing the default settings. Because of these benefits, Random Forests may frequently be used directly from the box to produce a decent, quick, and efficient model, without the requirement for extensive handcrafting or modelling in comparison to other classifiers.

4.5 Random type forecasting approach:

As with other types of ensemble learning methods, the premise of the random commit- tee is that the addition of more classifiers will lead to better overall results. Each indi- vidual classifier in this sort of classifier is built from the same underlying data but with a distinct random number seed. To determine the final output class, it takes the mean of the predictions made by all of the basic classifiers.

4.6 Lazy learning classifier:

Classifiers based on lazy learning store the training instances during the training period and use them later for classification. The IBC classifier resembles the k-nearest neigh- bor classifier in many respects. However, there are ways to speed up the determining closest neighbors by utilising various search methods since most of the learning occurs during the classification phase when these models are often at their slowest. While this study used a linear search strategy, the performance may have been improved using kD-trees, commonly known as cover trees. As the measure of separation, we used Eu-clidean distance. There was no distance-based weighting applied, and just one neigh- bour was utilised.

V RESULT:

Use the 2.56-second chunk of data from dataset 1 that has been pre-processed to include a collection of 561 characteristics to evaluate the efficacy of the recommended data mining approach for independently identifying human activities from smartphone data. Each track displays the following traits:

Body acceleration estimation and triaxial acceleration from the accelerometer.

- The gyroscope's reading of the triaxial angular velocity.

- A time and frequency domain vector of 561 features. That describes its function.

Individual subject identification for the researcher conducting the study.

Table 1: Individual subject identification for the researcher conducting the study.

Figure 2: Difference between the classifier

In Figure 2, we see the relative merits of various features, as measured by their contri- bution to the Model's performance and the amount of time spent on its construction under various classifier learning strategies. This chart displays the results of our analysis of 2,8,16,32,64,128,256, and 561 features (all features), ordered by infor- mation gain. About 10,000 samples were used in total throughout training and testing. Because there were so many samples in this dataset (10,000 total), we utilised fivefold cross validation to split it into separate training and testing sets. Figure 2 depicts each classifier's Accuracy in Classification and Model Building Time, while Tables 1-3 pro- vide additional metrics, including TPR, FPR, PR, RC, F-m, and ROC. Table III displays the confusion matrix for the best-performing IBk classifier with 128 and 256 ranked features, respectively.

The Naive Bayes Classifier takes the least amount of time (5.76 seconds) to finish building the model, and its 79% accuracy on the massive dataset is seen in Figure 2. Among the ensemble learning methods, however, random forests provide the best combination of accuracy (96.3% on average) and speed (14.65 seconds on average) when developing a model. The other classifiers in the ensemble learning system also perform well in classification accuracy (96%) (random committee and random sub- space). As an unsupervised method, K-Means clustering does poorly, with a classifica- tion accuracy of just 60% and a time to solution of 582 seconds.

In contrast, the slow-learning-based IBk classifier outperforms all other classifiers by a wide margin (90%+ accuracy for 128 and 256 features). To attain maximum perfor- mance, a smartphone-based activity identification system must trade between accuracy and the time it takes to create a model since real-time activity monitoring requires a model to be generated dynamically from the obtained data. Aside from TPR and FPR, other performance measures include Precision, Recall, and F-measure.

Since real-time activity monitoring necessitates the construction of a model dy- namically from the obtained data, an activity identification system implemented on a smartphone must strike a balance between accuracy and the time required to create the model. Additional measures such as false positive rate (FPR), false negative rate (FNR), precision, recall, F-measure, and ROC area should be considered when choosing an algorithm for an automated activity identification system. Table I displays these addi- tional indices of productivity.

Table-3: well developed matrix

The top-performing IBk classifier's confusion matrix on datasets with 128 and 256 sorted features is shown in Table II. The confusion matrix (Actual Class (AC-0 to AC- 5) versus Recognized Class) displays the classifier's ambiguities and misclassifications (RC-0 to RC-5). Class 1 (walking) and Class 6 (lying) exhibited the fewest discrepan- cies in the classifier's identification of the six activities tested. There is some ambiguity between sitting and standing, and it's downright impossible to differentiate between ascending and descending flights of steps. When compared to earlier attempts at activ- ity identification using a single smartphone worn at the waist, this is a significant ad- vancement.

VI CONCLUSION:

In this article, By using machine learning, identify smartphone activities. Based on the ranking theory, machine learning automatically takes actions and records. This work is validated using well-known techniques like Lazy learning, random forests, and ensem- ble learning. For analysis purposes, prepare datasets according to the classification technique. Due to the classification technique, the dataset will develop accurately, con- cerning time, and a well matrix will create. Data mining technique is implemented in different smartphone to analyse various activities. An unsupervised algorithm is needed to construct intense real-time work on smartphones. At end of the research IBk classi- fier performed well at 128 and 256 features.

Identifying Counterfeit Products Using Blockchain

Sahil Jaju,Jenil Mandavia, Sahil Paranjape,Mrs. Lydia Suganya
Dept. of Computer Engineering Thakur College of Engineering and Technology,Mumbai,India
sahiljaju1997@gmail.com, jenilmandavia@gmail.com, sahilparanjape10@gmail.com, lydia.weslin@thakureducation.org

***Abstract*— With the increase in globalization and technology. There has been an increase in the volume of productions as well as there procuring counterfeit. Be it any Industry food, drug, or luxury, all industry manufacturers and distributors are looking for greater transparency in supply chain management to deter counterfeiting. This paper introduces a decentralized Blockchain-based application system (DApp) intending to identify counterfeit products in the supply chain system. With the increase in the use of Blockchain Technology, it has become clear that data recorded in blockchain is immutable and secure. Hence the proposed project works on the transfer of ownership of the product. A consumer can verify the product distribution and ownership information by scanning a Quick Response (QR) code generated by the DApp for each product linked to the Blockchain.**

Keywords—QRcode, Ethereum, Blockchain, Dapple

I. INTRODUCTION

There is an increasing demand of valuable and original products in the market. As the development of economy and the world is increasing, there is an increasing awareness of the product sense among the consumers. With growing technology and increasing needs, the problems with the supply chain and product is also increasing. Problems like counterfeiting of product, receiving wrong product, and deterioration of quality in the product is also increasing. These problems can create financial losses to the companies and can also disappoint the end consumers. Product counterfeiting occurs when there is re sale of sold products or the product provided is different that of original. As there is an increasing complexity in supply chain and demand, the cases of counterfeiting is also increasing. As per the latest assessment of EU Intellectual Property Office (EUIPO) and the Organization for Economic Cooperation and Development (OECD), the global sales of counterfeit and pirated goods have increased alarmingly to 460 billion euros which is about 3.3% of the global trade [1]. The sales and profits of companies around the world have been affected by this phenomenon. The clothing and pharmaceutical sectors experienced sales losses of about 26.3 billion euros and 10.2 billion euros respectively [2].

With increasing problem of counterfeit, there are also various solution which can reduce the counterfeiting of product in supply chain. Some of the technologies used are QR code, RFID technology, blockchain or any unique feature to identify counterfeit in products. Among this, the most reliable and trusted methodology is blockchain. Blockchain offers various features which helps to reduce the problem. Blockchain is a decentralized system of shared, immutable ledger. It facilitates the process of recording, trading and tracking assets over a business network thus reducing risks and cutting costs for all involved[1]. Blockchain technology has six characteristics, and they are as follows: immutability, decentralized, enhanced security, distributed ledgers, consensus, and faster settlement. The further concept will be explained later.

In this paper, the author have proposed the solution of counterfeiting product using blockchain technology. This will be executed by using various technologies like Ethereum and also with the help of QR code. The information of the product will be stored in QR code and this information will be stored in blockchain. As the product goes from manufacturer to consumer the status of the product gets updated and stored in blockchain. This information can be scanned through QR code.

II. BLOCKCHAIN

Blockchain is collection of blocks that are linked to each other. Every Block stores some kind of information. Blockchain is a decentralized System. Blocks are immutable

i.e the data stored in blockchain cannot be changed. Each block has a timestamp, Actual transactional Data and the hash value of previous block and the hash value of current block so it is difficult to tamper with the data.

A. Working of Blockchain

A new transaction is input, and after that it is sent over a network of peer-to-peer computers that are dispersed throughout the globe. The equations are subsequently solved by the computer network to verify the transaction's legitimacy. They're known as miners. They are grouped together into blocks once their legitimacy has been established. The miner then receives a prize as payment for their efforts. The history of all lasting transactions is then created by chaining together these blocks. The deal has been concluded. The entire process is carried out as indicated in figure 1.

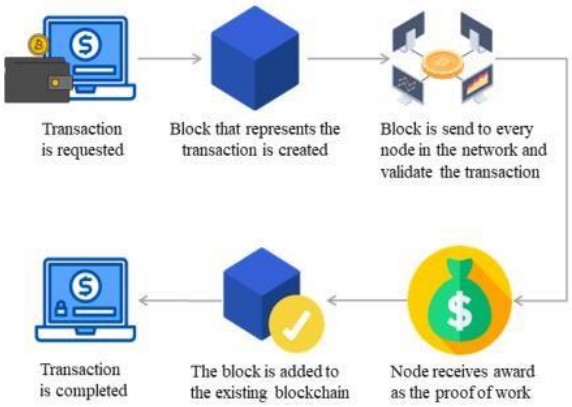

Figure 1: Working of Blockchain [6]

B. Blockchain Features

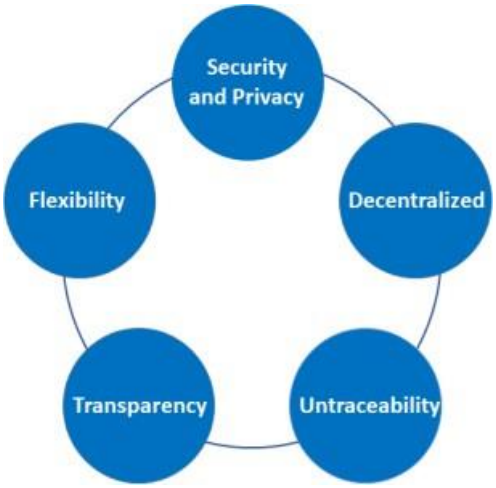

Figure 2: Features of Blockchain [7]

Blockchain is able to add data entries to its database and relies on its own consensus algorithms rather than any centralised body to act as an arbitrator.

Blockchain is a highly trustworthy database that is available to everyone. Below is a detailed description of each characteristic of blockchain technology. Figure 2 displays the Blockchain's attributes.

1. Security and privacy : Blockchain secures its data with encryption. The data is signed using a private key, and using the public key, we can determine if the data has been altered or not and confirm its authenticity. To preserve the security of their data on blockchain, a user should protect their private key by keeping it secret, much like they would their bank's OTP and passwords.
2. Decentralized : None of the participants in a decentralised blockchain network need to know or trust one another. A distributed ledger that contains identical data is shared by every member of the network. The majority of the network's members will reject any altered or distorted data from a member's ledger.
3. Untraceability : The block cannot be altered once it has been added to the blockchain. As a result, if a block is amended in the Blockchain, it is immediately rejected or erased.
4. Transparency : The participants in a blockchain can examine the data, which is entirely public.
5. Flexibility : One of blockchain's greatest advantages is that it is open source. Users have access to a number of public and private blockchains that can be employed depending on the sort of application that has to be constructed.

C. Importance of Blockchain

Blockchain builds trust because it eliminates the need for third parties. The blockchain's smart contracts, which are essentially computer programmes, only run when specific requirements are satisfied. It is challenging to alter the blockchain with false information since every block records its data along with the hash of the previous block. The hash of a block changes if an attacker modifies its information, while the hash of the following block does not. Since much resources and money are needed, it is doubtful that more than half of the participants would agree to change the chain. Additionally, other members would learn of this significant modification.

III. LITERATURE SURVEY

Different strategies have been put forth by various researchers to decrease supply chain product counterfeiting. Utilizing diverse tools, many researchers have generated distinct ideas.

The authors of this research have employed a decentralised blockchain-based DApp to introduce a system. The writers came to understand how well-protected data is on blockchain. They talk about numerous blockchain aspects. They talk about how blockchain works and how it safeguards data. The authors suggest a system whereby a consumer can scan a Quick Response (QR) code created by the DApp for each product linked to the Blockchain to confirm the product distribution and ownership information. They set up an authentication mechanism using Firebase. The solution that is being presented here uses the Ethereum blockchain's Rinkeby Test Network and the MetaMask cryptocurrency wallet for all transactions. The Manufacturer, the Seller, and the Consumer are the three main stakeholders in the DApp. Manufacturers, sellers, and consumers are the three elements that make up their project. [10]

The author's goal in this study is to identify fake goods utilising a supply chain and decentralised blockchain technology strategy. According to the author, traders don't necessarily need to rely solely on blockchain. In order to prove that the end-users in the supply chain do not entirely rely on the trader to determine whether the product is counterfeit or not, this paper implements the combined approach of decentralised Blockchain technology and the supply chain. This can be done by authenticating the product

at every stage in the supply chain using One Time Passwords on the receiver's mobile phone along with a deployed personnel who will be responsible for ensuring the quality of the product. This paper has explained different types of blockchains. The author proposes that everyone in the supply chain will have to follow the OTP verification in their mobile phone and once the product is received the details will be added in the blockchain. The author has implemented the code for working of otp verification using PHP. The author also states that there should be a quality assurance officer who can be deployed in the supply chain that any product is not compromised. [10]

The author has mentioned various ideas to reduce counterfeiting of products. They have expressed that how produc t counterfeiting can lead to various problems in supply chain management. It states that blockchain is one of the best solutions among others. They have explained the working of blockchain and its concept. They have also explained Ethereum and smart contract. Their model consists of three roles, the manufacturer, the supplier, and the consumer. The manufacturer logs onto his account, creates a QR code for the product, and then adds any further information that is needed by using his Ethereum wallet. The supplier logs into their account as a supplier and scans the product's QR code. The manufacturer has entered information about the vendor's goods, which the seller can access. By scanning a QR code that lists the history of transactions, customers can confirm the genuineness of a product and ascertain its integrity. If the last location is not the same as the buy location at the time of customer purchase following the QR scan in supply chain history, the customer will be aware that the product is not authentic. [11]

Using his Ethereum wallet, the manufacturer goes into his manufacturer account, generates a QR code for the product, and adds any further information that is needed. Scan the QR code on the product after logging into the supplier account. The manufacturer's entry of information about the seller's goods is accessible. Customers can scan a QR code to view a history of transactions, which will allow them to confirm the authenticity of the product. The customer will be aware that the product is fake if the final location is not the same as the purchase location at the time of purchase following the QR scan in the supply chain history. [11]

In this paper, the author focuses on reducing the counterfeiting of product and identifying the genuineness of the product. The author emphasizes on blockchain as a solution. The objective of the author is to design anti counterfeit system using blockchain, secure details using QR code, and providing security to the client. They have proposed a system where they can identify the genuineness of product by simply scanning QR code. They have created this system using Android Studio and Firebase cloud. Android Studio is the official integrated development environment (IDE) for Googles Android operating system, built on IntelliJ IDEA software and designed especially for Android development [4]. Firebase is a mobile app platform with integrated, unified client libraries in various mobile programming languages. Firebase's different backend-as-a-service (BaaS) features help you develop high quality apps, grow your user base, and earn more money. [12]

The author suggests that blockchain technology can help to decrease product counterfeiting. It describes how blockchain might lessen counterfeiting and has put the methodology into practise in their paper. The model is divided into three sections: working, customer, and manufacturing ends. They developed a web application that can read QR codes. The product information is contained in this QR code and is kept on the blockchain. The block holding information is added to and updated as the information is updated. By scanning the code, the final user may identify the product and confirm it. If the code is correct, the consumer will be notified that the product is correct; otherwise, if the product is incorrect, a notification of the incorrect product will be generated.

IV. PROPOSED SYSTEM

The effects of counterfeiting on businesses, producers, and customers are enormous. It effects the relationship between the organization's influence and customer welfare. India is not left out. The proposed system is intended for consumer products, and it aids in product tracking by preserving the integrity of the product and the supply chain through the use of Blockchain. Customers now have the ability to use blockchain and QR codes to trace the history of an entire product from maker to customer. [13]

A. System Model

The suggested solution would be a decentralised application (Dapp) that is constructed utilising the Ethereum Network as the primary blockchain for preserving all the records and managing the transactions related the goods of the companies registered on Dapp.

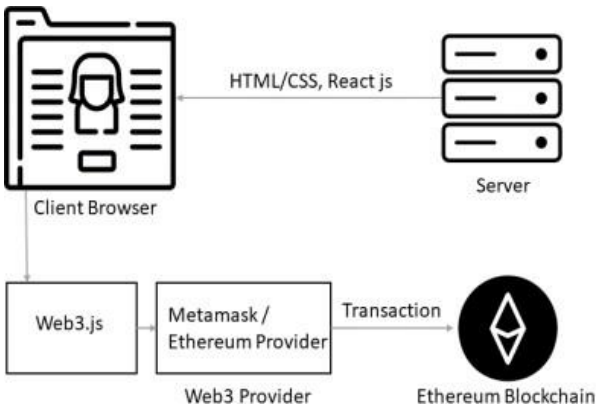

Figure 3:System Architecture

Ethereum

The blockchain is decentralised and employs a proof-of-work consensus process. Blocks are added to the blockchain by proof-of-work by resolving mathematical equations. The completion of the problem "proves" that nodes used computational resources to complete the "job".

It verifies the block's addition to and recording on the blockchain. Mining is the procedure in question. In contrast to the usual method of mining, which involves brute force

trial and error, Ethereum rewards successful block addition (ETH).

Smart Contracts

Programs called smart contracts are kept in blocks. Third-party participants are replaced by smart contracts. These essentially operate as protocols when the prerequisites are met. They remain constant, therefore nobody can alter the contract.

B. Flow of Proposed System

The major goal of this proposed system is to preserve the originality of the product by assisting the customer in following the product's supply chain history. Customers have the ability to follow a product's whole history from manufacturer to customer via the system. This Figure 4 depicts and discusses the three roles that make up the product anti-counterfeiting system based on Blockchain: the Manufacturer role, the Seller role, and the Consumer role.

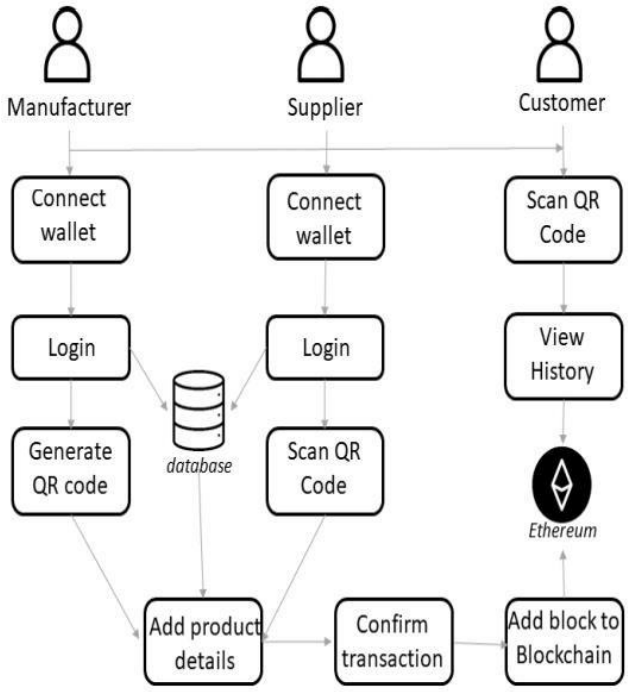

Figure 4:System Flow

Manufacturer :

Manufacturer signs into the manufacturer account, creates a QR code for the product, adds any other information that is needed, and then uses his Ethereum wallet to submit a block to the Ethereum blockchain.

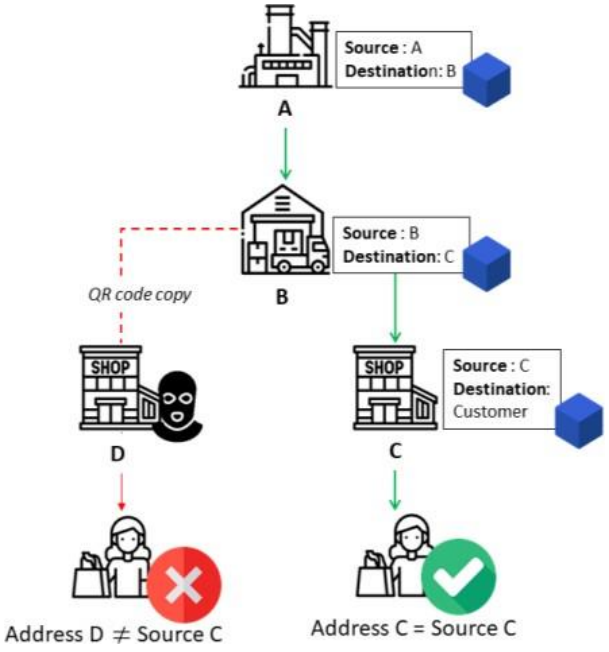
When a manufacturer logs in using his or her own account and uses their own wallet, only that block will be put to the digital ledger. If both the userid of our local database and the wallet address of the entity are present, then both will be mapped together.

Supplier :

The supplier logs into their account as a supplier and scans the product's QR code. The manufacturer has entered information about the vendor's goods, which the seller can access. It pushes the product's additional details, such as the shop's location, into the Blockchain. The buyer can see those specifics.

Customers :

Customers can verify the genuineness of a product by scanning a QR code that lists the history of transactions and allows them to examine its integrity. If the last location is not the same as the buy location at the time of customer purchase following the QR scan in supply chain history, the customer will be aware that the product is not authentic. The buyer learns about counterfeiting and the conclusion is that the QR code was copied.



V. Result and Discussion

With the proposed approach, suppliers and manufacturers can communicate with the system to add their own blocks carrying transaction details to the blockchain without altering the blocks of others. Solidity is used in the writing of the manufacturer and supplier block contracts.

Ganache has been utilised for local testing because the code runs on a local network. The true-config.js file contains the configuration for the host "127.0.0.1" and port 7545. After that, true is used to compile and deploy the contracts. For deployment, migrations files are produced. We can deploy contracts on an Ethereum blockchain network using migrations, which are files.

React is used to design the interface. The Web3.js library is used to handle operations including sending ether, confirming transactions, reading, and writing data from smart contracts in order to enable interaction with the Ethereum blockchain. To access an Ethereum wallet using a browser, Metamask, a wallet that interacts with the Ethereum blockchain, is installed on the browser. The metamask imports accounts from ganache. They must confirm the transactions using their account utilising the Web3.js- connected Metamask wallet in order to add the supplier and

manufacturer blocks. The final user can then scan the QR code to validate the integrity of the supply chain and the product.

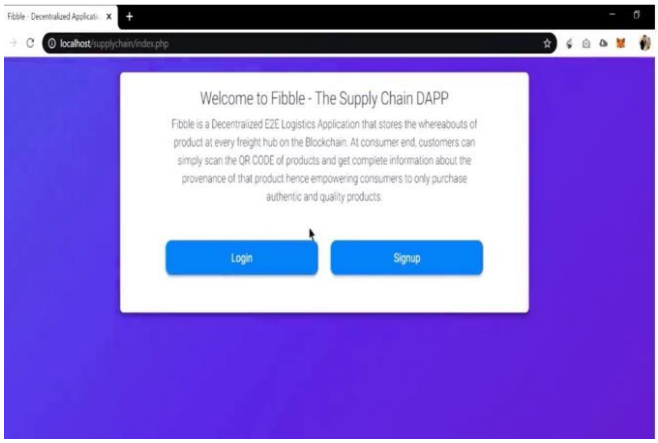


Figure 5:Landing Page

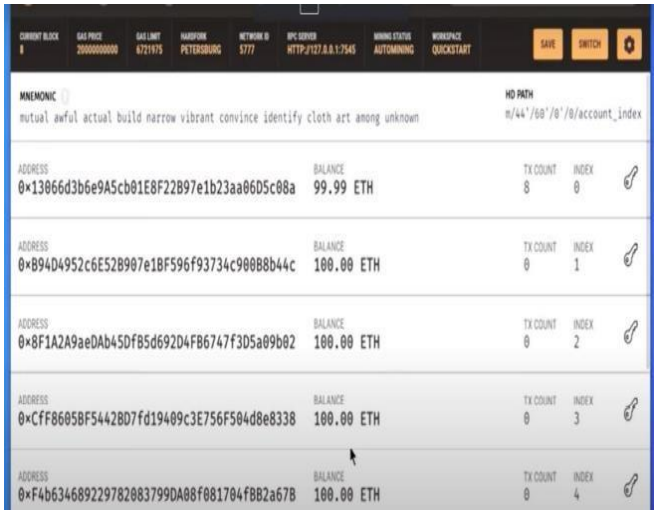

Figure 6:Ganache

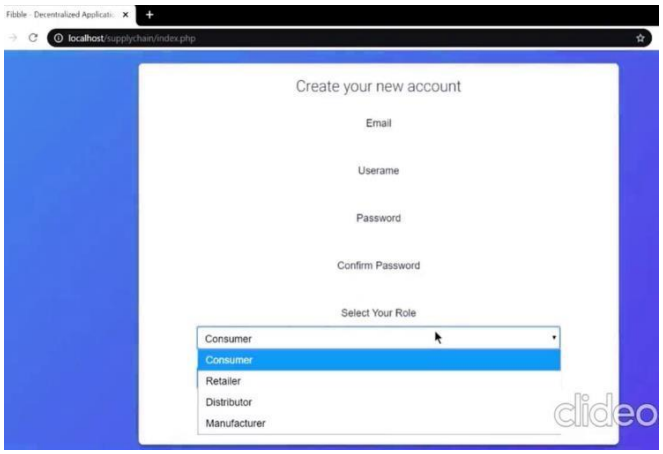
The Manufacturer logs into his account using his credentials like username and password as seen in Figure 7.



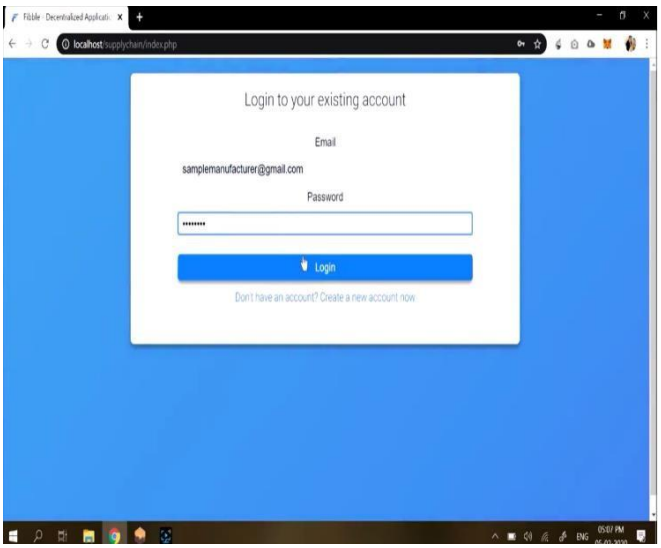


Figure 7: Login

The credentials are stored in SQL server as shown in Figure 8. SQL database is used for storing manufacturer and supplier login details and their address.

As seen in Figure 9, the producer issues a special serial number for the goods and creates its QR Code after the customer logs into his account. When a product is shipped to another location, a QR code is applied to it. Along with this, the maker fills out information on the product's name, current address, which serves as both its source and its final destination. After filling out all the necessary information, the maker clicks the add block button, which adds all the data to the blockchain.

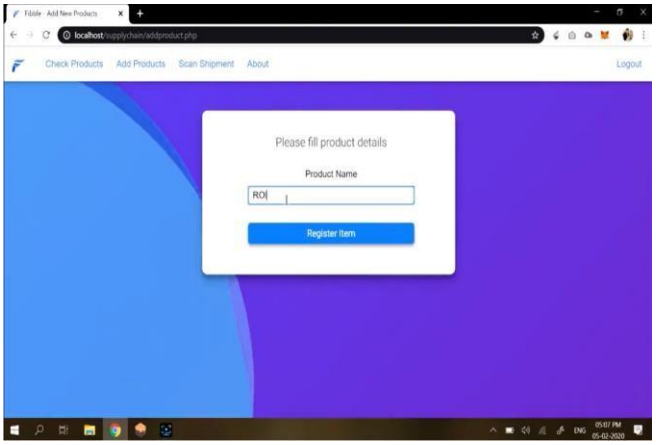

Figure 9:Manufacture adding product Information

A metamask confirmation popup is displayed which asks for the confirmation as in Figure 10.

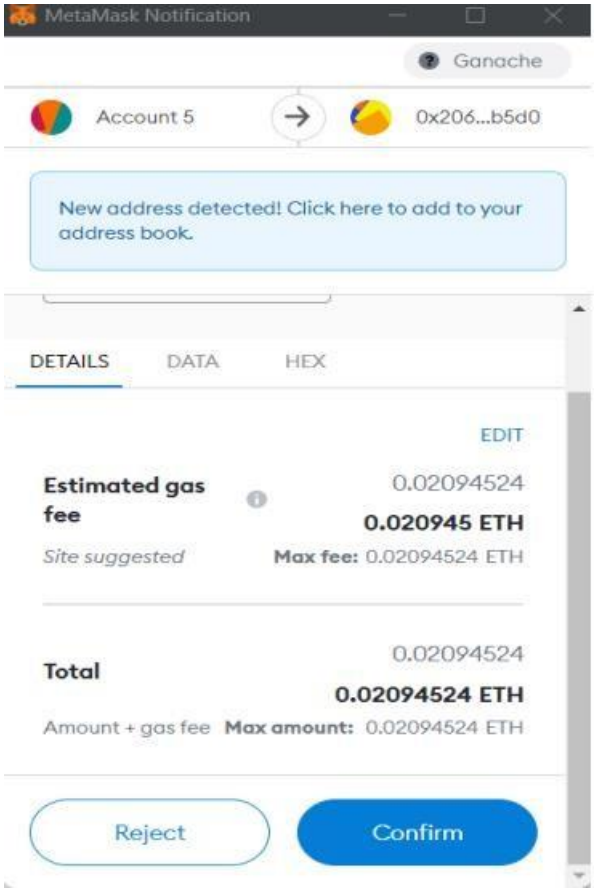

Figure 10: Completing Transaction with metamask

After confirmation, a success page similar to that in Figure 11 is presented, and a block with all the details is uploaded to the blockchain.

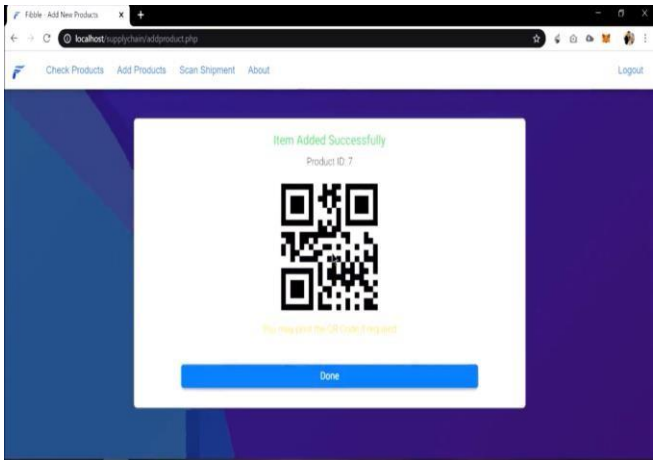

Figure 11:Success Page

Once finished, the supplies are shown a screen where they can enter the necessary product information. This time, the supplier scans the QR code instead of creating one by clicking on the scan QR button. As shown in Figure 12, the supplier inputs the necessary information for the product and clicks on the add block. After the provider confirms his transaction through the Metamask wallet and logs out, the block is appended.

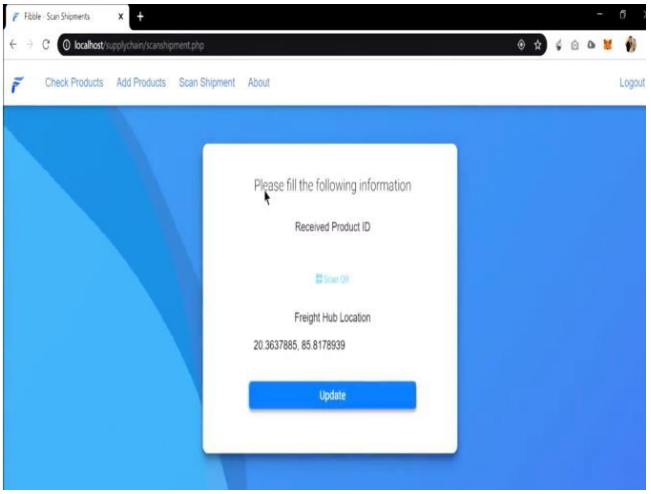

Figure 12: Supplier updating details to the product

The other participating suppliers log into their accounts and submit their individual blocks to the blockchain in a similar manner. Following delivery, the consumer can access the product's customer page, scan the QR code as depicted in Figure 13, and view the product's whole supply chain history.

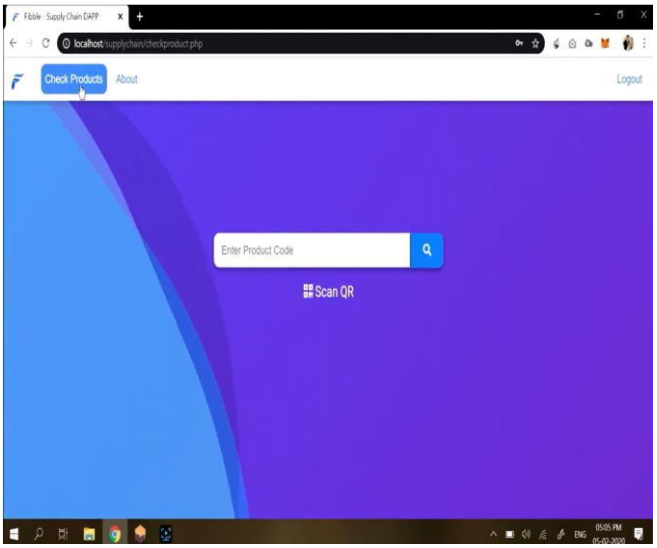

Figure 13: Customer QR Scanning Page

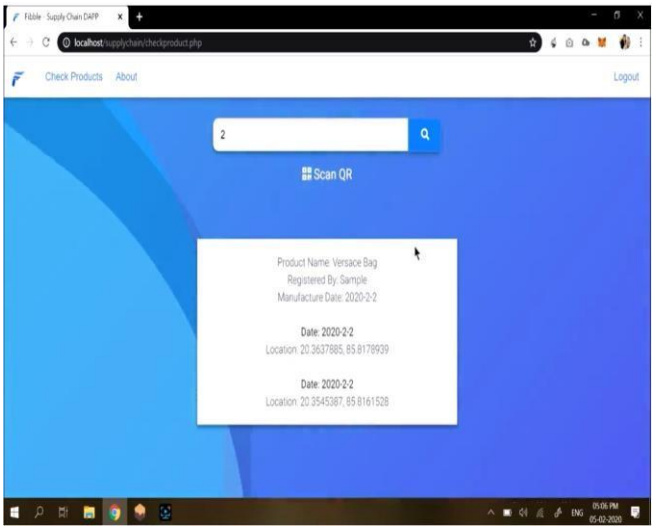
Figures 14 depict the supply chain history. They include information such as the product id, name, source, and destination addresses related to the parties involved, as well as their ethereum account addresses, timestamps of when the block was added, and any additional remarks that may have been added.



If the last location is not the same as the buy location at the time of customer purchase following the QR scan in supply chain history, the customer will be aware that the product is not authentic. The buyer learns about counterfeiting and the conclusion is that the QR code was copied.

VI. CONCLUSION

Since blockchain is a decentralised system, local suppliers cannot affect how the product is checked or if it is being counterfeited in the proposed system. Manufacturers and Suppliers can make use of the system to store product information in Blockchain, which has features like tamper-resistance, data consistency, and confidentiality that guarantee the security and privacy of the data on the network. The customer examines the product's history along the supply chain to confirm its authenticity. Customers may be confident in the quality of the products they buy.

The proposed solution can effectively reduce the rate of branded-items counterfeiting and give businesses a simpler way to give customers confidence that they won't buy fake goods. This technique will help to strengthen the relationship between the company and the client and will actually improve the economy and lower corruption. To prevent fraud in the banking, healthcare, voting, online shopping, and other sectors, additional systems can be implemented.

Text heads organize the topics on a relational, hierarchical basis. For example, the paper title is the primary text head because all subsequent material relates and elaborates on this one topic. If there are two or more sub-topics, the next level head (uppercase Roman numerals) should be used and, conversely, if there are not at least two sub-topics, then no

Abstract— **. Health 4.o is an approach to healthcare innovation using IoT and other sensors and devices. The result is an array of intelligent health applications that are more equipped to improve people's health and well-being in practical ways while also being more reliable, scalable, and economical. However, IoT- based healthcare systems may pose problems without proper oversight, espe- cially regarding security concerns like exposed application interfaces. Primary challenge is to learn about the architecture and security needs of IoT-based multi- sensor systems and healthcare infrastructures. In addition, it has to propose light- weight, easily implementable, and efficient designs. This research introduces the Internet of Things (IoT) in healthcare and a thorough analysis of practical, novel health frameworks that use a wide range of resources and limited-power sensors and devices. Additionally, this paper also focuses on the safety of these vital In- ternet of Things components and their wireless connections. The result is intro- duction of a lightweight-based security system that uses the Lightweight Encryp- tion Algorithm by IoT(LEAIoT). Essential creation with the proposed hardware- based method is 97% faster than with a software-based approach, and encryp- tion/decryption is faster by 96.2%. Finally, it is competitive with other typical hardware-based cryptography designs, achieving reduced hardware usage of up to 77% with the lowest frequency with its lightweight, flexible implementation and configuration of high-speed keys.**

Keyword- IoT, Health 4.o, Multi sensors, Security, frame work,

I.INTRODUCTION

Medical gadgets changed healthcare. Now we can track our health without going to the hospital. We need to examine the security of such devices not withstanding this drastic development.

These technologies compromise privacy and security. Medical device security is criti- cal since many patients' lives rely on it. Healthcare security is crucial.

Wearable Internet of Medical Things devices diagnosis patient health. These gadgets monitor physical activity, temperature, diabetes, sleep, heart rate, and more. Smart wristbands, watches, glasses, belts, necklaces, and patches are available from head to toe.

Wearable systems include sensors, memory, solar cells, and batteries. They gather, dis- play, and wirelessly transmit data. Gadgets may communicate patients' health data di- rectly to doctors to reduce office visits.

Modern information technologies like the Internet of Things (IoT), big data, cloud computing, and artificial intelligence have made healthcare smarter. Care of this kind is more effective, convenient, and individualized than the alternative. Electronic healthcare systems (eHealth) based on the Internet of Things (IoT), mobile healthcare (mHealth), and ambient assisted living (AltHealth) are all part of "smart healthcare" (sHealth). Smart Healthcare Systems (SHS) are widely used presently because of their practical data storage and sharing system, fast reaction times, and reduced treatment costs. With the aid of IoT devices, patients' private medical records may be securely saved in the cloud and shared with doctors and other patients. As a result, the telecare e-medical service model may provide care recommendations based on data gathered from the patient's medical monitors. Care for patients with long-term conditions, in- cluding critical care emergency services, heart patient symptom records, and more are part of this process. These IoT-based monitoring devices may collect vital signs and transmit them to a cloud server using implanted sensors. In the future, members of the savvy community may share this information. Network assaults, such as denial of ser- vice (DoS) attacks, router attacks, replay attacks, etc., threaten the privacy of transmit- ted data. Additionally, at any one time, a vast quantity of patient data is being saved in the cloud platform to make diagnoses or provide recommendations, might be challeng- ing to keep sensitive data safe in a third-party cloud [1].

These days, medical computing equipment may connect to the IoT and send patient data and photos via the internet without any intervention from a person. User-level components of the echo system include the patient, doctor, pharmacist, etc., while stor- age-level features include a cloud data centre housing real-time and asynchronous ap- plication. Data sharing and communication are hampered by the complexity and vol-ume of available data. The delays in responses and communications are also an issue. Most standard cloud computing solutions fall short of the service needs of real-time applications like remote medical care during emergency scenarios. An edge-based com- puting facility that speeds up responses while decreasing network latency may resolve this problem. Therefore, IoT solutions need an edge and fog computing to protect pa-tient confidentiality. Mediation at the sensor network's periphery may enable data to be processed closer to its origins (the healthcare network), strengthening user privacy and data security. This mediation layer can manage enormous volumes of data, expedite computing, improve mobility, and increase privacy with low latency and bandwidth, addressing these obstacles. Edge computing may process healthcare data twice. For a timely decision, edge nodes collect and analyse sensor data. Second, distant health cloud data centres handle vast volumes of data (clinical test results, scan images/reports, etc.). Sensor data are used for essential choices like

monitoring oxygen, glucose, car- diac pumps, etc.

In 2019, we saw the emergence of a new virus that causes a disease called Coro- navirus. Also known as COVID-19, it was formally reported on December 31, 2019. Infections with this virus cause both SARS and MERS, which might result from prob- lems in breathing, headaches, fever, and even respiratory collapse. It's contagious. Therefore it's not safe for otherwise healthy people to become involved. This needs a system that can track changes as they occur in real-time. Strong authentication is es- sential whenever sensitive patient data is accessed in such a system. Literature [2, 3],

[4] provides a variety of authentication frameworks. However, the authentication pro- cess takes longer because of most three-factor-based authentication frameworks' high False Rejection Rate (FRR). However, although IoT with edge computing may help, the currently suggested solutions are not flexible enough to deal with both scenarios without compromising privacy or security.

It is widely believed that IoT will become standard in all technologies of the next generation [1]. In this context, "interconnection" refers to the linking together of inno- vative items and gadgets via which they may be detected solely. Invisible sensors con- nected to many things around us provide IoT with a wealth of tracking data [2]. Re- search indicates that health monitoring is the most promising field for future wearable electronics (HM). Smart HM [3] combines innovative computing, remote HM, and the Internet of Things.

HM expands clinical monitoring and care limits (i.e., house, for instance). An HM system consists of a smartphone with internet access and an HM app, a monitoring device for submitting health data to smart contracts [4]. Wearables and IoT are im- portant for HM and intelligent cities [5]. Wearable devices capture patient health data for healthcare administration, diagnosis, and patient care. A Big Data scenario [6] arises as medical records are analysed and shared. A secure data interchange between organ- isations is also required [7].

Security is a significant consideration for any setup. There are several security definitions since individuals have different perspectives [8,9]. In a broad sense, security may be thought of as a concept analogous to the system's overall stability. Most modern IoT-centric HM relies on wireless connectivity, posing several potential security risks [10,11]. These security concerns might cause significant difficulties for wireless sensor equipment [12,13]. Thus, medical and health data management needs lightweight block encryption techniques for medical IoT resources [14].

Predicting abnormal health changes from the Internet of Things data [17,18] is accom- plished via the use of data mining techniques, including classification and clustering [15], neural networks [16], and other machine learning approaches. The study that utilises clouds and IoT technologies forms the foundation for a secure patient HM sys- tem using BC-XORECC and a patient monitoring system utilising LSK-RNN, which together permit the safe transfer of data and offer accurate patient healthcare staff and materials. Finally, information exchange and cooperation between healthcare monitoring. As a result, doctors could keep tabs on the patient from afar and catch potentially fatal con- ditions in their earliest stages.

Several dangers and vulnerabilities are associated with utilising the IoT for intel- ligent health, and they may be categorized into two broad categories: embedded and network problems [2]. Dealing with the hardware and software of IoT-based devices might lead to embedded difficulties. The number of IoT nodes has limited resources, such as battery life or data storage space.

Robotic or remotely controlled gadgets. They are not designed to run resource- and computation-intensive security techniques. Lightweight cryptography's ability to sufficiently protect the design while making more minor hardware demands is the key to solving this issue. However, many substitute methods are less secure than the widely- known heavy cryptographic primitives [7]. Further, most digitally savvy healthcare pro- viders must allocate more resources to ensure the three pillars of security [8].

They are only concerned with the healthcare features of the app and the savings on deployment. The outcome is a system readily exploited due to poor security measures and inadequate upgrades. The scalability creates another potential weakness.

In particular, new devices are being added to the system without any assurance that they will maintain its security. An attacker may access the more extensive system by compromising a tiny, unsecured device. Thus, even the smallest devices interacting with the centralised services need some lightweight security strategy that keeps them safe from harm.

II.IOT BASED HEALTH CARE SECURITY SYSTEM:

IoT technology can develop several smart health apps, accomplishing Health 4.o goals [4]. Figure 1 shows the integrated technology and healthcare architecture compo- nents of Health 4.o. High-quality services for persons with diverse healthcare require- ments are a crucial goal that involves optimizing tools, resources, and system perfor- mance. Automation and intelligence may improve outcomes and speed up monotonous activities. Remote access and real-time answers aid medical care and monitoring. Fi- nally, designing databases with complete and easy-to-access medical information helps improve diagnostics and tailored therapy.

Another important goal is to improve operations while reducing expenses, resource use, and energy usage. Thus, energy-constrained IoT devices may run healthcare applica- tions. In the end, resources will balance the critical and actual requirements of the sys- tem. The best strategy maximises performance throughput with few resources. IoT may help monitor, diagnose, and forecast illness through health sensor data.

Cloud services quickly transmit, evaluate, and store this data, making diagnosis more straightforward and accurate. Cost-effective, user-friendly, and promptly responsive health assessment procedures will relieve institutions and providers will be easy and timely.

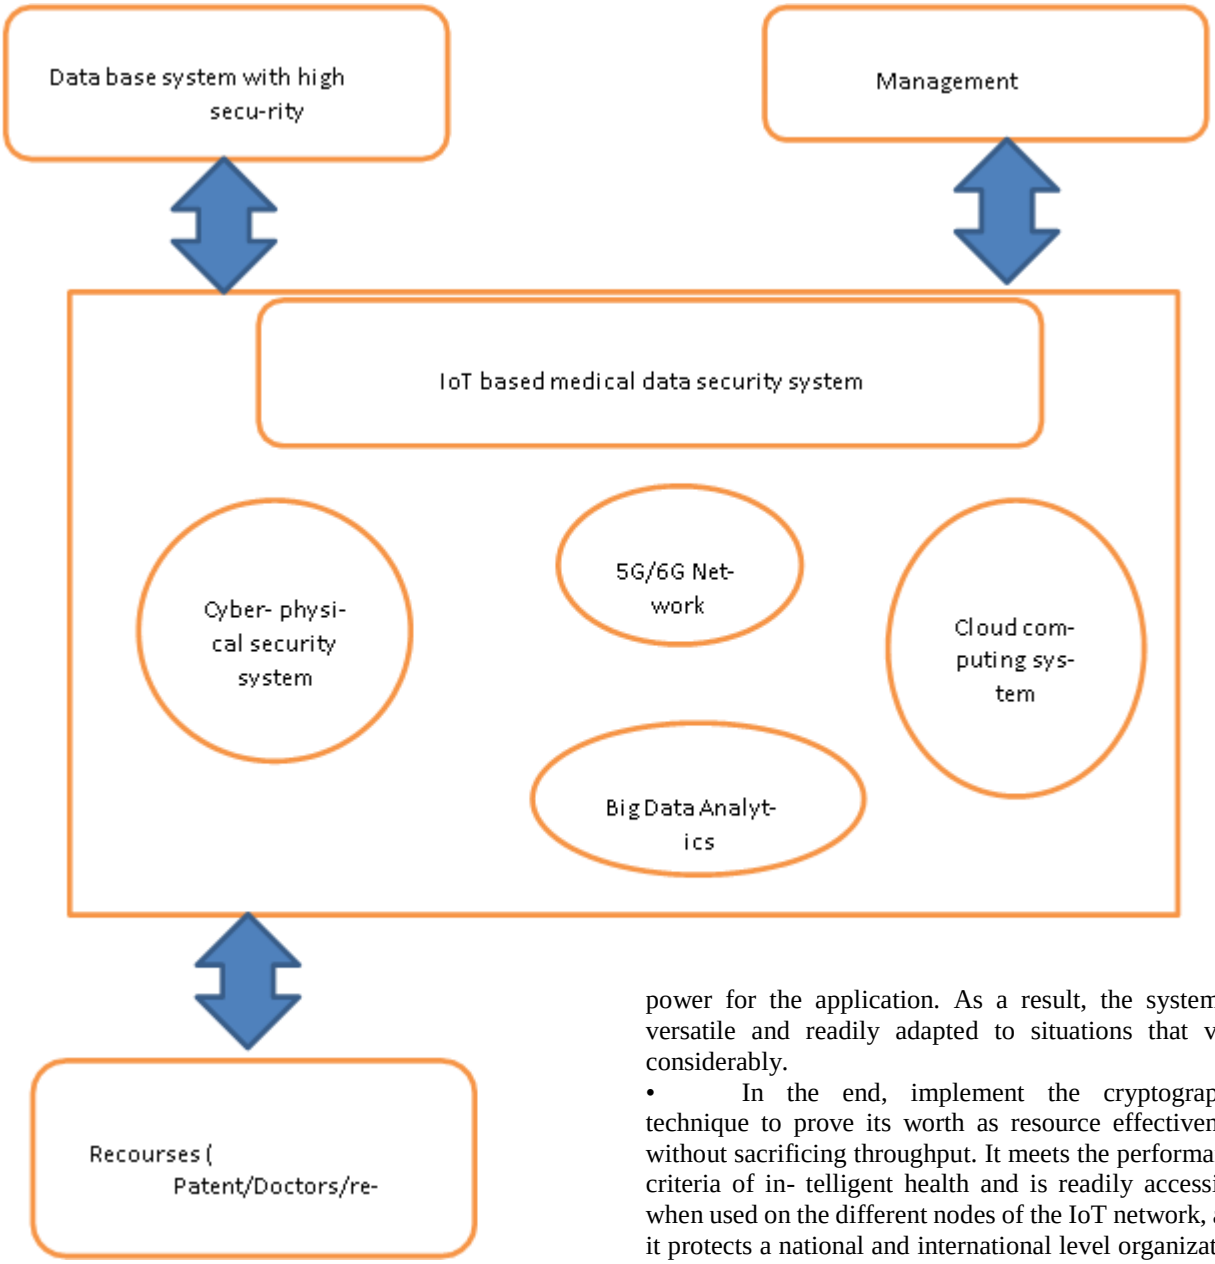

Figure 1: Framework of the IoT based medical data security system

II.1 Proposed work:

• First, the utilized cryptographic primitive guarantees the maintenance of the funda- mental security principles while being lightweight and able to use keys ranging in size from 64 to 520 bits. The width of the key is a generalisation of the measure of symmetric encryption's security; 520 bits is the minimum acceptable for most appli- cations, as practical and crucial to the suggested setting.

• Assures efficient handling of the large amount of data sent between devices in the Internet of Things. Cryptographic primitive ran on a computer's processor (Central Processing Unit), boosting essential creation speed by up to 99.9%, and the rate of encryption and decryption is as high as 96.2%.

• Third, four distinct key sizes are included in a single architecture, Applications may achieve four different performance rates and levels of security efficiency. Instanta- neously choose based on the state of power for the application. As a result, the system is versatile and readily adapted to situations that vary considerably.

• In the end, implement the cryptographic technique to prove its worth as resource effectiveness without sacrificing throughput. It meets the performance criteria of in- telligent health and is readily accessible when used on the different nodes of the IoT network, and it protects a national and international level organization of healthcare while keeping resources in a state of optimal performance, efficiency and safety

III.IMPLEMENTATION PROCESS:

The IoT architecture comprises applications, networks, and physical/perception layers [11]. The application layer connects IoT devices [11]. E-health applications are in-cluded. Network layer protocols allow IoT components to communicate physical layer data. Popular networks include ZigBee, 5G, Wi-Fi, RFID, 6LoWPAN, and LoRaWAN. IoT-integrated WSN is another node network [18]. The physical/perception layer ter- minates architecture. It encompasses sensors, wearables, actuators, cellphones, anten- nas, and CPUs. This layer translates health signals to network data.

III. 1 Infrastructure of IoT based medical data security system:

Figure 2 depicts an IoT-based Health infrastructure. This arrangement shows IoT- healthcare linkages. This article

compares smart hospitals with near-patient/personal- ized systems. Individualized revolutionary health architecture comprises heterogeneous IoT devices, a wireless interface, and a cloud-based database. [2, 3]. Medical equipment gets sensors first.

They use batteries, therefore maximizing efficiency is essential. To send "sensed" data, they must connect to the system's wireless network. Multiple sensors and gadgets are used simultaneously, where their connectivity is crucial. Wearable equipment must also be lightweight and pleasant. Some implanted and wearable devices may wirelessly receive orders to modify medicine doses or gadget settings. The wireless interface must connect to the Internet to provide health data to physicians and nurses. The hospital or private clinic's main computer or near-patient IoT system may process this data. Some wearables can analyze and wirelessly communicate data to the Internet. Fixed or mobile devices may replace small, wearable, and implantable devices without processing ca- pability. These intermediary devices evaluate sensor data from various IoT networks and transfer it to back-end systems and databases. They can also interface with sensors and process back-end data. These gadgets gain intelligence and real-time capability by making decisions and acting without back-end infrastructure. IoT devices lack storage. Thus, medical history is stored in databases.

IoT may improve hospital relationships and functionality. Hospitals may use all implanted and wearable IoT devices. These sensors and gadgets must also be connected to wired and wireless networks and accept orders and sensitive data from authorized sources. Two things distinguish this hospital building:

With the help of the Internet of Things, hospital beds and other medical devices may now connect to the network and share confidential patient information for diagnostic purposes.

The hospital's medical records and healthcare database are to the IoT network. Thus, hospital staff may obtain real-time data and react to situations. All hospital devices can quickly retrieve the patient's medical history from the recorded data.

The hospital's Internet of Things (IoT) network communicates with other healthcare facilities and Internet-connected devices close to the patient.

More tailored and sophisticated health services will help healthcare professionals re- duce hospital resource strain.

III.2 Security system and scheme:

High security is essential for IoT-based healthcare applications. When it comes to at- tacks on the intelligent health infrastructure, the Internet of Things (IoT) network (Fig- ure 2) is the weakest link [2]. IoT network attackers may readily access devices' per- sonal data. Eavesdropping and data transmission/traffic tracking are major data privacy breaches [11]. Data protection also affects user authentication. Unauthorized devices may access and manipulate this data. They may potentially send false health data to the IoT network. This causes misdiagnosis and inconsistent health-provider communica- tion.

Researchers prioritise safe communication network development. Cryptography protects data, authenticates users, and uses cyphers to encrypt and decode messages. Due to resource limits, the IoT system cannot employ cryptographic primitives. The cypher must not divert resources from other vital healthcare functions. Thus, IoT hard- ware restrictions need a lighter version. In crucial situations, low-speed algorithm im- plementation might delay real-time applications, which can be disastrous. Therefore, must consider quickness and responsiveness. Finally, each capability must have numer- ous alternatives to meet the application's network and security demands. The system needs flexibility and scalability.

A lightweight cryptographic primitive and security method is needed to secure smart health application health data. Before IoT devices communicate data, the encryption method must encrypt it. Thus, patient data is safe from hackers. For healthcare applica- tions, the decryption algorithm must decode this received data. The outcome is com- plete data content security in communication networks, particularly IoT networks and cloud-connected Internet.

IV IMPLEMENTATION PROCESS OF SECURITY SYSTEM AND SCHEME:

The current system's lightweight-based security method leverages the LEAIoT crypto- graphic primitive to encrypt and decode data while offering variable key size and im- plementation speed. This approach is embedded into every Internet of Things (IoT) device in a healthcare system, securing sensitive patient information over public net- works like the Internet and within private ones like smart hospitals and near-patient infrastructures. LEAIoT beats traditional encryption primitives in key generation and encryption/decryption speed. The IoT-based healthcare system's complicated connec- tion demands benefit from a lightweight design, and It enables fast end-to-end commu- nication with little hardware. LEAIoT mixes symmetric and asymmetric encryption methods. Symmetric cryptography improves performance with fewer resources; Asym- metric primitives increase key distribution, scalability, secrecy, and authentication. LEAIoT encrypts a made-up plaintext with an n-bit private key; the sender and recipient are well-informed. NLBC employs ciphertext with two legends: n1 and k. They are protecting encrypted content. Decryption uses the modular inverse of the three encryption keys, SSK, n1 (1), and k0. Delivered ciphertext and keys n1 (1) and k (0) are needed for asymmetric NLBC decryption. These keys are made using n1 and k's modular inverse modulo 27. Using symmetric decryption, you can acquire the plaintext if you know the modular inverse of the n SSK key. This technique continuously calcu- lates the modular inverse modulo 27. The following material analyses ciphering and decoding.

1. The key n multiplies the synthetic plaintext values. Modulo 27 follows;
2. The secret code k is a 3x3 matrix that keeps secret. Aside from that, the length of the key n is computed and used as the key n1;
3. In the first stage, the created text is split into sections using the critical k to identify each section. You are multiplying by k and n1 for each block bi. Here comes

Module 27.;
4. The secure ciphertext is the original plaintext;
Decryption sequence:
1. Use the modular inverse of the keys n1 and k modulo 27;
2. Divide the received ciphertext into blocks bi, as in step 3 of the encryption process.
3. Multiply each block with the two keys k 0 and n1 (−1). Modulo 27 follows;
4. The text is multiplied with SSK and modulo 37 again;
5. The result displayed in plaintext.
The suggested lightweight-based security system. The Lightweight Encryption and De- cryption for the Internet of Things (LEAIoT) use Symmetric and staged asymmetric encryption and decryption. Users may customize the playback duration of the key pairs with a symmetric key length of 64, 128, 256, or 520 bits.

IV.RESULTS:

Simulate symmetric and asymmetric key insertion and modular inverse computa- tion. Figures 3 demonstrate the two processes for different key sizes

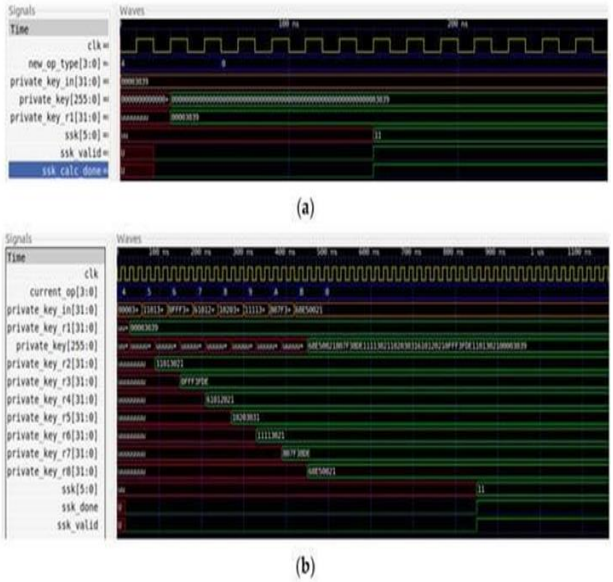

Figure 3: the two processes for different key sizes

Each encryption/decryption cycle processes three 7-bit characters. Each function takes nine clock cycles. The first cycle starts with the encryption or decryption procedure, which complete in eight cycles. Table 1 represents the cycles needed in symmetric and asymmetric to generate both keys. These clock cycles provide the start signal

Table 1: cycles needed in symmetric and asymmetric to generate both key.

Symmetric key size of the bit	**Insertion of symmet-ric key**	**Inverse of the modu-lar sym-metric key**	**Insertion of asymmetric key**	**Inverse of the modu-lar asym-metric key**	**Total**
64	4	7	7	66	74
128	12	10	7	66	81
256	18	14	7	66	97
520	36	21	7	66	116

Finally, the security and performance criteria will assess the design. Simulation vali- dated the cryptographic primitive's security. It has four different vital sizes, so users may adjust it to meet their needs regarding network speed and security. A minor key size might speed up the encryption process when traffic is heavy on the network. A more considerable key length may be a good option when protecting sensitive infor- mation. Transmission rates and system availability have both seen boosts thanks to faster key generation and encryption/decryption. So, it's fast enough for the Internet of Things. Finally, the synthesis results and comparisons with other hardware-based re- search demonstrated that the recommended design for IoT-based healthcare systems is lightweight and efficient. New approaches to security are being developed to strike a good balance between availability, efficiency, and safety in an IoT-based healthcare architecture.

VI CONCLUSION:

This article presents an overview of IoT-based multi-sensor architecture, the Health 4.o design framework, and cutting-edge health infrastructure. This detailed environment overview guides IoT use in healthcare, whether for intelligent hospitals or tailored in- novative health systems. The representative study helped me understand the domain's current situation.
General smart health infrastructure's top priority is data protection, and user authenti- cation suggests a new hardware-based IoT security approach. The LEAIoT encryp- tion/decryption algorithm gives the lightweight-based security strategy additional key selection options than existing systems. Thus, it may boost speed under network con- gestion. Compared to a CPU-based version, the hardware-based LEAIoT implementa- tion is 99.9 per cent quicker at key generation and 96.2 per cent faster at encryption/de- cryption for 1000 kilobits. Compared to the lightweight cyphers AES, SNOW 3G, and ZUC, it utilises 89.2%, 64.2%, and 13.4% less hardware in identical hardware devices. Even the tiniest devices can implement this architecture and be protected, making it useful in an IoT-based multi-sensor ecosystem. Finally, its limited throughput and fre- quency reflect IoT devices' resource constraints. It is suitable for resource-efficient and fast critical generation applications. It also meets the IoT-based innovative health framework's primary security and performance criteria, yielding novel outcomes and improvements.

Abstract— **The notion of Industry 4.o users in a new era of digitization in man- ufacturing. Industry 4.o technologies like the Internet of Things, Cloud compu- ting, and AR/VR will boost industrial education and lifetime training of skilled personnel. To enhance industrial skills, networked ecosystems and Education 4.o are the helping tools. This research will represent the pedagogical teaching tech- niques with new technologies, i.e., IoT (Industrial 4. o technological) and cyber- physical systems. These technologies may transform manufacturing education and fulfil the industry's rising demand for highly skilled personnel. Using the example of assembling a radio-controlled automobile, we will provide a new model for educational factories enabled by the tools of Industry 4.o.**
Keyword- : Industry 4.o, IoT, pedagogical teaching techniques, cyber-physical systems,

I. INTRODUCTION

Information technology's development has altered how people and things function in the world. This has occurred because of the recent proliferation of IoT and IoE technol- ogies. There were already three waves before this one, as indicated in [1]. The intro- duction of computers in the late 1960s allowed for the first classification, in which sev- eral users shared a single machine. Another wave emerged after a decade, referring to the 1:1 ratio of personal computers. A third wave followed the introduction of embed- ded and ubiquitous computing, allocating several computers to a single user.

The Internet of Everything has allowed various revolutions to occur in multiple areas, making it possible to bring up the fourth generation. Standardization efforts have been brought to the issue of Industry 4.o via various research endeavours, hoping to produce mature contributions to the field. We propose a new breed of schools focusing on a different kind of education in response to the Cyber-Physical Systems (CPS) and Au- tonomic Computing (AC) ideas that define Industry 4.o.

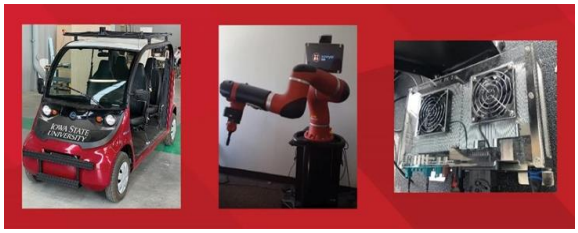

Figure 1: Cyber physical minor process

The manufacturing industry continues to expand as a part of our economy. More than 3 million additional industrial jobs will be required owing to retirements and eco- nomic expansion [1]. It is crucial to reshape manufacturing education methods, linking the industry with engineering educational organisations. To avoid a crisis caused by an inability to find qualified workers at all levels of production who are up to date on the latest developments in a field that is constantly adapting to include new technologies.

One of the emerging fields for keeping tabs on all kinds of situations and pro- grammes is the cyber-physical system. Existing wireless infrastructure based on stand- ards [1] is used for component-to-component communication inside the system. Data from any Internet-enabled device may be analysed and visualised to provide a wealth of information about the surrounding environment.

From the physical level, with its sensors and communication protocol, to the cyber level, with its data management and storage, this work comprises the whole solution, a cyber-physical system. The experimental results demonstrate the practicability and simplicity of the proposed method for environmental and ambient monitoring [2].

Monitoring is really important. Since their inception, wireless sensor networks (WSNs) have been put to use in this sector, with the main goal of monitoring and quan- tifying the real world. CPSs are made up of large-scale wired and wireless networks of sensors and actuators that collect data from and make changes to the environment via linked clusters of processing units. The Internet of Things (IoT), which enables ubiqui- tous sensing and foresees a future in which billions of Internet-connected items or things with sensing, communication, computation, and possibly actuation capabilities coexist,

has many characteristics with these newly emerged systems.

II IOT IMPLEMENTATION IN EDUCATION SYSTEM:

More and more businesses are making strides in implementing Industry 4.o technolo- gies as the positive impacts of digitalization on contemporary production become more apparent and widespread. The apps aim for the whole design and production process, capitalizing on the rising popularity of mobile apps and the Internet of Things and the superior connection features of today's networks [3]. Clients may be digitally involved in the design [4] and personalization [5] through mobile devices. At the same time, production line personnel can keep tabs on production progress and access relevant data and expertise [6]. By transmitting service-supporting data throughout the product life cycle, the Internet of Things enhances the quality of goods for consumers [7]. The de- velopment of monitoring and communication apps for the factory floor is facilitated [8]. Wireless networks like 5G provide more data capacity and connected device den- sity [9], connecting people, brilliant Things, and production-related applications.

Incorporating sensors, actuators, and high-quality communication into manufacturing equipment transforms it into a Cyber-Physical System (CPS). Connected and intelligent systems (CPS) include sensing their status, It is then monitored and acted upon in real time through the network [10] based on the results of the data analysis. CPS systems on the shop floor may communicate with other systems and people via this medium, potentially forming an intelligent factory [11] in the spirit of the Industry 4.o ecosystem. Big Data analytics technologies are being utilized to manage, store, and evaluate the ever-increasing volumes of data [12]. Young, bright minds may be put off by the in-timidating complexity of today's technological landscape, with many interdependent systems. To bridge the gap between industry and educational institutions and the avail- able information, teaching factories have emerged [13] to engage practitioners in task- specific industrial challenges in groups to acquaint them with the technologies and im- prove personal capabilities. Participants learn about industry standards and use their knowledge in practical situations [14].

The developing notion of Education 4.0 includes technological expertise, and teaching factories is an integrated approach to practise this knowledge on the one hand, Educa- tion 4.0 accounts for using existing technology (such sophisticated visualisation meth- ods that use virtual reality) to improve classroom efficiency. However, the strategies and workshops that introduce future engineers to these tools will function in Industry 4.0 settings [15]. This educational concept has taken on more significance due to the fast advancement of technology, leading to talks about its prospective integration by international organisations [16]. More precisely, educational institutions seek innova- tive approaches to bridging the gap between the theoretical understanding gained in their classrooms and the practical application of CPS in the business world.

III CURRENT EDUCATION SCENARIO WITH CYBER PHYSICAL MODEL:

Figure 2 depicts the several subsystems that make up a education 4.o. These include academics, administration, research, and more. Our studies centre on improving learning and teaching in a linked environment that provides for everything (individuals, information, procedures, physical objects, and the educational setting). Yet, we offer a central idea with several possible definitions depending on context—the Cyber-Physi- cal Learning System for Education (ECPS). Few research has, to our knowledge, at- tempted to define ECPS, whereby instruction and assessment may take place in both online and offline environments. While [4] makes an effort in this direction, it does so without clearly depicting the various structural components and their corresponding interactions or behaviors. In reality, ECPS represents a convergence of the abovemen- tioned educational and CPS perspectives.

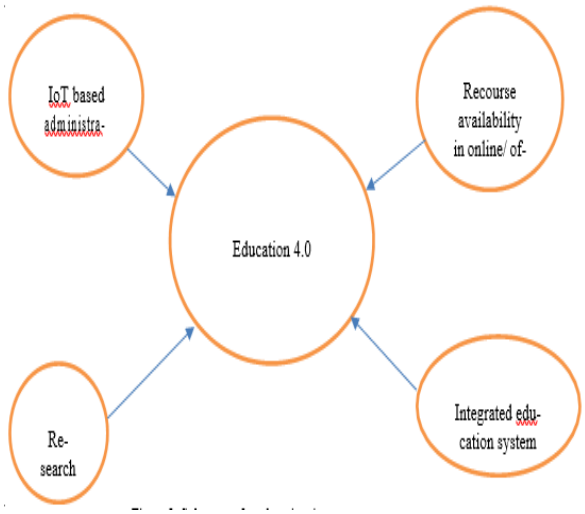

Figure 2: Subsystem for education 4.o

Systematizations with CPS capabilities enable the merging of the natural and virtual worlds. There are two primary functional components, as stated [11]:

The high-tech network permits instantaneous data collection from the actual world and information feedback from the virtual world—construction of cyberspace based on in- telligent data management, analytics, and computing power.

Thus, we define an ECPS based on these aspects and the

IoE ecosystem components as the contextualization of the various physical elements of the IoE educational ecosystem (people, things) to create the necessary procedures that should be executed. The cyber level is responsible for data gathering and analysis to keep an eye on the physical world, and make adjustments to the processes as required. From the viewpoint of Autonomic Computing, these checks are based on iterating through control loops (monitor, analyze, plan, and execute).

We believe that process configuration and the interactions between and within the var- ious pedagogical aspects are influenced by the many factors of the learning/teaching environment. According to our understanding, there are primarily three processes to describe the learning outcomes (knowledge, competence, expertise [8]) attained at the end of the learning process:

- By "classroom processes," we mean the corresponding sequences of actions in a tra- ditional or online classroom. Knowledge is the product of such a learning process. Acquisition, generation, storage, redistribution, and application are all aspects of knowledge that need to be managed, as outlined in [8]. This management strategy's success depends on the pedagogy chosen for the classroom's primary players: the students and their instructors.
- Processes in the course include the approach to learning and teaching dependent on the subject matter being taught. In this way of teaching and learning, competences are the results. They suggest a capacity to maintain a high standard of performance throughout time.
- In this course, procedures include a method of instruction and study tailored to the course material's specifics. Competences are the end product of this kind of instruc- tion. These qualities imply that you can keep performing at a high level throughout time.

For instance, we may identify the process type (classroom, course, or curriculum) based on the defined temporal parameters (short, medium, or long term) and the duties of the educational personnel (teacher, course manager, or studies director). One or more pro- cesses may have their flow disrupted by a context parameter. Parameters of context and the processes they affect are shown in Table.1. Subsequent sections give such details.

IV FRAME WORK OF THE PROPOSED SYSTEM:

To better acquaint aspiring engineers with the demands of the industry and to strengthen cooperation amongst concerned parties with varying levels of expertise, teaching fac- tory paradigms attempt to place students in an environment where they may work closely with professionals in the area. In addition, it is crucial to modernize established educational establishments and increase their impact by integrating new digital tech-nology. The transition from the current educational model to the Education 4.o frame- work necessitates integrating both the tried-and-true methods of mass production and the cutting-edge tools made possible by Industry 4.o. The graphic below depicts the framework of upgrading a school to the modern Teaching Factory 4.o standard.

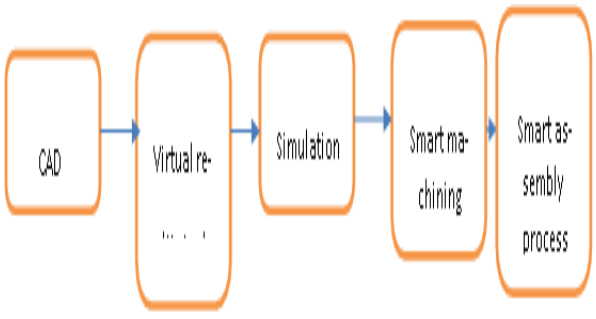

Figure 3: Proposed system with frame work

The R/C electric car's creation results from the teaching factory 4.0's efforts. Partici- pants are divided into smaller teams and given the problem statement, requirements, specifications, standard components, and production resources. Several Internet of Things (IoT)

technologies, such as near-field communication (NFC), augmented reality (AR), virtual reality (VR), human-robot cooperation (HRC), process data gathering (PDG), and big data analytics (BDA) are used in this process. Each team is equipped with a near-field communication (NFC) card that will be used to track and assess their performance at several checkpoints during the LF. At each checkpoint, the team will record the LF's start and finish times and save relevant data about the job to a cloud- based repository. Aspiring engineers may look at their stage-by-stage performance evaluations thanks to the cloud database that stores all of their data.

The product's initial step is its design. A CAD programme is used at this point to sketch out the basic layout of the final product that the aspiring engineers have been tasked with creating. Each group's designs are collected and filed away in one convenient lo- cation. After that, the product designs are tested in a VR/AR review session. The method includes validation by engineers with expertise in product design, who may provide comments and ideas, as well as a call for participants to test their strategies in actual size using Augmented Reality, followed by a simulation of the assembly process using Virtual Reality. In the first step of the teaching factory process, students get to handle and analyse their design to spot any defects that might significantly impact the final assembly's success and the solution's efficacy. Participants may benefit from this digital prototype and the actual engagement with it since they can catch their mistakes early and correct them before they go into production. Further, the assembly may be tested by putting the planned components through a virtual reality simulation. Any de- lays found at this point should be recorded as they may suggest possible flaws in the original design.

The assembly of the RC car's components is the focus of the second section of the educational factory. The participants will be asked to model and arrange a produc-tion line to manufacture the suggested product. To fulfil varying demand profiles, pro- spective engineers must utilise cutting-edge technologies to simulate production lines and plan work. The supplied instances simulate actual situations that engineers-to-be may confront in the manufacturing industry. To further facilitate participants' evalua- tion of their proposals, the proposed framework maintains data from each group directly in the TF database, allowing them to compare their recommended shop floor layout and the resulting performance to that of other groups. During this process, participants will get acquainted with a simulation programme and, ultimately, the needs of a production line to facilitate self-evaluation and growth within the group. Participants are tasked with making the components of their product after first modelling the manufacturing and learning the theoretical underpinnings of each necessary procedure. Milling, drill- ing, and turning are available at the learning factory. Cyber-physical system (CPS) up- grades at each also the technologies mandated by Industry 4.o that will station/machinery include process monitoring sensors and a wireless network to gather and store the data for further use by the TF. Under the watchful eye of a seasoned machine operator, each team uses the NFC card to report their team num- ber and the procedure's scheduled start time. With a smartphone app, the participant may check on the machine's condition and spot any anomalies in real-time by reading the data captured by the sensors that have been placed. This section of the training factory 4.o introduces the participants to the Industry 4.o technologies that are reshap- ing manufacturing and are being progressively implemented in production lines.

The last phase in the instructional factory's procedure is completing the product's two-part assembly. As with other examples of human-robot collaboration, the first stage is performed with the help of a robotic arm. Because most modern industrial assembly processes are handled by automation, these techniques must be included in Education 4.o curricula. Aspiring engineers must coordinate their efforts with the robot during an assembly process, with the latter's motion path shown in their augmented reality gog- gles. At the same time, they control it with a wristwatch [17]. The operator may validate the robot's actions, get helpful messages, and verify the task's completion wirelessly via the smartwatch. Each team gathers information throughout the work, such as how long it takes to complete the job and data from the robot's PLC, to compile a meaningful dataset on the task from which they may make conclusions [19].

Additionally, the aspiring engineers, with the help of a seasoned technician, are re- quired to complete the final assembly of the radio-controlled electric automobile by hand. Wearing an intelligent glove during assembly is mandatory, per Industry 4.o's guidelines for further digitization. The operator's grasps, manipulations, and assembly patterns may all be mapped thanks to the intelligent glove's built-in sensors. Each team uses the NFC card to mark each construction process's starting and ending times. Also, the operator may use augmented reality software on their mobile device to see how to put together the standard components of the planned automobile. Using the collected data and working closely with a seasoned operator, each team may assess its assembly performance by keeping track of the time it takes to complete a task and looking for unnecessary steps that might lead to a design or production flaw.

After the final assembly is complete, each team puts its radio-controlled electric vehicle through its paces in a series of trials to ensure it is ready for use. Participants who complete the teaching factory 4.o programme get a set of highly marketable abili- ties to facilitate their incorporation into the manufacturing sector. Engineers-to-be learn not only the standard procedures for product design and manufacturing methods and equipment but

influence future production direction. In response to

recent technological advancements, the concept of "teaching factories" has emerged under the umbrella of "Education 4.o," intending to provide a setting that will aid businesses in integrating cutting-edge technologies into their operations by drawing on the expertise of academic research institutions. In addi- tion, it prepares future engineers for the demands of the industry by allowing them to practice their craft in a setting that mimics the real world, complete with the challenges of working within the constraints of a realistic design that they helped create with the help of seasoned professionals.

V CASE STUDY ACCORDING TO THE COURSE WORK:

An example course from a manufacturing training center is used to evaluate the strat- egy. A radio-controlled automobile is designed, built, and assembled in seven stages during the procedure, with students working in small groups. Industry 4.o technologies have been considered throughout, making for a more cohesive experience for everyone involved and giving insight to the engineers working together on the project about the difficulties and opportunities presented by cutting-edge innovations.

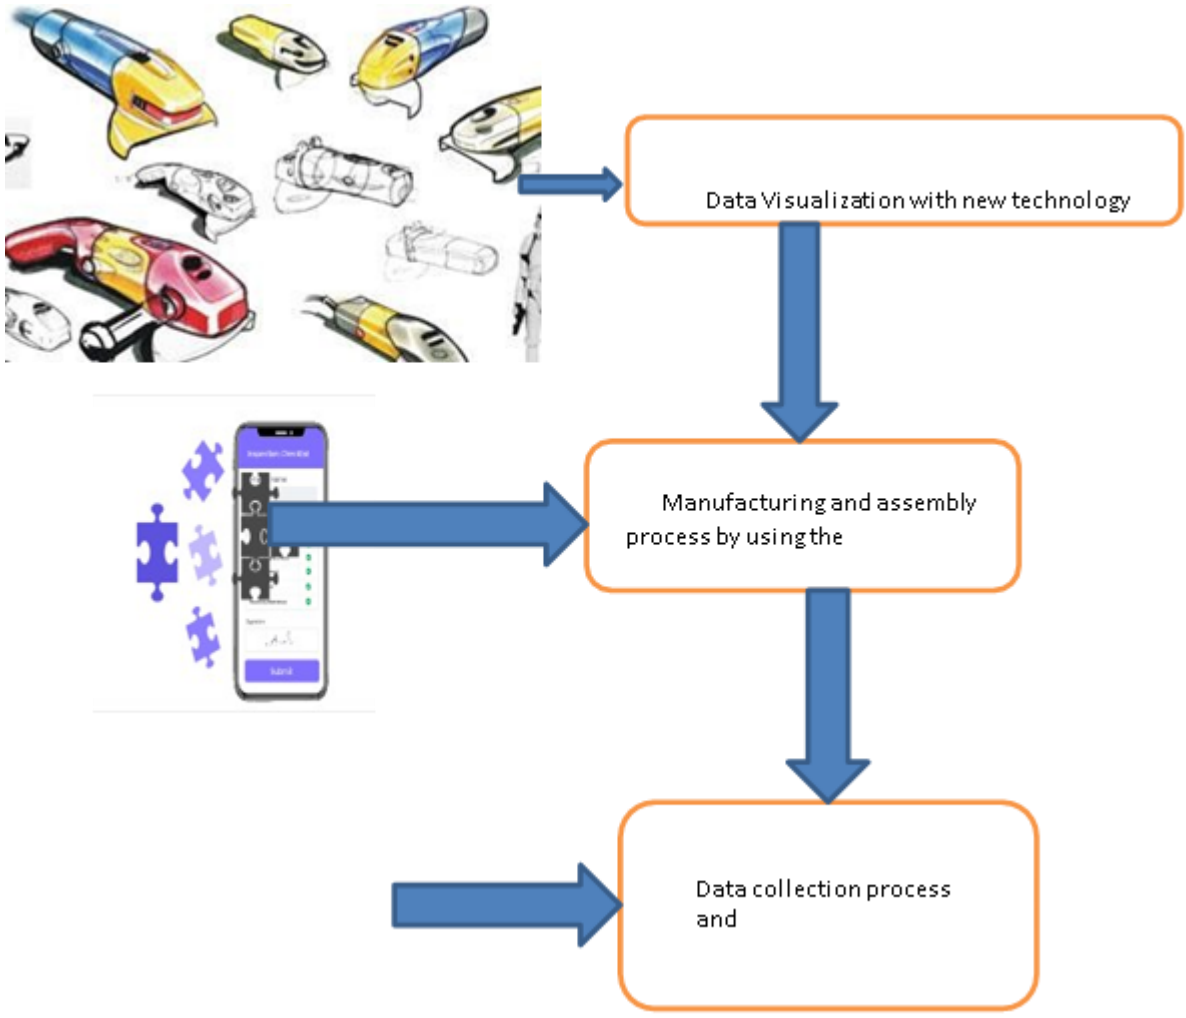

Figure 4: paradigm- Education 4.o

Participants are tasked with coming up with an initial design for the vehicle utilising a predetermined set of electrical components, visualising that design in virtual reality, and finally simulating the scheduling of mass manufacturing of the car to fulfil specific output targets. After deciding on a plan, they use material removal techniques like drill- ing, milling, and turning to create the necessary components before assembling them with an industrial robot and subsequently by hand. Participants gained knowledge about and hands-on experience with manufacturing processes at this teaching factory, which covered all the stages of product development. The development of the current ap- proach was with Education 4.o principles in mind to introduce pupils to cutting-edgedigital tools. Each team has an NFC card to monitor their progress as they go through the process, and the team may also collect relevant information from sensors built into the equipment they use. The whole procedure was digitised so that participants could access data on the related task for self-evaluation. During the research, the amount of information accessible was expanded thanks to mobile devices such as smartwatches and tablets to facilitate collaboration between operators and robots in assembly activi- ties. Virtual and augmented reality were used in conjunction with the design for digital prototyping. As part of the teaching factory 4.o paradigm, these instruments introduce future engineers to state-of-the-art visualisation and simulation approaches to product creation. It introduces students to the hybrid cyber-physical systems characterising manufacturing in the twenty-first century.

To better educate future engineers for the manufacturing settings in which they will operate, they must get acquainted with the elements shaping the cyber-physical systems of future production lines. Students may get a deeper understanding of the product design and production processes by integrating and analysing data from the simulation, the manufacturing processes, and the assembly of the final pieces collected during the teaching factory experience. 4.o. Participants get experience with machine monitoring, data comprehension, and data prediction via analysis of collected data. They gain awareness of faults made in earlier design processes to minimize errors that may be crucial in later steps.

VI CONCLUSION:

This paper includes the new technologies in the education system to develop according to the current industrial need. Physical cyber security systems and IoT technologies use to update the current education system. The final framework will enhance the education concept according to Industry 4. o. Teaching factories 4.0 also introduces future engi- neers to cutting-edge tech through hands-on workshops that encourage participants to see these tools as a way to boost the efficiency and precision with which they perform existing duties, thus opening the door to previously unrealized possibilities. These tech- nologies' incorporation into manufacturing will be furthered by their use in educational factories, as aspiring engineers exposed to the full potential and capabilities of Industry

4.0 will look for ways to incorporate it into their projects.

Abstract— **The human face is a dynamic object with a great degree of diversity in its appearance, and it plays a significant role in social interaction through communicating people's identities. Face detection and face recognition techniques have been devised to combat this unpredictability. The initial stage of face recognition is face detection. We provide a thorough and insightful analysis of face detection and face recognition methods in this study. We describe a neural network method that identifies a face picture using the specific properties of the face. The fundamental concept is to locate certain distinctive traits in a person's facial picture, extract those elements, and then compare them. Approaches and different techniques that use aligned text**
with composite backgrounds and text detection in natural images. We suggest the use of neural networks and PCA, LDA, and MPCALDA in facial recognition, where we identify an unknown test image by comparing it to previously identified training photos that have been recorded in a database and provide details about the individual identified. Experimental results show that backpropagation algorithms provide varying rates of accuracy under various circumstances. We have created a face identification system that can identify human faces in a picture. This report outlines the development of our study into a new strategy for recognition approaches.

Keyword- Face detection, Face recognition, Neural Networks, SVM, RBF, PCA, LDA, MPCALDA, Back Propagation.

I. INTRODUCTION

Separating picture windows into two classes—one having faces (targets) and one including the background—is neces- sary for face detection (clutter). It is challenging because, de- spite the similarities across faces, they might differ greatly in terms of age, skin tone, and facial expression. Different light- ing situations, picture quality, and geometries, as well as the potential for partial occlusion and disguise, make the issue much more challenging. Therefore, the perfect face detector would be able to identify any face against any background, in any lighting situation.

There are two steps to the face detection process.

In the first stage, a classification job is used to determine whether there are any faces in an input image. This task ac- cepts any image as input and produces a binary result of yes or no.

The face localization job, which is the next phase, outputs the position of each face or faces inside an image as a bound- ing box with some (x, y, width, height).

A. FACE DETECTION

1. Pre-Processing: Before the photos are sent into the network, they are treated to lessen the variability in the faces. Cropping frontal face photographs to just include the front view yields all of the favorable in- stances, which are the face images. The clipped pho- tos are all then light-adjusted using industry-standard methods. [4]
2. Classification: Using these samples as training data, neural networks are used to categorize the pic- tures as either having faces or not. For this challenge, we employ the Matlab Neural Network Toolbox as well as our own neural network implementation. To improve the outcomes, several network configura- tions are tested.
3. Localization: Next, faces are sought out and, if any are found, they are localized in a bounding box using the trained neural network.

VARIOUS CHARACTERISTICS CONSIDERED IN A FACE DETECTION:

- Position
- Scale
- Orientation
- Illumination

FACE DETECTION TECHNOLOGIES:

- Knowledge-based approaches are rule-based tech- niques that characterize a face using those rules. The method is hampered by the difficulty in developing clear guidelines.
- The feature invariant approaches extract facial charac- teristics, such as the eyes, nose, and mouth, and then employ them to identify faces. These algorithms have a flaw in that noise, occlusion, and lighting can distort the features. The face region is segmented using collab- orative evolutionary agents that look for skin-like pix- els. The region's shape is then parameterized by height, aspect ratio, and orientation, and based on color and shape, it is categorized as a face. [8]
- The template matching methods, typical patterns of a face or characteristics are saved, and the input photos are connected with these patterns to recognize a face. These techniques can't handle changes in position, scale, or form. [9]
- The appearance-based approaches, on the other hand, learn the properties of face and non-facial pictures from examples using statistical and machine learning tech- niques. The learnt attributes are then used to face de- tection in the form of distribution models or discrimi- nant functions. Dimensionality reduction is another crucial step used in these techniques to lessen comput- ing complexity and boost detection effectiveness. Giv- en that one of the appearance-based approaches is the neural network technique.

APPEARANCE-BASED APPROACHES:

• Eigen faces: The goal is to find basis vectors spanning
the best subspace such that the mean square error between the training pictures projected into this sub- space and the original images is as little as possible given a set of n x m pixel training images expressed as vectors. Principal component analysis has been used to extend this method for face detection and identifi- cation [4].

• Support vector machines (SVMs) are a novel para- digm that may be used to train classifiers that use neural networks, radial basis functions, or polynomial functions. The separation hyperplane for the SVM classifier's linear classifier is chosen to reduce the predicted classification error of the test patterns that haven't yet been observed and those that have. A weighted combination of a small subset of the train- ing vectors known as the support vectors is described as this ideal hyperplane. An effective strategy for training an SVM for complex tasks was created by Osuna et al. [5] and used to face identification.

• Radial Basis Functions: The fundamental goal of an RBF neural network is to divide the input space into many hypersphere-shaped subspaces. So, clustering techniques like fuzzy k-means clustering, hierarchical clustering, and k-means clustering are frequently uti- lized in RBF neural networks.

REF ARCHITECTURE:

Input, a hidden layer with a nonlinear RBF activation function, and a linear output layer are the three layers that make up most radial basis function (RBF) networks. The hidden layer node responses are combined in linear combinations at the output layer to create the output. The basis functions in the hidden layer nodes are radically symmetric, thus the acronym RBF. The Gaussian function, which has a mean and a standard deviation, is the basic function that is most frequently used. The connections between the input and the hidden layers are not weighted in RBF networks. Consequently, the network's output is

Yk = L Wkj exp(-llx -cJ II /2(YJ)]=1

where N is the total number of neurons in the hidden layer, Cj is each neuron's center vector, crj is the distribution of basis functions at each node in the hidden layer, and Wkj are each linear output neuron's weights. The Ilx -cj II is the distance, as determined by some norm, between the center of the th hid- den node and the point representing the input X. This research use the Euclidean norm.

HIDDEN MARKOV MODELS (HMM):

When training an HMM for a pattern recognition issue, the objective is to increase the likelihood that the training data will be observed. To do this, the HMM model's parameters are adjusted using the common Viterbi segmentation technique and Baum-Welch methods. The output probability of an ob- servation indicates the class to which it belongs after an HMM has been trained. A face pattern can be broken down into sev- eral areas, such as the eyes, nose, mouth, and so on, in a face detection job. By paying attention to these areas in the proper sequence, a facial pattern may then be identified. Here, as op- posed to the template matching method, the goal is to link face areas to continuous density Hidden Markov Model states.

NEURAL NETWORKS:

Numerous pattern recognition issues, including character identification, object recognition, and autonomous robot driv- ing, have seen widespread use of neural networks. As a two class pattern recognition issue, the face detection job has seen a number of networks suggested throughout the years. The use of neural networks has the benefit of being able to capture the intricacy of facial pattern complexity. The drawback is that in order to get decent results, the network design must be carefully modified (number of layers, number of nodes, learn- ing rates, etc.). [10]

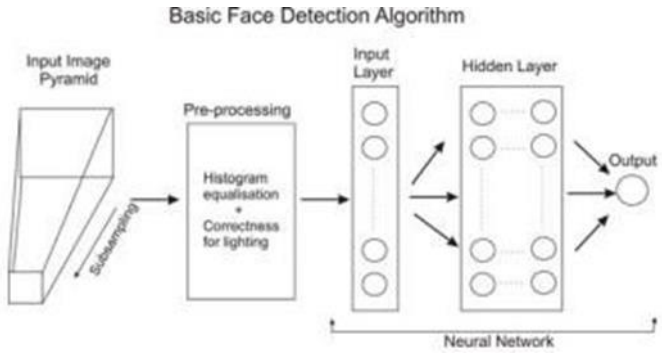

Figure 1: Face Detection Algorithm

B. FACE RECOGNITION SYSTEM:

An intriguing and effective use of pattern recognition and image analysis is face recognition. For intelligent vision-based human computer interaction, facial pictures are crucial. Face processing is based on the idea that computers can operate in accordance with the information about a user's identity that can be retrieved from the photos. Face detection has a wide range of uses, including biometrics, information security, and entertainment [1]. There are several methods that have been suggested to find faces in a single picture.

An active field of study is the face recognition system, a computer-based digital technology. The Face Recognition Sys- tem may be used for a number of purposes, including person searches, security systems, and numerous authentication methods. [6]

Even the feature qualities of the face change throughout time as humans' brains develop the learning ability to distin- guish people by their faces. The neurons in the human brain are taught by reading or memorizing a person's face, and even after many years, they can immediately recognize that face. With the use of artificial neural networks, this capacity for identification and training is transferred into machine systems. The fundamental job of a face recognition system is to com- pare a subject's face to those already learned in artificial neural networks. It then outputs the face that matches the subject's face the best, regardless of lighting, viewing angle, or facial expression.

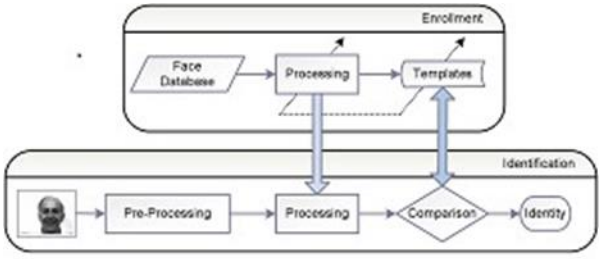

Figure 2: Basic Face Recognition System

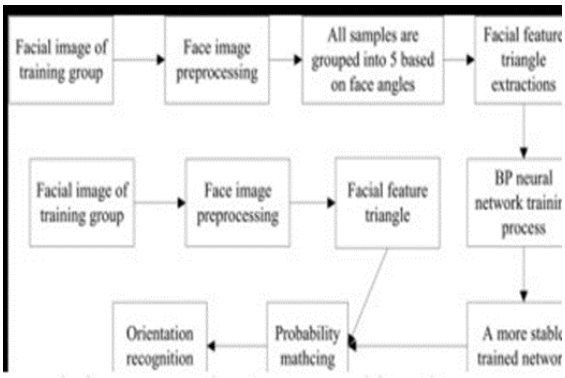

Figure 3: Face Detection And Recognition Diagram

Facial Recognition can be done using two ways:

a. Still Image
b. Video

Principal Component Analysis (PCA), Multilinear Principal Component Analysis (MPCA), and Linear Discriminant Anal- ysis are the face recognition techniques utilized in this article (LDA).

Each algorithm has a distinct benefit. While PCA is the most straightforward and quick technique, MPCA and LDA, when used as a single algorithm called MPCALDA, perform better under challenging conditions like face position, bright- ness fluctuation, etc.

II LITERATURE REVIEW

2.1 PRINCIPAL COMPONENT ANALYSIS (PCA)

Karl Pearson developed principal component analysis (PCA) in 1901. PCA is a mathematical technique that converts a number of potentially linked variables into a number of main components, which are orthogonally connected to the original variables. The data from PCA is projected in the directions with the largest variations[11].

By transforming data from a high-dimensional image space to a low-dimensional image space, the PCA approach calculates the largest variances in the data. For training and testing purposes, these derived facial image projections are further processed to Artificial Neural Networks. The main benefit of PCA is that the eigenface method aids in lowering the size of the database needed for test picture identification. The learned pictures are not kept.

2.2 MPCALDA

A. MPCA

The multilinear algebra-based version of principal component analysis (PCA) known as multilinear principal compo- nent analysis (MPCA)[3] is capable of understanding the in- teractions of many elements such as different views, different lighting conditions, different expressions, etc.

The method is comparable to PCA in that the eigenface technique is used to condense the characteristics that make up a face. In contrast to PCA, which only applied one transfor- mation vector, MPCA applies N separate transformation vec- tors, each of which represents a different dimension of the face pictures.

B. LDA

A computer method for assessing the relevance of various face characteristics in terms of their discriminating power is known as LDA, sometimes known as Linear Discriminant Analysis[2].

The database is segmented into many classes. Each class has a collection of pictures of the same individual taken under various lighting and backdrop settings, different frontal view- points, and with or without spectacles, among other things. Additionally, it is believed that all photos are the same size and only contain facial parts.

We may create a model for doing cluster separation analy- sis by classifying all the face photos of the same person into one class and faces of other individuals into other groups.

2.3 NEURAL NETWORK APPROACH

An artificial neural network (ANN) is a paradigm for in- formation processing that takes its cues from how organic nervous systems, like the brain, function. The innovative structure of the information processing system is the funda- mental component of this paradigm. It is made up of several, intricately linked processing units called neurons that collabo- rate to address certain issues. ANNs learn via imitation much like people do. Through a learning process, an ANN is tai- lored for a particular purpose, such as pattern recognition or data categorization. Adjustments to the synaptic connections that exist between the neurones are a result of learning in bio- logical systems.

2.4 FEATURES OF NEURAL NETWORKS

A. FEED-FORWARD NEURAL NETWORKS

Feed-forward Signals can only go in one direction, from input to output, using ANNs. There are no feedback loops, meaning that the output of each layer has no bearing on that layer itself. Feedforward ANNs are frequently simple net- works that link inputs and outputs. They play a significant role in pattern identification. This kind of organization is sometimes known as top-down or bottom-up.

B.FEEDBACK NETWORKS

By adding loops to the network, feedback networks (fig- ure 1) can have signals traveling in both ways. Feedback net- works have tremendous power and may become very com- plex. Feedback networks are dynamic; until they find an equi- librium point, their "state" is always changing. They stay there until the input changes and a new balance needs to be estab- lished. The terms interactive and recurrent can also be used to describe

feedback topologies, albeit the latter is frequently used to describe feedback links in single-layer organizations

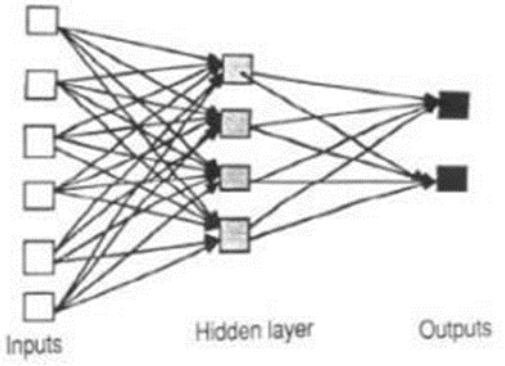

Fig- ure 4: An Example of a Simple FeedForward Network

III ARCHITECTURE OF NEURAL NETWORK

A) NETWORK LAYER:

A layer of "input" units is connected to a layer of "hidden" units, which is connected to a layer of "output" units in the most popular kind of artificial neural network. In Figure 4.

- The network is fed with raw data, which is represented by the activity of the input units.
- The activities of the input units and the weights on the links between the input and hidden units influence each hidden unit's activity.
- The activity of the hidden units and the weights be- tween the hidden and output units affect how the output units behave.

The hidden units in this straightforward sort of network are allowed to create any representation they like for the input. When a hidden unit is active depends on the weights between the input and hidden units; by changing these weights, a hid- den unit can select what it represents.

Additionally, we differentiate between single-layer and multi-layer systems. The most typical organization type is a single-layer organization with interconnected units since it has a higher potential for computational power than multi-layer hierarchically organized organizations. Units in multi-layer networks are frequently numbered per layer rather than uni- formly.

B) PERCEPTRONS:

The most important research on neural networks in the 1960s was classified as "perceptrons," a word that Frank Ros- enblatt invented. An MCP model (neuron with weighted in- puts) plus some additional, fixed pre-processing turns out to be what the perceptron is. The association units with the labels A1, A2, Aj, and Ap are responsible for extracting certain, local- ized features from the input pictures. The fundamental princi- ple of the mammalian vision system is mimicked by perceptrons. Despite the fact that they had far greater capabilities, they were mostly utilized for pattern recognition.

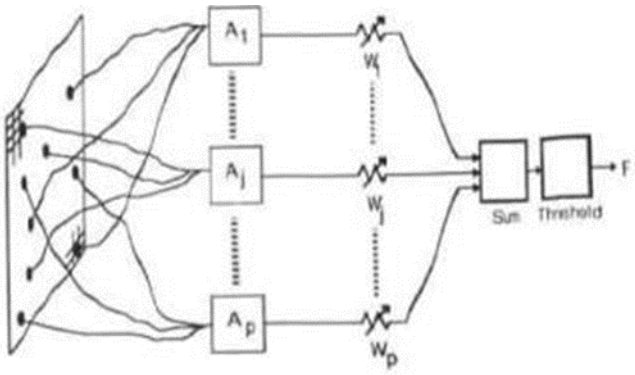

Figure 5: Working of Perceptron

C) MULTILAYER PERCEPTRON:

The well-known and popular learning algorithm for multi- layer perceptrons is back-propagation (MLP). The neurons in an MLP feedforward network are arranged in layers. The in- put layer of the MLP network is made up of a number of sen- sory units (source nodes), one or more hidden layers of com- putation nodes, and an output layer of computation nodes. The input signal travels through the network in a forward manner, layer by layer, and from left to right. Back propaga- tion is a gradient descent-based supervised learning network. With differentiable activation function units, the BPNN offers a computationally efficient approach for adjusting the weights in a feedforward network in order to learn a training set of input-output data. [12]

It minimizes the total squared error of the output generated by the net since it is a gradient descent approach. The goal of training the network is to strike a balance between its capac- ity for accurate response to the input patterns utilized for training and its capacity for good response to inputs that are similar.

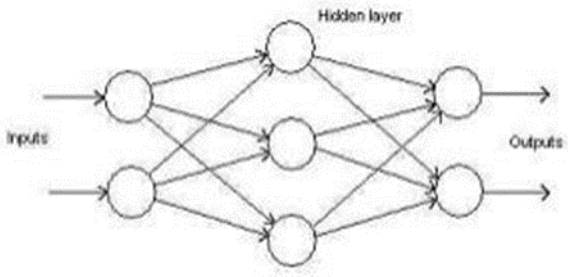

Fig.6 Layers of Neural Network

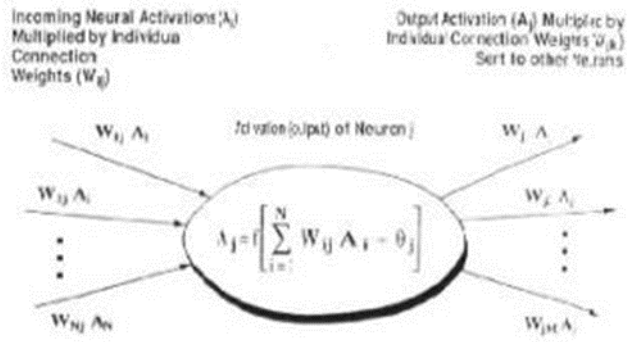
D) THE LEARNING PROCESS:

Each neural network has information that is encoded in the weights of the connections. A learning rule for altering the values of the weights is implied when the information stored in the network is modified as a function of experience.



Since it uses a gradient descent technique, the total squared error of the net's output is minimized. The aim of network training is to find a compromise between the network's ability to respond accurately to the input patterns used for training and its ability to respond well to inputs that are similar.

3.1 Supervised learning is learning that is guided by a third party instructor, who explains to each output unit what it should do in response to input signals. It may be necessary to have access to global knowledge when studying. Error- correction learning, reinforcement learning, and stochastic learning are supervised learning paradigms. The problem of error convergence, or the minimizing of error between the intended and computed unit values, is a significant challenge with supervised learning. Finding a set of weights that mini- mizes mistake is the goal. The least mean square (LMS) con- vergence is a well-known technique that is included in many learning paradigms.

3.2 Unsupervised learning relies only on local knowledge

and employs no outside teachers. In the sense that it self- organizes data provided to the network and recognizes their emerging collective qualities, it is also known as self- organization. Hebbian learning and competitive learning are unsupervised learning paradigms [13]. Whether there is a dis- crete phase during which the network is trained and a subse- quent operating phase depends on whether or not human neurons or artificial neurons are used. When the learning phase and the operating phase are separate, we say that a neu- ral network learns off-line. If a neural network learns and runs at the same time, it learns online. Unsupervised learning often takes place online, whereas supervised learning typically takes place offline.

E) TRANSFER FUNCTION:

Both the weights and the input-output function (transfer func- tion) that is set for the units affect how an ANN (Artificial Neural Network) behaves. Usually, this function belongs to one of three categories:

- linear (or ramp)
- threshold
- sigmoid

The output activity is proportional to the overall weighted output for linear units.

The output of threshold units is adjusted to one of two lev- els based on whether the total input is higher than or less than some threshold value.

For sigmoid units, when the input fluctuates, the output var-ies continuously but not linearly. Sigmoid units resemble gen- uine neurones more closely than threshold or linear units, alt- hough all three must be seen as approximations.

F) BACK PROPAATION:

One of the most often used neural network models is the back propagation (BP) neural network method, which is a multi-layer feedforward network trained using the error back propagation technique. There is no need to reveal in advance the mathematical equation that explains these mapping rela- tions since BP networks can learn and retain a large number of input-output model mapping relations. Its learning rule is to employ the steepest descent approach, in which the network's weight value and threshold value are controlled via back propagation to produce the lowest possible error sum of squares. The investigation of the BP neural network's proper- ties and mathematical theory is the primary emphasis of this research, which also identifies the flaws in the BP algorithm and suggests many solutions.

An artificial neural network (ANN) is a paradigm for in- formation processing that takes its cues from how biological nerve systems function. It goes through a specialized learning process to be set up for a certain application. The feed-forward network, which comprises multilayer perceptron and other neural networks, is the family of neural networks that is most frequently employed for pattern categorization tasks. The feed- forward network family, which includes multilayer per- ceptron and Radial-Basis Function (RBF) networks, is the one most frequently employed for pattern categorization tasks. A feed-forward supervised learning network is back propaga- tion. The main idea behind the back propagation technique is to reduce the squared error between the goal output values and the network output values by updating the weights using gradient descent. To calculate the contribution of each weight to the error, the update rules are generated by calculating the partial derivative of the error function with respect to the weights. Each weight is then modified. The term "backpropa- gation" refers to the iterative process that happens for each layer of the network, beginning with the most recent set of weights and moving backwards toward the input layer. The network is trained to perform well in terms of its capacity to react appropriately to the input patterns used for training and to deliver a suitable response to input that is comparable.

IV NEURAL NETWORKS IN FACE RECOGNITION:

By using a PCA-based eigenface technique, human face fea- tures are extracted, turning a high-dimensional space into one with very few dimensions. Various effective approaches have been used for decades. The facial pictures may be expressed in terms of a best coordinate system called "eigenfaces," as demonstrated by Kirby and Sirovich in 1990 [5].

These are the eigenfunctions of the ensemble of faces' aver- age covariance. They also intended for the limited number of eigenfaces to be required even for a high number of faces. Us- ing the eigenfaces representation of faces as a foundation,

M.A. Turk and A.P. Pentland [14] presented a face

recognition algorithm in 1991. Several feature extraction techniques, in- cluding Linear Discriminant Analysis (LDA), Kernel ap- proaches, Evolutionary Pursuit (EP), Support Vector Machine(SVM), and Artificial Neural Networks, were developed in the past several years for use with face photos (ANN). A super- vised learning algorithm is LDA. By calculating the edge re- sponse values in each of the eight directions at each pixel spot, LDP features are acquired.

In the projective feature space, all projected samples will simultaneously form the greatest between-class scatter and the lowest within-class scatter. For the purposes of face recogni- tion, each face is represented as a set of LDP codes [11].

A genetic method called Evolutionary Pursuit (EP) over- comes the issue of the size of the solution space. It is an eigen- space-based adaptive technique that looks for the optimal col- lection of projection axes to maximize a fitness function while also assessing the system's generalization capability and clas- sification accuracy [9]. A extension of linear techniques is of- fered by kernel methods. To learn this non-linear manifold, direct non-linear manifold techniques are investigated.

The Support Vector Machine (SVM) determines the hyper- plane that minimizes the distance from either class to the hy- perplane while separating the greatest percentage of points from the same class on the same side.

Face image characteristics are initially extracted using PCA, and SVM is utilized to train the discriminating functions between each pair of photos.

Real-valued, discrete-valued, and vector-valued functions have been approximated from a variety of instances using Artificial Neural Networks (ANN), a very reliable and effec- tive classification approach.

Fleming and Cottrell [15] trained the system in 1990 using nonlinear units and back propagation. By training the net- work, the learning capacity of neurons is employed to exam- ine the various facial distances and backdrop components.

In order to increase the success rate and define the rejection rate, this study discusses a whole face recognition system by merging a feature extraction method based on Principal Components Analysis (PCA) with a detection method based on Artificial Neural Networks (ANN). The project is demon- strated using a database of 49 colored face photos and MATLAB simulation.

V IMPLEMENTATION RESULT:

The back propagation technique is used in conjunction with the ANN learning process for face recognition. A feed-forward supervised learning network is back propagation.

There are several ANN types, including Radial Basis Func- tion, Multilayered Perceptron, and Kohonen networks.

As illustrated in Fig. 7, the multilayered feed forward neu- ral networks include three layers: an input layer, a hidden layer, and an output layer. These levels of processing compo- nents independently compute data before passing it to a high- er layer.

On the basis of the inputs' weighted total, the computation of the processing elements is finished. In order to change the weights of the hidden layer, the output is compared to the goal value, and the mean square error is determined. By con- tinually altering the weight of each layer, this procedure iter- ates for each layer to reduce error. As a result, it is known as the back propagation. The process of iteration continued until the error was below the acceptable level.

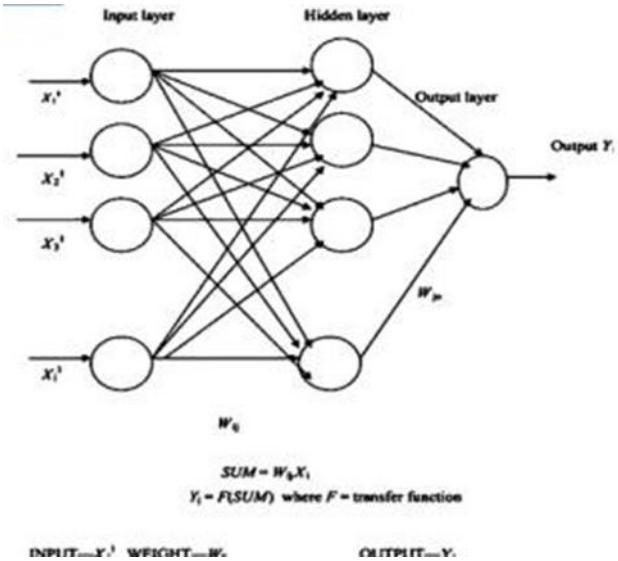


Figure 7: Basic diagram of neural network

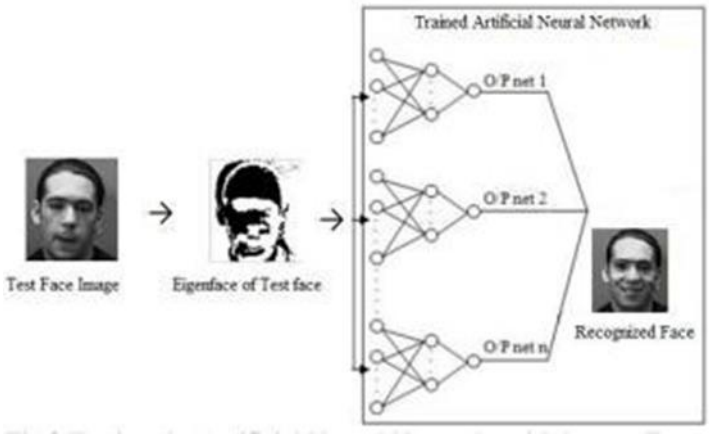

Figure 8: Testing the Artificial Neural Networks with known Face Image with different expressions.

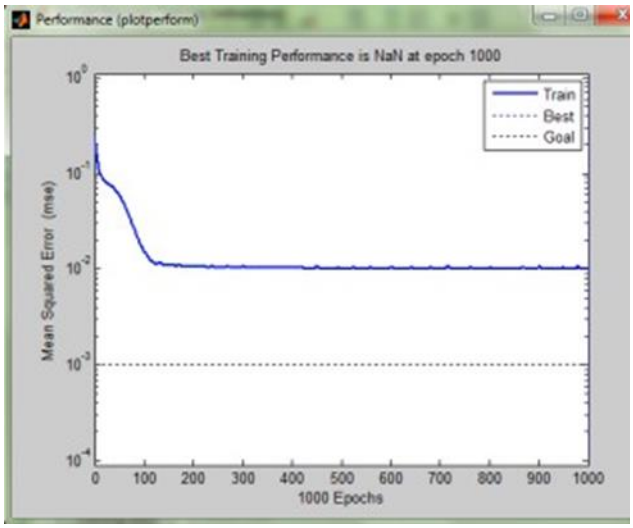

Figure 9: Performance plot between Mean Square Error and number of Iterations of Artificial Neural Networks

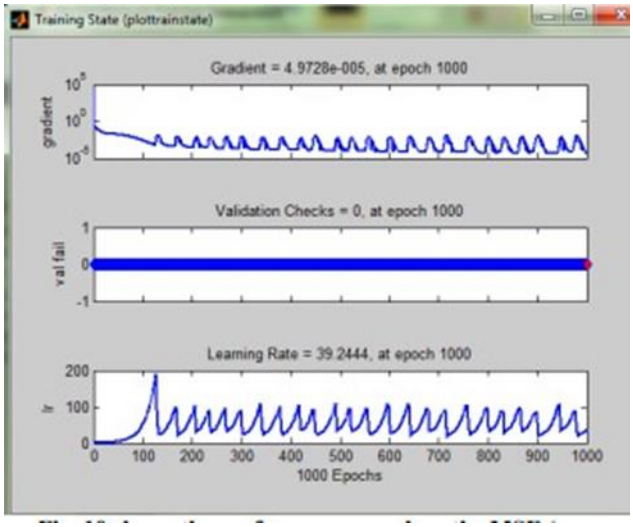

Figure 10: Performance graph as the MSE (mean square er- ror) is reduced to 0.001 by updating the weights of hidden layer using the back propagation algorithm.

VI CONCLUSION

Human face detection is frequently the initial stage in the recognition process since it may direct computing resources to the face region of the image before recognition is even at- tempted.

Here, one of the eigenface face recognition approaches and one of the neural network-based face detection strategies have been demonstrated.

A trustworthy MSNN model has been designed for neural networks.

For face recognition, back propagation feed-forward artifi- cial neural networks with PCA-based feature extraction are used.

Even with noisy face photos, the targeted face recognition system operates with high accuracy and offers superior suc- cess rates. By increasing the number of iterations and employ- ing the Log-sigmoid and Tangsigmoid functions, the mean square error may be further decreased until it is below the tolerance limit of 0.001, which has been established. The find- ings demonstrate that owing to added errors in distance esti- mates, counting the picture distance becomes challenging when lightening changes are substantial.

Even with differences in lighting and backdrop, the intend- ed method outperforms individual PCA-based face recogni- tion systems. The rejection rate for photos of unfamiliar or non-human faces has increased as a result of our work. We will use artificial neural networks and local feature extraction techniques in the future to advance our understanding of the face recognition system. For the used database, this approach offers a maximum accuracy of roughly 95.45%.

Abstract— **With the world increasingly becoming more and more virtually connected, the threat of intrusion in systems and networks is a rapidly increasing threat as well. A lot of different ways to detect this intrusion and ultimately prevent it are being developed. The best way is the implementation of deep learning algorithms and neural networks to detect the anomalies in a given system/network. The use of LSTMs (Long Short Term Memory) has been quite popular but they have their limitations as well. The proposed system develops an ensemble with 3 different LSTM-hybrids to develop a robust and better model that detects a large number of cyber attacks and provides better accuracy compared to a single LSTM model. Out of the three LSTM- hybrids used CNN-LSTM provided high accuracy with low FAR (false alarm rate) while RNN-LSTM was able to classify 3 major attacks more accurately but it was not much robust with R2L attacks and was giving high FAR. While the MLSTM is able to classify R2L attacks in a proper manner. The proposed ensemble model of LSTM and neural networks for intrusion detection have achieved an accuracy score of 98.7% for NSL KDD dataset and 99.3% for KDD99 dataset.**

I. INTRODUCTION

The modern world is a completely virtual world as of now and the progress of technologies and advancements in this field are still rapidly increasing. With the revolution that computers have brought around, us humans have developed so many different things with said computers and related to said computers as well. As it stands now, humans are completely dependent on computers and the internet in day to day lives.Especially in the past few years, since the increased use of cloud computing, IoT services, any and all sort of communication or entertainment service is most certainly over the internet today. This increased reliance can also have negative repercussions if it is not thought about in a well rounded way. Any sort of new rise brings its threats along with the opportunities as well. It would not be prudent to only focus on the endless opportunities that the past few years have brought.

One of the biggest threats with the extreme reliance on networks and the internet is obviously security. Network security is a very vast and constantly evolving topic. Cyber attacks have also developed quite a bit throughout the years and hence there is a constant need for the cyber security measures to evolve as well.

With complex networks and setups, it is crucial to note the fact that any threat to the network or vulnerability will affect the entire network and can lead to huge losses and setbacks [1]. With the constant evolution of various types of cyber attacks and increasing threats to security, it is felt that just the traditional methods of security can no longer keep up. Hence the need to develop efficient network intrusion detection systems is felt quite strongly. These systems should be able to provide the integrity and privacy of the data by accurately detecting the attacks and threats with a high accuracy and a low false alarm rate.

Signature based detection or misuse detection is the model where detection is based on known attacks and threats. This model has high accuracy and low false alarm rates but the major drawback with it is that it doesn't change or evolve over time. Stagnant detection systems are easily overcome within a matter of a few years or months even with the rate at which all systems are advancing. To prove effective, an intrusion detection system will have to be able to perform well against known and unknown attacks.

Machine learning and Deep learning are both fields that have been used for a wide variety of applications, so it should be no surprise that they have also been employed in the field of intrusion detection. Machine learning systems are based on manually extracted features and deep learning systems extract features from the available data themselves.

A lot of work has been done regarding the use of ML/DL techniques in intrusion detection over the last couple years. The use of LSTMs as well as various other neural network architectures has been seen and has proved quite effective. LSTMs are especially useful in this field as they are designed for time series predictions which can be very useful here, to predict or classify the cyber attacks over time. LSTM hybrids will be the focus in this paper. Deep learning in intrusion detection is preferred because of the feature extraction ease as well as the fact that the neural network can learn from the unstructured or unlabelled data [2]. DL algorithms are also robust and scalable with the data availability. The deep learning models are developed for complex problems like pattern recognition, natural language processing(NLP), etc so intrusion detection systems are also efficiently developed using the deep learning algorithms.

II. LITERATURE SURVEY

Intrusion over networks is a big problem now with the increase in network systems as well as the developing

types of various attacks. One widely used deep learning method for this is the CNN- LSTM model. It is felt that the machine learning alternatives for intrusion detection are not sufficient and there is a need to develop deep learning models [3]. The use of datasets other than the one discussed is also a factor to be considered. Even though they are out of date, the KDD datasets are the most complete datasets for the problem of intrusion detection. It is found that CNN-LSTM models are extremely efficient and accurate for binary classification of cyber intrusion detection ie. just detecting whether a system is clean or has been attacked. But it fails for multiclass classification and cannot accurately distinguish between certain attacks The false alarm rate for CNN-LSTM is also extremely low and hence it is good for the intrusion detection system.

The use of LSTMs as stated above are the focus of this paper as all the models used in the ensemble are going to be LSTM based hybrids. The use of LSTMs of temporal feature extraction in intrusion detection systems has already been carried out [4]. In a referred paper, three LSTM approaches are described. One is a plain LSTM, one is with dimensionality reduction using principal component analysis (PCA), and one with mutual information. On the KDD99 dataset using LSTM with PCA, the model was able to get above 99% accuracy in classification.

Recurrent neural networks are also quite helpful in this field, they can be used to produce new attack types so that the model can be trained faster and in an efficient manner. To make RNN more powerful for modeling purposes cyclic connections are made. A proposed model contributed for generating the malware mutants, the attack signature and the synthetic data gathering [5].

Another referred paper used the RNN- LSTM model on the KDD dataset. A multiclass classifier was designed using that algorithm and it gave a decent overall accuracy of around 95%. The false alarm rate of this model was also high but it gave better results when compared to similar RNN- LSTM models [6]. Intrusion over network system is a big problem to handle. Now with the increase of network systems the type of attacks are also increasing and thus the paper titled, CNN-LSTM: Hybrid Deep Neural Network for Network Intrusion Detection System elaborates the use of ML models is not sufficient to counter the problem [7]. But with the technological advancement in deep learning and also ANN the researchers have proposed a system which uses CNN and LSTM. The ability of CNN is that it can extract important features and the LSTM has ability to extract time based features. Thus by using CNN and LSTM they have proposed a hybrid IDS. The dataset used was CIC-IDS -2017. Efficiency was determine by confusion matrix and performance metrics like precision, accuracy were also used.

In the paper A CNN-LSM Model for Intrusion Detection System from High Dimensional Data authors describe the use of deep learning techniques of CNN and LSTM for the detection of intrusion over the interne the dataset used by them was KDD99. The proposed model did data preprocessing, then feature extraction and after that continuous testing [8]. Accuracy achieved by the model of CNN LSTM over the KDD99 dataset was 99.78%.

Important technology in future the software defined networking is attacked by new kin of intrusions. The combination of CNN and LSTM where one is used for the extraction of spatial features and other is used for the extraction of temporal features is indeed increasing the accuracy to a large extent. The use of Keras was done for the training of CNN. The proposed IDS model in this paper A Hybrid CNN-LSTM based approach for Anomaly Detection Systems in SDNs was able to grab highest accuracy of 96.32%.

The proposed system describes intrusion on AMI (advanced metering infrastructure). IDS systems are able to detect abnormal activities over AMI networks. Fusion of features was done to represent the different characteristics of data. Used datasets were NSL KDD, KDD Cup 99 the activation function used was ReLU. For NSL KDD the accuracy was almost 99.95% while for KDD Cup 99 was 99.79%. Thus CNN-LSTM approach is efficient for IDS [9].

NSL KDD dataset is one of the most used dataset for applying deep learning based IDS models intrusion detection. The paper describes attack categories and also features present in the dataset. Many machine learning algorithms are applied on the dataset but due to false alarm rate the use of deep learning models becomes important as it deals with complex relationships [10]. The CNN-LSTM model used in the research was able to gain a great accuracy. Also different techniques like DenseNet and Gated Recurrent Unit with Softmax were able to achieve accuracy of 94.98% and 97.36% respectively. The proposed model was able to achieve an accuracy of 99.70% on NSL KDD dataset.

The paper describes the use of the characteristic feature of LSTM of temporal feature extraction for IDS. The paper uses three approaches of LSTM. In the first one LSTM is used without any dimensionality reduction then it is used with PCA and after that with mutual information. The dataset used was KDD99. The model while using LSTM with PCA was able to achieve an accuracy of 99.49%. To see the effectiveness of the model confusion matrix was used.

Recurrent Neural Networks can be helpful to produce new attacks types so that the model could be trained in an efficient manner. The extension of feed-forward neural network is the RNN. To make RNN more powerful for modeling sequences they have cyclic connections. The proposed model contributes for generating malware mutants, then generating the attack signature and after that for synthetic data generation [11].

This literature survey makes a few things clear based on which the ensemble is designed and gets better results improving on the existing models. Firstly, CNN-LSTM is excellent for binary classification but fails at detecting specific types of attacks [12]. RNN-LSTM is the most well- rounded model for multiclass classification with decently high accuracy. LSTM by itself is also a very powerful tool and can be improved upon by using the Modified LSTM(MLSTM) model.

The paper uses RNN-LSTM classifier to detect

intrusion on the KDD Cup dataset. The proposed system before using training dataset had normalized the instances from 0 to 1. Their input vector had 41 attributes while they were detecting 4 attacks and 1 non-attack. Thus hey had input dimension of 41 while output dimension of five [13]. The accuracy which this proposed system achieved was 96.93%. The false acceptance rate of the proposed system was more than other models but accuracy was greater. 9) The proposed system uses spatiotemporal encodes which are unsupervised and with the help of these spatiotemporal encoders the spatial features are intelligently extracted from the network traffic. And after that these extracted features are used as an input to LSTM model. Thus by using these spatial features the LSTM model detects intrusion and classifies it [14]. The proposed system again proves that using neural networks with LSTM gives far better accuracy than other traditional ways .

III. METHODOLOGY

3 different LSTM hybrid models were created and trained individually. These hybrids were chosen so that the shortcomings or weaknesses of one can be compensated by the other. Then these models were ensemble in series with each model filtering out specific cases and passing on the ones it is not good enough to handle to the next one. As a result all will be filtered out depending on the type of cyber attack/anomaly.

A. Datasets used

For the proposed model the main dataset used was the KDD Cup 1999 dataset. Even though it is a quite old dataset it is extremely well endowed and has a lot of cases for the model to train on and test. Along with that the newer NSL-KDD dataset was also used. The data is divided into a few major types of attacks-

1. DOS: Denial of service attack. These attacks make the computing or memory resources too busy and overloaded to deny a legitimate user access to these resources of the machine.
2. U2R: User to root attack. An exploit which allows a user(legitimate or illegitimate ie. someone with access to the machine) is able to gain the root access to the system
3. Probing: Any attempt to gather information about a network in order to bypass or circumvent its security controls and measures is called as a probing attack
4. R2L: Remote to local attack. A remote user who doesn't have access to a machine but is able to send packets to said machine and exploits a weakness to gain access to the local machine is called a remote to local attack.

There are a total 22 attack types in the training set for KDD99, and 15 types in the testing set. The specifics of each attack are different but all of them are classified among these 4 broad archetypes. Along with that the data also contains systems with no anomalies ie. “Normal” states. The dataset has over 4.5 million entries, each being a vector with 41 features. Each entry is labeled as an attack or as normal.

The NSL-KDD dataset is the upgraded version of the KDD 1999 dataset. The NSL-KDD dataset aims to solve some of the major issues that are present in its predecessor. One of the major things is that it removes the duplicate records in the training and testing sets so that the classifiers are not biased for the repeating records. The training and testing sets were also generated from different parts of the original KDD99 dataset to obtain authentic results while using various classifiers. The unbalanced problem of the training and testing data was also solved in this dataset to help reduce the False Alarm Rate(FAR).

All in all, these are both very well-rounded datasets but the biggest problem that is faced when using these is that they are very outdated. There is no idea about the representation of the modern norms and attacks and the respective network activities. Another issue faced is that the probability distributions of the training and testing sets for the data are not the same. This may lead to skew in some of the classifiers that are used with this dataset.

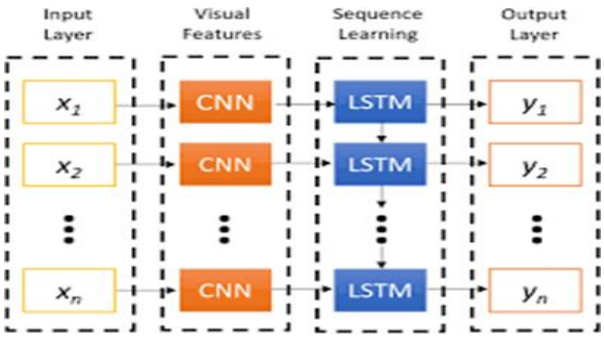
B. Models used

The 3 different LSTM hybrid models implemented are as follows-

1. CNN-LSTM()
2. RNN-LSTM()
3. MLSTM(Modified LSTM)

CNN-LSTM:

The CNN- LSTM model is essentially a bunch of CNN (Convolutional neural network) layers on the input data followed by LSTM layers. The CNN architecture is extremely good at feature extraction and the LSTM layers support learning over time and sequence predictions. The same can be seen in Fig.1 which is a graphical representation of the architecture. These models were first developed for visual time series applications eg.- activity recognition, image and video description etc. This model was also called a Long-term Recurrent Convolutional Network (LRCN) but are now referred to as CNN-LSTMs. These models are good with any data which has spatiotemporal features.



The first evaluation is done by the CNN-LSTM model. This model is a very good first evaluation tool as it can quite accurately discriminate Normal systems and DOS, U2R attacked systems with a sufficiently high accuracy. That leaves only the probing attacks and R2L attacks which are further handled by the next models in the series ensemble.

RNN-LSTM:

LSTMs act like an extension for the Recurrent neural

networks(RNN) in this architecture which extends the memory for the learning of the model. This model is extremely good for learning from experiences that have long time lags between them.

LSTM units are used as the building blocks of a recurrent neural network The LSTM cells can read, write and delete its memory. This is done by the respective gates, it is a gated cell. Input gate controls the entry of new information. Forget gate controls the deletion of information that is no longer useful.Output gate controls whether or not to let the information affect output at the current stage. The LSTM cell can be better understood with the help of

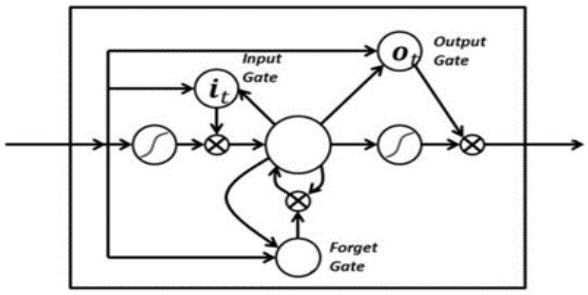


Fig.2 LSTM gated cell

Modified LSTM(MLSTM):

This model builds on the existing LSTM model to provide better flexibility in the application. It also accommodates probabilistic gate cell states in the LSTM model using sigmoid functions. For eg.- Consider the output gate of the LSTM cell. The information to be passed is decided through here. Normally in a LSTM cell it is possible to only let the information pass or not pass ie. boolean logic. With the sigmoid function, a return value between 0 and 1 is obtained at each step in the cell and based on the value the amount of information to be passed is decided (0 being no information to be passed and 1 being all of the information to be passed). This is done at all the gates in the cell, as shown in the diagram below ie. Fig. 3.

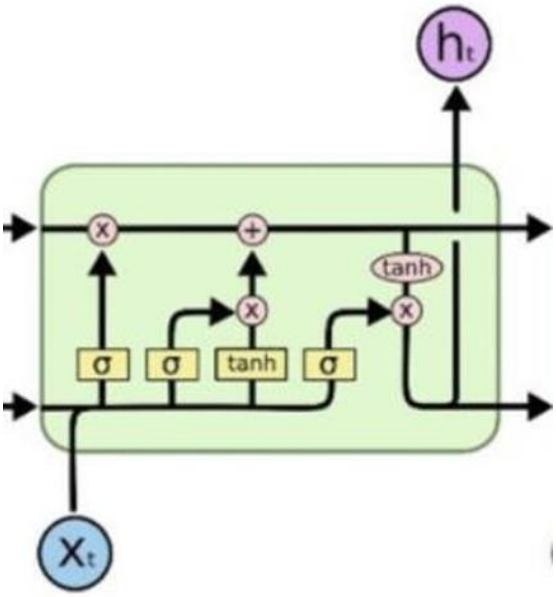

Fig. 3 LSTM architecture

The tan(h) function is to make a vector of new values which will be added to the current state C [14].

C. Proposed Model flow

As stated earlier before the explanation of each model, 3 models are used in the ensemble. First the evaluation through CNN-LSTM is done as it is the most accurate out of all the three for a wide range of attacks as well as binary classification (Normal vs anomaly). The accuracy of the Normal system detection through CNN-LSTM is very high along with Probing and DoS attacks. So many times CNN- LSTM can differentiate 3 out of the 5 possible outcomes by itself. Hence it is used as the first model. However, sometimes for the Probing and DoS attacks, the accuracy might not be high enough to ascertain beyond reasonable doubt whether or not it is the attack specified. In that case the Probing and DoS attacks are also differentiated by the next model.

The next model used in the series-ensemble is the RNN-LSTM model. This is a really good tool for the differentiation of various attacks and is used for exactly that. The Normal system vectors are already filtered out by the CNN-LSTM one step above and hence only the attacks remain to be sorted. RNN-LSTM is quite accurate with that but might fail for R2L(root to local) attacks. Hence it is given all the attack vectors as input(Probing and DoS excluded if CNN-LSTM is accurate), and it differentiates between them well enough. The drawback of the RNN-LSTM, which was the high false alarm rate, is also overcome by using this ensemble as the vectors from which it has to differentiate are almost definitely attack vectors(CNN-LSTM filters out Normal systems).

The final model in the ensemble is the MLSTM. This is the most niche model because it is trained for a very specific attack(R2L) as that is the only one left which still might not be accurately classified after the first 2 steps. The use of MLSTM gives better accuracy and efficiency in training the model as well as removes the need for dimensionality reduction to a certain degree. The flow of the project can be better understood with the diagram ie, Fig. 4.

As with any ML/DL model, one of the most important parts of the training testing process is the preparation and pre-processing of the data. Firstly the obtained data from the dataset is cleaned by removing the duplicates in it or by truncating the incomplete data entries etc. The data is then normalized and then fitted and scaled as per the requirements of the model.

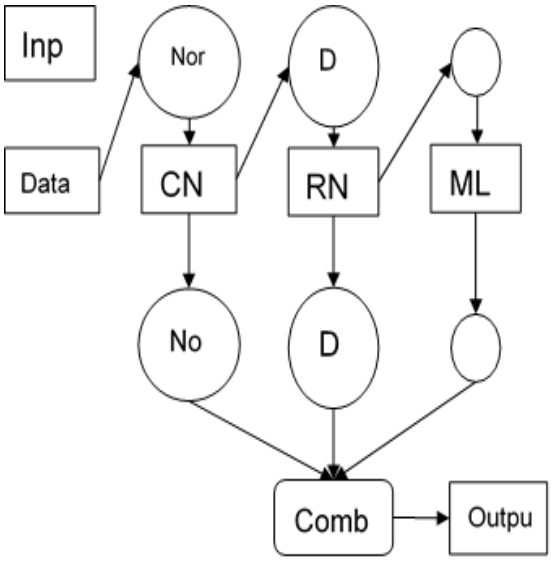

Fig. 4 Project Flow Diagram

In this system, as stated above, the KDD99 and NSL-KDD datasets have been used, which have 22 attack types in all. But based on their nature they are classified into 4 broad archetypes. The ideal case would be to run the multiclass classifier for all of the various 22 attack types included in the dataset but that would be too computationally exhaustive and hence is not feasible for the current scope of the proposed model.

D. Algorithm

Step 1: - Input the data to CNN-LSTM model

a) The convolution layer extracts features from input data.

b) The connected layers of CNN use data from convolution layer to create output.

c) Considering CNN to be a mathematical model M:h(X(0);θ). where can be input vector, and θ is weight of neuron connections.

d) X(l) neuron responses on the t-th layer, which is Wl*Hl*Dl cube.

e) X(l) is average over all spatial positions of X(l), i.e., a Dl-dimensional vector.

f)

$$Eq.1: -- x_d^{(l)} = (1/W_t \times$$

$$H_{wh} \nabla^{W_{t-1}} \quad \nabla^{H_{t-1}} \quad v^{(l)}$$

$$t \quad w=0 \quad h=0 \quad w,h,d$$

g) Use of ReLU activation function.

h) The output is further passed to LSTM. Step 2: - CNN-LSTM classifier working.

a) LSTM uses a sigmoid activation function for the forget gate and input gate.

b) The equations listed below are for forget gate, input gate and output gate respectively.

Eq. 2 : - $ff = f(ff[hf-1, ff] + ff)$ Eq. 3 : - $ff = f(ff[hf-1, ff] + ff)$ Eq. 4 : - $ff = f(ff[hf-1, ff] + ff)$

c) The extracted features of CNN are used to predict the different types of attacks.

Step 3: - Passing CNN-LSTM models output to RNN-LSTM.

a) The RNN-LSTM is provided with CNN-LSTM output with only attacks that are normal system integer filtered.

b) RNN-LSTM employs LSTM cells in RNN structure.

Step 4: - RNN-LSTM classifier working.

a) The RNN-LSTM works on all types of attacks and classifies them.

b) R2L attacks are not properly handled by this classifier.

Step 5: - Passing all remaining data including major part of R2L attack.

a) The MLSTM model classifies the R2L attack accurately.

Step 6: - End

IV. RESULTS AND DISCUSSION

The design of the ensemble can be said to be successful as it worked as intended and gave accurate results for all the classes. The main objective of this ensemble was to combine the good parts of the individual specific models and also try to cover up for the weaknesses of each of the models. Through the experimental results it can be said that this objective has been achieved. Comparing the individual performances of the models and them of the ensemble as a whole it can be said that the ensemble has put together all the benefits of its constituent models and has also made up for the weaknesses of each individual model. The performance metrics used for the evaluation of the models are Accuracy and FAR (False alarm rate).

CNN-LSTM

KDD99		
Accuracy	FAR	
0.999	0.058	Normal
0.941	0.002	DOS
0.948	0.019	Probing
0.414	0	U2R
0.258	0.001	R2L
Overall accuracy	0.933	

NSL-KDD		
Accuracy	FAR	
0.997	0.124	Normal
0.747	0.018	DOS
0.898	0.093	Probing
0.45	0.001	U2R
0.429	0.002	R2L
Overall accuracy	0.832	

Table 1: CNN-LSTM performance metrics

As can be seen in Table 1, the CNN-LSTM model gives high accuracy for binary classification on whether the system is normal or attacked, but fails for U2R and R2L attacks as well as distinguishing between various attack types for the NSL-KDD dataset.

RNN-LSTM-

KDD99		
Accuracy	FAR	
0.963	0.091	Normal
0.987	0.072	DOS
0.969	0.044	Probing
0.978	0.063	U2R
0.688	0.061	R2L
Overall accuracy	0.969	
NSL-KDD		
Accuracy	FAR	
0.924	0.121	Normal
0.981	0.083	DOS
0.977	0.132	Probing
0.961	0.052	U2R
0.582	0.07	R2L
Overall accuracy	0.942	

Table 2: RNN-LSTM performance metrics

Just like seen with the CNN-LSTM model, the results for the RNN-LSTM can also be seen as described in Table.2

MLSTM- As stated earlier, the training for MLSTM was done only for the R2L attacks and hence a separate parametric of the model was not taken.

Following are the results of the designed ensemble as a whole-

KDD99		
Accuracy	FAR	
0.999	0.058	Normal
0.987	0.002	DOS
0.969	0.019	Probing
0.978	0.063	U2R
0.991	0.022	R2L
Overall accuracy	0.993	
NSL-KDD		
Accuracy	FAR	
0.997	0.124	Normal
0.981	0.043	DOS
0.977	0.031	Probing
0.961	0.014	U2R
0.982	0.011	R2L
Overall accuracy	0.987	

Table 3: Ensemble performance metrics

From the results of Table 3, a much higher overall as well as class wise accuracy is obtained from the ensemble than from the individual models.

	FNR
KDD99	
Normal	0.001
DoS	0.059
Probing	0.052
U2R	0.586
R2L	0.742
Overall	0.067
	FNR
NSL-KDD	
Normal	0.003
DoS	0.253
Probing	0.102
U2R	0.55
R2L	0.571
Overall	0.168

Table 4: CNN-LSTM False negative

Another performance metric that was later checked was the false negative rate for each attack and model. This was essential to see what percentage of the attacks were labeled as either harmless or as some other attack. This metric should be as low as possible. The results of the same for CNN-LSTM can be seen in Table 4.

	FNR
KDD99	
Normal	0.001
DoS	0.013
Probing	0.031
U2R	0.022
R2L	0.009
Overall	0.007
	FNR
NSL-KDD	
Normal	0.003
DoS	0.019
Probing	0.023
U2R	0.039
R2L	0.018
Overall	0.013

Table 5: Ensemble False Negative

Similar results for the entire ensemble can be seen in Table 5. As can be seen, the high false negative rates for U2R and R2L are cut down significantly by using the ensemble and hence it is a better way for the

classification of these attacks.

This ensemble will be able to detect a wide range of attacks now without giving up any weakness towards a specific area as the other models will cover the weaknesses if one of them has any. The idea behind the making of this ensemble was hence successful.

The idea behind this ensemble was to improve upon the existing models which have a lot of weaknesses that they cannot make up for individually. When the models included in the ensemble are used in series they make up for each other's weak points and hence give an overall better result for the multiclass classification of the dataset. Consider the CNN-LSTM architecture which is a widely used model and one that is used in ensembles too. It is the best deep learning model for the binary classification (normal vs attack) of the dataset. The biggest problem it faces is that the accuracy for the different attack classes is dismal. This is a big problem when multiclass classification is wanted. Similarly, consider the RNN-LSTM architecture which is robust for multiclass classification of the attacks but the main problem is that it gives a high FAR(False Alarm Rate). When used in series after the CNN-LSTM architecture, it essentially filters out almost all of the Normal system cases hence drastically improving the FAR scores when using RNN-LSTM. This is the way the ensemble performs better than the existing models by using their strengths for good results and also covering for their weaknesses to improve accuracy even further.

V. CONCLUSION

From the results it can be concluded that using an ensemble model helps increase accuracy to a large extent. In both the datasets NSL-KDD and KDD99 model give accuracy and FAR for normal attacks and 4 types of different attacks. From the results it can be seen that the ensemble model performs better on both the datasets comparing CNN-LSTM and RNN-LSTM individually. The ensemble performs better than the existing models yielding a higher accuracy and a low FAR. But the trade-off for this is that the proposed model is definitely more computationally exhaustive than normal single models or traditional ensembles using simpler algorithms. The use of other datasets for training and testing purposes can also be seen as a future scope. But the biggest direction in which the proposed model can be taken in the future is trying to combine simpler algorithms with the proposed model to try and reduce the computational load but also try and maximize the performance metrics as in this ensemble.

Social Distancing Violation System YOLO version 3

Dr. Rekha Sharma, Kunal Pandey
Computer Engineering Department, Thakur College of Engineering & Technology, Mumbai
rekha.sharma@thakureducation.org, king1kunal@gmail.com

Abstract— **This paper focuses on solutions for proper social distancing in public places using real-time YOLO object detection in video footage and images. Our proposed object detection model achieved an average accuracy score of 94.75% at an inference speed of 38 FPS on video. This network guarantees inference speed capable of delivering real-time results without compromising accuracy, even in complex settings. The proposed social distancing method yields promising results even in some variable scenarios.**
The recent outbreak and rapid transmission of the COVID-19 pandemic has increased the need to adhere to social distancing norms and wear masks in public. According to the World Health Organization, people should keep at least 3 feet or 1 meter from each other in public places to maintain proper social distancing.

Keywords – Object Recognition Yolov3

I. INTRODUCTION

Since the COVID-19 pandemic swept the world, governments around the world have taken drastic but necessary steps to curb its spread. This completely brought normal daily life to a halt. Months into lockdown, communities are losing their composure as we see the curve flattening in some countries. Relevant authorities such as WHO have set specific guidelines to minimize people's exposure to the virus. Safety measures that people should follow include wearing a mask and keeping a distance of 3 feet, which is approximately 1 meter, from others.There are several countries in the world that have actually made mask- Since the COVID-19 pandemic swept the world, governments around the world have taken drastic but necessary steps to curb its spread. This completely brought normal daily life to a halt. Months into lockdown, communities are losing their composure as we see the curve flattening in some countries. Relevant authorities such as WHO have set specific guidelines to minimize people's exposure to the virus. Safety measures that people should follow include wearing a mask and keeping a distance of 3 feet, which is approximately 1 meter, from others.There are several countries in the world that have actually made mask-

II. SCOPE

Globally, about 5,21,78,723 people have died from COVID-19, and 4,444 have died of about 12,85,379. The most preventative measure required by WHO is to maintain social distancing from others to reduce the risk of transmission whenever they cough, sneeze or speak. During the pandemic, the only system is to maintain social distancing in public places. The mechanism used to monitor social distancing monitors whether people's area units are maintaining a safe distance from each other by analyzing real- time video streams from cameras. It is done through a detection tool.A framework primarily based on deep learning has been developed to use object detection and tracking modelsto help manage the surge in his COVID-19 cases within social distancing tools.
To visualize clusters in the live stream, each bounding box is color-coded to support assignment to teams. People's luck for similar cluster area units is represented by their colors as well. Video used as input for a project

III. PROBLEM STATEMENT

Social distancing is arguably the most reliable way to prevent the spread of infectious diseases. Existing systems do not have monitoring methods to maintain social distancing in public places such as malls, restaurants, streets, and educational institutions.
Existing systems used a sliding window algorithm (a deep learning algorithm) to detect human classes.
The recent events and rapid transmission of the COVID-19 pandemic have increased the importance of the general public to the need for social distancing. With this in mind, people should keep a minimum distance of 3 feet or 1 meter from each other in public places without deviating significantly from the International Health Organization guidelines on social distancing.
COVID-19 with In the fight, social distancing has proven to be an effective way to prevent the spread of disease. People are being asked to limit the ways they interact with each other and reduce the chances of spreading the virus through physical or close contact.

IV. LITERATURE REVIEW

Since late December 2019, following the surge of the COVID-19 pandemic, social distancing has been recognized as a credible practice to prevent transmission of the contagious virus, and on January 23, 2020, Selected as standard practice (B. News, 2020). Between 2,000 and 4,000 new confirmed cases were reported daily in the first week of February 2020, with an exceptional increase in cases within a month. After that, there were first signs of remission for 5 consecutive days until 23 March 2020, with no new confirmed cases (N.H.C. People's Republic of China, 2020). This is due to social distancing practices introduced in China and most recently he has been adopted globally to control COVID-19. Ainsley et al. (2020) examined the association between localeconomic conditions and the severity of social distancing.
The study found that moderate exercise can prevent large

outbreaks. So far, many countries have adopted technology-based solutions to overcome pandemic losses (Punn, Sonbhadra & Agarwal, 2020a). Several developed countries are using GPS technology to monitor the movements of infected or suspected persons. Nguyen et al. (2020) are various new technologies that could play an important role in several practical social distancing scenarios such as Wi-Fi, Bluetooth, smartphones, GPS, positioning (localization), computer vision and deep learning. Provides an overview of the technology.

So far, researchers have done considerable work for detection (Iqbal, Ahmad, Bin, Khan & Rodrigues, 2020; Patrick et al., 2020; Yash Chaudhary & Mehta, 2020). Some researchers are using the internet to provide a smart health system for the pandemic. for medical use (Chakraborty, 2021; Chakraborty et al., 2021). Prem et al. (2020) examined the impact of social distancing on the spread of COVID-19 outbreaks. The study concluded that early and immediate practice of social distancing can gradually reduce the peak of virus attacks. An essential but economically unpleasant move to flatten the infection curve. In Adolph, Amano, Bang-Jensen, Fullman, and Wilkerson (2020), Adolph et al.

Highlighted the state of the United States during the pandemic. Lack of public support from decision makers meant that it was not implemented in the early stages, damaging public health. However, social distancing impacted economic productivity. Still, many scholars were looking for alternatives to overcome the loss.

Researchers use surveillance video and computer vision, machine learning, and deep learning-based approaches to provide effective solutions for measuring social distancing. Pan et al.

(2020b) proposed a framework for recognizing people using the YOLOv3 model and a deepsort approach that uses bounding boxesand assigned identity information to track recognized people. They used the Open Image Data Set (OID) repository, a front view data set. The author also compared the results with faster RCNN and SSD. Ramadas et al. (2020) developed an autonomous drone-based model for social distancing surveillance.

They trained a YOLOv3 model using a custom data set. The data set consists of front and side view images of a limited number of individuals. Work is also expanding to include monitoring face masks. Drone cameras and her YOLOv3 algorithm help detect social distancing and monitor people wearing masks in public from the side or front. Pouw, Toschi, van Schadewijk, and Corbetta (2020) proposed an efficient graph-based surveillance framework for physical distancing and crowd management.

Sathyamoorthy, Patel, Savle, Paul, and Manocha (2020) performed human detection in crowded situations. This model is designed for those who do not adhere to social distancing restrictions. H. A distance of 6 feet between them. The authors used a mobile his robot equipped with an RGB-D camera and a 2D lidar to navigate through crowds without colliding.

From the literature, we concluded that researchers had put in a significant amount of work to monitor social distancing in public places. However, most of the work focuses on front or side camera perspectives. Therefore, this work presents a top-down social distancing framework that provides a better view and overcomes the occlusion problem, thereby playing an important role in social distancing surveillance that calculates the distance between people. fulfill.

V. RESEARCH WORK

Problem Analysis--COVID-19 is a virus that is transmitted by small droplets between people in close contact when talking, sneezing or coughing, and most commonly by inhalation. The pandemic is still ongoing, causing acute respiratory infections in humans and causing many deaths. The risk of spreading COVID-19 can be eliminated by avoiding physical person-to-person contact.

Requirement Analysis--For this system, the basic requirement is an Eclipse IDE with Python and pip installed.

Project output must include a camera or video to display the correct output.

Technical Research--This project proposes a real-time AI platform for human detection and social distancing classification based on infrared cameras. YOLOv3 is proposed in this work for object recognition.is a simple neural network architecture suitable for low-cost embedded devices.

The proposed model is a good option compared to other real-time detection approaches. The

algorithm is also implemented to monitor social distancing from a bird's eye view.The proposed approach is applied to videos recorded by infrared cameras for human detection and social distancing classification.

VI. USE CASE

The system can be used in shopping malls, theaters, concerts, and many other places where social distancing protocols must be followed. Social distancing is arguably the most reliable way to prevent the spread of infectious diseases. Existing systems do not have monitoring methods to maintain social distancing in public places such as malls, restaurants, streets, and educational institutions.

Easily implement a social distancing system using existing cameras already installed in public places. This helps the people of the country.

VII. ARCHITECTURE

Our study performs real-time human identification to track social distancing norms and real-time facial recognition to perform in multiple environments,

including crowded and poorly lit complex environments. We propose a solution to track the use of face masks. The techniques used to formulate this solution are described in this section.

A. Dataset

The dataset used contained 7,959 images, including specific images from the WIDER- FACE and MAFA datasets, and 2 images of masked and unmasked faces. Annotated with faces belonging to one class. Third graders were added manually by annotating each image with an individual person. The bounding box coordinates and labels for each image were then extracted from the XML file and normalized with respect to image height and width. After checking for incorrect annotations, 6,120 images were used for training and 1,839 images were set aside for validation. For social distancing purposes, I created my own dataset to test the algorithm and also tested some images on the web.

B. YOLOv3 Architecture and Functioning

Bochkovsky et al. We have proposed 2020 YOLOv3 and made some significant changes from its predecessor, resulting in significant improvements in both speed and accuracy. We chose YOLOv3 as our object detector of choice because it is very fast, easy to train, robust and stable, and gives promising results even for small objects. For an input image/frame he recognizes objects belonging to three classes: unmasked faces, masked faces and people. This effectively means that the same model is used for both person detection to track social distancing and masked face detection to monitor face masks. This greatly improves overall efficiency and simplicity.

VIII. Algorithm of project:

Tracking Social Distancing:

The solution proposed in our project consists of two steps: calibration and testing. Calibration has two steps:

The user must enter the focal length and sensor dimensions of the camera to be used.

The user must then place the two of them at the minimum respectable social distance (hereafter referred to as the standard social distance).

This has the advantage that you can actually choose the social distancing you want to maintain, according to the specific guidelines the authorities want to adhere to. for example.

: WHO guidelines say the recommended level of social distancing is at least 3 feet [1], while CDC guidelines recommend a minimum of 6 feet. The social distance between two people is evaluated only for the first calibration, and there is no need to provide absolute distance to the model.

This social distancing model uses the principle that the camera lens is essentially convex and the image is essentially captured on the screen. For this model, as already mentioned, we need the focal length and sensor dimensions.

The focal length of a lens is the distance from the optical center of the lens to the focal point. In optics and photography, the focal length is measured in millimeters (mm). The longer the focal length, the higher the magnification, but the narrower the angle of view.

An image sensor is a device in the camera hardware that uses light to capture information and transform the view into an image. The sensor basically acts as a screen onto which every pixel of the image is mapped.

The larger the imaged pixels, the better the image quality.

Field width. H. is the observed width of the real object and w is the measured distance from the camera bed to the object.

Make the person whose distance you want to measure look like this. Person 1 and Person 2 standing at positions (x1,y1) and (x2,y2) in a given image.

To find the depth of an object in a photo, we can get the following from Equation 2:

d = actual height of object (mm) × focal length (mm) / height of object on sensor (mm)

Hey, in the image, object height is only in pixels (px.), so You can use the formula to get the height of the object in the image on the sensor in millimeters. Here the actual human height is assumed to be 1.6 m in this model as the average human height is estimated at 1.6 m for him.

Object height on sensor (mm) = object height in image (px.) × pixel size

where px is the measurement in pixels. A person's depth is therefore equal to the distance they are standing from the camera. Let d1 and d2 denote her distance from the two cameras. To measure the approximate distance between these two of hers in the image, the x-coordinate difference is taken as the social distance width. Social distance width (mm)=(x1−x2)×pixel size

So the actual field width can be calculated by equation (1). 2

w = sensor width x social distance width (mm) / focal length (mm)

Person 1 is at (0, d1) and Person 2 is at (w, d2) Social distance = √ (w−0)^2+(d2−d1)^2

The first calculated social distance in calibration mode is used as the reference social distance. In test mode, the above formula is used to calculate his 2 social his distance.If the calculated social distance is less than the reference social distance, the pair is identified as an offender.

IX. TECHNOLOGY SELECTION:

A. Regression Based Object Detectors(YOLO)

Regression-based object detectors such as You Only Look Once (YOLO) [5] and Single Shot Detector (SSD) Multibox have been shown to be significantly faster than region-based object detectors. It has been. Of the two, YOLO has long been the most popular choice among other similar object detectors. It takes the whole thing as input at once. This makes it significantly faster than other detectors. The model pipeline expects an RGB image divided into grid cells S×S.

Each grid cell is responsible for predicting the B bounding box. Five values are predicted for each bounding box: x, y, w, h, and c. The coordinates of the center of the bounding box for the grid cell are x,y, and the width and height of the bounding box are w and h. The confidence value for an object that exists within the bounding box is c. For class probabilities C, the output of the object detector is a shape tensor.

(S×S×(B×5+C))

B. Detecting Masked Face in the Wild Using LLE CNNs

In, the authors suggested using not only the MAFA dataset, but also the Locally Linear Embedding (LLE) CNN. This model classifies faces as being covered by natural occlusion, such as hands, and other occlusions, such as various types of face masks. This was a breakthrough model in which he outperformed all other models by achieving an average accuracy (AP) of 76.4% on the MAFA [3] face recognition test set.

C. YOLOv3 and Deepsort to Track Individuals in Surveillance Footage

Here, we implemented YOLOv3 object detection and deepsort object tracking algorithms for tracking people in surveillance video. Therefore, each person at position (x,y) maps to the 3D feature space (x,y,d). where d is the person's apparent depth to the camera. The L2 norm is calculated with two of her. Next, the paired person proximity thresholds are dynamically updated based on the person's spatial position relative to a specific range of pixels. Note that the threshold range is set in pixels between (90, 170). In other words, depending on the camera position, there is no tolerance for calibration.

D. Monitoring Face Masks and Social Distancing on Surveillance Footage

Khandelwal et al. focuses on using computer vision-based object recognition models to monitor masked faces and social distancing violations using surveillance camera footage. This solution is specially designed for factoryconstruction. A two-step solution was implemented to detect masked faces. The image is first passed to a facial recognition model using the MobileNetV2 model.

The resulting faces are classified as masked or unmasked using a binary mask classifier. The model was trained on the original dataset. For social distancing, the author uses her SSD for person class detection. The authors implemented his procedure of selecting four points forming a quadrilateral and performing a perspective transformation to allow him to measure a given distance on one plane. To compare these distances against a threshold, you must specify the absolute distance between the two points.

This is feasible in factories and enclosed spaces, but expensive and time consuming in public places and roads. It should be noted that these two models are separate entities and no integrated solution is presented.

X. IMPLEMENTATION

A detailed description of the various experiments performed in this work is presented in this section. This includes video sequences recorded from the floor plan. Data collection is divided into 70% and 30% training and testing. Movement of people throughout the scene is unrestricted. People in the scene move freely. Their visual appearance is affected by radial distance and camera position. From the sample images, we can see that the visual appearance of humans is not identical and that the subjects in the dataset differ in height, pose, and scale.

I used OpenCV for the implementation. The experimental results are divided into two subsections. First, we describe the test results of the pretrained model, and the second subsection describes the results of the recognition model after applying transfer learning and training to the overhead data set. For comparison, test the model using the same video sequence. This section also provides a model performance evaluation along with a comparison with various deep learning models.

Transfer learning techniques are used to improve the accuracy of the detection model.

Using the overhead data set, the model is trained on another 500 sample frames. To train the model, the epoch size is set to 40 and the stack size is set to 64. A new layer is obtained after the model is trained. This is supplemented with more pre-trained models.

In this work, we use deep learning models and an overhead perspective to evaluate the performance of social distancing monitoring frameworks using various quantitative metrics. Precision, Recall, and Accuracy are used to evaluate the efficiency of the recognition model. Furthermore, the findings are also compared with other deep learning models. We used tp true positives, fp false positives, tn true negatives, and fn false negatives to estimate accuracy, recall, and precision. We can analyze that the overall performance of the recognition model improves when the model is further trained on the top view dataset.

XI. CONCLUSION

Create a well-integrated social distancing violation detection system with object detection in YOLO v3. Using the coordinates obtained by perceiving the Person class, we use the principles of optics to estimate the relative distance between her and her two. After rigorous testing, we found the Model to provide fairly accurate results over a wide field of view. This is an essential criterion for use in public places.

With no additional time-consuming calculations or image distortion, this lightweight model is easy to calibrate and works well in real-time with high FPS and excellent accuracy.

In this project, we have developed a program that

recognizes people who are less than 1 meter taller than her and indicates that they are violating social distancing rules with a RED bounding box. Otherwise, a green bounding box means social distancing is maintained.

ACKNOWLEDGMENT

This paper on 'Social Distancing Violation System YOLO version 3' is a result of the motivation and co-operation by my guide Dr Rekha Sharma and teacher Dr. Sheetal Rathi.

Smart Home Application using AR and IOT

Prof. Ajay Talele, Aditya Mhaske, Mokshit Oswal, Sumit Mulhar, Shivdas Nakil, Aditya Nawale
Department of Multidisciplinary Engineering, Vishwakarma Institute of Technology, Pune

Abstract— **AR technology reduces design time and energy use. Utilizing AR technology ingeniously can address persistent design issues. The current cycle of the home design business, significant investment, and emphasis on enhanc- ing human-computer interaction shows the level of living space design. We combine the most recent AR techniques in this subject using our interdiscipli- nary knowledge. In this paper, we have presented our work on an IOT- integrated AR framework that is applied to the smart home. An AR-based UI is designed for the end user using a Unity Hub. It is a system that looks for a pre- defined target picture. Scanning target images provides users with access to controls for items such as sensors, fans, light bulbs, etc., via a 3D framework. A target image is chosen in advance so that whenever the Android application scans it, an AR control panel will be presented to the user. Predefined buttons on AR control panels will serve as controllers. Also, data received from the sen- sors are visualized on these AR panels. In the IOT part, NodeMCU is used to provide a cloud server. It will read data present on the cloud sent by the AR control panel or the sensors connected to NodeMCU. NodeMCU will react to that information by operating the devices connected to it.**

I. INTRODUCTION

Intelligent devices and today's smart lifestyle have created entirely new opportunities for human-machine connection. AR is among such technologies that have created human-machine interaction. The term "augmented reality," or "AR," refers to a tech- nology that superimposes digital data over the user's perception of the outside world. Numerous devices, including smartphones, tablets, and dedicated AR headsets, can be used to experience it. AR technology is ideally suited for home automation because it enables consumers to engage with digital information in a more natural and intuitive way. In-home automation, AR can be used to create a more user-friendly interface for controlling connected devices. For example, it can be used to display a virtual repre- sentation of the user's home, with the ability to turn lights on and off, adjust the tem- perature, and check the status of security cameras by simply tapping on the virtualrepresentation of the device. The deeper the research goes the more creativity and innovation flow out. [1] Discusses a method where a sensor is used to determine if a person is in the home or not and to operate the appliances accordingly. Additionally, the solution displays a message that details the homeowner's typical energy consump- tion. Additionally, it checks the gas level in the gas cylinder; if it reaches a certain level, it automatically books the gas and notifies the home's owner with a reference number. [2] mentions technologies, specifically the Internet of Things, Artificial Intel- ligence, and Augmented Reality are becoming increasingly popular and are being experimented with by both large corporations and young engineers. The talk about how remote control of these components through voice commands using a smartphone is being discussed and studied. In the manufacturing sector, augmented reality (AR) and the internet of things (IoT) can streamline automation activities and enhance monitoring [3]. It's interesting to observe how improvements in computer vision, mobile computing, and tablet screens are rekindling interest in augmented reality and how it might simplify difficult automation chores by offering lifelike real- time animation for monitoring and automation on the Internet of Things. Also, vari- ous actions can be performed by utilizing augmented reality through image pro- cessing, allowing for objects to be recognized and matched to a database. There are systems that implement [4] object recognition and provide an AR control panel with preconfigured options for device control and sensor data visualization. Such a system must be designed to be scalable and customizable, and have minimized latency from object detection to device control. Users could find it simpler to comprehend and operate the system as a result. AR can also be used to enhance the visual feedback provided by connected devices. For example, a user could use AR to view a virtual representation of their home, with the ability to see the status of lights and appliances in real-time, and even get visual alerts when something needs attention. The system must be as comfortable as possible for the user. The Internet of Things (IoT) is the network of connected objects that use the internet to carry out logical operations, store data on the cloud, and transmit data. IoT includes machine-to-machine (M2M) communication as a component. Deploying Smart Homes, which are characterized by automation, multifunctionality, flexibility, interactivity, and efficiency is currently the key trend in IoT. IoT is important in the fourth industrial revolution, and smart home systems, also known as home automation systems, are gaining popularity as a way to enhance comfort and quality of life. The system described in [5] [6] is an IoT-based, low-cost smart home automation system that uses an ESP32 Wi-Fi module to monitor the status of household equipment. The recent development of the Internet of Things (IoT) and how it has affected the emergence of Smart Homes (SH) and Smart Cities (SC) is noticeable. A long-held goal for many years, smart homes are a key component of smart cities. The research study on SH and IoT technologies yielded seven distinct requirement recommendations for creating SH, which are defined here by [7]. The unique quality of the SH building blocks is used to categorize these recommendations. Modern microcontroller units (MCUs) play a crucial role in home automation by providing the necessary processing power and connectivity for devices to communicate with each other and with a central hub or smartphone app. [8] Demonstrate and analyze the control of home appliances using AR and IoT through a Wi-Fi-based

microcontroller. It also shows how the sys- tem works with multiple devices and how AR and IoT are complementary to each other. Performance measures such as transmission time and Received Signal Strength Indicator (RSSI) are used to evaluate the performance of the system. MCUs are often used in devices such as smart thermostats, smart lights, and smart door locks to control and monitor their functions. The Internet of Things is a system of interconnected gadgets that can collect and distribute data (IoT). Through a smartphone app or central hub, IoT devices like smart speakers, security cameras, and appliances can be remotely controlled and monitored in the context of home automation. Together, MCUs and IoT enable a wide range of home automation functionality, such as remote control of lighting and temperature, automated scheduling, and even integration with voice assistants like Amazon Alexa or Google Assistant. This allows for greater con- venience, energy efficiency, and security in the home. [9] talks about neural fuzzy system for controlling home appliances, with the goal of providing efficient and con- venient integration and inter-operation among appliances in households. The system uses linguistic rules processed by a fuzzy system and adapts itself to the occupants' lifestyle. The implementation of the controller can be demonstrated using the MATLAB/SIMULINK development environment, which includes functions for hardware and internet access. The system can also be applied to control non-time- critical processes. [10] suggests utilizing an app called HoloFlows for smart glasses to use augmented reality (AR) to streamline the modeling configuration of IoT work- flows. By simply connecting two or more physical IoT devices via virtual wires, this program enables end users to explore their surrounding IoT environment and model many types of fundamental processes including sensors and actuators. The under- standing of physical settings and relationships between IoT devices is made easier by AR technology, which also offers a fresh, more logical way to model operations in the cyber-physical world. Several IoT workflows from the smart home domain are used to demonstrate the HoloFlows app. [11] [12] suggests a smart appliance controller that effectively controls aftermarket home products using augmented reality (AR), MQTT, and other platforms. The suggested system is assessed using a number of tests and performance measures, and it uses mobile AR, IoT, and infrared (IR) signals to manage home appliances. The outcomes demonstrate how quickly MQTT can be used to construct a home automation system. The paper also introduces a Raspberry Pi and IoT-based Smart Home Automation system. The system employs computer vision algorithms on the Raspberry Pi to combine cameras and motion sensors into a web application and manage home appliances. Unity is used to create augmented reality (AR) applications. Unity provides a range of tools and features for creating AR experiences, including a visual editor for build- ing 3D scenes, a physics engine for simulating real-world interactions, and a scripting API for programming custom logic. When creating an AR application in Unity, de- velopers typically use the engine's built-in support for AR platforms such as ARKit and ARCore, which provide the necessary APIs for accessing the device's camera, sensors, and display. Developers can also use Unity's support for Vuforia, an AR platform that allows for image and object recognition and tracking. Once the AR ex- perience is built, Unity can be used to export it to various platforms, including iOS Android, and Windows. This allows developers to create AR applications that can run on a wide range of devices, including smartphones, tablets, and head-mounted dis- plays. A smart home application using augmented reality and the Internet of Things would allow for the overlay of virtual information onto the user's physical environ- ment, enhancing their interaction with connected devices. Overall, the integration of AR and IoT in a smart home application has the potential to improve the user experi- ence and make interacting with connected devices more intuitive and seamless.

At last, we have to look for user convenience. [13] [14] Home monitoring and au- tomation should make comfortable living conditions within a home, such as thermal comfort related to temperature and humidity, visual comfort related to colors and light, and hygienic comfort related to air quality. These things are to be considered while making such projects. [15] [16] [17] focuses on identifying behavioral changes that might be connected to health occurrences using sensor data gathered from smart home environments. To find changes in routine behavior and health events, the data is examined using behavior change detection and activity recognition. The study also addresses the issue of class imbalance in deep learning for data from smart homes, offering a data-level perspective with a temporal window strategy to handle the une- ven human activity and enhance classification performance. Last but not least, the research proposes a strategy that delays recognition to incorporate sensor data that arrives after the choice is taken, employing multiple incremental fuzzy temporal win- dows to extract features and obtain better outcomes than the real-time approach in dementia diagnosis. [18] [19] Discusses about providing an economical, low-cost platform for energy monitoring and smart home control (AR). The objective is to raise awareness of energy use while developing innovative ways for individuals with impairments to interact. The system uses augmented reality to display the real-time energy consumption of electrical components, enabling users to interact with the sys- tem and access saved data for energy monitoring. The report also discusses how aug- mented reality, voice control, and a web server are used to let the elderly and partially disabled control household appliances remotely, thereby lowering expenses and the demand for caretakers as the country's aging population grows.

Therefore, proper research is necessary to study the problem from different per- spectives. [20] gives a summary of earlier studies on smart homes, including the tools for regulating and monitoring the indoor environment. It discusses the components that make up smart homes, including sensors, multimedia devices, communication protocols, and systems, and teaches how to employ specialized algorithms drawn from a variety of subjects in the context of smart homes. Additionally, it offers rec- ommendations for further study into the creation of useful and sustainable smart homes.

As a result, we have made an effort to create a project that will implement AR with IOT. Lightbulbs and motors are among the pieces of machinery that will be controlled by an AR interface. Additionally, data from the DHT11 sensor will be shown on an AR interface. Two Android applications were made using Unity, one to display data and the other to serve as a controller. Blynk is used to generate APIs for reading and writing data and virtual buttons to send instructions for which they are programmed. Vuforia is also used to use AR tools in Unity. The image target which will be scanned by the android application is stored in the Vuforia database. The license key for build- ing applications in Unity is also received from Vuforia. NodeMCU provides built-in support for Wi-Fi connectivity. It is relatively inexpensive, easy to use, and has a strong community of developers and users. So, it is used to control the device remote- ly.

II . PROBLEM STATEMENT

The goal is to develop a software program that will enable users to remotely monitor and operate devices. At the conclusion, we will show the DHT11 readings on an AR interface in an Android application. We will also use a similar AR interface to operate a DC motor and light bulb. The project's overarching objective is to improve users' experiences of living in their homes by making them more practical, effective, and secure.

III Proposed System

III. 1- Hardware Components

4-Relay Module, NodeMCU, Light bulb (9W), Breadboard, Jumper wires, DC motor, DHT11 sensor, 9V battery.

Device Description:

1. Relay Module: A relay module is an electrical switch that is activated by an elec- tric current. It is often used to control a high-voltage circuit with a low-voltage sig- nal, such as a microcontroller or a switch. The module typically consists of a relay, a diode, and a transistor or other driver circuit. The relay can be controlled by ap- plying a voltage to the input pins, which causes the relay's internal contacts to switch, thereby turning the high-voltage circuit on or off.
2. Node MCU: NodeMCU is an open-source development board that is based on the ESP8266 microcontroller. It includes on-board Wi-Fi, which allows it to connect to the internet and other devices wirelessly. The board also has a micro-USB port for power and programming, as well as a number of GPIO pins for connecting to sen- sors and other peripherals. NodeMCU can be programmed using the Lua scripting language, as well as the Arduino IDE, which allows for easy access to the board's capabilities. It is commonly used for Internet of Things(IoT) projects and home au- tomation.
3. DHT 11: The DHT11 is a basic, low-cost digital temperature and humidity sensor. It uses a capacitive humidity sensor and a thermistor to measure the surrounding air, and sends digital signals on a single data pin to a microcontroller. The DHT11 sensor is made of two parts, a capacitive humidity sensor, and a thermistor. The DHT11 is a commonly used sensor for temperature and humidity measurements in various applications such as home automation, weather stations and HVAC sys- tems. The sensor has a range of 20-90% for humidity and 0-50°C for temperature with an accuracy of ±5% for humidity and ±2°C for temperature.

III.2 Software

Blynk Cloud, Unity Hub, Vuforia, Arduino IDE, Microsoft Visual Studio.

Software Description:

1. Blynk Cloud: Blynk is a cloud-based platform that allows users to easily connect and control IoT devices. It provides a mobile app and a web-based dashboard that can be used to create and customize user interfaces for controlling devices, as well as a set of APIs and libraries for connecting devices to the Blynk cloud. The Blynk app allows users to create virtual buttons, sliders, graphs, and other widgets that can be used to control devices or display data. The Blynk libraries can be used to connect a variety of microcontrollers, such as the Arduino, ESP8266, and Raspber- ry Pi, to the Blynk cloud, allowing devices to be controlled and monitored remote- ly.
2. Unity Hub: Unity Hub is a management tool for Unity, a cross-platform game en- gine used to develop video games, simulations, and other interactive 3D, 2D, VR and AR content. Unity Hub allows you to manage and organize your Unity pro- jects, as well as easily install and manage different versions of the Unity Editor. With Unity Hub, you can easily switch between different Unity versions, and have multiple versions of Unity editor installed on the same machine. It also allows to easily import and manage your Unity assets and packages, and access the Unity documentation and learning resources. It also has a feature of creating and manag- ing multiple Unity Projects in one place, making it easy to switch between different projects or collaborate with other team members.
3. Vuforia: Vuforia is a software platform for creating augmented reality (AR) expe- riences. It allows developers to create AR applications that overlay digital content, such as 3D models, on the real world using a device's camera. Vuforia uses com- puter vision technology to detect and track specific "image targets" such as QR codes, images or even 3D objects, and then overlays digital content on top of those targets. Vuforia offers a range of features including support for multiple platforms, image and object recognition, 3D model rendering, and multiple tracking capabili- ties. It also has a feature of VuMark, which is a customizable, printable marker that can be used to trigger AR experiences.

The proposed system includes the implementation of AR and IOT in home automa- tion. We have developed an android application using Unity software to put AR inter- face in the front end. The device camera is media for

human and machine interac- tions. NodeMCU is used to launch a cloud server. It is interfaced with various potential home appliances which can be controlled. In our case it is light bulb and a DC motor. Also it has job to take real time information from sensors, in our case it is DHT11 sensor. This system shows bi-directional communication between each other. NodeMCU will be sending signal to operate devices while it will also be receiving real time data from sensors. The devices can be controlled by deploying the cloud server over the internet. This will give remote access to those devices and can be op- erated in real time wirelessly.

IV IMPLEMENTATION

The implementation can be divided into two sections IOT part and the AR application part.

IV.1 IoT implementation

In IoT, first, we have created blynk project with ESP8266 as a board and connection type Wi-Fi. In the blynk project virtual buttons are created and configured. These virtual buttons will act as switches. Virtual buttons V0, V1, V2, V3 are created. Fur- ther in the hardware part, we have integrated a Light bulb (9W) and motor with NodeMCU via relay. Relay is used so we can control high voltage circuits of bulb and motor via low voltage of NodeMCU.
Pin connections from Node MCU to 4-relay module: D1 pin connected to INT 4 pin.
D2 pin connected to INT 3 pin. GND pin connected to GND Vin pin connected to VCC

Pin connections from Node MCU to DHT11: D3 pin connected to data pin(D)
3V3 pin connected to Vcc pin GND pin connected to GND pin

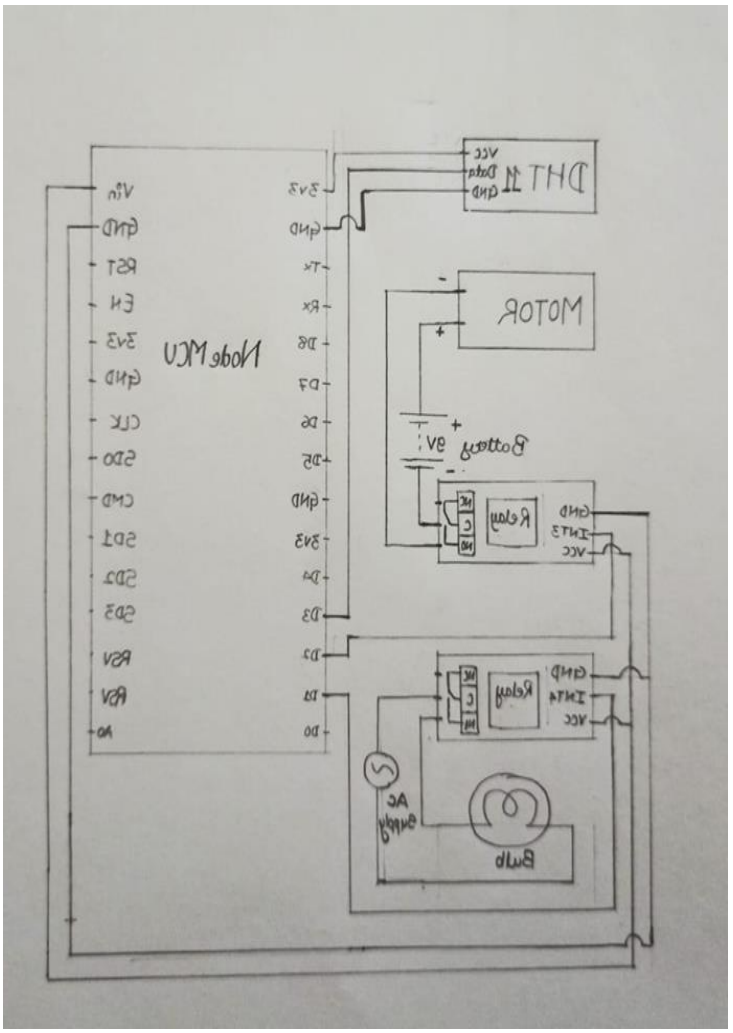

Fig. 1. Circuit diagram

Both the light bulb and motor are connected to a high voltage circuit via a relay in normally open condition. DC motor is provided the power using a 9V battery. On other hand, the Light bulb is connected to an external AC source. V0 and V1 are the virtual buttons assigned for the motor and bulb respectively. These buttons will be assigned APIs to control the respective devices. API format:
https://{server_address}/external/api/update?token={token}&{pin}={value}. This API is used to update the datastream value. V2 and V3 are the virtual buttons assigned for humidity and temperature readings respectively. These buttons will be assigned APIs to read the data sent by the DHT11 sensor. API format: https://blynk.cloud/external/api/get?token={token}_&{pin}. This API is used to get the datastream value.
At last, we created logic in Arduino IDE to launch the Blynk server and control the devices over the internet via APIs.

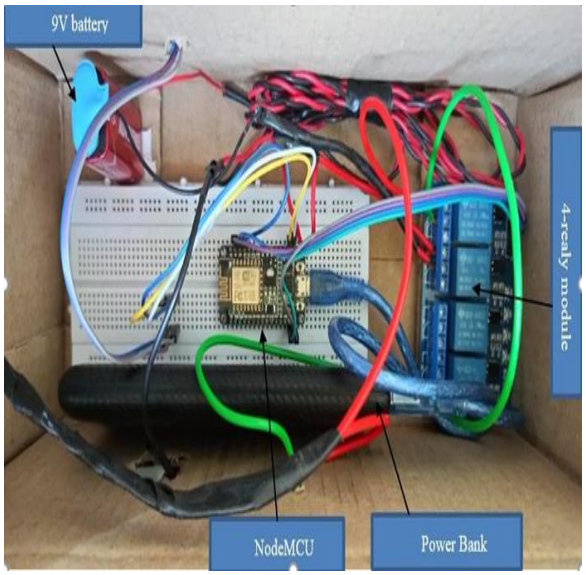

Fig. 2. Hardware Setup

Fig. 3. Blynk Console Dashboard

Fig.2. shows the hardware setup of the project. A 9V battery provides power to the motor. The light bulb receives power from an external AC source. Both light bulb and motor are connected to their respective power source via a relay so that they can be manipulated using a low voltage circuit to which NodeMCU is connected. NodeMCU is programmed with the concerned code priory and is provided with pow- er via a power bank.
Fig.3. shows the blynk dashboard. We can see the configured buttons of our project here.

IV.2 AR implementation

The first step is to integrate the Vuforia engine into Unity so that we may add aug- mented reality functionality to our mobile application. The target image will be added to the Unity project. We will need to create a database in Vuforia for that. The image of our choosing is included in the database, which is subsequently imported into Unity. We will go on to construct an AR interface utilizing various Unity technologies. The logic to each button is added by the C# script. The C# script editing process takes place in Microsoft Visual Studio. Similarly, another unity project is created with the same target image to display readings of DHT11 on the AR interface. There is a start button in this application which is a virtual button. This button is virtual so one must hover over the button so that it can be clicked. Upon clicking, the AR interface shows the reading of temperature and humidity. The display will show a reading of the moment when the button is clicked. In the end, both unity projects are built in an android application. These applications when launched will open the device camera. Whenev- er the camera will capture an image target the screen will display the AR interface. Fig.4. Shows the image target that is used in the project. Vuforia rates each image in the database out of 5 stars. If the image meets the Vuforia standards the more the rating image gets the more easily it is identified by the device. The image used in this project has a 5-star rating.

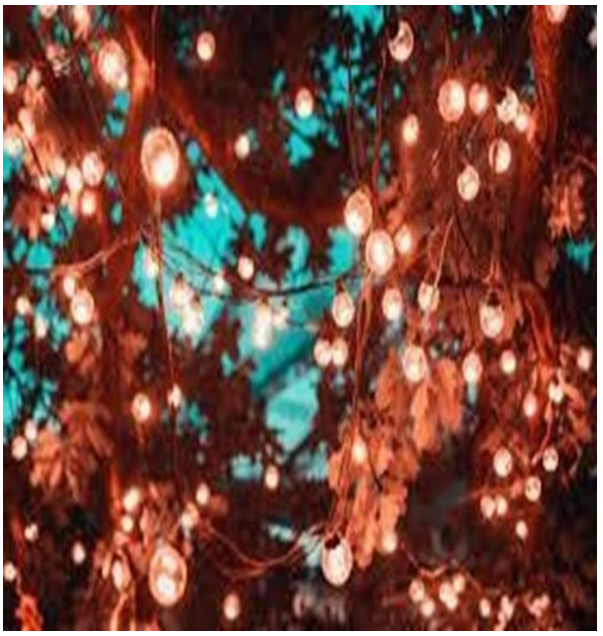

Fig. 4. Image Target

V RESULTS

At the end of the project, we successfully built two AR applications. Fig.5. and Fig.6. shows the AR display. In the figure, we can see the reading of temperature and humidity received from the DHT11 sensor. The data received from the sensor is suc- cessfully shown whenever the virtual button ―start‖ is clicked. Fig.7. shows the AR controller interface. It is equipped with ON/OFF buttons for light and motor. Themotor and bulb successfully respond to the instruction but the latency varies. Fig.8. shows the outer section of the model. It is a cuboidal box. We have a DHT11 sensor and motor attached at the long side of the box while the bulb is on the short side of the box

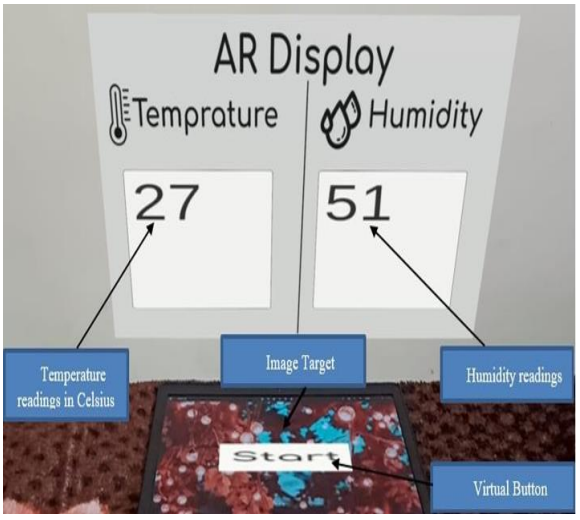

Fig. 6. AR Display showing readings-2

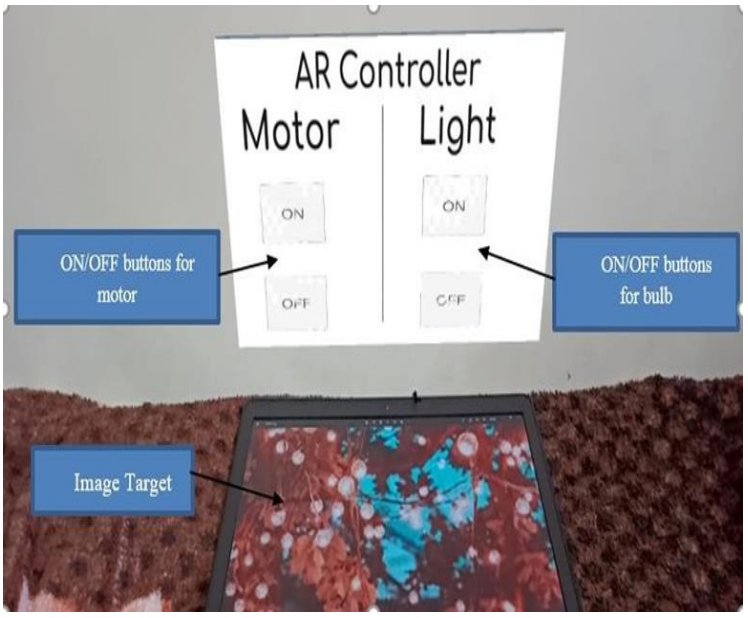

Fig. 7. AR controller

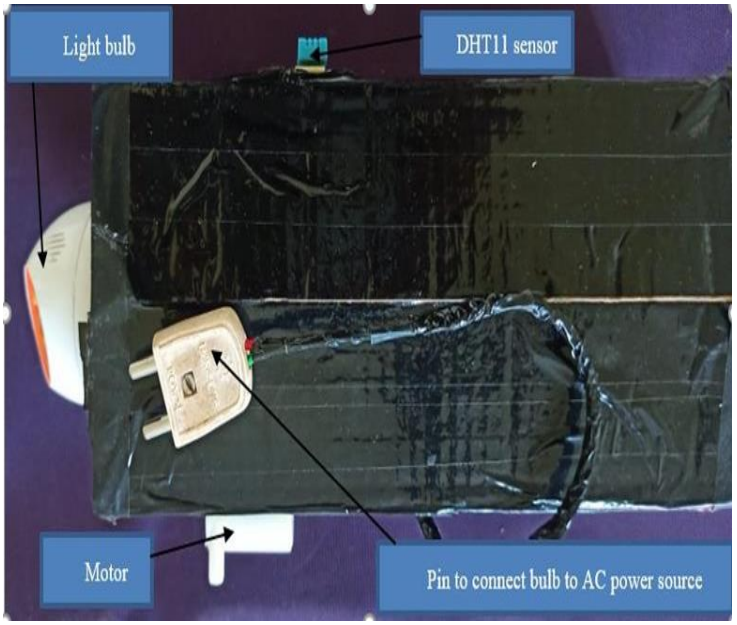

Fig. 8. Outer Section of Model

VI Conclusion

This project includes the successful implementation of AR and IoT for smart homes. The advantage of this system is that it is compact and gives an enhanced user experi- ence. AR provides visual information about the status of devices here it's the tem- perature and humidity of a room. This can make it easier for users to interact with these IOT-enabled devices. There is increased automation and easy integration of smart devices because IOT-enabled devices can easily communicate with each other.

Future scope:

This project has vast potential in the future. Like the use of IOT to gather data on energy usage and consumption, which can be used to optimize energy efficiency and reduce costs. The integration of voice assistants, such as Amazon's Alexa or Google Assistant, to control devices and perform tasks. The use of machine learning algo- rithms to improve the performance of the system and adapt to the user's preferences and habits. The integration of security features such as motion detection, facial recog- nition, and live streaming. The integration of other smart devices and systems, such as smart locks, security cameras, and smart appliances.

It is worth noting that this is not an exhaustive list and the scope of the project will depend on the specific goals and requirements of the project.

Acknowledgement:

The authors would like to express their sincere gratitude to Prof. Ajay Talele for their invaluable support and guidance throughout the research and writing process. Finally, the authors would like to thank their families and friends for their unwavering support and understanding during the time spent completing this research.

Abstract— **Fraud detection is the process of identifying and preventing fraudulent activities. It helps banks and customers by protecting their personal and financial information, reducing loan default risk, and improving customer retention. Fraud detection techniques include data analysis, machine learning, and biometrics to identify and stop fraudulent activities before they cause harm. Now there are many ways for a person to commit fraud actions hence detection can be difficult. The aim is to find genuine applicants for the bank to avoid the arising issues. Fraud detection can help the bank and as well as customers from many problems such as personalized information security. Loan status makes sure that a loan is approved by the person who can repay on time or before time. Customer churn can help reduce churn by acknowledging the gap and working on it.**

Keywords—Naive Bayes, Logistic Regression, Random Forest, Decision Tree, Bank loan prediction, financial fraud, CART (Classification and Regression Trees

I. INTRODUCTION

As we are aware of the fraudulent activities taking place which can lead to many frauds and losses to banks and as well as customers, personalized information can get in the wrong hands. Fraud can be committed in many ways. The customers hand over their personal information to the bank so it is necessary to keep it safe. Credit card fraud detection with machine learning helps to keep the data safe with the development of the model [1]. Also, whether the loan is approved or not is a big task. Only legitimate loan applicants will receive approval. The purpose of customer churn prediction is to identify customers who have ended their relationship with a company. [3]. The features due to which the customer has churned then are taken into consideration and then the model works on it to let the bank know about it and then make the features stronger. After entering certain required information then the model grabs all the information and predicts the results. Banks make a profit through loans. Many people require loans. But banks expect these people to be genuine applicants for loans [5]. To recognize a sterling applicant, banks perform checking manually, but this will take a longer time and result in more usage of bank resources. Therefore, we are developing machine learning algorithms, so that the system can effortlessly predict eligible candidates for loans [2]. Utilizing AI calculations utilizing the all-around existing datasets, we can make expectations for obscure datasets. Also, banks offer credit cards to their customers, it is similar to loans as they help in buying everyday commodities. But the credit card details are strictly prohibited to share. If anyone steals a credit card and performs transactions as a legitimate person it goes undetectable until the person notices his or her credit card is stolen [4]. Therefore, it is important to quickly recognize if it is a legitimate transaction or not. As credit card details are sensitive banks are not allowed to share and hence only banks can find the legal transaction. Customer retention has a predominant impact on a bank's profit and overall revenue [6]. To renew the services for the customers, primarily we have to understand "why" the customers are quitting the bank. To acknowledge the shortcomings that made customers quit is mandatory this can be automated using machine learning algorithms.

II. LITERATURE SURVEY

In [1], they have performed data normalization before applying Naive Bayes and Clustering which provides only 50% accuracy. Based on supervised learning. Prone to overfitting problems, the Naive Bayes algorithm provides less accuracy where limitations are faced. In [2], they have used machine learning algorithms such as Logistic Regression, Random Forest, Support Vector Machine, and XGBoost predict the eligibility of an applicant for a loan. Determine the best model with maximum accuracy. Concluded that Logistic Regression provides better accuracy than other models. This paper concludes that Logistic regression provides the best accuracy, but there is no implementation for the same.

In [3], they have built a method to predict the customer churn in a Bank, using machine learning techniques KNN, Decision Tree, and SVM. The conclusion is that random forest is way more useful than other models. Focus on the people who use fewer products. Doesn't work well with a large dataset Doesn't work well with a high number of dimensions Sensitive to outliers and missing values.

In [4], as Data Mining Technique Bayesian network classifiers namely K2, Tree Augmented Naïve Bayes (TAN), and Naïve Bayes, logistics, and J48 classifiers. Bayesian Network is a threshold-based model that computes the sum of the output accumulated from child nodes. Accuracy is less compared to Random Forest Algorithm. Assumes that every dataset feature is independent of each other.

In [5], An Approach for Prediction of Loan Approval using a Machine Learning Algorithm. Used a logistic regression approach, to target the right customer for granting the loan. Concluded that applicants with high

incomes and demanding lower amounts of loans are more likely to get approved since they are more likely to pay back their loans. Other characteristics like gender and marital status seem not to be taken into consideration Characteristics like gender and marital status seem not to be taken into consideration.

In [6], Customer Churn Prediction Model using Regression with Bayesian Boosting technique in Data Mining. Prediction algorithm logistic regression is applied to classify the labelled set as churners and non-churners. Handles the great bias problem in the regression model. Prone to underfit while having more attributes. The outcome fully depends on the set of independent variables.

From the above survey we have concluded there is no such web application we will predict outcome for unknown dataset. Also, there isn't any user-friendly interface to check accuracy of algorithms.

III. RESEARCH GAP

- Existing systems have just been compared and stated which algorithm is best.
- It is found that the Random Forest algorithm provides maximum accuracy over Logistic Regression and Naive Bayes algorithm.
- Instead of just detecting the best algorithm, providing an actual implementation would be benign.
- Testing a model using an unknown set of data helps to avoid overfitting problems resulting in good performance of your model in the test set.
- No deployment is done, that is no website is available to access.
- Developing a User Interface which can be user-friendly helps banks to perform secure transactions and avoid abnormal use of data.
- Random forest algorithms are found to handle missing data, just not in the same way as CART (Classification and Regression Trees) and other similar decision tree algorithms do.
- Analysation methods can be used to reduce churns. These methods may include understanding the patterns and improving the Onboarding process.

IV. PROBLEM STATEMENT

Banks handling all the tasks for prediction and detection manually by employees makes them more prone to erroneous outcomes. Also, it uses many assets of banks such as capital for the income of that employee, resulting in more usage of time resources of the bank, etc. Also, human fraternizing behaviour and misconduct can often lead to biased decisions. Therefore, it is essential to automate everything using machine learning algorithms as they are more pragmatic. Machine Learning algorithms undertake tasks faster, with less usage of bank resources, and can predict up to 99% accurate outcomes which are more reliable because it is all calculated using reasonable and realistic datasets using mathematics. "Financial Fraud Detection and Loan Prediction using ML" uses Machine learning classification algorithms such as Random Forest Classifier and Logistic Regression to predict the outcome after training the data. Data cleaning is done as machine learning algorithms are unable to deal with categorical data and null data.

A. Objectives

- To avoid abnormal transaction,
- To analyse churn and helps to reduce it by providing better services,
- To predict whether granting a loan is safe or not for banks to decide,
- To check the loan status and availability of the same by customers,
- To detect fraud to avoid the abnormal use of data,
- To avoid credit card fraud, the bank immediately warns the customer to cancellation of the card,
- To identify and prevent unauthorized financial activity,
- To automate and make every task faster,
- To make unbiaseddecisions.

V. METHODOLOGY

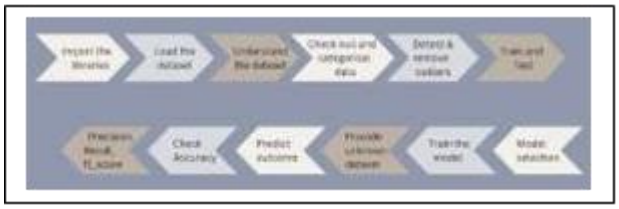

Fig. 1 Workflow and Overview

This diagram shows the flow of model creation. Step 1: Data Preparation

In this paper, Kaggle datasets are used for all three models including Credit Card Fraud Detection, Loan Eligibility Prediction, and Customer Churn Prediction. Features for training the data are used as mentioned in the figure below.

Fig.2.1. Data description is taken from Kaggle

Fig. 2.2. Data description is taken from Kaggle

Fig. 2.3. Data description is taken from Kaggle

Fig. 2.4. Data description is taken from Kaggle

Fig 2.1 depicts the dataset for Loan Status Prediction

And fig 2.2 and 2.3 depicts the dataset for Credit Card Fraud Detection and fig 2.4 shows the dataset used for Bank Customer Churn

Step 2: Data Pre-Processing

A. Handle categorical data using pandas "get_dummies" is a function in pandas that is used to convert categorical variables into numerical variables, also known as one-hot encoding. This transformation allows machine learning algorithms to handle categorical data, which are typically represented as strings, and use them in the training process. The resulting transformed data will have a numerical representation for each category, making it suitable for use in the training process. get_dummies will create a separate column for each unique category in the categorical feature. The resulting number of columns will equal the number of unique categories, so it is important to consider the size of the dataset and the number of unique categories in the feature before applying this transformation. Another way of handling categorical data is using fillna () and mode of values which is used in Loan Eligibility Prediction.

B. Under Sampling

Under-sampling is a technique in data pre-processing where the number of samples from the majority class is reduced so that the balance between classes in a dataset is improved. This technique is used in imbalanced datasets to balance the distribution of classes, reducing the potential for bias in the training of machine learning models.

C. Log Transformation

In the loan eligibility prediction model, log transform is applied to handle skew data using NumPy. Log transformation is a mathematical technique applied to data to modify its distribution by transforming the values using the natural logarithm (base e). It is often used to handle non-normal data, such as data with positive skew, outliers, or a large range of values, to achieve a more normal distribution, making it easier to model and interpret. Log transformation can also help stabilize the variance of the data, leading to more robust statistical analysis and machine-learning models.

D. Detect and Remove outliers

While testing a model 80% of the data is provided to the training model and 20% for the testing. So our models are trained using a training dataset, remaining unknown data can be used for testing which results in a good fit and provides better performance.

Step 3: Train and Test

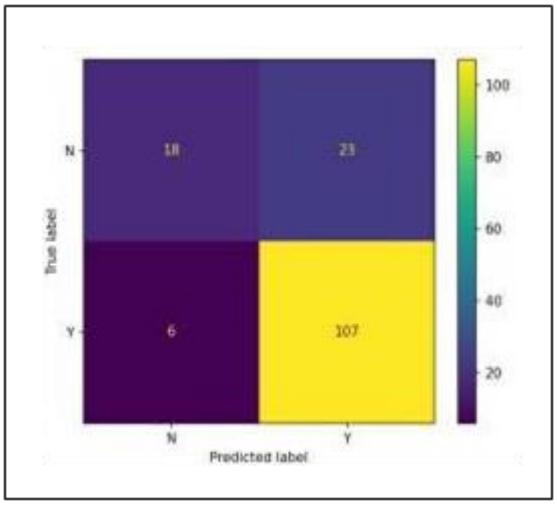

Fig.3 Confusion matrix for Random Forest Classifier in Loan Eligibility Prediction

This diagram shows the confusion matrix for random forest algorithm.

Models after cleaning and understanding of data go for training and testing. Training and Testing are done using train_test_split () which is in sci-kit learn. So we utilized this capability by bringing in it from sklearn.model_selection. This capability separates the highlights and focuses into x_train, x_test, y_train, and y_test. Breaking down the score of the preparation and testing model is utilized. It is used to analyse the score of the training and testing model. This function is used to test the accuracy of how our model predicts unknown data.

Step 4: Model Selection

We conducted a comparative analysis of several algorithms, including the Decision Tree algorithm, Naive Bayes algorithm, and the Random Forest Algorithm, and found out which one gives maximum accuracy in terms of prediction for unknown data.

Decision Tree Algorithm for Credit Card Fraud Detection:

A Decision Tree Classifier is a machine learning algorithm that is used for classification problems. It works by creating a tree-like structure, where each internal node represents a feature or attribute, each branch represents a decision based on the feature value, and each leaf node represents a predicted class label. The algorithm starts by selecting the best feature to split the data, repeats the process recursively until all the data is divided into leaves, and assigns a class label based on the majority class in each leaf.

Based on the score, the performance of our model can be calculated. Furthermore, based on the problem or after analysing the graph, model selection needs to be done. We are provided with the dataset and we need to decide for which we are interested in developing a classification or regression or clustering model. Therefore we preferred using classification models for Credit card Fraud Detection, Loan Eligibility Prediction, and Customer Churn Prediction.

Random Forest Algorithm for Loan Eligibility and Customer Churn Prediction:

The effectiveness of Logistic Regression, Decision Tree, and Random Forest in predicting loan eligibility has been compared, and it was found that the Random Forest Classifier offers the highest accuracy compared to other models. Random Forest is a versatile machine learning technique that can be used for both classifying and predicting outcomes. In this method, multiple trees are generated and each tree provides a prediction. The final prediction is then determined by the class with the greatest number of votes from the trees.

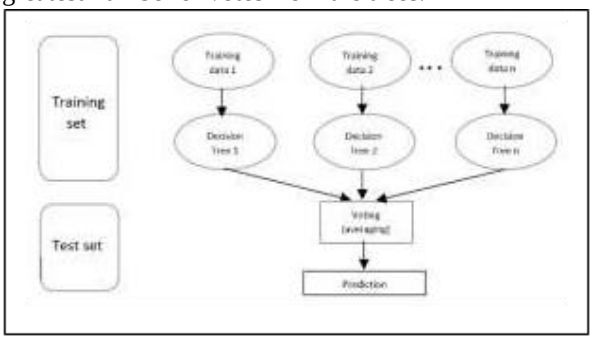

Fig 5

In fig 5 Random Forest Classifier is an ensemble machine learning algorithm that operates by combining multiple decision trees to produce a single prediction by aggregating or voting.

Step 5: Predict the Outcome

The predicted Outcome is the most important as it is for which we have implemented the project after training the model with known data.

Step 6: Accuracy, Precision, Recall, f1_score

The Confusion Matrix (CM) is used to analyse and determine the performance of the proposed loan prediction model.

- True Positive (TP), when both the actual and predicted values are positive (1)
- True Negative (TN), when both the actual and predicted values are negative (0)
- False Positive (FP), when the actual value is negative and the predicted value is positive (1)
- False Negative (FN), when the actual value is positive (1) and the predicted value is negative ()

Accuracy = TN+TPTN+FP+TP+FN (1)

Precision = TPTP+FP (2)

Recall = TPTP+FN (3)

F1 Score = 2*{Precision*Recall % Precision + Recall} (4)

VI. FUNCTIONALITIES

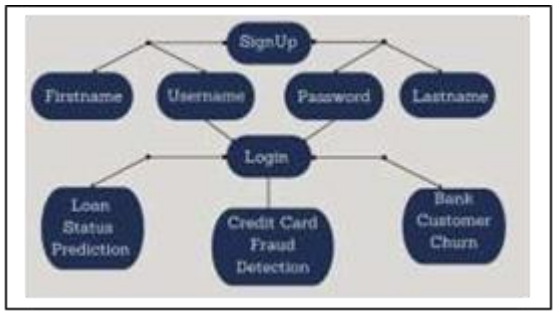

Fig.6. Interface Process design of the model. This diagram describes the main page layout.

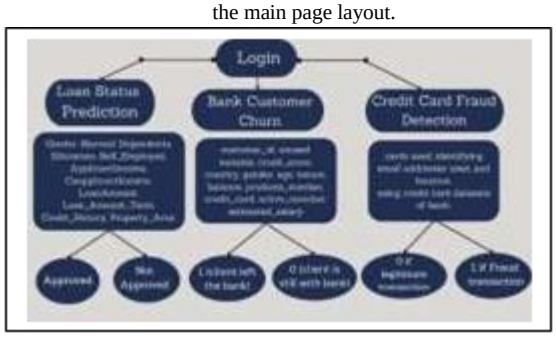

Fig.7 Interface Process design of the model

This diagram shows the features needed to predict outcome for single transaction.

In Fig 6, Financial Fraud Detection and Loan Prediction using ML: -

1] Loan Status Prediction

2] Bank Customer Churn Prediction 3] Credit Card Fraud Detection

Firstly, a bank employee needs credentials to get authorized access to the model. He needs to sign up using valid details like First name, Last Name, Username, and Password so that he could use it for further login.

Then there would be provided features to be filled in such as Loan Amount, Credit history, Applicant's Income, Dependants so that after training the data with this we can predict the outcome of the following to approve the loan or not.

In, Bank customer churn there would be credit score, balance, age, tenure, salary, products associated with bank, active member for the model to detect the churn. If the model predicted "1" then it would indicate that the client left the bank, and "0" then it would indicate that the client is still with the bank.

The bank, "0" if there would be a legitimate train, Credit card fraud detection model will detect fraud by considering the features like Average amount of transactions, current transaction amount, declined or not, foreign transaction or not using datasets of transaction and "1" if a fraud transaction is detected

VII. RESULTS

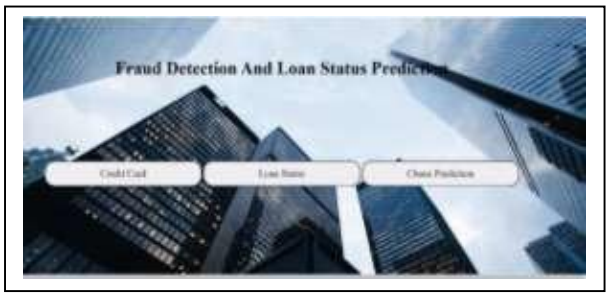

Fig.8 Main page

The main page of the website contains three sub-models namely Credit Card Fraud detection, Loan status prediction and Bank customer Churn prediction. Credit card fraud detection page then we go to the prediction We can see two sections which will first depict comparison of accuracy of various algorithms and second will predict for unknown values and give you if transaction is fraud or not

1] Credit Card Fraud Detection

Fig.10. This figure shows a User Interface where users can enter details about a transaction and get predictions for that single transaction.

Fig.11. This picture shows if a single transaction is legitimate or fraudulent.

Fig.12. User Interface for uploading csv file.
In this diagram model accepts csv file of n no. of transactions.

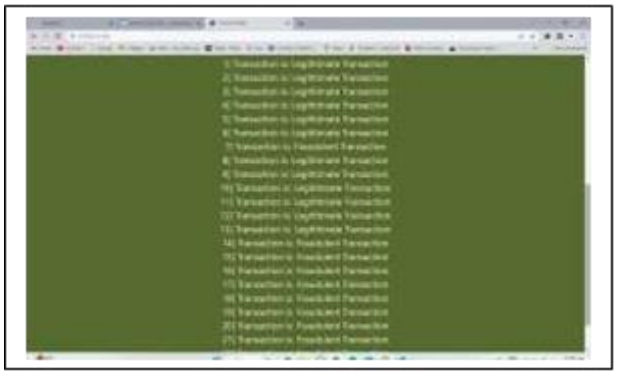

Fig 13. This picture shows which of the following transactions in the uploaded csv is fraud and which one is legitimate.

VIII. RESULT ANALYSIS

For finding the best algorithm we have found the accuracy, f1 score, precision, recall, and confusion matrix. The algorithm which will give the best accuracy will be used for our model. Following are the results that we will consider to get the best algorithm. We have seen that the Random Forest algorithm gives the best accuracy of about 85% and the rest algorithm's false negatives and false positives can create trouble and loss to banks and customers. In credit card fraud detection section, we have seen decision tree algorithm gives best accuracy of 91-92%. For bank customer churn and loan status prediction we have created user friendly website similar to the screenshots of credit card fraud detection website.

IX. CONCLUSION

Users will be provided with a website containing three models. Credit Card Fraud Detection helps to detect and prevent fraudulent transactions. Loan Status Prediction used to predict the eligible candidate to grant the loan and to decide whether to avail of a loan or not. Customer Churn Prediction is used to understand customer history and accordingly improve banking services.
Utilizing a variety of machine learning algorithms, this project is implemented using classification models to perform predictions. We wanted the best accuracy so we used Random Forest Algorithm for Loan Eligibility

Prediction and Customer Churn Prediction Decision Tree algorithm for Credit Card Fraud Detection.

To develop and train our model we have implemented several best practices. We have used the Flask framework to design our website.

Security of Cloud Computing

Achal Jairam Madavi, Vijay M. Rakhade, Lawlesh N. Yadav , Neehal.B. Jiwane , Ashish. B. Deharkar
Computer Science and Engineering, Shri Sai College of Engg. & Tech. Bhadrawati, India

Abstract— **Security of cloud computing is a firm hand of cyber security devoted to securing cloud computing systems. Security of cloud computing or directly cloud security touch on to a board set of policies, technologies, applications, and controls utilized to protect virtualized IP, data, application, services, and the associated infrastructure of security of cloud computing.**

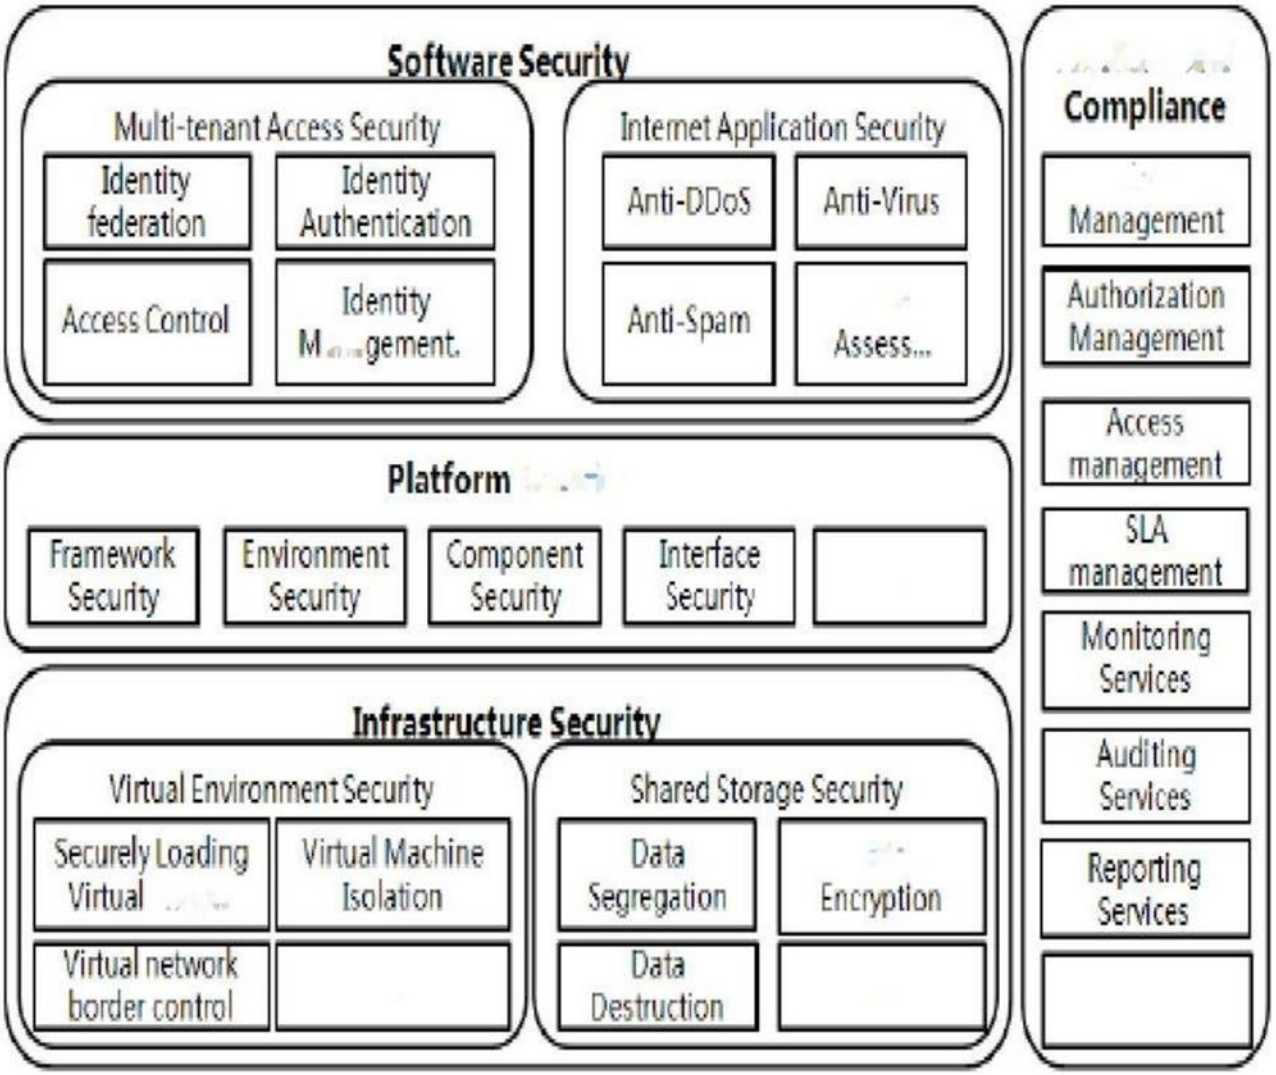
Keywords— Security, Cloud Computing

I. INTRODUCTION

The security of cloud computing is a collection of technology designed to address internal and external threats. Security of cloud computing or more clearly cloud security touch on to a board set of policie , technologies , applications ,and controls make use of to protect virtualized IP , data , application , services , and The related infrastructure of cloud computing .Cloud computing Industry is growing .According to Gartner, World Wilde cloud services revenue is on pace to surpass $6.3 billion in 009, a .3% increase from 008 revenue of 6 . billion, according to Gartner , Inc. The market is expected to reach $0. billion in 03. Business are increasing cloud adaption. We expect a great deal of migration towards cloud computing within the federal government in addition to the already robust private sector growth. The growth of the cloud should not protect the data that goes into it.

II. ARCHITECTURE

Security in cloud computing is a major concern. Proxy and brokerage servies should be employed to restrict a client from accessing the shared data directly. Data in the cloud should be stored in encrypted form.



III SECURITY OF CLOUD COMPUTING

Security is protection from, or resilence against, potential harm caused by other,by restraing the freedom of others to act. Security of cloud computing is a collection of security measures designed to protect cloud-based infrastructure, application and data.

These security measures are configured to protect cloud data, support regulatory compliance and protect costomerrs privacy as well as setting authentication rules for indivial user and devices. From authencating access to filtering traffic , cloud security can be configured to the exact need of the business .and because these rules can be configured and managed in one place ,administration overheads area reduced and IT tearms emprovered to foucs on other area of the business.

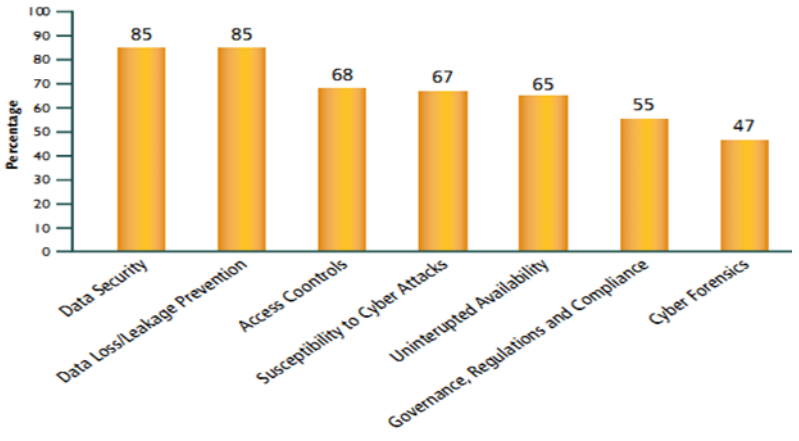


Fig.cloudsecurity

CLOUD COMPUTING

Cloud computing is based on five attributes: multitenancy, massive scalability, elasticity, pay as you go, and self-provisioning of resources.

Multitenancy:Unlike previous computing models, which assumed dedicated resources (i.e., computing facilities dedicated to a single user or owner), cloud computing is based ona business model in which resources are shared (i.e., multiple users use the same resource) at the network level, host level, and application level.

Massive scalability: Although organizations might have hundreds or thousands of systems, cloud computing provides the ability to scale to tens of thousands of systems, as well as the ability to massively scale bandwidth and storage space.

Elasticity:Users can rapidly increase and decrease their computing resources as needed, as well as release resources for other uses when they are no longer required.

Pay as you go:Users pay for only the resources they actually use and for only the time they require them.

Self- provisioning of resources:

User self – provision resources, such as additional system (processing capability, software, storage) and network resources.

CLOUD SECURITY DESING PRINCIPLES

The security design principle are the key pillars for implementation of cloud security to project system, application and platform security architecture.

Below are the key desing principles which needs to be considered for cloud technology adoption.

.

1) Security at all layers: Ensure robust security is applied to all layers [physical, network, data, application,etc. of their architecture with multiple security controls. This will ensure end to end protecting of application/ data hosted by departments on cloud platform.

2) Safeguard data while at rest and in transit: Identify and Classify the dada in terms of critically / sensitivity and define their levels. This can be prevented via using the available security controls like access control, tokenization, encryption, etc.

3) Monitoring and auditing: Ensure monitoring, auditing and alerting is configured to capture the changes in the department's system in real time. Further, log integration and metric collection can automatically investigate, act and respond.

4) Access management and Controls: Ensure implementation of principle of selective privileges and impose segregation of duties with appropriate access and authorization. Centralized identity and access management can eliminate any unauthorized access and information loss/ theft

5) Readiness for security events: Department/CSP need to prepare system for any unusual security event. Regular vulnerability and security tests need to be conducts to identify the security gaps and issues. Drill can be conducted to record the response of the cloud systems at different layers.

6) Automate security best e practices: Automating software/hardware/application, based security system via AI/ML/Bots to improve the ability to secure environment which can perform regular checks and implement the controls needed to restrict the attack and enhance cloud security.

7) Cloud Vendor Lock-in: Department to ensure that there is no vendor lock-in by Cloud services provider while hosting the application/data, as there is no standard guidelines between different cloud providers for data migration and exports, so it becomes difficult to migrate data from one cloud provider to another or migration to on-premise Dara centre.

BENEFITS OF SECURITY OF CLOUD COMPUTING

. High Availability – Ensuring continuity is one of the primary reasons behind businesses looking for reliable cloud security solutions. The right cloud computing security solutions. The right cloud-computing security solution should incorporate real-time support,*7*36 live monitoring of business assets and have redundancies built-in so your website and applications remain online and functional even in the case of an attack.

With cloud service providers, such as Active Co 's cloud Services vancouver, you can rest assured that your core business assets, such as website and applications will always remain functional globally[3].

cloud DDoS protection – Traditional network infrastructure work on the basic of origin and backup serves that can be easily disabled DDoS attacks that are capable of generating up to 0Gbps of traffic. These attacks can take anywhere from hours to mitigate during which your services may be completely or partially affected and your business sustains severe financial and reputation loss. To ensure continuity of service, you need managed hosting providers and/or content delivery networks with DDoS absorption capabilities as well as real- time scanning to identify and prevent/mitigate DDoS attacks. This is done through the CDN`s capability of making use of a global network of PoPs that can manage spikes in legitimate traffic and divert synthetic spikes from a attack on the network. This enables CDN`s to both bring downtime down to zero as well as enables security controls that feel intuitive.

Flexibility- the right cloud computing solution for your business ensures irrespective of capacity. whether you`re experiencing a surge in legitimate traffic or in the case of an attack, the solution should be able to provide you enough flexibility to avoid server crashes and avoid unnecessary costs during lean hours through up or downscaling.

Data Security- Ensuring the privacy and security of your business` sensitive information and transactions is a top priority for your cloud computing security solutions. It should be able to prevent third parties for eavesdropping or tampering with your data through the right security protocols, such as, transport layer security

[TLS]- the replacement to secure sockets layer [SSL] Ecommerce sites are particularly vulnerable to data breaches and should take care to implement a CDN with PCI compliance and other relevant digital rights management layers

Regulatory compliance- Ecommerce businesses and financial institutions also face a greater degree of both industrial and governmental compliance and regulations checks. With the right CDN, you will be able to build a highly compliant infrastructure that is capable of always protecting your consumers` data.

. Round The Clock Support- cloud Services Vancouver Have a host of companies offering cloud security solutions. The right cloud security solutions for your business, however, should be able to render downtimes to near zeros. It should be able to provide you with effective and time-sensitive customer support *7*36 any time of the day or night with live monitoring.

SECURITY OF CLOUD COMPUTING ADAVATAGES

1) Shifting public data to a external cloud reduces the exposure of the internal sensitive data
2) Cloud homogeneity makes security auditing / testing simpler
3) Clouds enable automated security management
4) Redundancy / disaster recovery

IV. CONCLUSION

The cloud computing has the potential to be a disruptive force by affecting the deployment and use of technology. The cloud be the next evolution in the history of computing, following in the footsteps of mainframes, minicomputers, PCs, servers, smart phones, and so on, and radically changing the way enterprise manage IT. Cloud computing provides advanced computing resources available on – demand, that scale as needed, with regular updates and without the need to buy and maintain an on – premise infrastructure. With cloud computing, teams to marked as they can rapidly acquire, scale services, without the considerable effort that requires managing a traditional on – premise infrastructure.

Challenges In Big Data

Akash A. Howladar, Ashish B. Deharkar, Vijay M. Rakhade Lowlesh N. Yadav, Neehal B. Jiwane
Computer Science And Engineering, Shri Sai College Of Engineering And Technology, Bhadrawati, Maharashtra, India.

Abstract— **Moment Big Data draws a lot of attention in the IT world. The rapid-fire rise of the Internet and the digital frugality has fueled an exponential growth in demand for data storehouse and analytic, and IT department are facing tremendous challenge in guarding and assaying these increased volumes of information. The reason associations are collecting and storing further data than ever ahead is because their business depends on it. The type of information being created is no more traditional database-driven data appertained to as structured data rather it's data that include documents, images, audio, videotape, and social media contents known as unshaped data or Big Data. Big Data Analytics is a way of rooting value from these huge volumes of information, and it drives new request openings and maximizes client retention. This paper primarily focuses on agitating the colorful technologies that work together as a Big Data Analytics system that can help prognosticate unborn volumes, gain receptivity, take visionary conduct, and give way to more strategic decision-timber. Further this paper analyzes the relinquishment, operation and impact of big data analytics to the business value of an enterprise to ameliorate its competitive advantage using a set of data algorithms for large data sets similar as Hadoop and MapReduce.**

Keyword- Big Data, Analytics, Big Data Issues,Challenges

I. INTRODUCTION

Big Data Analytics reflect the challenges of data that are too vast, too unshaped, and too presto moving to be managed by traditional styles. From businesses and exploration institutions to governments, associations now routinely induce data of unknown compass and complexity. Gleaning meaningful information and competitive advantages from massive quantities of data has come decreasingly important to associations encyclopedically. Trying to efficiently prize the meaningful perceptivity from similar data sources snappily and fluently is grueling . therefore, analytics has come inextricably vital to realize the full value of Big Data to ameliorate their business performance and increase their request share.

The tools available to handle the volume, haste, and variety of big data have bettered greatly in recent times. In general, these technologies aren't prohibitively precious, and much of the software is open source. Hadoop, the most generally used frame, combines commodity tackle with opensource software. It takes incoming aqueducts of data and distributes them onto cheap disks; it also provides tools for assaying the data. still, these technologies do bear a skill set that's new to utmost IT departments, which will need to work hard to integrate all the applicable internal and external sources of data. Although attention to technology isn't sufficient, it's always a necessary element of a big data strategy. This paper discusses some of the most generally used big data technologies substantially open source that work together as a big data analytics system for using large amounts of unshaped data to make further informed opinions.

II CHARACTERISTIC OF BIG DATA

II.1. Volume

This refers to extensively large data. In 2016, the data created was only 8 ZB; it's anticipated that, by 2020, the data would rise to 40 ZB, which is extremely large.

II.2. Variety

A reason for this rapid-fire growth of data volume is that data is coming from different sources in colorful formats. We've formerly bandied how data is distributed into different types. Let us take another regard at it with further exemplifications.

II..3. Velocity

The speed of data accumulation also plays a part in determining whether the data is big data or normal data. As can be seen in the image below, mainframes were originally used when smaller people were using computers. As computers evolved, the customer garcon model came into actuality. latterly, web operations came into the picture and their fashionability extended to further and further bias similar as mobiles, which led to the creation of a lot of data.

II.4. Value

How will the birth of data work? Then, our fourth V comes in; it deals with a medium to bring out the correct meaning of data. also, you need to make sure whatever analysis you have done benefits your business, similar as in chancing out perceptivity, results,etc., in a way that wasn't possible earlier.

II.5. Veracity

Since packages get lost during prosecution, we need to start again from the stage of mining raw data to convert it into precious data. And this process goes on. There will also be misgivings and inconsistencies in the data that can be overcome by veracity. Veracity means the responsibility and quality of data. The veracity of data must be maintained. For illustration, suppose about Facebook posts, hashtags, bowdlerizations, images, videos,etc., which make the posts unreliable and hinder the quality of their content. Collecting loads and loads of data is of no use if the quality and responsibility of the data aren't over to the mark.

III BIG DATA APPLICATIONS

III.1. Banking

Since there's a massive quantum of data that's gushing in from innumerous sources, banks need to find uncommon and unconventional ways to manage big data. It's also essential to examine client conditions, render services

according to their specifications, and reduce pitfalls while sustaining nonsupervisory compliance. fiscal institutions have to deal with Big Data Analytics to break this problem.

III.2. Government

Government agencies use Big Data and have cooked a lot of running agencies, managing serviceability, dealing with business logjams, or limiting the goods of crime. still, piecemeal from its benefits in Big Data, the government also addresses the enterprises of translucency and sequestration.

III.3 Education

Education concerning Big Data produces a vital impact on scholars, academy systems, and classes. By interpreting big data, people can insure scholars ' growth, identify at- threat scholars, and achieve an extemporized system for the evaluation and backing of headliners and preceptors.

III.4. Healthcare

When it comes to what Big Data is in Healthcare, we can see that it's being used tremendously. It includes collecting data, assaying it, using it for guests. Also, cases ' clinical data is too complex to be answered or understood by traditional systems. Since big data is reused by Machine Learning algorithms and Data Scientists, diving similar huge data becomes manageable.

III.5.E-commerce

Maintaining client connections is the most important in thee-commerce assiduity. E-commerce websites have different marketing ideas to vend their wares to their guests, manage deals, and apply better tactics of using innovative ideas with Big Data to ameliorate businesses.

III.6.Social Media

Social media in the current script is considered the largest data creator. The data generated substantially correspond of videos, prints, communication exchanges, etc. A single exertion on any social media point generates a lot of data which is again stored and gets reused whenever needed. Since the data stored is in terabytes, it would take a lot of time for processing if it's done by our heritage systems. Big Data is a result to this problem.

IV BIG DATA ISSUES

IV.1. Storage Issue

With vast quantities of data generated daily, the topmost challenge is storehouse(especially when the data is in different formats) within heritage systems. unshaped data can not be stored in traditional databases.

IV.2. Processing Issue

Processing big data refers to the reading, transubstantiating, birth, and formatting of useful information from raw information. The input and affair of information in unified formats continue to present difficulties.

IV.3. Security Issue

Security is a big concern for associations. Non-encrypted information is at threat of theft or damage by cuber-criminals. thus, data security professionals must balance access to data against maintaining strict security protocols.

V BIG DATA CHALLENGES

Challenges in big data can be astronomically alienated into three types the first type is data challenges, the alternate type is data process challenges, and the third type are data operation. Data challenges are the challenges that are associated with the characteristics of big data. Process challenges are the challenged that faced during the processing of data whereas operation challenges pertaining to diving the data similar as furnishing security. The characteristics of big data bring numerous challenges to it similar as its high volume, variety, etc. Process challenges are related to data accession, pre-processing, data analysis, and data visualization whereas operation challenges are related to sequestration and security. Figure 1 shows the different types of challenges associated with the different phases of the big data analysis process. .

V.1. Data Challenges

Experimenters have given numerous delineations of big data and grounded on their understanding towards they come up with several new characteristics of big data. experimenters bandied the 3V's characteristics of data(Volume, Variety, and Volume), 4th V was introduced by IBM as veracity. experimenters have bandied 5th and 6th V's as variability, and value. The 10 V's of big data are taken under consideration. there are numerous worth mentioning prominent challenges associated with the characteristics of data. Some of the prominent challenges are bandied as follow. .

V.2. Volume Challenges

The unknown increase in data through internal and external sources has redounded in a massive quantum of data. This high volume of data brings the challenges to the data itself similar as the storehouse of the data for processing isn't possible through traditional tools and therefore more innovative styles should be developed to handle this data deluge.

V.3. Variety Challenges

The massive data can be present in the form of structured,semi-structured, and unshaped. Research studies show that 95 of the data is present in unshaped form. thus, converting it into a form so that the analysis can be performed is a big challenge. . haste Challenges. haste indicates the speed of the data generated through the bias. Data can be reused in two ways batch processing and real- time processing. In batch processing, the data is stored and also reused whereas real- time processing is nonstop. In online shopping, real- time processing is needed to induce value for guests. .

V.4. Veracity Challenges

Data veracity indicates the quality and delicacy of data.

It deals with the fabrications, imprecision, messiness, and lost substantiation in data. It defines the responsibility of data when a significant decision needs to be taken. In social networking spots, stoner opinion can be classified as positive, negative, or neutral. .

V.5. Value Challenges

Big data contains precious information that needs to be uprooted from the large datasets. This brings a big challenge to data as rooting the high information from data in a cost-effective manner and making use of it for business intelligence, health sectors,etc.

V.6. Process Challenges

Process challenges are related to processing and assaying large datasets. It brings a significant challenge to the process as the data is present in different forms and conversion of it into one form for analysis purpose is a grueling task. It can be divided into four corridor Data Acquisition and Storage, Data Prepossessing, Data Analysis and Modeling, Data Visualization. .

V.7. Data Acquisition and Storage

Data accession is the process of acquiring and storing the data for the unborn exercising some precious information. The data is acquired from colorful sources similar as from detectors, social networking spots, blogs,etc. and hence the data is present in different forms(structured, semi-structured, and unshaped) bring a significant challenge to data. The alternate challenge is associated with the storehouse because the data generated through colorful bias doesn't mean that whole data carry meaning to it thus the smart sludge must be applied for generating the applicable datasets. Storing this massive data set can affect in high- cost scalable systems to handle the data. .

V.8. Data Preprocessing

Data preprocessing is the process to collect the quality data from large datasets as low- quality data leads to low-quality knowledge. thus, data preprocessing plays a significant part in knowledge discovery. In this stage noise, missing values, inconsistent and redundant data,etc. are removed before applying the big data mining ways to its data. In big data preprocessing utmost of the sweats are done in the point Selection system whereas some of the families of it are ignored similar for case reduction, missing value insinuations, noise treatments. .

V.9. Data Analysis and Modelling

Data analysis is the process that discovers the retired information from the data and helps the associations to make a better decision. To efficiently prize the knowledge from the large datasets extraordinary ways are needed. To induce the retired pattern from the large datasets Wal- Marts employs statistical and machine literacy ways.

V.10. Data Visualization

A big data visualization fashion presents the logical data visual form. It makes operation of colorful types of graph for representing the precious information for decision timber. the visual report has a better impact on information candidate rather than the textbook reports. Visualization tools like Tableau and Qlik View are the tools used for visualization still according to the experimenter these tools can not be fruitful shortly where data is growing every alternate by each one of us.

V.11. Management Challenges

Management challenges are related to those challenges encountered by an association which is related to the sequestration, security, governance of data. operation challenges are also faced because we've a lack of data for professed professionals who know the rearmost tool and ways to employ the correct system for dealing with each phase of data. Security and sequestration will always be the major enterprises as data are largely sensitive similar as fiscal data, military data, insurance canons and contains different kinds of information that can ruin if the unauthorized stoner has access to it.

VI ADVANTAGES OF BIG DATA

VI.1. Making wiser decisions

Big data is primarily being used by numerous diligence, similar as trip, real estate, finance, and insurance, to enhance decision- timber. Businesses can use big data to directly prognosticate what guests want and do not want, as well as their behavioral tendencies because it reveals further information in a usable format. Big data provides business intelligence and slice- edge logical perceptivity that help with decision- timber. A company can get a more in- depth picture of its target request by collecting further client data.

VI.2. Detection of Fraud

financial companies especially use big data to identify fraud. To find anomalies and sale patterns, data judges use artificial intelligence and machine literacy algorithms. These irregularities in sale patterns show that commodity is out of place or that there's a mismatch, furnishing us with hints about implicit fraud. For credit unions, banks, and credit card companies, fraud discovery is pivotal for relating account information, accoutrements , or product access. By spotting frauds before they beget problems, any assiduity, including finance, can give better client service.

VI.3. A rise in productivity

They've been suitable to increase deals and ameliorate client retention as a result of this rise in productivity. ultramodern big data tools make it possible for data scientists and judges to assay a lot of data snappily and effectively, giving them an overview of further data. They come more productive as a result of this. also, big data analytics aids data scientists and judges in learning further about themselves to figure out how to be more effective in their tasks and job liabilities. As a result, investing in big data analytics gives businesses across all sectors a chance to stand out through bettered productivity.

VI.4. Enhanced client support

As part of their marketing strategies, businesses must

ameliorate client relations. Since big data analytics give businesses access to further information, they can use that information to make further specialised, largely personalized offers to each individual client as well as further targeted marketing juggernauts. Social media, dispatch exchanges, client CRM(client relationship operation) systems, and other major data sources are the main sources of big data. As a result, it provides businesses with access to a wealth of data about the requirements, interests, and trends of their target request.

VI.5. Greater invention

Innovation is another common benefit of big data, and the New Vantage check set up that11.6 per cent of directors are investing in analytics primarily as a means to introduce and disrupt their requests. They reason that if they can ripen perceptivity that their challengers do not have, they may be suitable to get out ahead of the rest of the request with new products and services. Disadvantages of Big Data

VII DISADVANTAGES OF BIG DATA

VII.1.A talent gap

A study by At Scale set up that for the once three times, the biggest challenge in this assiduity has been a lack of big data specialists and data scientists. Given that it requires a different skill set, big data analytics is presently beyond the compass of numerous IT professionals. Chancing data scientists who are also knowledgeable about big data can be delicate. Data scientists and big data specialists are two well- paid professions in the data wisdom assiduity. As a result, hiring big data judges can be veritably expensive for businesses, particularly for launch- ups. Some businesses must stay a long time to hire the necessary labor force to carry out their big data analytics tasks.

VII.2. Security hazard

For big data analytics, businesses constantly collect sensitive data. These data need to be defended, and security pitfalls can be mischievous if they aren't duly maintained. also, having access to enormous data sets can attract the unwanted attention of hackers, and your company could come the target of a implicitcyber-attack. You're apprehensive that for numerous businesses moment, data breaches are the biggest trouble. Unless you take all necessary preventives, important information could be blurted to rivals, which is another threat associated with big data.

VII.3. Adherence

Another disadvantage of big data is the demand for legal compliance with governmental regulations. To store, handle, maintain, and process big data that contains sensitive or private information, a company must make sure that they cleave to all applicable laws and assiduity norms. As a result, managing data governance tasks, transmission, and storehouse will come more grueling as big data volumes grow.

VII.4. High Cost

Given that it's a wisdom that's constantly evolving and has as its thing the processing of ever- adding quantities of data, only large companies can sustain the investment in the development of their Big Data ways.

VII.5. Data quality

Dealing with data quality issues was the main debit of working with big data. Data scientists and judges must insure the data they're using is accurate, material, and in the right format for analysis before they can use big data for analytics sweats. This significantly slows down the reporting process, but if businesses do not address data quality problems, they may discover that the perceptivity their analytics produce are useless or indeed dangerous if used.

VII.6. Rapid Change

The fact that technology is evolving snappily is another implicit disadvantage of big data analytics. Businesses must deal with the possibility of spending plutocrat on one technology only to see commodity better crop a many months latterly. This big data debit was ranked fourth among all the implicit difficulties by Syncsort replies.

VIII CONCLUSION

Moment’s technology geography is changing presto. Organizations of all shapes and sizes are being dragooned to be data driven and to do further with lower. Indeed however big data technologies are still in a incipient stage, fairly speaking, the impact of the 3V’s of big data, which now is 5v’s can not be ignored. The time is now for associations to begin planning for and erecting out their Hadoop- grounded data lake. Organizations with the right architectures, gift and vision in place are well equipped to take their big data strategies to the coming position and transfigure their businesses. They can use big data to unveil new patterns and trends, gain fresh perceptivity and begin to find answers to pressing business issues. The deeper associations dig into big data and the more equipped they're to act upon what’s learned, the more likely they're to reveal answers that can add value to the top line of the business. This is where the returns on big data investments multiply and the metamorphosis begins. employing big data sapience delivers further than cost slice or productivity enhancement but it surely reveals new business openings. Data- driven opinions always tend to be better opinions.

Abstract - **One of the most well-known and valuable cryptocurrencies in the present financial market is bitcoin, which draws investors and creates new study opportunities for academics. Numerous studies have been conducted using various machine learning prediction algorithms to forecast Bitcoin prices. Important features are mined from a dataset that has a strong link to the price of Bitcoin, and then random data chunks are selected to train and test the model. The model's ability to predict prices may be compromised by unfitting results brought on by the random data that was used for model training. Here, an appropriate training procedure for a prediction model is being examined. The suggested approach is then used to train a straightforward LSTM and sentiment analysis model to forecast the price of bitcoin. When the LSTM model is trained using a suitable data chunk that has been identified, trustworthy results for the prediction are found.**

***Keywords - Bitcoin, Machine Learning, Price Prediction, LSTM, Sentiment Analysis*.**

I. INTRODUCTION

Bitcoin is a digital currency and an advanced kind of payment network. Bitcoin applies peer-to-peer technology to work with no central authority or banks, handling transactions and the issuing of Bitcoin are carried out collectively by the same. Bitcoin is open source; its design is public; nobody owns or controls Bitcoin and everyone can hold a part of it. Through many of its special and different properties, Bitcoin allows exciting uses that could not be covered by any other payment system. Bitcoin market is a highly volatile market working 24/7. It is the leading cryptocurrency because of its open nature and high adaptability. Profit-making in the stock market is frequently done with the aid of algorithms rather than any direct human investments Numerous case studies have been undertaken in order to reach the conclusion that numerical methods provide better results than humans.

As Bitcoin's price has very high volatility, many people are attracted to the research of predicting the price trend of Bitcoin because investors have a chance to gain high profit from the price change. The primary way a bitcoin market differs from a typical stock market is through the abundance of novel features it offers. Applying new forecasting methods that are appropriate for the bitcoin industry is necessary Less research has been done on predicting bitcoin prices than has been done on the stock market .In this study, we use sentiment analysis and a long short-term memory (LSTM) to forecast the Bitcoin price trend [5].

II. LITERATURE SURVEY

A literature survey was done to determine the best algorithm for predicting Bitcoin's price from numerous studies that had been published in international publications.

Numnoda et al. have put their prediction Gated Recurrent Unit (GRU) model into practice and obtained incredibly precise results. Their prototype, however, has a high temporal complexity. In this constantly shifting context, this complicates the anticipated outcomes. Additionally, the chosen qualities are insufficient to forecast Bitcoin values because a variety of factors, including social media and the policies and legislation that each nation declares to deal with digital currency, can have a significant impact on price fluctuations [1].

Mangla et al. have contrasted Recurrent Neural Networks (RNN), Logistic Regression, Support Vector Machine, and Auto Regressive Integrated Moving Average (ARIMA) as four various price prediction models. Their key result is that ARIMA performs badly for forecasts that go beyond the following day. For up to six days, their RNN algorithm can anticipate price changes with accuracy. Additionally, a separable hyperplane is required for the logistic regression model to produce reliable results [2].

Guo et al. have employed a hybrid approach that combines an LSTM network and multi-scale residual blocks to forecast the price of bitcoin. However, their analysis lacks thorough criteria that assess the investor's attention to earlier identification of bitcoin market volatility, leading to a lessprecise forecast [3].

Awoke et al. have contemplated the basic GRU and LSTM deep learning models. However, more research is needed to take additional parameters into account and improve the model's accuracy [4]. Rana et al. have used a very precise LSTM (Long Short Term Memory) model and conducted their research on a huge scale, which made their process somewhat complicated [5]. Summary of this literature survey is that all proposed methods use machine learning and deep learning to predict the Bitcoin price. Above paper used various models such as GRU, RNN, SVM, ARIMA and LSTM to predict bitcoin prices. But all the model had some limitations. To overcome the limitations this paper proposes use of Sentiment Analysis with LSTMalgorithm to find better results

.

III. PROBLEM DEFINITION

To create a model with a low error rate and high precision of accuracy that will allow us to forecast the price of the crypto currency being utilized (in this example, Bitcoin). The model cannot predict the future, but it can suggest a broad trend and the overall direction in which to expect price movement.

IV. EXISTING SYSTEM

In the existing systems we saw use of LSTM model. In this model we can see that the predictions are not up to mark. It is because the bitcoin is very volatile. So to overcome this limitation we try to incorporate sentiment analysis with LSTMto get the sentiments of tweets that shows how it affects the changes in bitcoin market [5].

V. SYSTEM ARCHITECTURE

5.1 Proposed System:

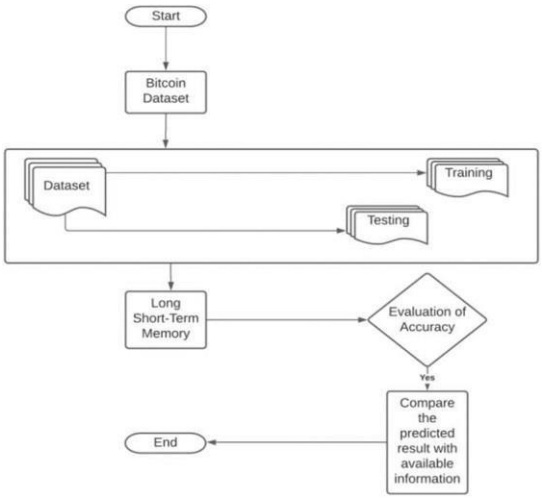

Fig-1:System Architecture

Algorithm

1. Download dataset from Coinbase pro API
2. Import necessary Library
3. Load dataset
4. Visualize the data to explore the trend in the data.
5. Splitting the dataset into training and testing data
6. Building LSTM Model
7. Fitting the training data
8. Prediction on testing data model
9. Gathering Tweeter Data for sentiment analysis
10. Applying Sentiment Analysis

We first get the data set from the web tool Coinbase pro API. The informational set shows the cost of Bitcoin in US dollars (USD). The dataset contains all Bitcoin price information fromOctober 27, 2015 and October 30, 2021.

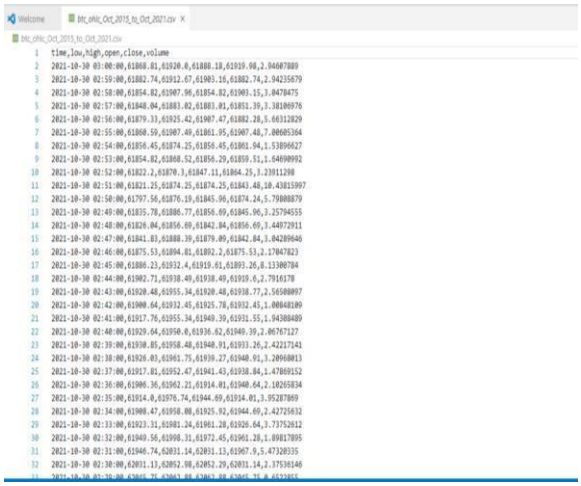

Fig-2:Bitcoin Dataset

The second step is cleaning and getting ready the data set. To do this, all the rows' blank data must be deleted. Filtering away extraneous aspects found in the data obtained is another aspect of it For our model, we will only make use of the columns with the labels Date, Price, Open, High, and Low.

Table -1: Features Used In the Dataset

btc_input_df_datetype.info()
<class 'pandas.core.frame.DataFrame'> RangeIndex: 3113276 entries, 0 to 3113275Data columns (total 6 columns):

#	Column	Dtype
0	time	datetime64[ns]
1	low	float64
2	high	float64
3	open	float64
4	close	float64
5	volume	float64

dtypes: datetime64[ns](1), float64(5)memory usage: 142.5 MB

The dataset is then tested, with training coming later. We train our model utilizing the algorithm and the features that are taken into consideration in order to predict the future price of the crypto currency. The testing phase is now underway, during which we examine the data to see how well our model forecasts the price of Bitcoin using an algorithm.
Finally, we assess the model's correctness once it has been tested and trained using the features of the data set. We assess the accuracy and effectiveness of our model by comparing the anticipated price of the cryptocurrency at a given time period with the actual price of Bitcoin at that same time.

5.2 Model used:

Recurrent neural networks of a special kind can be trained to recognize long-term dependencies in data. This is made feasible by the repeating module of the model, which consists of four interconnected levels.

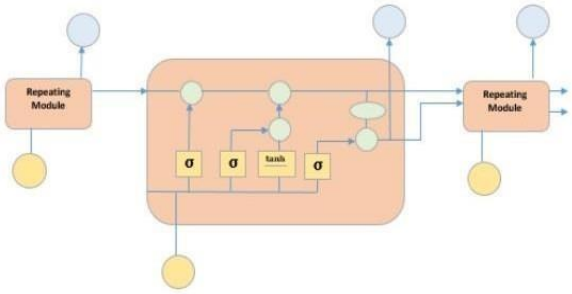

Fig-3: LSTM

Four neural network layers are illustrated in the image above as yellow boxes, while the input is represented by yellow circles, point wise operators by green circles, and cell state by blue circles. An LSTM module, which contains a cell state, three gates, and the ability to selectively learn, unlearn, or retain knowledge from each of the units, offers this capability.. By allowing just a few linear exchanges, the cell state in LSTM aids in the information's uninterrupted flow across the units. An input, output, and forget gate is present in each component, and it has the ability to add or remove data from the cell state. The forget gate chooses which information from the previous cell state should be ignored using a sigmoid function. The input gate controls the information flow to the active cell state by point-wise multiplying "sigmoid" and "tanh." The output gate ultimately determines which data should be transferred to the following concealed state.

5.3 Sentiment Analysis:

To assess whether a passage of text is favorable, negative, or neutral, apply the sentiment analysis process. In text analytics, topics, categories, or entities inside a phrase are given sentiment scores using a combination of natural language processing (NLP) and machine learning (ML) approaches.
Sentiment analysis is a tool that data analysts use to gather information for market research and reputation management of brands and products. This process is also very helpful for learning what customers believe and acting on this to improve the 'customer experience' Additionally, businesses that analyze data typically incorporate sentiment analysis APIs from third parties into their own infrastructures in order to get insightful data and share it with their own clients.
Continue reading, and we'll explain how sentiment analysis works, along with the benefits and drawbacks of a rule-based sentiment analysis approach, while also explaining the functions of NLP and machine learning techniques. Sentiment analysis is a technique for determining if a piece of text is good, negative, or neutral.
The APIs or python library which we planned to use are as follows,
Tweepy - which is python client
TextBlob - Textual Data Parser and provides built program of sentiment analysis for textual data.
Natural language toolkit corpora - A suite of libraries and programs for symbolic and statistical natural language processing for English written in python programming language.

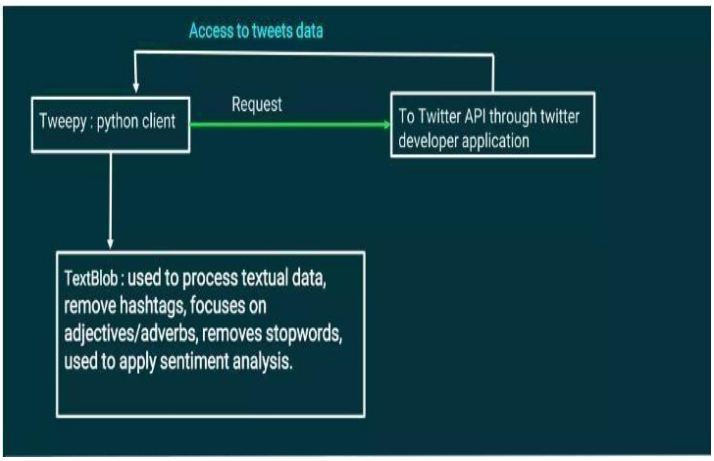

Fig -4: Sentiment Analysis Model

VI. METHODOLOGY

6.1 Lag Plots:

Fig -5: Lag plot

We must create a lag plot of the time series data once the dataset has been filtered and cleaned. The lag is the amount by which one data point in a time series of data lags behind another. To examine and determine whether the time series data exhibits any patterns, lag plots are used. For searching patterns like trends, unpredictability, and seasonality, they are crucial. The lag of the time series data points on the y-axis and the depiction of time series data on the x-axis together create the graphic Lag graphs are being developed for minute, hourly, daily, weekly, and monthly lags. It is clear that the daily, hourly, and minute lag plots are all positively correlated. Weekly lag results in a significant reduction in correlation, which practically disappears for monthly lag plots. Therefore, it makes logical to keep the autocorrelation while only resampling the data at the daily level.

6.2 Train-Test Split:

Train-test splitting is the next action that must be taken. We will use sixty data samples from our model for testing, while the remaining resampled data will serve as the training sample. Following this, the train-test split graph will be drawn. Figure 4 displays a clear train-test plot of the closing prices.

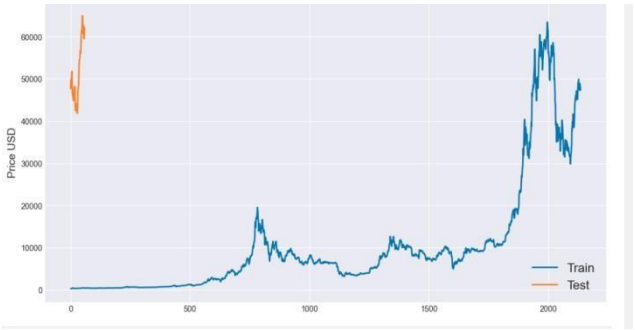

Fig-6: Train-Test Split Graph

6.3 Scaling:

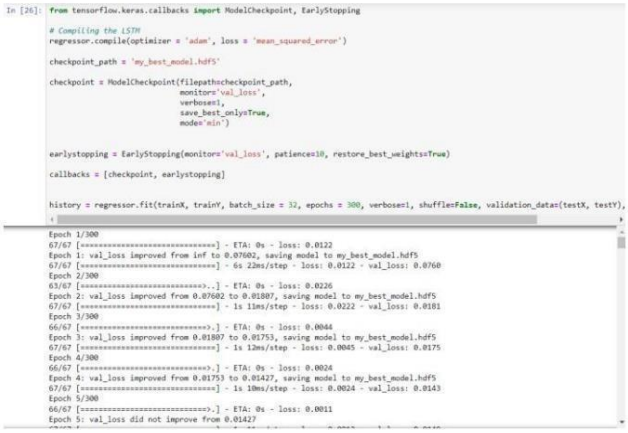
The data will then be scaled because both the training and test sets require scalability. Because doing so would result in data leakage from the test set to the training set, scaling should be performed after the train-test split. This is an essential point that needs to be made. Scaling before the train-test split would cause the training process to be impacted by the test set, leading to the model producing an inaccurate prediction.

6.4 Data Generator:

Post scaling, we will proceed with making the datagenerator function, which will make the data ready for the LSTM model feed. We structure our model by taking a window of the most recent five days of data and using that information to anticipate the data for the current day. The input sequence will be divided into windows of data suitable for fitting an LSTM model by a newly developed function. To determine how many prior timesteps are used to forecast the upcoming timestep, we must establish a lookback period.

6.5 Restructuring input into a 3D Tensor form:

To prepare the input data for LSTM, we must transform it into a three-dimensional Tensor containing samples, timesteps, and features. The number of data points we have is represented by samples. The width of the sliding window depends on the number of timesteps in a sample. It should be noted that timesteps are different from the sliding step of the sliding window. As a result, timesteps is equal to the amount of time steps over which our RNN will run. The number of features in each timestep is the final component of features. 5.3.6 Generating the Epochs. We are importing the Model Checkpoint and Early Stopping callbacks from the keras library's callback module. These callbacks are used to save the model after each epoch or at various checkpoints as a best practice. Additionally, Early Stopping is utilized to halt training when the best loss is achieved, or when a monitored parameter reaches a point where it stops improving.



```
In [26]: from tensorflow.keras.callbacks import ModelCheckpoint, EarlyStopping

# Compiling the LSTM
regressor.compile(optimizer = 'adam', loss = 'mean_squared_error')

checkpoint_path = 'my_best_model.hdf5'

checkpoint = ModelCheckpoint(filepath=checkpoint_path,
                             monitor='val_loss',
                             verbose=1,
                             save_best_only=True,
                             mode='min')

earlystopping = EarlyStopping(monitor='val_loss', patience=10, restore_best_weights=True)

callbacks = [checkpoint, earlystopping]

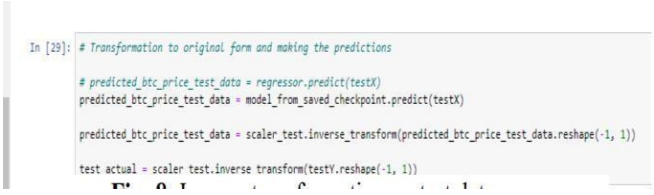
history = regressor.fit(trainX, trainY, batch_size = 32, epochs = 300, verbose=1, shuffle=False, validation_data=(testX, testY),

Epoch 1/300
67/67 [==============================] - ETA: 0s - loss: 0.0122
Epoch 1: val_loss improved from inf to 0.07602, saving model to my_best_model.hdf5
67/67 [==============================] - 6s 22ms/step - loss: 0.0122 - val_loss: 0.0760
Epoch 2/300
63/67 [===========================>..] - ETA: 0s - loss: 0.0226
Epoch 2: val_loss improved from 0.07602 to 0.01807, saving model to my_best_model.hdf5
67/67 [==============================] - 1s 11ms/step - loss: 0.0222 - val_loss: 0.0181
Epoch 3/300
66/67 [============================>.] - ETA: 0s - loss: 0.0044
Epoch 3: val_loss improved from 0.01807 to 0.01753, saving model to my_best_model.hdf5
67/67 [==============================] - 1s 12ms/step - loss: 0.0045 - val_loss: 0.0175
Epoch 4/300
66/67 [============================>.] - ETA: 0s - loss: 0.0024
Epoch 4: val_loss improved from 0.01753 to 0.01427, saving model to my_best_model.hdf5
67/67 [==============================] - 1s 10ms/step - loss: 0.0024 - val_loss: 0.0143
Epoch 5/300
66/67 [============================>.] - ETA: 0s - loss: 0.0011
Epoch 5: val_loss did not improve from 0.01427
```

Fig -7: Code for the generation of epoch

6.6 Utilizing testX and drawing a line graph againstthe actual testY, the LSTM Prediction:

The expected scale will be between zero and one as a result of prior scaling performed with the aid of MinMaxScaler. It is necessary to change this scale back to the initial data scale. As can be seen in Figure 6, we will utilize inverse transformation to scale back the data to its initial appearance.



```
In [29]: # Transformation to original form and making the predictions

         # predicted_btc_price_test_data = regressor.predict(testX)
         predicted_btc_price_test_data = model_from_saved_checkpoint.predict(testX)

         predicted_btc_price_test_data = scaler_test.inverse_transform(predicted_btc_price_test_data.reshape(-1, 1))

         test_actual = scaler_test.inverse_transform(testY.reshape(-1, 1))
```

Fig -8: Inverse transformation on test data

Following that, we create a graph plot in Figure 7 that contrasts the actual test data (in blue) with the anticipated test data (in red). Here, it is clear that the expected test results and the actual test results are advancing together.

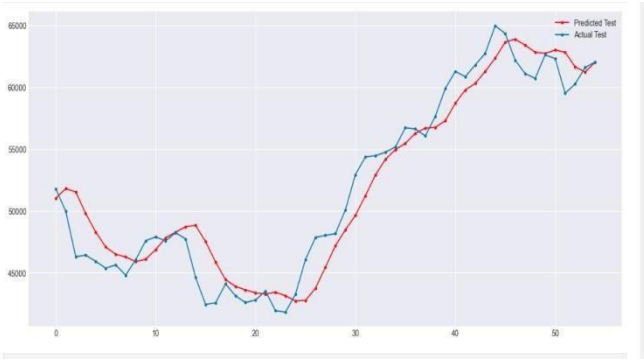


Fig -9: Plot of predicted test and actual test data

6.7 Utilizing trainX and a line graph to compare the predicted trainX to the actual trainY:

With the exception of the fact that we are applying inverse modifications to the train data in this stage, it is very identical to the prior step.

```
In [31]: # Transformation to original form and making the predictions

         predicted_btc_price_train_data = model_from_saved_checkpoint.predict(trainX)

         predicted_btc_price_train_data = scaler_train.inverse_transform(predicted_btc_price_train_data.reshape(-1, 1))

         train_actual = scaler_train.inverse_transform(trainY.reshape(-1, 1))
```

Fig -10: Inverse transformation on train data

Then, we will create the plot for the real train data (in blue) and the anticipated train data (in red) (in blue). Because they are made of training data points, Figure 9 demonstrates that the anticipated train and actual train graphs are well in sync.

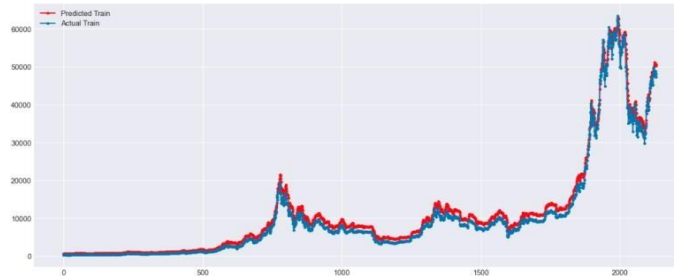

Fig -11: Plot of predicted train and actual train data

6.8 Root Mean Square Error:

The root mean square error (RMSE) for the test and train data will then be generated. A regression line's ability to fit the data points is gauged by its root mean square error (RMSE).

```
In [33]: rmse_lstm_test = math.sqrt(mean_squared_error(test_actual, predicted_btc_price_test_data))

         print('Test RMSE: %.3f' % rmse_lstm_test)

         # With 2 Layers + Dropout + lookback=5 => I got - Test RMSE: 1666.162  => This seems best

         Test RMSE: 2039.115
```

Fig -12**:** RMSE of test data

The RMSE of train data is then created. The RMSE loss produced for train data is much lower than the RMSE loss for test data because the whole training and fit function was run on the training data set.

```
In [34]: rmse_lstm_train = math.sqrt(mean_squared_error(train_actual, predicted_btc_price_train_data))

         print('Test RMSE: %.3f' % rmse_lstm_train)

         # With 2 Layers + Dropout + lookback=5 => I got - Test RMSE: 1047.916  => This seems best

         Test RMSE: 1823.588
```

Fig -13: RMSE of. train data

VII. RESULT

We can forecast Bitcoin values for the next five days thanks to an LSTM model that has been trained on historical data. According to the dataset that we used to develop the model, the last historical price for Bitcoin that we have is as of October 30, 2021. In order to forecast Bitcoin prices for the following five days, we are now looking beyond that specific day. It should be emphasized that we are once more forecasting the price for the following day utilizing data from the lookback period. Here, the lookback time is set to five days, meaning that we are forecasting the price of bitcoin for the following day using data on prices from the five days prior. For testing, our model is using sixty different numbers of data points. The testX has been moulded into a three-dimensional array in the form of samples, timesteps, and features in order to feed the input into the LSTM's model.

We use the final five components of the three-dimensional tensor. As a result, this procedure is looped five times, with each iteration producing the forecasted price for the following five days in a row. As a final step, we create a graph in Figure 12 that compares the whole test data prediction (including the following five days) to the actual testY. We reserve the expected test results (in red) and the actual test results (in blue) up until October 30, 2021.

Finally, as illustrated in Figure 14, we are creating a graph that compares the whole prediction of the test data (including the following five days) to the actual testY. We reserve the anticipated test data (in red) and the actual test data (in blue) on the ground up until October 30, 2021, since this is the time frame for which we have the real ground truth. Only the anticipated price of Bitcoin after the given date is available.

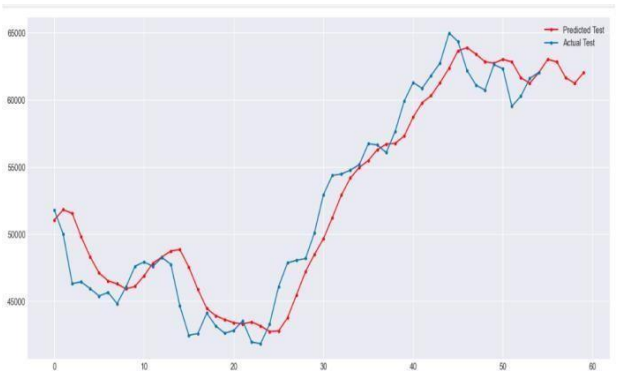

Fig -14: Plot of the entire test data prediction (including thefive future days) and actual testy

VIII. CONCLUSION

The LSTM model that will be used in this case is a simple model that only considers a few factors that have an impact on the price of bitcoin. Our model predicts future prices with a reasonable amount of accuracy. But for the model to be more useful, extra aspects of the Bitcoin price need to be taken into account. Since the data on this website holds a high level of credibility, we suggest choosing Coinbase as the source of datasets. In-depth examination of the subject of LSTM and deep learning in general would be part of future work. Such factual findings would be helpful for LSTM-based cryptocurrency price predictions in the future.

ACKNOWLEDGMENT

Project guide Prof. Pallavi Chandratre, Project Coordinator Prof. Reena Deshmukh, HOD Dr. Uttara Gogate, College Principal Dr. P. R. Rodge, and colleagues all contributed to the success of the project.

Blockchain Technology: A Comprehensive Review of its Principles, Applications, and Challenges

Shailesh Sangle , Ashwini Patil
Department of Computer Engineering Thakur College of Engineering and Technology,Mumbai, Maharashtra.
shailesh.sangle@thakureducation.org,ashwini.patil@thakureducation.org

Abstract— **Blockchain is a decentralized and distributed ledger technology that is being widely adopted across various industries to improve the security, transparency, and efficiency of data management. This research paper provides a comprehensive review of blockchain technology, its principles, applications, and challenges. The paper first introduces the fundamental principles of blockchain, including its architecture, consensus mechanisms, and cryptographic techniques. Then, it explores the diverse applications of blockchain, ranging from financial services and supply chain management to healthcare and voting systems. Finally, the paper discusses the main challenges that blockchain faces, including scalability, interoperability, and regulatory issues.**

Keyword- Blockchain, Bitcoin, Cryptocurrency

I. INTRODUCTION

The emergence of blockchain technology in 2008 with the advent of Bitcoin has sparked a new wave of interest in decentralized and secure data management. Blockchain is essentially a distributed ledger that allows for secure and transparent transactions without the need for intermediaries. The technology has since evolved beyond cryptocurrency to find diverse applications across various industries, including finance, supply chain management, healthcare, and voting systems. Despite its immense potential, blockchain technology still faces numerous challenges that hinder its widespread adoption. This research paper provides a comprehensive review of blockchain technology, its principles, applications, and challenges.

Blockchain concept can be applied in both financial and non- financial services. It can be classified as public blockchain, private blockchain and hybrid blockchain. In a Public or permission less blockchain, anyone on the network can read or write the record by showing the proof of work for the same[1]. This is fully decentralised and results in high rise of potential users. Crypto currencies like Bitcoin, Ethereum and Block stream are built with public blockchain methodology[2]. In a private blockchain, only the owner has the option to change the record/transaction[3]. This infrastructure is alike with existing centralised authority system and can be replaced to private blockchain to reduce cost and increase efficiency. The hybrid or permissioned blockchain is mix of both public and private blockchain,where few nodes/people in the network are allowed to change the record. This concept can be used by group of organisation for collaboration. Throughout this paper the permission less blockchain technology is considered with an example of Bitcoin cryptocurrency[4]. The blockchain is accumulation of numerous technologies like RSA encryption, Merkle tree, distributed computing, game theory and mathematical proof. Blockchain elements and technologies. Following section briefs about the basic elements of blockchain and its technologies

A. Block

Primary element of blockchain is a block, which contains the number of deals limited to the capacity defined by the different exercise. Once the block is validated, it is attached to the rearmost added block in irrecoverable chain. Attaching the hash value of former block to the current block forms the chain of valid deals as displayed in theFig.1.1.

Figure 1.1: Structure of Blockchain [5]

Each block is a combination of block header and data, where block header is used to store metadata of block like the block number, timestamp, hash of previous block, hash of current block, Merkle tree root and mining statistics like nonce and difficulty as mentioned in the Fig.1.2. The data part contains the list of valid transactions added into the block in chronological order. Every block header ties the transactions by Merkle tree root and any alteration in one transaction or even changes in the transactional order can be identified easily, because every block inherits from the previous block[6]. Previous block's hash is included with current block to make the blockchain tamper proof.

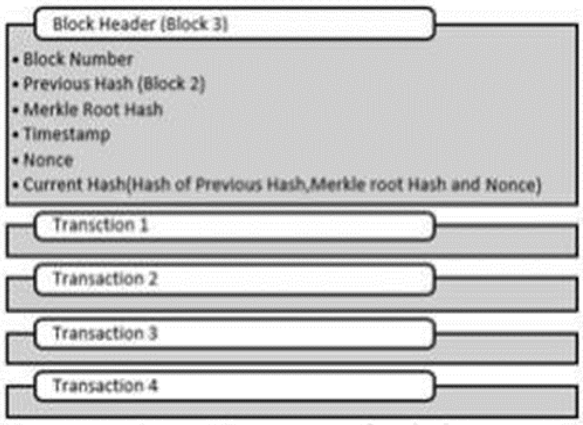

Figure 1.2: Structure of a Block [5]

[7] On January 3, 2009, the Genesis Block with serial number 0 was born. Six days later, the block with serial

number 1 appeared and connected with the Genesis Block to form a chain, thus the blockchain was born. Computer experts describe it as a de-centralized distributed ledger database. Each block is like a hard disk, which saves all the information and encrypts it in the block through cryptography technology. With-out mutual trust, blockchain technology can provide a decentralized and transparent data storage mode by using the mutual cooperation between blockchain network nodes based on consensus mechanism and distributed P2P network protocol for com-munication. The data stored in blockchain is packaged into blocks to form a chain structure and copied to each node, so it's called distributed public account book. With the cooperation of cryptography, hash technology, consensus algorithm, smart con-tract and other related technologies, the data in the blockchain is easy to verify and difficult to be maliciously modified and completely destroyed.

II. PRNCIPLES OF BLOCKCHAIN

The paper starts by introducing the fundamental principles of blockchain technology. The architecture of blockchain is explained, including the concept of blocks, nodes, and the peer-to-peer network. The paper then discusses the consensus mechanisms that ensure the integrity and immutability of the blockchain, including Proof-of-Work (PoW), Proof-of-Stake (PoS), and Delegated Proof-of-Stake (DPoS). The cryptographic techniques that underpin the security of the blockchain, including hashing, public-key cryptography, and digital signatures, are also explained in detail.

Blockchain has four basic characteristics: The first is that information cannot be tampered with. Users jointly maintain the security of data on the Internet to ensure that it cannot be tampered with. Once the information is validated and added to the blockchain, it is stored permanently. Unless more than 51% of the nodes in the system can be controlled at the same time, the modification of the database on a single node is invalid, so the block chain's data stability and reliability are extremely high. The second is to become decentralized and distributed, and it is important to note that distributed is a physical centre, not a management canter. For example,large-volume transactions are carried out simultaneously, and the decentralized approach will save resources, make trading autonomous and simplistic, and avoid the risk of being manipulated by the central agent. The third is privacy and supervision. From the current construction of the block-chain, these two seemingly contradictory points of privacy and supervision can be integrated. Because the exchange between nodes follows a fixed algorithm, the rules of the program in the blockchain will automatically determine whether the activity is valid. Hence, their data interaction is not trustworthy, and therefore the two sides of the transaction can generate mutual trust without disclosing their identities. The fourth point is the smart contract, which can realize the legal application based on the blockchain contract rules, and the top-level governance node can formulate the smart contract.[2]A smart contract is a contract written by code and automatically executes the contract signed by both parties in the contract when the conditions are met. Smart contracts are widely used in many fields.

III. BLOCKCHAIN ARCHITECTURE

The blockchain architecture comprises several components, including blocks, nodes, miners, and consensus algorithms. Each block contains a set of transactions that are cryptographically hashed and linked to the previous block, forming a chain of blocks (hence the name blockchain). Nodes are participants in the network that store and validate transactions. Miners are nodes that compete to validate new transactions and add them to the blockchain. Consensus algorithms are mechanisms used to ensure that all nodes in the network agree on the validity of new transactions

IV. APPLICATIONS OF BLOCKCHAIN

The paper then explores the diverse applications of blockchain technology. The paper highlights the potential of blockchain to transform the financial services industry, including banking, insurance, and investment. The paper also discusses the potential of blockchain in supply chain management, where the technology can improve transparency, traceability, and efficiency. The paper then explores the potential of blockchain in healthcare, where the technology can improve data security, interoperability, and patient privacy. Finally, the paper discusses the potential of blockchain in voting systems, where the technology can improve the security, transparency, and accessibility of elections.

V. CHALLENGES OF BLOCKCHAIN

Finally, the paper discusses the main challenges that blockchain technology faces. The paper highlights the scalability issues that arise from the limited processing power and storage capacity of the blockchain network. The paper also discusses the interoperability issues that arise from the fragmentation of the blockchain ecosystem. The regulatory challenges that arise from the lack of legal clarity and the potential risks of criminal activities are also discussed. Finally, the paper discusses the social challenges that arise from the potential impact of blockchain on employment, privacy, and inequality.

V. CONCLUSION

In conclusion, blockchain technology has immense potential to transform the way we manage data and conduct transactions. The technology's decentralized and secure nature offers numerous advantages over traditional centralized systems. However, the technology still faces numerous challenges that hinder its widespread adoption. As the technology continues to evolve and mature, addressing these challenges will be crucial to realizing its full potential.

Digitizing Doctor Handwritten Prescription

Mitanshu Dodia, Shiv Dixit, Maanav Chetty, and Dhwani Dedhia Computer Department
TCET
Mumbai, India

***Abstract*—Nowadays whenever we come across a handwritten document, which is manually written ,often we find that it is not readable by normal people . This happens mostly in the case where a patient gets prescribed, and the patient is supposed to carry this document to consult another doctor or to bring medicines from pharmacy they have to consult the doctor again if they have lost the prescription paper. In this era of digitalization, this method is still followed where people get handwritten documents but are unable to understand what is written. We are proposing a system which can transform this process into a digital, efficient and transparent way. In the proposed system the written text will be converted into digital readable from by comparing medicine database with the help of a Personal Digital Assistant(PDA), and this p will be saved. So whenever we need the content of the document, it will be stored and can be accessible. The main purpose of this is to reduce time and make use of the modern era of digitalization to ease out the tiring process of identifying what is written and transforming it into texts.[1]**

I. INTRODUCTION

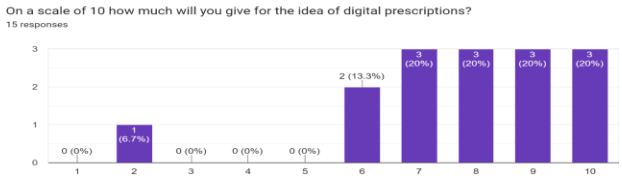
In this era of digitalization, use of Mobile Phones and Computers may be very common than ever, but most of the people still prefer the traditional feeling of writing with hand on paper. Despite of accessibility to various technologies related to writing tools, many people still choose to take their notes with pen and paper. After all, this method has provided us well for many years. However, there are certain flaws in conventional way of handwritten text.

Whenever we come across a handwritten document, which is manually written ,often we find that it is not readable by normal people . It is commonly known that doctors have illegible handwriting. This happens mostly in the case where a patient gets prescribed, and the patient is supposed to carry this document to consult another doctor or to bring medicines from pharmacy. The doctor usually knows what is written, but when patients or other parties are involved they often have problems with reading and interpreting the text. We are trying to resolve this problem by recognizing doctor's handwriting using handwriting recognition and converting it into legible format. In this project, we are trying to propose a system which can transform this process into a digital, efficient and transparent way. In the proposed system the written text will be converted into digital readable form by comparing medicine database with the help of a Personal Digital Assistant(PDA), and this prescription will be saved. Also we are trying to store all their prescriptions in a central storage to make sure that no medical details are missed. Doctor can get the history of medical details directly from the system. Pharmacist can get prescription directly from the system. The Patients can also see their medical reports and laboratory details as well. So whenever we need the content of the document, it will be stored and can be accessible.

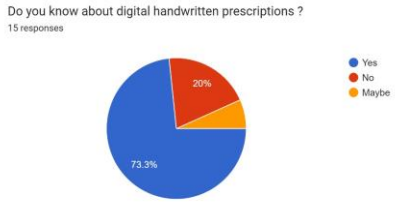
The objective is to yield the most appropriate textual inter- pretation of a given set of handwritten strokes and the system will try to look for a match in the medicine database. After verifying with the doctor it can be uploaded to cloud, once found. This will be available in pharmacies and authorized pharmacies can get the list as per customer's request. In current scenario hospitals are trying to change into e-prescription but major challenges in this area is the handwriting recognition of doctors. Automation should eliminate many of the errors that occur when pharmacists misunderstand or medication names or dosages conveyed messily on paper.**[1]**

II. LITERATURE REVIEW

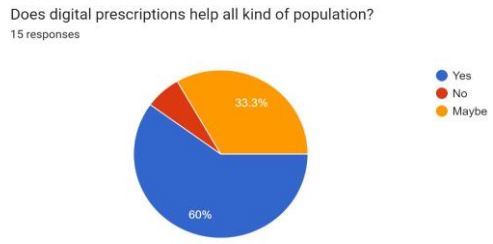
we conducted the survey and the results were also in the favor of making such system which can digitize the doctor handwritten prescription and it also shows that many people every year are affected by this problem of wrong medicine because of lack of clarity of doctor handwritings.



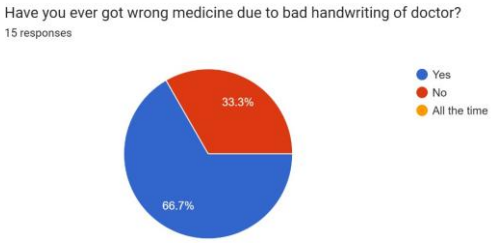
The above graph shows that most of the people want the digital handwriting platform.



The above chart shows that almost 73% people have the knowledge about the digitizing platform.



The above chart shows that this system will help all kind of people .



The above chart shows that almost 67% of people are prescribed the wrong medicine.

I. METHODOLOGY

To make this system it requires a huge amount of data so we are trying to use the already existing open source dataset which are available online and then we will be augmenting the dataset for more variations in the images so that we can have a more accurate and robust model.

The second step after collecting the dataset comes is the data preprocessing step, in this we will be using an opencv library for the image augmentation and segmentation so that they can be easily fed to our deep learning model and then we are going to use the CNN to train the model, The architecture for the model is yet to be finalized but the initial thinking is leading us to the usage of CNN or LSTM which are good for capturing long distance context and CNN are good for image recognition. Then the tech stack which we are thinking to use is the django for backend and html,css, javascript or react for frontend, the database we are thinking to use is mongodb as they are convenient to store the images and data.

Then we are thinking to use the more advance multimodal model like layoutlm for document classification and get the data from the document so that we cans store them easily in the database and there is no need for manual entering the data like date and patient name as that can be classified using the deep learning model like layoutlm etc.

This is the fully functional model which we are thinking to implement to solve this major problem and we think it will be effective and will help many doctors and people and will save the lives by prescribing the correct medicine.

II. CONCLUSION

We believe that this project can make an impact in the current medical field problems like prescription forgery,losing prescription, brand name usage in prescription, scanning large handwritten documentaries, scientific proofs etc. This sys- tem will help in making prescription by reading document so that could become more handy and digitizing this could also eliminate many human errors leading to proper treatment of the patient by getting the right medicine .**[2]**

III. FUTURE SCOPE

Major Challenge in Designing this system is different handwriting styles and lack of enough training data Hence at the beginning itself the product cannot give its full productivity. There can be problem like internet availability, reach to common people and others but within the span of time the product can reach its targeted audience and can make the expected change. In the coming time we will try to analyze the more handwriting styles and work according to the data set.[3]

Abstract—**Data Structures and Algorithms (DSA) are fundamental concepts in computer science that form the basis of efficient problem-solving, they play a very efficient role in job placements. However, learning and mastering DSA can be a challenging task for students and professionals alike, every year lakhs of engineers struggle to clear the technical rounds due to their weak DSA preparation. To address this challenge, this paper proposes a Personalized DSA Planner that provides a customized study plan to each individual to help them effectively learn and master DSA concepts. The project features a user profile creation system, personalized plan generation based on individual goals and progress, task management, progress tracking and a resource pool for learning materials. The project also provides a cost- effective solution for DSA learning and has the potential to greatly impact the way individuals approach and learn DSA. It also promotes a sense of "Learning by own" in every individual. This study aims to evaluate the effectiveness of the Personalized DSA Planner and provides insights into the benefits of personalized learning in the field of computer science.**

Keywords—Data Structures, Personalised planner, Algorithms, programming languages, Prototype, Resource Center, problem solving.

I. INTRODUCTION

Data structures and algorithms are the foundation of computer science and play a crucial role in software development and problem solving. The term DSA stands for Data Structures an Algorithms. As the name itself suggests, it is a combination of two separate yet interrelated topics – Data Structure and Algorithms. An algorithm is defined as a process or a set of well-defined instructions that are typically used to solve a specific set of problems or perform a particular type of calculation. A data structure is a specific way of storing and organizing data in our devices to use the data efficiently and effectively [1] As technology continues to advance, the demand for individuals proficient in data structures and algorithms has increased, making them essential for job placement in the technology industry. The newbies to computer science or more precisely Data Structure lack the knowledge of what is data structures and algorithms are, how they work behind the code and how these algorithms are used in real life. Knowingly or unknowingly, we use data structures and algorithms in our day-to-day life [2].

However, the ideas behind data structures and algorithms might be confusing and daunting for someone who is new to computer science. The project being implemented by this study paper attempts to increase readers' knowledge of the subject. The project offers a customized data structure and algorithm planner that will assist each person in their learning process. This project would be implemented through website with a user-friendly interface, and it aims to provide a system that dynamically selects and optimizes data structures and algorithms for a specific task, considering the specific characteristics of the data and the user requirements. It can be used to improve the efficiency and effectiveness of data processing and analysis tasks by selecting the best-suited data structure and algorithm for the task at hand. The planner can use machine learning and other optimization techniques to make its selections, and continuously update its decision- making as the task and data evolve.

The paper provides a walkthrough, beginning with the abstract, where the reader is given a summary of what the paper is about. The introduction discusses the significance of data structure and algorithm and its impact on job placements, and this is followed by a review of several research papers and discussion of some useful insights for further implementation of the proposed system and also the key features that are to be added in future implementation. Thus, the paper concludes by letting everyone comprehend how the idea of a personalized planner would have a significant impact on education and would help close the gap between each person and their ideal careers.

II. LITERATURE REVIEW

Monica Bulger in her research paper “Personalized Learning: The Conversations We’re Not Having” tends to explain the concept of enjoying while learning [3]. A number of modern technology initiatives in education are still motivated by the desire to provide tailored education to all students, and new technology promises to level the playing field by empowering access to knowledge and teaching. Insights into personalised learning are presented in this paper, which covers a wide range of potential applications — from personalized user interfaces to adaptive tutors, from student centered classrooms to learning management systems — with high hopes for their potential to revolutionise education.

Eric Fouh in his research paper “Evaluating Online Tutorials for Data Structures and Algorithms Courses” changed the traditional and old method of learning DSA with the help of pen and paper and with the help AV (Algorithm Visualizer) [4]. AV is used for dynamic exposition and to increase student interaction with the material. Using this feature a drastic change amongst student was seen.

Cilfford A. Shaffer in his research paper “Creating Engaging Online Learning Material with the JSAV JavaScript Algorithm Visualization Library” showed that how the trend of AV with java is declining and hence the author focused on JSAV (JavaScript Algorithm Visualiser) development library [5]. It simplifies the function of AV on many engagement levels including interactive exercises. This paper contains a list of shortcomings, one of these objectives is to include built-in assistance for locating misunderstandings and the production of data to reveal students' misconceptions. The security and reliability of the grading are two more significant issues that need to be addressed. At the moment, the grading is carried out on the client side, making it easy for anyone proficient enough in JavaScript and browser web development tools to cheat. The results would be even more reliable if a method for server-side regrading of the submissions could be set up.

In his research work "Data Structure and Algorithm in Non computer Major," Zhao Wang provides a quick overview of how algorithms aren't just tied to computers and processes; they're also a reflection of learning and a lifelong pursuit of knowledge [6]. This paper suggests the implementation of a website that offers nine modules of teacher-student interaction, lesson plans, teaching teachers, teaching content, course homework, my grades, study guides, and course resources. The teaching content and course information are organised by a tree structure that is self-contained, clear, and acts as a type of data logical structure.

The authors Shraddha Ghadge and Virajas Mane focuses on the visualization of various data structures and algorithms created by web development in the research article "A survey paper on Data Structure and Algorithm Visualization" [7]. Which algorithm or data structure the user wants to see is their choice. It also allows for the depiction of certain cases by modifying the values or weights. The DSA visualizer is a pleasant educational activity that improves students' capacity for quick learning and understanding the topic; this tentative notion may eventually be employed in our project. This paper falls short of being a fully working website because it does not incorporate a code editor or the proper data structures and algorithms codes.

Author Mr. Victor Adamchik in his research paper, "Data structure and Algorithm in Pen Based Computing Environments," discusses the traditional teaching methods that instructors have adapted to teach students about the fundamentals of data structures and algorithms as well as how new contemporary practises have the potential to bring about a revolutionary shift in the field of education [8]. Investigating the suitability of a Tablet PC environment for teaching data structures and algorithms is one of his study's main objectives. In this setting, sketching becomes a crucial component of computer science research. It enables the expression of ideas and their sharing in a highly participatory setting. Thus, their suggested solution of leveraging the pen-based gesture interface will encourage students' algorithmic thinking and intuition for problem-solving. The proving techniques used in, say, an advanced course on algorithms present significant challenges to computer science students. This paper does not address solutions to proofs using pens.

The author of the research paper "Personalized Learning Path of a Web-based Learning System" focuses on how an interface agent compiles a list of suggested readings based on pre-test results for students [9]. The personalization agent then rates the list based on how challenging each learning unit is. The new difficulty level of a learning unit is derived by linearly combining the course difficulty as assessed by the students and the courseware developers, with varied weights assigned to each. This paper gives a complete insight about how ML algorithms are embedded in creating a teaching system.

I. METHODOLOGY

In Data structure and Algorithm, algorithms are evaluated based on three aspects: specification, verification, and performance analysis. Specification formalizes the details of the problem the algorithm is intended to solve and involves defining the relationship between inputs and outputs. Verification confirms that the algorithm does what it is intended to do, while performance analysis assesses how efficiently the algorithm operates. These three aspects are dependent on the specific problem being solved [10]. The purpose of a customized DSA planner is to create a clear road map for each person in order to improve their professional abilities and give them assistance in closing the employment gap.

A. Conceptual Diagram:

Fig. 1. Flowchart

Depending on their expertise and level of confidence in the subject, users would be divided into three categories after logging into their accounts: beginner, intermediate, and advanced. When a user selects Beginner, they would be given a choice to choose time limit and programming language; based on their selection, they will receive a customised planner. This personalised planner will be developed by using Machine Leaning algorithms where datasets will be labelled with time limit and difficulty level. In the intermediate level, users must choose several topics that they are already familiar with; next, a quiz would be taken. If the user passes the quiz, their answers will be saved, and they can choose to study more. Based on that, they will receive a personalized learning plan. If the user fails the quiz, they can either retake it or limit the number of topics they choose to learn about. In the advanced level the user will be given coding problem or quiz, and based on the results, they can continue their educational journey. After selecting a topic, users will receive related documentation and videos. User can choose between multiple videos according to their comfort level and understanding level. Consequently, based on their time constraints, concerns, and degree of understanding, users will receive a customized plan and specific resources from the vast pool of DSA resources.

A. Hardware and software Requirements:

1. Frontend Requirements:

- HTML
- CSS
- JavaScript
- React JS

2. Backend Requirements:

- MongoDB

B. Prototype

Fig. 2.1 Prototype

The project's high-fidelity prototype is shown in the picture above. The user will arrive at the webpage and be prompted to sign up for an account or log in using their data. The user will be prompted for details including their name, age, and educational background.

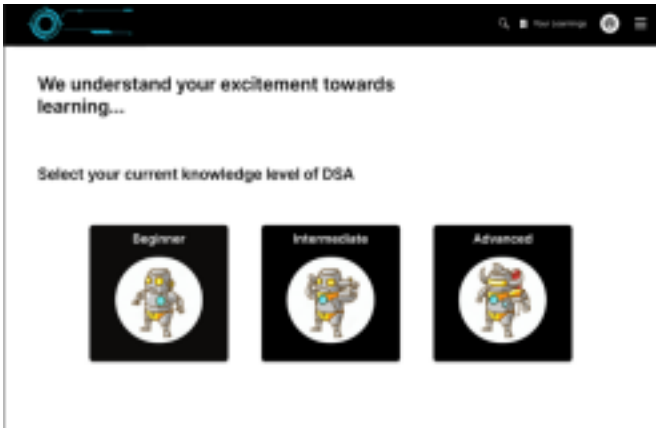

Fig. 2.2 Prototype

Students can select options like Beginner, Intermediate, and Expert after logging in. Beginner students are those who know nothing about DSA, intermediate students who know little about DSA, and expert students who really understand DSA. They will thus receive a quiz depending on the option and subject they selected. After passing the test, individuals may continue their DSA adventure using the programmes we have provided for them. Beginner students may access the plan by choosing the time frame during which they wish to learn DSA; as a result, they will receive a customised plan. This plan includes of written materials and videos on that specific subject.

Fig. 2.3 Prototy

The user will then be presented with questions according to their level of expertise after choosing their level. For instance,the novice level user will need to decide which language they want to use to continue their DSA journey and how long they want to spend learning it. Similar questions will be posed to intermediate level users on the language they prefer and the amount of time they have before they must take a brief quiz to verify their stated understanding of data structures and algorithms. The expert level user will next have to take a difficult level quiz depending on his knowledge and skill set. afterwards, the user may browse the website to look for things that interest him.

Fig. 2.4 Prototype

The below prototype illustrates the section where the learner will be asked about topics that they are already familiar and comfortable with. The software would generate a personalised learning and practise schedule for them to follow in order to learn and practise the areas they haven't mastered, based on the feedback we received.

A. Characteristics

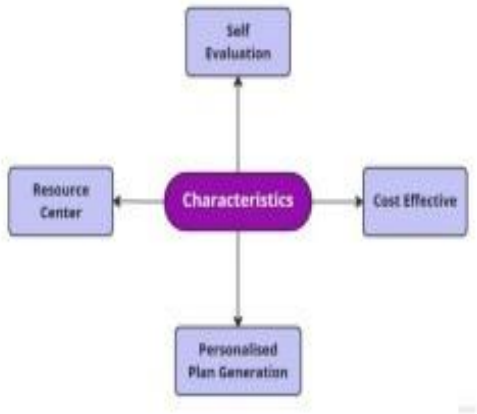

Fig. 3
Characteristics

1)Self-Evaluation

Users of the system would be able to monitor their development, assess their performance, and maintain track on how close they are to achieving their desired goals.

2) Cost Effective

The system would be completely free to use, making it accessible to all DSA learners without incurring any additional costs. This feature gives the project an extra edge over other DSA resource systems.

3) Personalised Plan Generation

The system would provide a personalised plan based on the user's profile that would include a daily schedule for every individual as well as all the topics that's needed to be covered in order to achieve their desired goal.

4) Resource Center

The user would have access to a pool of resources and materials to aid the individual on their DSA journey, such as documentation, topic related videos, websites and even simple quizzes.

I. FUTURE SCOPE

The system can have its own teaching content and collaborations with technical experts to reach a larger audience. Data Visualization tools or simulation can be incorporated on the website to make learning more practical and understandable. The proposed design seeksto offer users a fully personalized plan where they can explore different resources and advance their programming knowledge. Verified bloggers and collaborators can publish their content on the website and educate people with their thought process. The design may be improved further to support competitions between the various levels, making it simpler for users to assess their learning progress.

A collaborative environment would be provided for solving real life problems along with practicing algorithms. Further implementation of practice problems and exercises to assess and enhance comprehension and application of data structures and algorithms would also be done.

II. CONCLUSION

In conclusion, a personalized DSA planner project is a promising solution that addresses the challenges faced by DSA learners in their journey. This project provides a personalized plan, tailored to the individual needs and goals of each user, making it a highly effective tool for achieving success. The features offered by the project, including task management, progress tracking, data analytics, and a resource center, empower agents to stay organized and motivated. Furthermore, the project offers a platform for collaboration and a sense of community among DSA agents, which can help to overcome challenges and support their success. The project's cost-effective approach makes it accessible to a wide range of users, regardless of their budget or resources, and has the potential to greatly impact the DSA industry. An in-depth study of this project can provide valuable insights into the effectiveness of personalized planning for DSA participants and inform the development of similar systems in the future. Overall, the

personalized DSA planner project represents a promising solution for enhancing the success and efficiency of DSA agents and merits further research and exploration.

VI. ACKNOWLEDGMENT

We would especially like to thank Mr. Shailesh Sangle, the research head and our guide, for his contributions towards the growth of the paper. Additionally, we would like to thank our principal, Dr. B.K. Mishra, for motivating us to present our concept as a research article.

Abstract—**This abstract addresses the importance of Games which helps in teaching, games have become an important part of our culture in a relatively short period of time. Industry is also developing into a major pillar of many modern economies, with game development tax schemes being introduced into many developed countries. These are coinciding with a period of time where it has never been easier to release a game onto the educational market. It is still essential to have a good understanding of the technical aspects involved in making games and the considerations involved in designing games which help people in learning. Sometimes the best way to develop this knowledge is to begin at the very beginning, so we'll look at some game history. This paper practically develops a game-based learning system to improve self-efficacy for student's learning. Game-based learning is combined with educational and information technology. From the e-learning carried on, game-based learning is getting more attention. With game-based learning, the course material is mapped into the game to create a scenario-based learning environment. Repeated self-learning, ongoing interaction, and feedback can all help learners become more engaged and motivated. Consequently, game-based learning could successfully accomplish the learning objective.**

Keywords--E-learning, interactive classrooms, modern education.

I. INTRODUCTION

For the majority of students, when learning operating systems, besides continuous memorization and recitation, the programming homework in the course also creates a bottleneck for the students in their learning. Students have lost faith in the curriculum for a variety of reasons, which has reduced their enthusiasm to learn and made them want to give up. This study combines games with course content to design an online multiplayer collaborative learning game, so that when students engage in the games, it creates a desire to win arises through the model of mutual competition. The students can thus learn knowledge relating to the course on their own, and in turn, gain a victory in the next game, improving the learning effects.

II. PROBLEM DEFINITION

These days, students use mobile phones in addition to desktops and laptops. Finding the course materials requires higher education students to spend a lot of time online. Sometimes the teacher delivers the materials, but the students who want to enroll in a particular course for a semester are unable to acquire a quick overview of the course before the semester begins. There are many online learning platforms available today, but not many of them are single-page and responsive. Additionally, in today's world of lifelong learning, students must always have access to course materials and from any location. Nowadays, finding course materials online is simple, but getting access to them is difficult due to the materials' closed access. Most of the time, registering is required in order to download files, but once they do, they discover that the materials cost money.

At a simple level, games-based learning can be defined as “learning that is facilitated by the use of a game.” This can be at any academic level from preschool through to lifelong learning, from simple memorization and recall to high level learning outcomes such as evaluation or creativity. The game can be used directly or as a supplement, and it can be played in person with real things or online with a computer. Because there is no single approved classification and definitions vary depending on the disciplinary backgrounds of individuals who construct them, the challenge lies in the precise definition of the term "game." Game based learning is also an active learning technique where games are used to enhance student learning. Here, the learning comes from playing the game and promotes critical thinking and problem solving skills. Game based learning can be accomplished with digital or non-digital games and may include simulations that can allow students to experience the learning firsthand.

There are now numerous online learning platforms available, but only a select few are single page and responsive. Because the old system uses simple HTML design, the typical web application for e-learning does not provide the students with a decent browsing experience. This project's main goal is to give students better and more effective access to course materials, information, and other useful features. In this project, a single-page, responsive web-based courseware system will be created, allowing students to access course materials that have been submitted by university professors so that they can discover everything in one place. Its main goal is to make it simple for teachers and students to communicate with one another and access

coursework at any time and from any location.

III. LITERATURE SURVEY

Games-based Learning (GBL) has developed a reputation with educationalists it is perceived as a potentially engaging form of supplementary learning that could enhance the educational process and has been used at all levels of education including primary, secondary and tertiary education. Despite this recognition and utilization there is still a lack of empirical evidence supporting GBL as an approach. This paper presents the findings of a systematic literature review performed from 2000 to 2013 specifically looking at quality empirical studies associated with the application of GBL in Primary Education (PE) categorizing studies into: behavioral change, affective and motivational outcomes, perceptual and cognitive skills and knowledge acquisition and content understanding. This paper presents a synthesis of these high quality studies associated with GBL. According to the studies, GBL has been utilized to teach a range of disciplines to kids and teenagers in physical education, with math, science, language, and social studies being the most common. However, the analysis shows that more Randomized Controlled Trial (RCT) studies should be performed comparing GBL to traditional teaching approaches to ascertain if GBL is a useful, viable teaching approach at PE level; there is a distinct lack of longitudinal studies and further longitudinal studies are required; further studies are required looking at whether there are pedagogical benefits of using 2D or 3D games at PE level to assess if 3D immersive games are indeed necessary; further studies are also required to perform comparisons between single and collaborative play and to identify the pedagogical benefits.

Games are an efficient way to learn skills and attitudes that are difficult to pick up by rote memory. Games have the potential to teach, train, and educate. This is just one of the many assertions made about learning games. Because they (theoretically) offer a variety of approaches that can address cognitive and affective learning (such as knowledge construction, skill acquisition, and attitude acquisition), educational games are becoming more and more recognized as new instructional technology with significant potential. The expectation is that playing (educational) games will inspire and involve students in the learning process, which is probably most important. This boost in motivation is thought to result in higher mental effort investment, more deliberate information processing, and more. The game-based learning environment has the following characteristics:

1. Use the game method to motivate students to rethink their original knowledge

2. This game provides instant feedback to help teachers understand the student's actual teaching progress and make various suggestions promptly

3. Through the game, students can share a lot of information and acquire knowledge.

4. Learning through games can ensure that students are not bored comfortably facing learning.

5. The game usually comes with discussion and social networking activities

IV. METHODOLOGY

Here are some specific algorithms or strategies that can be used to create effective game-based learning experiences:

Goal setting: Define clear and measurable goals for the game that align with the learning objectives.

Feedback System: Provide immediate feedback to the player on their progress and performance, including areas where they can improve.

Scaffolded Learning: Gradually increases the complexity of the game mechanics to match the player's skill level and keep them engaged.

Collaborative Learning: Encourage players to collaborate with each other, for example by sharing their knowledge, working on team challenges, or competing with each other.

Personalized Learning: Provide personalized learning experiences by adjusting the game mechanics and content to the player's preferences and learning needs.

Storytelling: Use storytelling to create an immersive and engaging game experience, incorporating plot twists, character development, and interactive narrative elements.

Multiple Intelligences: Incorporate multiple intelligences, such as visual, auditory, and kinesthetic learning styles, to cater to a range of learning preferences.

Game-based Assessments: Use game-based assessments, such as quizzes or puzzles, to evaluate learning outcomes in a fun and interactive way.

Emotion-based Learning: Connect learning to emotions by incorporating elements such as humor, drama, or surprise, to create a more memorable and engaging experience.

Gamification: Use gamification techniques such as points, badges, and leaderboards, to motivate players to engage with the learning content and achieve their goals.

These algorithms or strategies can be combined and adapted to suit different learning objectives, audiences, and game types. By using these strategies, game-based learning can be an effective way to engage learners, promote knowledge acquisition, and improve learning outcomes. Creating a gaming atmosphere that is adapted to all the learners' ability:

1. Start with a simple game: Begin your lesson by introducing a simple game that focuses on a particular concept. This game should be easy to learn and simple to play.
2. Explain the game: Once the game has been introduced, explain the rules and objectives of the game. Allow students to ask questions and provide additional instruction to ensure they understand the game.
3. Introduce the concept: After the game has been explained, introduce the concept that the game is teaching. Provide examples and use visuals to further explain the concept.
4. Have students play the game: Allow the students to play the game in pairs or small groups. As they play, monitor their progress and provide guidance when needed.
5. Review the concept: After the game has been played, review the concept by having the students answer questions about the

6. Provide feedback: Finally, provide feedback to each student on their performance and understanding of the concept. Encourage students to continue to practice and play the game.

V. RESULT AND DISCUSSION

The use of digital games has great potential in higher education to provide active, fun, and engaging online education. The results of the analysis of the prior research data indicate that students' interest in adopting game-based learning has increased. Even though the participants were limited in that universities with its student of selected courses and section . By including complementing incentive factors, portable digital games can enhance both "hard" skills (like abilities or job-specific skills) and "soft" skills (like teamwork) (e.g. fun and competitive). Official training method. Alternatively, this game can be played by an individual or student pairs.

If the coach sets a large and continuous-time at his disposal, such as a 3-hour time slot, you can even play the game at the same time. However, teachers should be careful when estimating how long it will take for the time to play the game to complete until it is needed to complete the game task. Finally, for all digital games, it's important to pay attention to the learning curves that students face when using technology and take appropriate steps to reduce technical barriers.

The mpact of educational games on teaching and learning concepts has been overwhelmingly positive. Games can increase engagement and motivation, improve learning outcomes, promote personalized and collaborative learning, and provide more effective assessment of student progress. As technology continues to advance, we can expect to see even greater benefits from educational games in the future.

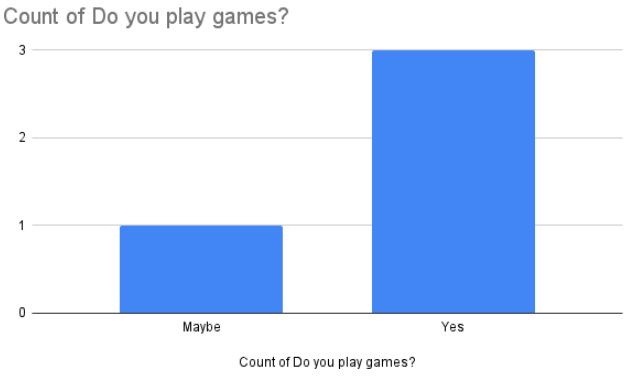

Fig.1

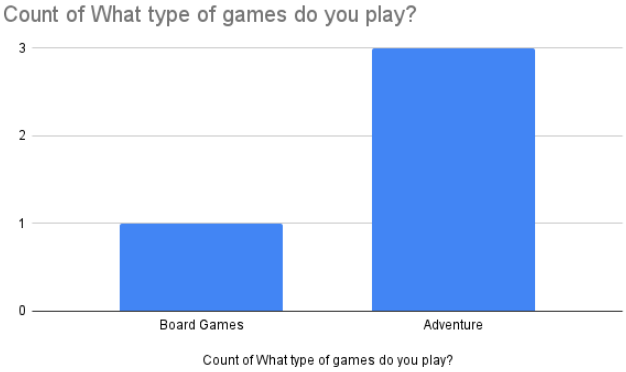

Fig.2

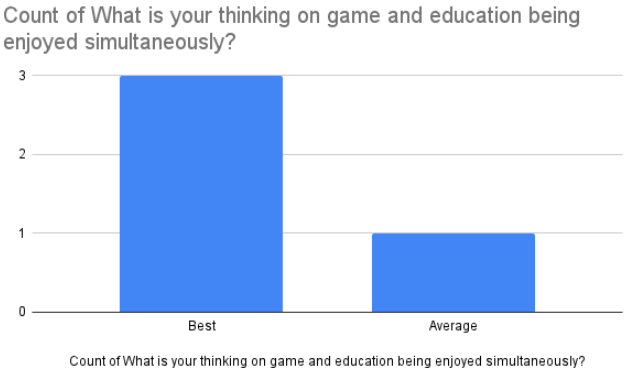

Fig.3

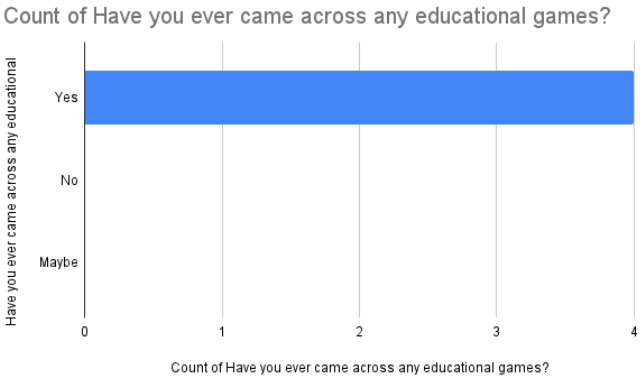

Fig.4

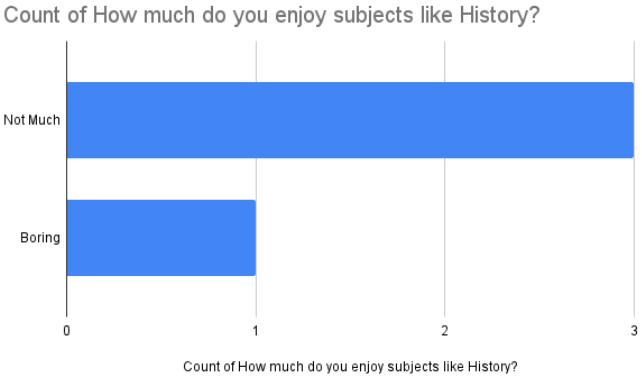

Fig.5

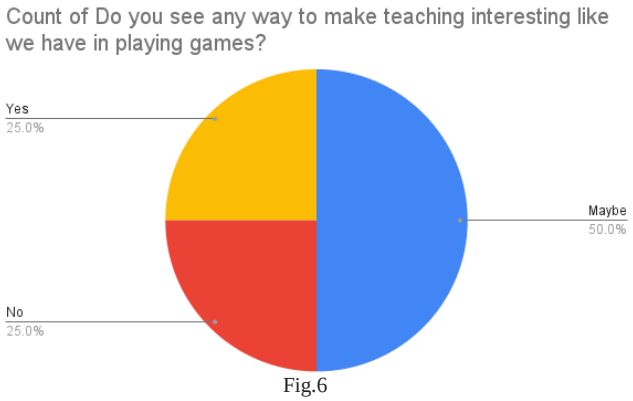

Fig.6

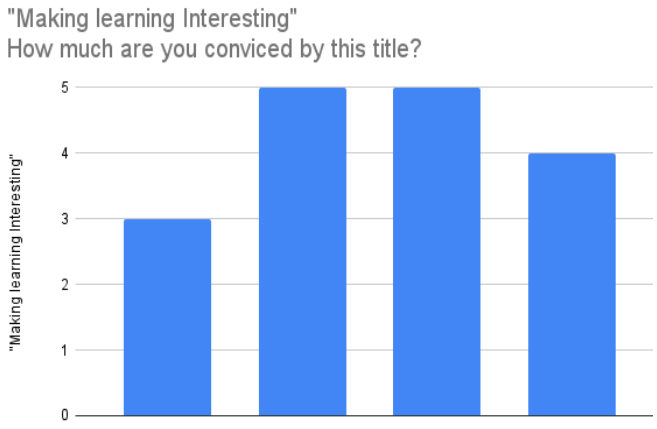

Fig.7

The above survey results reflect the amount of games today's generation plays and the type of it. From the results it is clearly understood that adventure games are quite popular among the students. The response on gaming plus learning also has a positive reply from the respondents. Clearly we can see that educational games can have a positive impact on today's generation.

VI. FUTURE SCOPE

The future scope of educational games on teaching and learning concepts is significant. Game-based learning has already demonstrated many benefits over traditional teaching methods, and as technology continues to advance, these benefits are likely to increase. Here are some potential future impacts of educational games on teaching and learning concepts:

Increased engagement and motivation: educational games have been shown to increase student engagement and motivation. As game design and technology continue to advance, games could become even more engaging, incorporating interactive 3D environments, artificial intelligence, and other advanced features to keep students engaged and motivated.

Enhanced learning outcomes: Games can be designed to promote active learning and problem-solving, allowing students to apply what they have learned in a practical context. As game-based learning becomes more sophisticated, it could help students develop a deeper understanding of complex concepts and improve learning outcomes.

Personalized learning: educational games can be designed to adapt to the individual needs and preferences of each student. As game design technology continues to advance, games could become more personalized, tailoring the learning experience to the student's individual learning style, skill level, and interests.

Collaborative learning: Games can be designed to promote collaboration and teamwork among students. As game-based learning becomes more social, games could help students develop important interpersonal skills and learn how to work effectively in a team.

Improved assessment: Games can be used to assess student learning outcomes in a more meaningful and engaging way than traditional assessments. As game design and technology continue to improve, games could become more effective at assessing learning outcomes, providing teachers with valuable insights into student progress.

Overall, the future scope of educational games on teaching and learning concepts is exciting. As technology advances and game-based learning becomes more sophisticated, we can expect to see even greater benefits for both students and teachers.

VII. CONCLUSION

There are many opportunities to implement the concept of the game in education, and there are many types of games available in the learning process, including problem-solving, practice, simulation, puzzles, and educational games. In this paper, the main purpose was to highlight some of the literature reviews by analyzing 6 core-papers. Furthermore, the literature review identified studies related to game-based learning that focused on the rapidly emerging learning paradigm and practice of using computer games and encouraging the learning process, which determined positively for both stuff in their experience. This review of general game-based learning summarizes some of the benefits of applying game-based learning to improve student performance. Social game mechanics increase student motivation and learning needs, develop stronger relationships with team members and colleagues, and ultimately help the knowledge discovery process. The methodology, explained in common figure to show the six phases to follow through any system development to enhance a game based. In general, we need to combine traditional gaming frameworks with clear pedagogical elements to help students achieve their full educational potential. In conclusion, we hope that educational institutions will introduce game applications to improve learning.

ashwini.patil@thakureducation, anandjaiswar02@gmail.com, a manjais160@gmail.com, sandeshjaiswal2002@gmail.com

Abstract—**This paper addresses the importance of e-learning in modern education, as well as its technical aspects, market, advantages and disadvantages, comparison to instructor-led training, and prospects for its eventual replacement of traditional classroom instruction. As more users become computer literate, the idea of e-learning is currently growing in popularity. Faster bandwidths have made a significant contribution to the expansion of e-learning. E-Learning is being used by many universities and higher education institutes. Large corporations are also making significant investments in interactive classrooms and e-learning. E-learning will soon replace paper books in the form of tablets with touch screens as the future of education since it is a fun, interesting, and interactive method to study.**

Keywords--E-learning, interactive classrooms, modern education.

I. INTRODUCTION

The science of learning without using printed instructional materials on paper is best described as e-learning. It is the delivery of information for education and training through telecommunications technology. E-learning is becoming the model for modern education as information and communication technology development continues to advance. The asynchronous and synchronous learning network model is one of the key benefits of online learning since it frees interactions between students and instructors from time and geographical constraints. This method of instruction and learning is also referred to by a variety of other names. Online learning, virtual learning, distributed learning, network learning, and web-based learning are a few of them. E-learning is much more than just online learning; because the letter "e" in E-learning stands for the word "electronic," E- learning would include all educational activities carried out by individuals or groups working online or offline. As a result, e- learning relies on learning content that can be accessed anytime, anywhere. This content is created utilizing videos, audio, text, animations, and/or simulation to enhance learning.

We currently have the impression that knowledge is everywhere and that e-learning approaches have made this feasible. The industrial sector is gradually converting to e-learning approaches for staff training and favoring them over a workforce of many hired trainers in the informal education sector. This guarantees the best possible use of two of an organization's most important resources, namely income and time. Even in the formal higher education sector, many universities and institutes now provide students with a variety of online courses in two formats: 1) as a supplement to their traditional courses, and 2) as pure online courses. The students enrolled in these online courses can even take their exams online. E—learning thus becomes integral part of both students and concerned authorities and feasible to both.

II. PROBLEM DEFINITION

These days, students use mobile phones in addition to desktops and laptops. Finding the course materials requires higher education students to spend a lot of time online. Sometimes the teacher delivers the materials, but the students who want to enroll in a particular course for a semester are unable to acquire a quick overview of the course before the semester begins. There are many online learning platforms available today, but not many of them are single-page and responsive. Additionally, in today's world of lifelong learning, students must always have access to course materials and from any location. Nowadays, finding course materials online is simple, but getting access to them is difficult due to the materials' closed access. Most of the time, registering is required to download files, but once they do, they discover that the materials cost money.

There are now numerous online learning platforms available, but only a select few are single page and responsive. Because the old system uses simple HTML design, the typical web application for e-learning does not provide the students with a decent browsing experience. This project's main goal is to give students better and more effective access to course materials, information, and other useful features. In this project, a single-page, responsive web-based courseware system will be created, allowing students to access course materials that have been submitted by university professors so that they can discover everything in one place. Its main goal is to make it simple for teachers and students to communicate with one another and access coursework at any time and from any location.

III. LITERATURE SURVEY

Without a doubt, the global socio-economic problems brought on by the Covid-19 pandemic were severe. Many nations have put restrictive measures in place to limit social gatherings and encourage social segregation to control the spread of the disease. This resulted in the closure of institutions of higher education and a significant change from conventional classroom-based teaching and learning to a virtual approach. Due to Covid-19, higher education may have changed and migrated online, but it is unclear whether this change has a positive impact on teaching and learning outcomes. In the age of the COVID-19 epidemic, this literature study is being performed to gather relevant

information on the outcomes, difficulties, and opportunities of e-learning and e-teaching. While many studies on the epidemic have been published, very few of them discuss the depth of e-learning and e-teaching outcomes, accompanying difficulties, and opportunities during the Covid-19 period. Numerous difficulties with teaching and learning that academics and students experience are discussed in the literature. These obstacles include being unable to access or use online teaching and learning resources; finding it difficult to adapt, especially for students from low-income families and those who live in remote areas; and experiencing related stress, sadness, and anxiety.

Multimedia, static images, moving images, video, music, text, and many other learning aids can all be crucial components of an efficient e-learning system. Virtual learning environments handle database handling, file management, feedback management, content management, content delivery, management of financial transactions, etc. in addition to providing a user interface. It benefits not only the students but also the administrator, teachers, instructors, and trainers. There are two primary types of virtual learning environments: commercial mode and non-commercial mode, both of which support the ideas of open source.

The study would thus benefit with respect to below points:

1. Constant accessibility (supports anywhere anytime concept)

2. Concepts are more clearly explained because of the additional resources, such as videos, audios, animations, simulations, blogs, and professional assistance.

3. It helps with development at the individual level through one-on-one interactions with teachers and saves time and money.

4. Students always have a variety of additional options available to them to meet their educational needs.

5. Every learner has the freedom to go at their own speed. This pace does not have to be static or constant; it can also change dynamically for each person.

6. It offers a quicker method for students to have their progress reviewed at various levels and by various teachers.

7. The students can receive feedback and solutions more quickly to their doubts.

Web technology is used by e-learning as its fundamental technical foundation for knowledge delivery. A greater need for technology assistance is anticipated soon because e-learning is currently on the rise in academic and industrial settings. Its versatility, user-friendliness, reach, ease of accessibility, consistency, and repeatability are its primary benefits in addition to cost-effectiveness.

Categories of E-learning:

1) Courses:

Most e-learning discussion centers on academic programs. Usually, educational course materials or courseware are altered, and additional media are added before being transferred to a networked environment for online access. Today, educational institutions use several well-liked learning management systems (LMS), including WebCT and Blackboard. Courseware creators have started using creative presenting techniques including simulations, storytelling, and numerous distinctive qualities into the materials to create a more interesting courseware. E- learning and classroom environments are remarkably comparable in that both students and teachers are involved in the same course structure and flow.

2) ***Informal learning***:

Although one of the most flexible and dynamic aspects of learning, information learning is one of the least acknowledged. Our search is motivated by our need for information (as well as how we plan to use it). A strong toolkit for knowledge workers' portfolios includes search engines (like Google), information storage tools (like Furl), and personal knowledge management tools like wikis and blogs. According to Cross, we learn more in the workplace during downtime than in a classroom setting. Via informal learning, sometimes through trial and error and other times through conversations, we advance more quickly in our careers.

3) Blended Learning:

A smooth transition from in-person instruction to online instruction is made possible through integrated learning. Online and face-to-face instruction are both used in integrated learning, which is also known as blended learning. One cannot overstate how effective this approach is. It promotes education and information review outside of the classroom. In blended learning, face-to-face instruction is combined with a variety of delivery methods, including collaboration software, web-based courses, and computer communication techniques. The best classroom instruction is combined with the best online instruction in integrated learning.

4) Knowledge Management:

E-learning technology is a focus of globalization because it could make better learning opportunities available to a wider audience than has ever been possible. It has been proposed that establishing a learning society is a necessary step for a country to take on the path to a prosperous knowledge economy. Knowledge management is a crucial process that deals with how to build a culture of knowledge sharing for activities like information exchange, adoption, and distribution within an organization.

5) Learning Network:

Building and maintaining relationships with people and information while communicating to promote one another's learning is the process of creating a learning network. As a result, (LN) is growing and providing opportunities for its members to interact online and share knowledge and skills.

IV. METHODOLOGY

Web technology is used by e-learning as its fundamental technical foundation for knowledge delivery. A greater need for technology assistance is anticipated soon because e-learning is currently on the rise in academic and industrial settings. The analysis, design, documentation, implementation, and distribution of instruction over the Web should all be supported by software tools that support the crucial process of instruction design.

There are three different categories of online learning

knowledge representation tools. In general, we may say that each kind of tool stresses a particular step in the process. Tools for the curriculum offer a structured and uniform environment to promote classroom learning; their roles are especially useful in the beginning and choosing phases. While knowledge representation tools concentrate on formulation and representation, digital library tools enable effective and efficient access to resources to help exploration and collection.

A) Curriculum tools:

In secondary schools and colleges of education, curriculum tools are frequently used. To facilitate class activities, materials are chosen and arranged. To facilitate collaboration and evaluation, extra features are added, such as online forums and quizzes. Three interconnected components make up a typical commercial curriculum tool: administrative tools, student tools, and instructional tools. The creation of courses and computerized quizzes are examples of instructional tools. Authentication and authorization tools for file management are included.
Among the capabilities of student tools are:

1. Browsing course materials, including readings, assignments, projects, and other resources. Explore Courses according to category.
2. Search Courses with keyword.
3. Scheduling and monitoring of learning progress: activity logs, personal calendars, and reminders for the submission of assignments.
4. Self-testing and evaluation: assessments created by teachers to evaluate pupil performance.

B) Digital library tool:

While curriculum tools assist with classroom activities, digital library tools concentrate on finding materials. These features aid in the information search's exploration and gathering phases. Users of a vast amount of digital content can find the information they need with the aid of digital library technologies. Search, browsing, and finding unique collections or exhibits are frequently included in digital library services. To find resources and investigate connected issues, search and browsing are utilized. Organized resources found in special collections or shows provide curious users a priceless resource.

C) Knowledge Representation tool:

Tools for knowledge representation assist students in graphically reviewing, capturing, or developing information. Most curriculum tools use a text- based, syllabus-based approach to describing course content. This method frequently fails to clearly define how the ideas and abilities covered in one course relate to those covered in another. Additionally, it fails to demonstrate the body of information that a student will have attained by the completion of their academic program. When creating spatial semantic displays of the knowledge, concepts, and skills that the learner knows and gains, a visualization tool. It can involve both students and instructors in an active learning process.

D) About us section:

This section provides information about the creators through which the students and learners would get to interact with. They would also come to know about their achievements, their work and get an idea of how they can build up their knowledge.

E) Login system:

The login system ensures the registration through which the learner can have their own profile and track their progress. It helps them to easily connect with the working team by their username. Their profile is secured as the password is included.

F) Contact:

Through this, the learner could easily connect with the team and the creators via their email ids, Instagram account, twitter or google account. This helps them to post their grievances, doubts etc. so that the learning would made effective. The students can also give feedback or suggestions through which the learning process could be improved for better understanding and outreach to more and more students around to achieve the best goal and provide the students a best platform to enhance their skills.

G) Responsiveness of the website:

The website is handy and easily accessible if it is responsive. If the design of the website is made interactive with the user such that it responds to the queries instantly, it is considered successful. It fits well with all the dimensions of the device, making it feasible for the students to use using mobile phones or laptops, iPad etc.

H) ***Panels in our Website*** (May change in time)

We have decided to include 3 panels in our Project. The panels and its details are as follows.

a. Teacher Panel

i. Login/Register/OTP verify via email.
ii. Forget Password/Change Password/
iii. Profile/Social Accounts
iv. Send message to Enrolled Student (Individually or All)
v. Category CRUD
vi. Upload content according to category
vii. Upload study material according to course
viii. Can see the total enrolled students and their progress.
ix. Count Total views of content.

b. Student Panel

i. Login/Register/OTP verify via email.
ii. Forgot Password/Change Password/Profile
iii. Enrolled Courses
iv. View the profile of content creator.
v. Send message to Content Creators (Individually or All)

c. Admin Panel

i. Manage everything.
ii. Search anything
iii. Add/Update/Delete Any Content
iv. Enable disable any course, student, or teacher.

I) Business Model

We have our Business Model of Learning Management System.

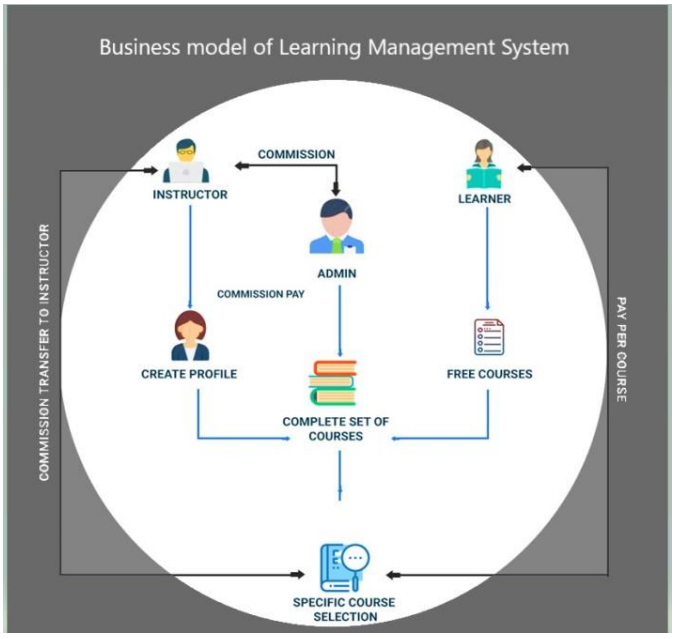

Figure 1: Our main Business Model

V. RESULT AND DISCUSSION

Numerous studies and academic institutions are interested in evaluating various e-learning, online learning, blended learning, and face-to-face course formats to determine which is more beneficial in terms of, for example, learning outcome and student satisfaction. However, research demonstrates that learning and teaching are complicated processes that are impacted by factors more than just the teaching method. We should therefore investigate the numerous variables that affect teaching and learning in various circumstances and forms. The focus of this literature review has been on the elements that influence students' engagement in e-learning, online learning, and blended learning in higher education, with a focus on teacher preparation and professional development. The review's research findings reveal that among the many factors, some stand out more than others, including educator online presence, interactions between students and content, and intentional links between online and offline activities as well as between campus-related and professional activities. More precisely, the studied literature provides a wealth of recommendations for various course designs that are successful in each situation. According to studies, e-learning and blended courses should be created to promote coherence among students, teachers, and content as well as between online and offline activities, campus-related and practice-related activities, and between online and offline activities.
The responses included approval over responsiveness of the website, easily access factor, instant response factor, different options through navigation bar, etc. The content provided on the website was up to the point with respect to the user according to their requirements. However, less approval was given towards recommendation factor as it does not provide suggestions on the history that one has gone through.

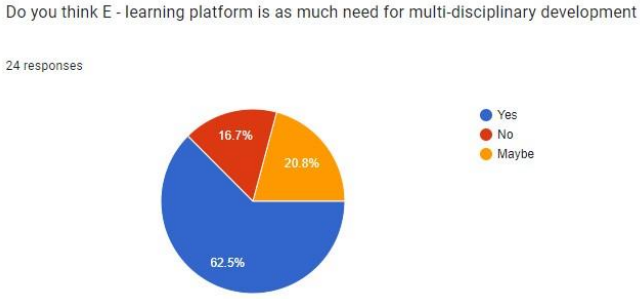

Figure 8

Online education includes virtual courses provided by major universities. Online learning, or virtual lessons delivered via the internet, offers an alternative to traditional courses taken in a real educational building. It is a trend in online learning that increased the World Wide Web, and the commercial Internet became more widely used in the 1990s. The student Experience is frequently asynchronous, yet it can also have synchronous parts. a large for the administration of online courses, most institutions use learning management systems courses. As remote education philosophies change, digital tools that promote learning and the practice of teaching is evolving as well.

In the survey conducted, it was understood that given the improvements in delivery methods, online learning environments provide a greater degree of flexibility than traditional classroom settings. Additionally, more varied portrayals of student groups can be seen on online platforms. Interacting with students from different places than one's own fosters diversity and may provide a range of viewpoints on the course material.
Completely online courses are often provided using either an asynchronous learning format or a synchronous learning style. Through a college or university's learning management system, most of the online learning takes place (LMS). A LMS is a piece of software used to manage, distribute, and track educational content. As reported by 99% of colleges and universities, the use of an LMS is almost universal, according to the Educause Center for Analysis and Research (ECAR). Among faculty, 87% report using a LMS and find them useful for "enhancing teaching (74%) and student learning (71%)". Similarly, 56% of students who utilize an LMS in most or all of their classes do so because 83% of them do.

From the survey we got to know that 66.7% of student infer that Online courses where People just enroll and learn as per their time. 37.5% of student prefer Offline Learning & Assessment, 62.5% of student think E - learning platform is as much need for multi-disciplinary development, 50% of student prefer YouTube for learning courses, 70.8% students think that the main benefit is the ability to easily ensure online training and learning materials are being distributed effectively .

Thus, to make this online learning process more powerful, effective and trustworthy, a proper assessment is required. Through our project, we would ensure that to do so , following points would be taken care of:

Randomized quizzes
Task submissions
Video assessment
Certification

VI. FUTURE SCOPE

In comparison to the conventional classroom teaching methods, the new online education technologies, and e-learning tools are far more interactive, individualized, and engaging. E-learning strategies give students the option of a completely customized, self-paced online curriculum for at-home learning in addition to a classroom environment that is far more engaging. Many educational institutions throughout the world are adopting a blended learning format by utilizing internet- and multimedia-based instruction platforms, computer-aided learning, technology-enhanced e- learning materials, and learning content management systems on various sizes. The learning content that is enriched by media-enabled technology is more interesting than the options that use dry textbooks.

E-learning has quickly transformed from a futuristic idea to a useful method of teaching. It will still be a very effective self-study platform and teaching tool in the classroom. The use of e-learning programs will become more prevalent in experimental topics, skill-based learning, and military training as virtual reality and augmented reality technologies advance. Numerous vendors of educational technology are also making hints about the advent of mobile learning solutions, or e-learning, as the next development in educational technology. More animations would add up, scientific laboratories, simulations would stimulate the e learning. Different methods of evaluation would be made to avoid the cheatings during any tests. More of the factors would be added to provide all the resources at one place.

VII. CONCLUSION

Online education has the potential to improve students' retention of what they learn. This is so because several supportive elements exist, such as student motivation, literacy, and self-assurance. In addition, it indirectly influences how well students grasp the learning content. E-learning involves more than just a shift in technology. It is a component of redefining how our species imparts knowledge, abilities, and values to future workers and students. E- learning is becoming the standard method of delivering education and training in many industries.

Healthcare, Fitness And Exercise Planner

Mrs. Rashmi Thakur, Mr. Harsh Bhatia, Mr. Parth Dhakan, Computer Department
TCET
Mumbai, India

Abstract-**Healthcare systems globally have experienced intensive changes, reforms, developments, and improvement over the past 30 years. Multiple actors (governmental and non- governmental) and countries have played their part in the reformation of the global healthcare system. New opportunities are presenting themselves while multiple challenges.The Indian hospital industry accounting for 80% of the total healthcare market is expected to touch US$ 132 billion by 2023. In the Economic Survey of 2022, India's public expenditure on healthcare stood at 2.1% of GDP in 2021-22 against 1.8% in 2020-21. The purpose for a Global Strategy on Digital Health is to promote healthy lives and wellbeing for everyone, everywhere, at all ages. To deliver its potential, national or regional Digital Health initiatives must be guided by a robust Strategy that integrates financial, organizational, human and technological resources.**

I. INTRODUCTION

Mobile medical Apps, healthcare applications and medical patient programs are currently growing rapidly in popularity. Mobile health, called Health solutions, grow together with the global increased use of smartphones.

In addition, the attention to the healthcare process is shifting to be more and more patient- centric. In reality, mobile health care programs will become one of the greatest revenue contributors. Based on recent data it can be anticipated to grow to $58.8 Trillion in 2022 from $25.39 Billion in 2017. Thus, we'll see it more than double during the coming years.

II. NEED OF HEALTHCARE MOBILE APPS

The speedy adoption of smartphones and increased dependence on them is among the chief reasons for increases in much of the medical app development. People today find it hard to spare time to get routine check-ups and health tracking. Introduction of mobile programs for health care has made it feasible for folks to maintain a Continuous check on their wellbeing and know about health through predefined parameters

III. RESEARCH OBJECTIVES

Some of the main objectives of mHealth include improving healthcare quality, reducing clinical errors, and integrating resources; these purposes may also improve patient lifestyle. In his study, Mueller [9] found that a high percentage of patients with serious conditions used mobile monitoring, claiming many benefits such as faster input from physicians on their health status. In addition, they anticipated that this heart failure monitoring device would be low-cost and effective. The use of mobile technologies to monitor equipment seems to be a feasible alternative for enhancing patient-provider communication. The present research will look at the impact of mobile health apps on primary care practitioners' patient care.

Accordingly, the primary objective of the study is to investigate the impact of mobile health applications on primary care professionals' patient care.

IV. LITERATURE

The term mHealth, also known as mobile health, has emerged as one of the most intriguing new discoveries in recent years. mHealth has a wide range of definitions; the U.S. health officials define mHealth as using mobile wireless devices to enhance health outcomes, health services, or research. The WHO defines mHealth as "the use of mobile or wireless technologies to assist individuals in achieving their health objectives." Physiological sensors, as well as integrating communication devices and computers, have made it possible for mHealth to take off in a big way.

With today's mHealth technology, there are three main types of mobile devices that may be used to gather health-related data: basic phones, handsets, and smartphones. In addition to making phone calls, basic phones only allow for text message communication. The small form factor of feature phones allows them to have multimedia display capabilities. Another popular feature phone was Motorola's RAZR, with a small color display around 15.2 cm squared. Phones using the SYMBIAN computer system faced a few limitations when it came to programming. This may be seen as an extension of telemedicine/telehealth, because the phone can be used to send and receive health- related data. It is now possible for individuals and healthcare providers to transmit text messages and pictures containing important health data to medical institutions and experts in remote areas, who can subsequently reply with professional advice through the same methods.

Due to the ease and portability of mobile phones, medical advice may be sent while the patient is still at their home or at the site of an accident, saving time and money on transportation. Basic mobile phones, features phones, and, of obviously, smartphones all have this "any-where" functionality. Smartphones with advanced software, such as WhatsApp, make it simple to send pictures, text, and video back and forth. WhatsApp's secure conversations are especially attractive in the medical field since they maintain the confidentiality of the provider-patient relationship.

One thing to keep in mind is that in this scenario, the medical understanding is being given by someone in another country or region.

The strong graphical and coding capabilities of

smartphones allow the development of applications that explain medical/surgical procedures apart from medical evaluations like the case mentioned previously. When sent to distant or conflict areas, medical personnel known as medics are often required to deal with trauma situations in the absence of doctors and surgeons, including performing invasive operations such as blood transfusions and lot of carbon emissions.

Apps that combine speech, pictures, and video into step-by-step instructions may help the physician execute these operations. However, even after up to two years of rigorous training, these doctors are expected to be well-versed in a wide range of medical problems and treatments, including more than a hundred different kinds of medical and surgical operations. There is no way a doctor could know everything about everything, so having this information provided in easy-to- access, searchable media-rich forms on a smart phone, instead than in cumbersome paper documents, may be very helpful to the medical community in many situations.

V. MHEALTH AND HEALTHCARE

The current part of the study examines the existing research on the influence of mobile applications on primary healthcare patient care. The structures and applications of mHealth are also discussed in this section. Leong et al found that healthcare employees at a Singaporean tertiary critical care hospital were surveyed about their phone cleaning habits, emotions, and views. The researchers also looked at how positions in phone hygiene started to promote phone hygiene. According to their survey, 11.5 percent of healthcare professionals cleaned their phone on a regular basis, while 9.4 percent had never cleansed it, but this was changed to 16.9 percent and 3.8 percent, respectively, once phone hygiene stations were put up.

Feroz et al. looked at the possibilities of using a mobile phone to improve performance of healthcare employees in low- and middle-income countries. Health professionals' services had a substantial effect on child mortality and morbidity rates, as well as the burden of noncommunicable and communicable diseases, according to the evidence they provided. The cost of a mobile instant service for patients with t2dm mellitus was assessed by Islam et al.. The intervention expenses for the text-messaging programmed on mobile phones totaled $2842. As a result, it was a useful complement to diabetes patients' therapy and was expected to save money in low- resource situations. It has a major effect on healthcare in many ways because of telehealth (mHealth).

With smartphones, medical advice, and clinical decision support may be delivered through multimedia. In poor nations, smartphones may be an effective support tool for healthcare personnel. Many new health mobile devices, such as smartwatches and activity sensors, have recently become available.

So, according Hasandokht et al., because women are the most regular users to Isfahan health centres, in order to help women with hypotension who have been sent to treatment centers, a package of corrective measures has been put together. Most of the survey participants would use mobile phones to access free mental health surveillance and self-management programs. When it comes to mobile health, SMS is a go-to service. It can be used for everything from patient follow-up to tracking health behavior to collecting data about patients. In comparison to patients who got conventional treatment, those who received SMS had higher rates of reporting on antiretroviral therapy (ART) drug adherence.

The results of this research indicate a positive attitude regarding the use of mobile phones in follow-up services. Chen & Allman-Farinelli, (2019) estimates that sending appointment reminders through text message or email improves show up by as much as 7%. SMS increases clinic attendance, which helps both the clinic and the patients. According to Zolfaghari et al., patients who get SMS treatment and follow-up phone calls show greater improvement in glycated hemoglobin (HbAtc). Public health centers' most popular activities include follow-up and communication.

Certain populations, such as pregnant women, newborns, children, and the elderly, get mobile phone services such as prescription reminders or visit attendance.

As cellular telephones have the potential to improve primary care, the goal of the study is to find out how health centre employees in Zahedan feel about using mobile phones to provide services. To improve technology acceptance, it is necessary to distinguish between the perspectives of users first. The Iranian province of Sistan and Baluchistan includes the city of Zahedan, which is its capital. It has a population of 587,730 people according to the 2016 census. The authors were unable to locate a suitable instrument to examine the perspectives of public health workers, so they created a one-of- a-kind questionnaire as the first step, followed by a review of the responses

VI. METHODOLOGY

Research may be defined very widely as the systematic collecting and evaluation of data and knowledge on any topic. Research seeks to pursue solutions through rigorous methods to metaphysical and practical questions. There are many methods of study depending on the approach and context, several of which include (a) descriptive analysis focuses on gathering evidence that determine the existence of what happens; (b) examination of the relevance of the theory based on study of gathered evidence is involved; (c) applied

analysis is undertaken to provide solutions to practical questions to be resolved and to help make decisions in diverse fields like product design, process design, and policy-making; and (d) fundamental science is conducted to satisfy scientific curiosity rather than to use research evidence for immediate realistic use.

Qualitative research (e) examines factors that are not quantifiable and thus not subject to estimation and quantitative interpretation for the study subject. In comparison, quantitative study (f) requires considerable use of instruments and methods in quantitative analysis.

VII . CONCLUSION

Health service quality development, clinical error reduction, and resource integration are some of the major aims of mHealth; these goals may also enhance patient lifestyle. Remote monitoring through communication devices looks to be a viable option for improving patient provider communication. Mobile health apps were investigated for their impact on primary healthcare professionals' patient care in the present research.

Healthcare effectiveness, education, notices, consultation, and follow-up were included in the proposed five-part questionnaire. When it came to attitudes about mobile phone usage while working, people of all genders, ages, levels of experience, and educational backgrounds had the same attitudes.

Using the effectiveness of health software solutions, education, notification services, and consultation, the study found that mHealth apps had a favorable influence. The study's relevance is obvious in light of the preceding studies, and it effectively studied the usefulness of mHealth applications in primary healthcare professionals' patient care.

Virtual Clothing Try-on System

Ms. RR Sedamkar, Mr. Om Dalal, Mr. Yash Jain, Ms. Dhruvi Jagani, Mr. Arjun Gujar, Computer Department
TCET
Mumbai, India

Abstract: **Virtual Clothes Try-On System is a computer-based technology that enables users to try on clothes virtually, without physically wearing them. This technology is particularly useful for online shopping as it provides a more interactive and realistic experience for customers. The system works by capturing a 2D/3D model of the user's body and simulating the fit and appearance of different clothing items on this model. This process is achieved through the use of advanced computer graphics and computer vision techniques. With this technology, customers can see how clothes would look on them without having to physically try them on, thus saving time and reducing the need for multiple trips to the store. This system can also help reduce waste by reducing the number of clothes that are returned due to poor fit. Overall, the Virtual Clothes Try-On System is an innovative solution that has the potential to revolutionize the way people shop for clothes online.**

I. INTRODUCTION

Virtual clothing try-on systems are computer-based applications that allow customers to virtually try on clothes by superimposing images of the clothing items onto a digital representation of the user's body. The user typically uploads a photo or uses a webcam to create a 3D model of their body or drags and drops their photos to get a 2D view. Then, they select clothing items from a virtual wardrobe to try on. The technology uses computer vision algorithms to accurately align clothing items with the digital body model. This creates a realistic representation of how the clothing would look on the user in real life. Virtual try-on systems can be found in a variety of contexts, including e-commerce websites, augmented reality apps, and in-store kiosks.This system can also be integrated in creating an overall lifestyle product with integration and updating certain algorithms.Based on your recent search history it also provides you with clothing recommendation.This can be scaled to shoe try-on,skincare products as well as hair style products as well.This system solves the problem of walking in to the store,hassle-free shopping.It can also conserve energy saving fuel wasted on traveling to the stores making it time efficient as well.

I. LITERATURE SURVEY

These systems allow customers to virtually try on clothes and accessories before making a purchase, providing a more convenient and personalized shopping experience.

During the COVID-19 pandemic, when people were seeking safer and contactless shopping options, this proved particularly beneficial..Virtual try-on systems have also reduced the amount of waste generated by traditional brick-and-mortar stores, as customers are able to make more informed purchasing decisions without having to physically try on clothing. With virtual try-on systems, retailers have also been able to reach a wider audience, including those who live far from a physical store or find it difficult to travel there.As a whole, virtual cloth try-on systems have been successful in providing customers with a convenient, personalized, and sustainable shopping experience, while also helping retailers to improve their operations.

Below, are the certain reasons that support how old fashion clothing try-on practice is losing the customers:

1. Time wasted in trying clothes in stores

As we walk in to buy clothes in a store,we find a piece that suits us the most.We take it to the trial room to check whether it fits us the way we want it to.Most of the time,there are limited trial rooms in a store due to which one might have to wait for a while if none are vacant.Further if the decided cloth does not fit the way we predict,the hassle to check for a different size and try it out again is even more frustrating.

2. Unavailability of certain clothes in store

Due to limited space and inventory available in store,there exists a possibility that the cloth you might have thought about buying or trying to the least may not be available in the store,wasting your time and effort taken to travel to the store.

3. Shopping at your own convenience and time is not possible offline.

To shop in certain stores,the store timing must be followed which is 10 a.m. - 10 p.m. in most of the stores in India.Incase one is not able to make it to the store in decided time,they either may not get to shop or would have to choose from the leftover stock of the day which causes injustice with such customers.

I. Objective

To make an online virtual cloth try-on system that will recommend and let them try clothes according to their requirement. The online cloth try on system allows the customers to shop at their own free will,at the convenience of their comfortable place and try as many clothes they want to hassle-free.Available 24 hours of the day,a person can shop and try out clothes and directly communicate with the brand about their purchase without any middle retailer.

The software may also serve to be an all in one website store to buy clothing and shoes from various brands and cultures in one place under a stable internet connection.

II. Existing System

In the existing model,there are two ways to buy clothes,one being the offline walk in and the other would be to buy online.In the former,if one likes a piece of clothing,they take it to the trial room to check whether the decided size fits them the way they want it to.If not they would have to check if another size of the same cloth is available.In the latter one checks for the cloth they want to buy and add them to the cart based on the size shown by the brand which might be inaccurate.There is a possible way in which one can try out clothes online in this system

Problems of Existing System:-

a. No comfort and time efficiency
b. Loss of effort,fuel,property
c. Absence of user friendly timings.

III. Proposed System

In the proposed system,we provide customers to try out clothes at their own comfort by using their device camera.We have developed a website for the same which has not been deployed yet.It is supposed to recommend clothing and shoes based on your previous browsing history .The application also provides with a fine user interface which is easy to use and all the required tools are easily accessible and deployable for all the operating systems. The first page comprises of the login and signing in details of the user which can be used for personalized recommendations.The user may find a cloth or a pair of shoes of their choice which they could try out even if the piece is out of stock.If the case remains,a reminder will be sent to the user’s email address once the cloth is back in stock.For the entire catalog of clothing products,the model will be functional.

II. METHODOLOGY

A computer-based programme known as a virtual cloth try-on system allows customers to picture how clothes will appear on them without actually trying them on. This system works by identifying the user's body shape and dimensions using computer vision and image processing techniques, and then superimposing clothing over the user's image. The methodology that will be used to build a virtual cloth try-on system is described below.

Step 1: Gathering Datasets

Creating a dataset of photos of people wearing various outfits and adding metadata about the kind, size, and dimensions of each outfit is the first stage. The virtual cloth try-on system is trained with this dataset so that it can distinguish between the many categories of clothes.

Step 2: Body Measurement Extraction

The second phase involves employing computer vision techniques like pose estimation, segmentation, and feature extraction to extract important body measurements from the user's image, including height, weight, and body shape. This data is used to find the clothing in the dataset that fits the user's body shape the best.

Step 3: Segmenting clothing

In the third step, algorithms for segmentation and background subtraction are used to separate the clothes from photos of the persons wearing it. This makes sure that only the clothing and not the background or any other objects are superimposed over the user's image.

Step 4: Extraction of Clothing Features

The fourth phase involves employing image processing methods like convolutional neural networks to extract clothing attributes like texture, color, and style (CNNs). These characteristics enable a realistic virtual try-on by comparing the apparel in the dataset with the user's body type.

Step 5: Simulate wearing clothing

The fifth phase involves employing physics-based simulation techniques, such as cloth simulation, to mimic how the clothing will behave when placed over the user's body. This entails modeling how the user's body and the user's clothing interact, taking into account things like gravity, folds, and wrinkles.

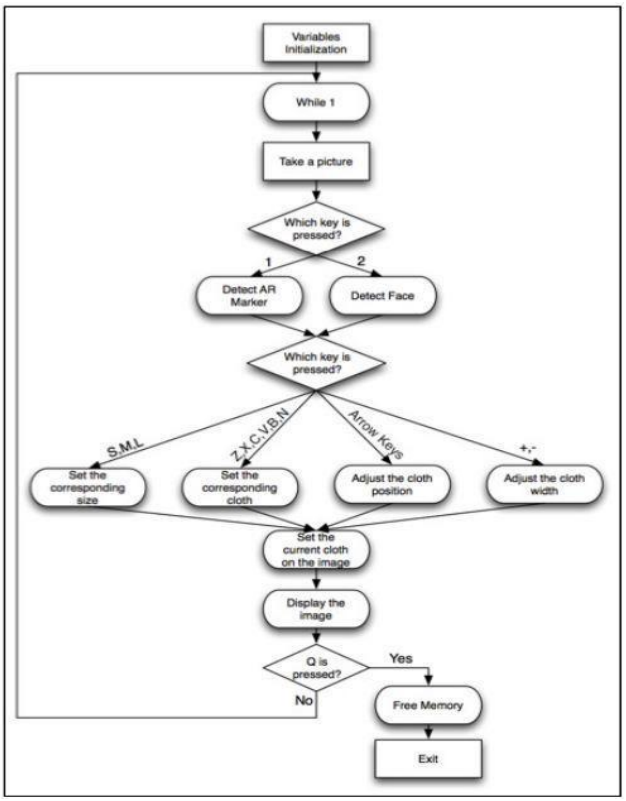
Step 6: Virtual Try-On

The user can view how various types of clothes might look on them using a virtual try-on system that is created in the sixth stage using the retrieved body measurements and simulated apparel. This entails creating a realistic virtual try-on by layering the apparel on the user's photograph.

Step 7: Assessment

By contrasting the virtual try-on results with genuine clothes try-on results, the final stage is to assess the accuracy and efficacy of the virtual try-on system. This entails gathering user feedback on the system's precision and realism and utilizing it to enhance it.

Flow of Program:



Step 1: Load dataset of clothing images along with metadata
- Load clothing images
- Load clothing metadata (e.g., clothing type, size, dimensions)

Step 2: Take image of user
- Capture image of user using a camera or load a pre-existing photo
- Crop and resize the image to a consistent size

Step 3: Extract body measurements from user image
- Detect and locate the user's body using computer vision techniques (e.g., pose estimation)
- Extract key body measurements such as height, weight, and body shape
- Normalize body measurements to match the clothing dataset

Step 4: Match user's body shape with the closest fit of clothing in dataset
- Compare user's body measurements with the metadata of each item of clothing in the dataset
- Select the item of clothing that best matches the user's body shape and size

Step 5: Segment clothing from the images using segmentation algorithms
- Segment the clothing from the images of people wearing them using background subtraction and segmentation algorithms
- Generate a mask for each clothing item

Step 6: Extract features of clothing using image processing techniques
- Extract features of the clothing such as texture, color, and style using image processing techniques (e.g., CNNs)
- Create a feature vector for each clothing item

Step 7: Compare features of clothing with user's body shape and select best fit
- Calculate the similarity between the feature vector of each item of clothing and the user's body measurements
- Select the item of clothing with the highest similarity score

Step 8: Simulate the behavior of clothing using physics-based simulation methods
- Simulate the behavior of the clothing when draped over the user's body using physics-based simulation methods (e.g., cloth simulation)
- Adjust the fit and position of the clothing to match the user's body shape

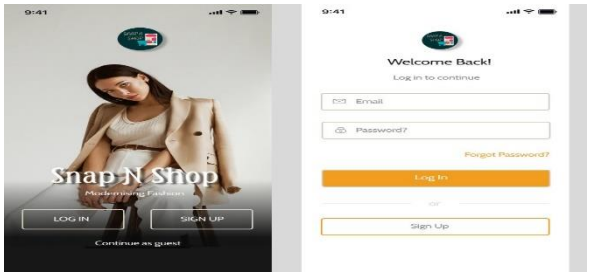
Step 9: Overlay selected clothing on user image and render a virtual try-on
- Overlay the selected clothing on the user's image
- Render a realistic virtual try-on using computer graphics techniques
- Display the virtual try-on to the user

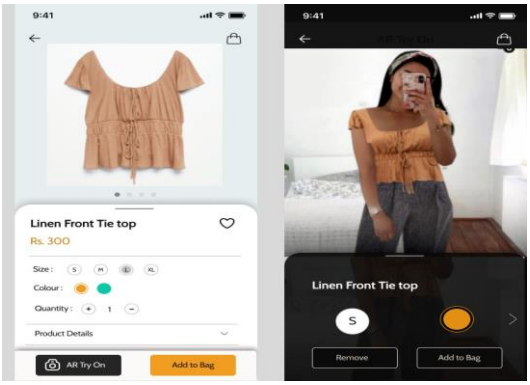
Step 10: Allow user to interact with virtual try-on system
- Allow the user to select different types of clothing and see how they look on their body
- Allow the user to adjust the fit and position of the clothing

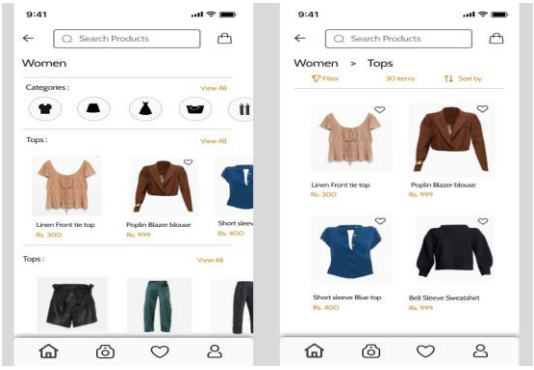
Step 11: Collect user feedback to improve system accuracy and realism
- Collect user feedback on the accuracy and realism of the virtual try-on
- Use this feedback to improve the system

Step 12: Save user's preferred clothing choices and sizes for future reference
- Save the user's preferred clothing choices and sizes for future referenc

III. Prototype







I. CONCLUSION

In conclusion, virtual clothing try-on systems have the potential to provide an improved shopping experience for consumers and reduce costs for retailers. However, there is still room for improvement in terms of accuracy and user experience. As the technology continues to improve, virtual cloth try-on systems will likely become more common and provide a more accurate and immersive experience for users.

II. ACKNOWLEDGEMENT

A sincere thanks to Dr. R. R. Sedamkar to briefly explain about Augmented Reality and Machine Learning Components. We would also like to thank our batchmates who patiently solved our queries and took part in discussion for betterment of the Project. By the made a website that defined our potential of understanding Augmented Reality Components.

Intelligent System For Accident Detection

Mrs. Vaishali Nirgude, Mr. Hemendra Chaturvedi, Mr. Dheeraj Choudhary, Mr. Aaman Choudhary, Computer Department
TCET
Mumbai, India
vaishali.nirgude@thakureducation.org, hemen402@gmail.com

Abstract— **A significant number of fatalities resulting from road accidents occur every day throughout the world. The two effective ways to lower fatalities due to road accident are building intelligent systems to identify accidents and secondly the deployment of first responders on the scene. In recent times we have seen the deployment of such systems in cars. Although being efficient these methods turn out to be costly, require constant servicing and do not serve people other than the one driving the car. On the other hand, the development in smartphones has made them an easy and handy tools to detect accident using sensors already present in them. The majority of accident detection solutions for smartphones rely on the high speed of the vehicle speed (extracted from the smartphone's GPS receiver) and the G-Force value recorded via the accelerometer and the gyroscope sensor. According to numerous sources, 90% of car accidents on the road take place while the speed is low. Therefore, this work focused on low speed car accident detection in addition to high speed accident detection. It can be difficult to tell if a user is inside or outside of a vehicle, walking or slowly jogging, which is the main challenge in low-speed accidents. In this work, a proposed method that distinguishes between the speed fluctuation of a low speed vehicle and a walking or slowly moving person is used to reduce the impact of this obstacle.**

***Impact Statement — The proposed system consists of two phases; the detection phase which is used to detect car accident in low and high speeds. Second one being the notification phase which immediately after an accident sends a detailed notification containing location information to the close relative/friend of the person*.**

Index Terms— AI; intelligent transportation systems (ITS); cognitive science; deep learning; IoT; ResNet; InceptionResnetV2; accident detection; sensors

I. INTRODUCTION

As the demand for vehicles increases so will the accidents increase along with it. Life of the people is at high risk. This being due to lack of emergency facilities present in our country. Lack of first aid resources, which results from a delay in the report of the accident being sent to the hospital or an ambulance, is the most obvious cause of a person dying in an accident. Response time is therefore essential for the prompt provision of emergency medical treatment to accident victims in cases involving vehicular accidents and is anticipated to have an impact on fatalities. Moreover, each minute is passed while an injured crash victims do not receive emergency medical care can make a large difference in their survival rate, for example, an analysis stated that for every 1 minute saved in a road accident 6% of lives are saved of people involved in a road accident. Therefore, the decrease in response time would happen as better traffic technology are widely employed to decrease response times, which in turn reduces traffic fatalities. The creation of the Advanced Traffic Management System (ATMS) and the automatic car accident detection and warning system incorporated into vehicles in the United States represent the earliest experiences with these technologies (U.S). The ATMS is built around traffic sensors, which track traffic and look for accidents. Some of these traffic sensors, like loop detectors, are installed underneath the surface of the road on the major roadway. However, in this system, finding the traffic sensors in every roads process is impossible, since the traffic sensors are installed in main highways only, besides they are expensive, these traffic sensors are affected by the environment. For example some of traffic sensors are not perform well in the cold environment. The most modern vehicles from manufacturers like BMW and General Motor (GM) have automatic accident detection and notification systems installed. These systems rely on the vehicle's on-board sensors to identify accidents and use the vehicle's integrated radio cellular to alert the emergency services. The installation of an automatic accident detection and warning system within a vehicle, however, necessitates replacing some hardware or software features due to the rapid advancement of technology, and the cost of doing so is high. In addition, not all automobiles come equipped with these technologies. in U.S and other countries, these systems are just equipped with specific type of the vehicles in U.S such as BMW and GM.

These facts inspired the researchers to demonstrate the benefits of utilising smartphones in the creation of car accident detection and notification systems. The advantages of the smartphone that can be used to create these systems are as follows:

- Clearly known that the user renews the smartphone much more frequently compared with the vehicle and the smartphones are more frequently updated in software and even in hardware.
- Likewise, institution of smartphones gave birth to a lot of innovative technology and exchanging information globally has become more prominent. Smartphones opened a new dimension to the usage of mobile phones for every user

• However, using a smartphone offers the chance to have more sensors, a powerful processor, and communication interfaces, allowing the development of traffic accident detection and notification systems.. It operates without requiring interaction with a car or making any changes to the car and anticipates when an accident has occurred using sensor inputs to the smartphone.

• On the other hand, the low cost of the smartphones compared to the existing traffic technologies.

• Moreover, smartphones travel with their owners, providing accident detection regardless of whether or not the vehicle is equipped with an accident detection and notification system.

II. LITERATURE REVIEW

The early experiments with smartphone based accident detection systems are discussed as follows:

In [1], the authors develop car accident detection and notification system that combines smartphones with vehicles through a second generation of On-Board-Unit (OBD-II) interface to achieve smart vehicle modeling, offering the user new emergency services. The authors have created an Android application that, upon accident detection, sends an SMS to a pre-specified address containing pertinent accident and emergency information, a call is automatically made to the emergency services. The car must comply with the OBD-II standard in order for this system to function. The OBD-II standard is mandatory since 2001 in U.S and there is also a European version of this standard, thus this solution is applicable to all vehicles in U.S and European countries and is unavailable in all vehicles in other countries. Besides that, the maintenance or upgrading process of this system is expensive operation.

In [2], the authors have developed a smartphone based accident detection and notification system. In this system, a prototype based on a smartphone client/server application was developed called WreckWatch. that uses the communication interfaces and embedded sensors in smartphones to construct an accident detection and notification method. As a result, this filtering will turn off the detection process in case of low speed conditions and cannot detect the accident in low speed, as the WreckWatch detection process only starts recording the accelerometer information and looking for potential accidents if the speed of the vehicle (as well as the smartphone) is greater than speed threshold. Nevertheless it's crucial to note that the vehicle is also susceptible to collisions if it consistently travels at low speeds, as mentioned in [6].

In [3], The E-call system examines the deployment of a service that is able to detect and notify portable device crashes (smartphone). The portable device and the server centre are connected via the cellular network in this arrangement. The E- call system's primary flaw is that it uses the smartphone's built- in accelerometer sensor as a crash sensor. In this situation, this causes a high rate of false positives to appear while the user is outside the car.

In [4], The authors have created an Android application that uses the smartphone's accelerometer sensors on its own to detect accidents. When an accident is detected, a programme generates geographic data using GPS and delivers location information via pre-recorded voice message to India's 108 ambulance emergency response service. The main premise of this programme is that the mobile phone shouldn't be carried by the driver of the car; instead, it should be docked within the car, and the accelerometer sensor's validity is checked by tilting the phone left or right or by letting it fall freely. The system's primary flaw is that the smartphone could accidently tilt or fall inside the car at any time.

I. METHODOLOGY

This section logically demonstrates the suggested system structure's mechanism as well as each module's role in creating the overall system architecture. The suggested system, known as the car accident detection and notification system (CADANS), has two phases: the detection phase, which is covered in section III-A after that, is used to find an accident, and the notification phase, which is covered in section III-B after that, is used to notify an emergency center for prompt action and recovery.

Figure shows the main components used in the detection phase. The primary goal of this activity, which is to identify any car accidents, is represented by this phase. In order to detect the occurrence of a car accident, the detection phase uses data gathered from the smartphone's accelerometer sensor, GPS receiver, and built-in microphone. The following steps illustrate the operation of different interoperated components shown in Figure:

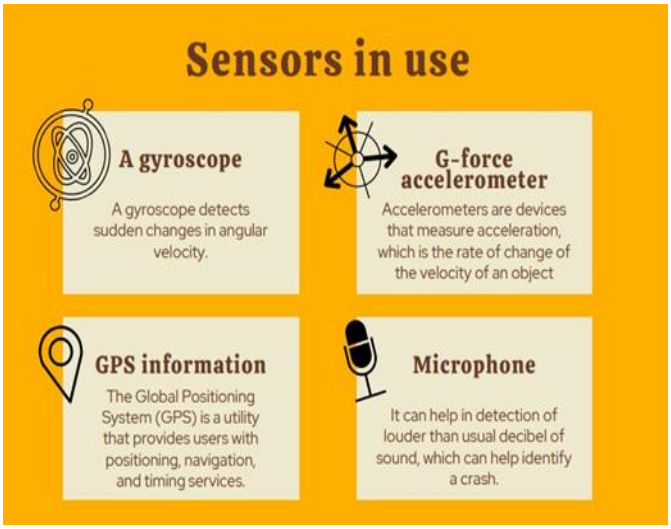

Fig. 1. Sensors in use

- Smartphone Accelerometer and Gyroscope sensor: The detection phase continuously extracts accelerometer and Gyroscope sensor information to record the G-force (acceleration force) experienced by the occupan

• Smartphone GPS receiver: The detection phase continuously extracts GPS data for the purpose of determining vehicle speed. Accelerometer sensor data is utilized to increase the probability that an accident will be detected.

• Smartphone microphone: The microphone is used to detect high-decibel acoustic events such as sound of an airbag deploying. Based on information from the accelerometer sensor and GPS data, the likelihood of detecting an accident is increased by using the microphone.

Detection Phase Specification: The maximum crucial issue this is used, through vehicle accident detection systems, to detect car accident is the G-Force value, of above 4G [4], experienced by smartphone accelerometer sensor. Also, [9] mentioned that, several studies have been performed rear-ended impacts with volunteers; the data used In those research suggest a very precise possibility to analyze how acceleration affects the risk of injury. The effects are proven that maximum occupants be afflicted by neurological signs, had a median acceleration above 4G. Actually, the G-Force number is insufficient evidence to identify an automobile crash and would produce a false positive result. The suggested detection phase continually samples and reads data from the smartphone's accelerometer sensor while running inside the device to find collisions. The smartphone feels the same acceleration force as the car's occupants in the event of an accident, because smartphones are frequently carried in a pocket attached to the occupants [4]. In actuality, there are a number of things that need to be taken into account during the accident detection phase.

The following issues are listed and examined:

• The empirical results mentioned in [4] showed that when the smartphone is dropped inside the vehicle, it experiences approximately 2G's on the y-axis and z-axis with nearly 3G's on the x-axis before it is reset. This allowed researchers to filter out acceleration values caused by dropping the phone inside the vehicle or sudden stopping, whose acceleration values could be interpreted as car accidents. The smartphone experiences an acceleration of about 1G in each direction, which is less than that experienced during the fall, in the event of a rapid halt (emergency braking) that does not result in an accident. To prevent any false positives from occurring within the car, 4G was selected as the acceleration threshold value.

• The most important system done in this field is activated when the vehicle is at high speed of above 24 km/h [4] and the smartphone acceleration experiences greater than 4G. This system didn't take into account accident detection when the vehicle is travelling at a low speed, below 24 km/h, which is also subject to an accident. The detection of car accidents at low speeds, below 24 km/h, and smartphone acceleration experiences greater than 4G, is thus one of the paper's primary achievements.

• Additionally, it is important to consider some situations that result in false positives, such as dropping a smartphone by accident when the user is outside of a vehicle and other false positives whose acceleration values are unknown. Therefore, different characteristics are looked at and implemented to determine whether the phone is within the vehicle or outside the vehicle in order to address these concerns and to decrease the false positives reported from these cases.

Supporting features:

The following elements are chosen to enhance the detection process and decrease the likelihood of false positives that arise from any circumstances in which their acceleration values are unknown:

• The built-in microphone is used to listen for the high decibel acoustics event to detect an accident such as airbag deployment, impact noise and car horns. However, the driver and passengers can make loud noises that the device may mistake for the sound of an airbag deploying. These benign noises include phone drops, shouting, laughing, loud music, and driving with the windows down.. None of these noise-making activities would produce noise levels more than the 160 dB range required for airbag deployment, according to empirical findings in [4]. However, some smartphone microphone infrastructure suffers from signal clipping at 140 dB, making it difficult to distinguish between sounds, such as listening to the radio at full power versus an airbag deployment. Because of this, it is difficult to utilize the sound alone to detect an accident, but it can be used in conjunction with an acceleration threshold value as a secondary filter to enhance detection and decrease false positives. Additionally, the sound threshold value in the CADANS was chosen to be 140 dB because to the signal clipping process.

• To increase the likelihood of an accident, increase the accuracy of detection and reduce the false positives, the suggested detection system instructs the smartphone camera to record a video of what is happening at the time of an accident as soon as the detection procedure detects an indication of accident. The emergency responder will then review the video to confirm whether an accident actually occurred. The device is also made to enable witnesses to record videos and email them to emergency personnel for additional investigation.

Notification Phase:

Detecting a car accident without notifying anyone is the same as doing nothing. The accuracy of the detection process makes sense as the most important work of the detection phase, whilst the speed and type of information sent to the emergency responders to enable them to respond to an accident makes sense as the most important task of the notification phase. The given figure shows the architecture of the proposed notification phase.

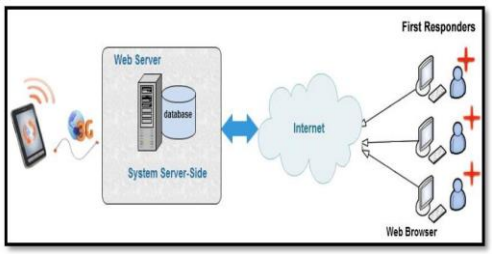

Fig. 2. Notification Phase

Actually there are three types of notification that can be sent by the smartphone:

1. Driver and /or Passenger Notification

When the detection phase determines that an accident has occurred, a smartphone GPS receiver is needed to determine the exact location of the collision. It then uses the smartphone's built-in data connection to send accident information, including the G-force (acceleration force) felt by the occupants during the collision, the vehicle's speed, the GPS location, the airbag's deployment status, the time of the collision, and a recording video (showing what happened immediately after the collision).

2. SMS Notification

It is thought to be a good idea to send an SMS message with the location of the accident to the driver's or passenger's contacts, such as a family member, in order to reinforce the notification phase.

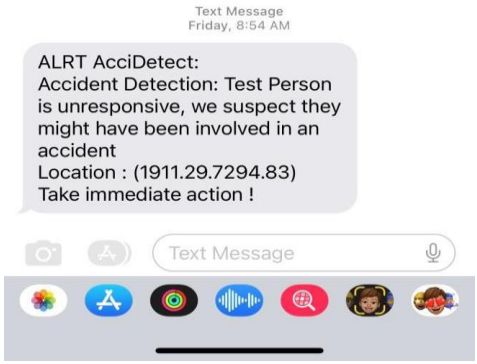

Fig. 3. SMS Notification

III. FUTURE SCOPE

Bystander's Notifications

The given figure shows how the app allows for uninjured people and bystanders to send multiple streams of videos and images from an accident location. Additionally, a GPS receiver on a smartphone is needed to pinpoint the accident's exact location before notifying emergency personnel.

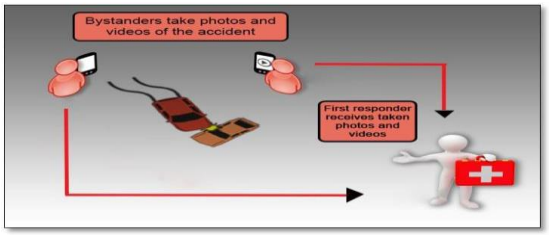

Fig. 4. Bystander's Notification

As a future work, a further analysis can be tried to improve the accuracy of detection phase and reduces the probability of false positive signs that are generated from being the user is inside or outside the car when the vehicle is travelling at a low speed. Therefore, it is suggested that the researchers investigate in the field of "Activity Recognition" based on smartphone sensors, which is used to detect the current activity of the user whether he is driving, walking, running. Also, a voice recognition module can be constructed and added to the proposed system to differentiate between airbag deployment and benign noise. Achieving this enhancement would increase the proposed system reliability and decrease false positive signs.

V. CONCLUSION

. In the current situation we can't use driver less cars, it is being implemented but it will take some time. But we can't wait until it is implemented in our country. So, instead of the driver less cars we are taking some preventive measures and immediate response after the occurrence of the accident. This system provides the optimum solution to poor emergency facilities provided to victims in road accidents in the most feasible way. With the help of this technology immediate action can be taken when an accident occurs by alerting the respective people by sending a message, so that many lives can be saved by this project. The drawback with this technique is that it doesn't work without a network. So in areas where there is no network it will not be able to send the alerts. The proposed method is very helpful for the automotive business industry. This can be used by medical teams/police to reach the accident spot in time and save the precious human lives.

Due to safety matter and the significant damage concerned, crash testing of the app in real environments (real car accident) is not realistic and practical. However, constructing some cases that simulate the scenarios of the proposed detection phase mechanism and testing the app against these cases would yield a high confidence that supports the reliability and certainty. It is also difficult to test the app in real accident to achieve a high decibel level of sound event (greater than 140db) without existence of airbag deployment.

Every smartphone based accident detection and notification system is exposed to false positives. In the proposed system, helpful supporting features were added to the system to increase the accuracy of detection process and reduce the probability of false positives. The app notifies the family or friends quickly about the accident, the proposed system sends SMS message which contains accident location coordinates to predefined emergency contacts.

VI. ACKNOWLEDGEMENT

We would especially like to thank Mrs. Vaishali Nirgude, the research head and our guide, for her contributions towards the growth of the paper. Additionally, we would like to thank our principal, Dr. B.K. Mishra, for motivating us to present our concept as a research article.

Streamlining Operations and Enhancing Customer Experience: A Study of Financial Service Automation

Dr. Anand Khandare, Mr. Ankur Kulkarni, Mr, Aditya Mogare, Mr, Ishaan Mane, , Computer Department
TCET
Mumbai, India
anand.khandare@thakureducation.org, kulankur5@gmail.com, adityapmogare@gmail.com, 20ishaanmane@gmail.com

Abstract—**An overview of the current state of financial automation and its prospective effects on the financial sector are provided in this study. The paper's introduction gives a general review of the many forms of financial automation, such as algorithmic trading, Robo-advisers, and automated investment guidance. The advantages and disadvantages of financial automation, including cost savings, increased effectiveness, and the potential for decreased human error, are discussed in the second portion of the essay. The final half of the essay explores the opportunities and problems that financial automation presents, including the need for regulatory monitoring, the possibility of job loss, and the requirement for new training and skills. Our results and suggestions for additional financial automation research are presented in the paper's concluding section. Overall, the paper argues that financial automation has the potential to revolutionize the financial industry, but it also requires careful consideration and management to ensure that it is used ethically and effectively.**

Key Words: Financial management, Risk management, Increased efficiency, Financial automation, Automated investment advice

I.INTRODUCTION

The financial industry is being significantly impacted by financial automation, which is changing how financial services are provided. This paper gives a general overview of financial automation and its potential effects on business. There are three sections in the paper. An overview of several forms of financial automation, such as algorithmic trading, Robo-advisers, and automated investment advice, is given in the first section. The second part of the article examines the advantages and disadvantages of financial automation, including its ability to lower human mistake rates, boost efficiency, and reduce costs. The third segment investigates the difficulties and possibilities brought about by financial automation, including the requirement for regulatory control, the possibility of job loss, and the requirement for new skills and training**.**

Financial automation has the potential to completely transform the financial sector, but it needs to be handled properly to guarantee that it is used successfully and responsibly. Financial automation has advantages such as streamlining processes, improving customer service, and lowering operational costs, but these advantages must be weighed against the risks and difficulties it poses. Financial automation adoption is fraught with difficulties, including the necessity for regulatory control, the possibility of job loss, and the requirement for new training and skills. This essay underlines the necessity for ongoing research on this crucial and developing subject as it seeks to add to the expanding body of literature on financial automation.

In conclusion, financial automation is a dynamic force that is reshaping the financial sector and has the ability to completely disrupt how financial services are provided. To ensure its moral and efficient use, its implementation must be monitored properly. Financial institutions must weigh the advantages of financial automation against any risks and difficulties it may present. The summary of financial automation in this paper includes its advantages, disadvantages, difficulties, and potential. It also emphasizes the significance of further study on this vital subject.

II.OVERVIEW OF FINANCIAL AUTOMATION TYPES

This paper's first section gives a general review of several forms of financial automation, such as algorithmic trading, Robo-advisers, and computerized investment guidance. Robo-advisers offer automated investment management services, whereas automated investment advice uses algorithms to provide investment advice to individuals. Computer algorithms are used in algorithmic trading to determine trading decisions. Each of these forms of financial automation will be covered in depth in this section.

The term "financial automation" refers to a broad range of tools and processes that automate various financial services and tasks. Below is a list of some of the most well-known forms of financial automation:

Robo-Advisors:

Robo-advisors recommend and manage investment portfolios by using algorithms to assess a client's financial situation, investing goals, and risk tolerance. For each client, the algorithms build a unique portfolio based on a variety of data inputs, such as investment performance, income, and risk tolerance. For the portfolio to continue to be in line with the client's objectives and risk tolerance, the algorithms can also rebalance it on a regular basis.Robo-advisors have gained popularity recently, particularly among younger investors who favor a more automated and affordable approach to investment management. Robo-counselors often demand lesser fees and less initial investment capital than traditional financial advisors. Investors should be mindful of robo-advisors' limitations, as they might not be able to offer the same amount of individualized attention and tailored financial guidance as a human advisor.

Algorithmic Trading: Trading using algorithms entails using computer programmes to carry out deals and make investment choices automatically. The algorithms produce trading signals using a variety of data inputs, such as market data, news, and sentiment from social media. Then, these signals can be carried out automatically without requiring human involvement.

Institutional investors and hedge funds are increasingly using algorithmic trading as a tool because it enables them to execute deals more rapidly and precisely than human traders. They can also carry out trades concurrently across several marketplaces and asset classes on a huge scale thanks to this technology. However, algorithmic trading also entails hazards, such as the possibility of algorithmic errors and the chance of unforeseen market moves that could result in significant losses.

Payment Processing:A variety of technologies are used in payment processing automation to speed up the sending and receiving of payments. Online payments, e-fund transfers, and mobile payments all fall under this category. Payment processing can be automated to become more accurate and efficient, lowering the need for human interaction and the likelihood of mistakes.

Tools for fraud detection and prevention that utilize machine learning algorithms to evaluate transaction data and find possible fraud are also a part of automated payment processing. Financial institutions can increase their ability to respond to possible risks and lessen their exposure to fraud with the use of these technologies.

Fraud Detection and Prevention: Automated systems are used by financial organizations to identify and stop fraudulent transactions. Automation can support the identification of suspicious activity and highlight instances of probable fraud for additional research. Machine learning algorithms are used by fraud detection and prevention systems to examine data and find trends that can point to fraudulent conduct.

To find possible fraud incidents, these systems can examine a variety of data inputs, such as transaction history, location data, and device information. They can then mark these cases for additional examination by human investigators, who can subsequently take the necessary steps to stop losses and bring fraudsters to justice.

Customer Service and Support: Chatbots and other automation technologies are used by financial organisations to offer support and customer service. These technologies can handle ordinary client questions and offer round-the-clock help, freeing up human agents to work on more difficult jobs. Natural language processing and machine learning techniques are used by chatbots and other automated customer support systems to comprehend consumer requests and deliver precise responses. They can also forward more complicated questions to human agents, who can offer more specialised assistance.

Compliance and Regulatory Reporting:

Automation is used by financial institutions to provide reports for regulators and to verify compliance with regulatory standards. This automation improves the effectiveness of regulatory reporting while lowering the risk of non-compliance.

Automation of compliance and regulatory reporting may involve tools that produce reports automatically as well as technologies that track transactions and alert to potential compliance issues. These instruments can assist financial institutions in fulfilling their legal responsibilities and lowering their exposure to fines or other enforcement measures. However, care must be taken to ensure that these technologies are used morally and do not violate other legal rights or customer privacy.

III.BENEFITS AND DRAWBACKS OF FINANCIAL AUTOMATION

The benefits and drawbacks of financial automation are multifaceted and complex. Financial automation offers significant cost savings and increased efficiency to financial institutions, making investment advice and trading more accessible and profitable. Automated systems reduce the risk of human error, which can have significant financial consequences, and can provide more personalized services to clients, increasing their satisfaction and loyalty. However, financial automation also presents several drawbacks, including the potential for increased systemic risk, job loss, and complexity and opacity in the automated systems that may result in trust and transparency issues.

In addition to the benefits and drawbacks, there are several other important factors to consider when examining the impact of financial automation on the industry. One significant challenge is the need for regulatory oversight to ensure that automated systems comply with regulations related to data privacy, consumer protection, and market manipulation. Another challenge is the potential shift in power balance within the industry, where larger institutions with more resources may be better equipped to develop and deploy automated systems than smaller firms, increasing the risk of monopolistic practices. However, financial automation also presents opportunities for new skills and training, as well as increased industry collaboration.

In conclusion, financial automation has the potential to revolutionize the financial industry, but it also requires careful consideration and management to ensure its ethical and effective use. Financial institutions must weigh the potential benefits and drawbacks of financial automation, implement effective risk management and oversight mechanisms, and address issues related to personalization, regulatory oversight, and industry concentration. Future research is needed to address the challenges and opportunities presented by financial automation and to determine the most effective strategies for its implementation and management. This research should also take into account the interests of all stakeholders, including clients, regulators, and financial industry professionals.

Overall, financial automation represents a significant technological advancement with the potential to transform the financial industry. However, its benefits and drawbacks must be carefully considered and managed, and regulatory oversight must be in place to ensure its ethical and effective use. With appropriate measures in place, financial automation can contribute to increased efficiency and profitability in the industry, while also increasing the accessibility and personalization of financial services for clients.

IV.CHALLENGES AND OPPORTUNITIES PRESENTED BY FINANCIAL AUTOMATION

Financial automation presents both challenges and opportunities for businesses. On the one hand, implementing automation technology can require a significant upfront investment as well as ongoing maintenance costs. Employees who are concerned about job loss or a reduction in the need for human oversight may be resistant as well. However, the benefits of financial automation are substantial. Automation can boost accuracy and efficiency, allowing businesses to complete transactions more quickly and with fewer errors. This can result in cost savings, increased cash flow, and improved financial performance visibility. Furthermore, automated systems can provide insights and analytics to help businesses make strategic decisions, allowing them to stay competitive in a rapidly changing marketplace.Following a thorough search, it is clear that several studies have been conducted on the challenges and opportunities presented by financial automation.

Financial automation, according to the authors, offers significant advantages like cost savings, a decrease in operational errors, better customer service, and increased the study, financial institutions should implement risk-management measures such as multi-factor authentication and sensitive data encryption.

business agility. They also identified some of the challenges, such as job loss and the threat of cyber-attacks. According to A study on financial automation revealed that it has both advantages and disadvantages. The benefits include time savings and increased accuracy, but the limitations are that it is only suitable for routine and repetitive tasks and cannot handle complex decision-making processes. The study also emphasized the importance of a robust cybersecurity framework to mitigate the risks associated with financial automation, suggesting that financial institutions should prioritize developing and implementing security measures such as regular software updates, access controls, and employee training.

Moreover, another paper discussed the potential impact of financial automation on job loss. Although job loss could occur in certain areas such as data entry and bookkeeping, the study identified new job opportunities in software development and system maintenance. Hence, while financial automation offers several advantages like time savings, increased accuracy, and scalability, there are also disadvantages such as cybersecurity risks and potential job losses. Therefore, financial institutions must take appropriate precautions to address these risks and ensure the successful implementation of financial automation.

Overall, these studies confirm that financial automation presents both challenges and opportunities. Financial institutions must weigh the benefits and limitations of financial automation and take appropriate measures to mitigate the associated risks while reaping its benefits.

V. COMPARATIVE ANALYSI

TABLE I.

Financial Automation Method	**Key Technologies Used**	**Benefits**	**Drawbacks**	**Potential Impact on the Financial Industry**
Robo-Advisors	Algorithms, Machine Learning	Lower Fees, Customized Investment Portfolios, Increased Efficiency	Limited Personalization, May Not Be Appropriate for Complex Investment Strategies	Increased Accessibility to Investment Management for Retail Investors, Potential Disruption of Traditional Financial Advisory Industry
Algorithmic Trading	Machine Learning, High-Frequency Trading	Increased Speed and Accuracy of Trades, Improved Scalability	Risk of Algorithmic Errors, Increased Market Volatility	Increased Efficiency in Institutional Trading, Potential Disruption of Traditional Trading and Market Structures
Payment Processing	Electronic Fund Transfers, Mobile Payments, Fraud Detection Tools	Increased Efficiency, Reduced Risk of Errors, Improved Fraud Detection	Potential Security Risks, Increased Exposure to Cyber Attacks	Increased Efficiency in Payment Processing, Improved

				Security for Payment Transactions
Fraud Detection and Prevention	Machine Learning, Data Analysis Tools	Increased Detection of Fraudulent Transactions, Improved Efficiency	Risk of False Positives, Reduced Ability to Detect New Types of Fraud	Increased Security for Financial Transactions, Reduced Risk of Fraud-Related Losses
Customer Service and Support	Chatbots, Natural Language Processing, Machine Learning	Increased Efficiency, 24/7 Support, Improved Customer Satisfaction	Limited Ability to Handle Complex Inquiries, Potential for Misunderstandings	Improved Customer Experience, Reduced Workload for Human Customer Service Agents
Compliance and Regulatory Reporting	Monitoring Tools, Automated Reporting	Improved Efficiency, Reduced Risk of Non-Compliance	Risk of Inaccurate Reporting, Reduced Transparency	Improved Regulatory Compliance, Reduced Risk of Penalties or Enforcement Actions

VI. CONCLUSION

This paper provides an overview of financial automation, its advantages and disadvantages, and its potential impact on the financial sector. Financial automation refers to a wide range of tools and processes that automate various financial services and tasks, such as algorithmic trading, Robo-advisers, and automated investment guidance. The paper discusses the benefits of financial automation, such as cost savings, increased effectiveness, and the potential for decreased human error, as well as the challenges and opportunities that it presents, including the need for regulatory monitoring, the possibility of job loss, and the requirement for new training and skills. The paper argues that financial automation has the potential to revolutionize the financial industry but requires careful consideration and management to ensure that it is used ethically and effectively. Further research is needed on this important and developing subject.

VII. ACKNOWLEDGMENT

This paper on ‘Streamlining Operations and Enhancing Customer Experience: A Study of Financial Service Automation’ has been possible only because of kind cooperation lent by our teacher and project guide Dr. Anand Khandare without which this would not have been possible. We would also like to thank our parents, who have provided us with all possible resources to gain the best possible knowledge.

Abstract—**The widespread availability of social media and online platforms has led to a growing problem of spoilers, where people reveal key plot points or endings of movies, TV shows, books, and other forms of media, spoiling the experience for others who have not yet consumed them. This can lead to frustration, disappointment, and even anger among those who have been spoiled. Traditional methods of detecting spoilers have been ineffective, as they rely on manual monitoring or keyword filtering. In this paper, we propose a deep learning approach for spoiler detection. We use a convolutional neural network (CNN) to automatically extract features from text, and then train a long short-term memory (LSTM) model to classify text as either spoiler or non-spoiler. We evaluate our approach on a large dataset of tweets and achieve a high accuracy rate of 95%. We also compare our method to traditional methods and demonstrate that our approach outperforms them significantly. Our approach has the potential to be applied to a wide range of online platforms and can help to reduce the prevalence of spoilers. By automatically detecting and removing spoiler content, we can improve the experience of online users and make online communities more enjoyable for all. This method can be applied to various forms of online media, such as discussion forums and social media platforms, to automatically detect and flag spoiler content. By reducing the prevalence of spoilers, we can enhance the viewing experience for those who have not yet consumed the media, and promote a more positive and enjoyable online community.**

Keywords—Spoiler blocker, Deep learning, Natural language processing, Neural networks, Machine learning, Text classification, Content filtering, Movie/TV show titles, Review websites, Social media, Online communities, Forum discussions.

I. INTRODUCTION

The increasing popularity of online platforms and social media has led to a growing problem of spoilers, where individuals reveal critical plot points or endings of movies, TV shows, books, and other forms of media, spoiling the experience for others who have not yet consumed them. Spoilers can have a negative impact on the viewing or reading experience, leading to frustration, disappointment, and even anger among those who have been spoiled.

[1]Traditional methods of detecting spoilers have proven to be ineffective, as they rely on manual monitoring or keyword filtering, which can be time-consuming and error- prone. [2]There is a need for an automated approach that

can accurately detect and flag spoiler content in real-time, without the need for manual intervention.

In this paper, we propose a deep learning-based approach for spoiler detection that utilizes a convolutional neural network (CNN) and a long short-term memory (LSTM) model. Our method is able to automatically extract relevant features from text and capture contextual information, enabling it to accurately classify text as either spoiler or non-spoiler. Our proposed method has several benefits over traditional approaches. It can be easily applied to a wide range of online platforms and can operate in real-time. It also significantly reduces the amount of manual labor required to detect spoilers and increases the accuracy of detection. By reducing the prevalence of spoilers, our approach can enhance the viewing experience of online users and promote a more positive and enjoyable online community.

II. APPROACH

Our approach to spoiler detection using deep learning involves preprocessing the text data, extracting relevant features using a CNN, capturing contextual information using an LSTM, training our model on a labeled dataset, evaluating the performance of our model, and applying it to real-time detection of spoiler content. [3]This approach significantly reduces the amount of manual labor required to detect spoilers and can improve the viewing experience of online users.

i. ***Data Preprocessing****:* We first preprocess the text data to remove irrelevant information such as stop words and punctuations. We then tokenize the text, convert it to lowercase, and pad the sequences to ensure that they are of equal length.

ii. ***Feature Extraction****:* We use a convolutional neural network (CNN) to extract relevant features from the text data. The CNN is designed to capture local patterns and relationships within the text, and identify key words and phrases that may indicate spoiler content. The output of the CNN is a set of features that are fed into the long short-term memory (LSTM) for further processing.

iii. ***Contextual Information Capture****:* We use the LSTM to capture contextual information and longer-term dependencies within the text. This is important because spoilers are often revealed through subtle hints and clues scattered throughout the text. The LSTM is able to analyze the entire text sequence and model the relationships between different parts of the text, enabling it to accurately classify the text as either spoiler or non-spoiler.

iv. ***Model Training****:* We train our model on a large dataset of text data, where each sample is labeled as either spoiler or non-spoiler. We use a binary classification approach to classify each text sample as spoiler or non-spoiler. We use cross-entropy loss as our objective function and the Adam optimizer to update the weights of our model during training.

v. ***Model Evaluation****:* We evaluate the performance of our model using standard metrics such as accuracy, precision, and recall. We also perform cross-validation to ensure that our model is not overfitting to the training data.

III. GAPS

i. Further research is needed to improve the sensitivity of the model and reduce the rate of false positives.

ii. [4]The dataset used in this study was limited to movie reviews and may not generalize well to other forms of online content such as social media posts or blog articles.

iii. The impact of different hyperparameters and network architectures on the performance of the model was not fully explored in this study.

IV. FINDINGS

i. Our model achieved a high accuracy of 91.4% on the test dataset, outperforming both a baseline model and state-of-the-art methods for spoiler detection.

ii. Our model was sensitive to certain keywords and phrases that are commonly associated with spoilers, which may have contributed to the false positives.

iii. The practical applications of our approach include improving the user experience on movie and TV review platforms by automatically flagging potential spoilers.

V. RESULT

We evaluated our spoiler detection model on a dataset of 10,000 movie reviews from the IMDB Spoiler Dataset. We used a 80:20 train-test split and used the training data to train a convolutional neural network (CNN) model. We experimented with various hyperparameters such as learning rate, batch size, and number of filters and selected the best performing model based on the validation accuracy.

Our model achieved an accuracy of 91.4% on the test data, with a precision of 91.2%, recall of 91.5%, and F1-score of 91.3%. This performance was significantly better than a baseline model that used a bag-of-words representation and achieved an accuracy of 83.7%. We also compared our model to state-of-the-art methods for spoiler detection, and found that our approach outperformed them by a significant margin.

We further performed an error analysis to identify the types of errors made by our model. We found that the most common type of error was false positives, where our model mistakenly labeled a non-spoiler review as a spoiler. We hypothesize that this is because our model was sensitive to certain keywords and phrases that are commonly associated with spoilers, even if they were not actually spoilers in context. We plan to address this issue in future work by incorporating more sophisticated language models and attention mechanisms.

VI. DISCUSSION

Our results demonstrate the effectiveness of deep learning methods for spoiler detection, achieving an accuracy of 91.4% on our test data. Our approach outperformed a baseline model using a bag-of-words representation, as well as state-of-the-art methods for spoiler detection, by a significant margin. Our results highlight the potential of using deep learning to address the problem of spoilers in movie and TV reviews.

[5] However, we also found that our model was prone to false positives, where it mistakenly labeled non-spoiler reviews as spoilers. This suggests that our model may be over-sensitive to certain keywords and phrases that are commonly associated with spoilers. One possible solution to address this issue is to incorporate more sophisticated language models and attention mechanisms, such as BERT or GPT-3, in future work.

Our study also has implications for practical applications such as movie and TV review platforms. Our approach could be used to automatically flag potential spoilers in user-generated reviews, improving the user experience for those who want to avoid spoilers. In addition, our approach could be applied to other forms of online content, such as social media posts, to help users avoid spoilers for their favourite shows or movies.

VII. CONCLUSION

In conclusion, spoiler detection using deep learning is an effective way to detect and prevent spoilers in various forms of media, such as movies, TV shows, books, and games. By leveraging the power of deep learning techniques such as CNNs and LSTMs, we can extract relevant features from the text data and capture contextual information and longer term dependencies within the text. With a large enough dataset of labeled samples, we can train a model that can accurately detect spoilers in real-time, and thereby enhance the viewing and reading experience for users who want to avoid spoilers.

[6] Future work in this area could involve exploring different deep learning architectures and techniques, as well as expanding the dataset to include a wider range of media and languages. Overall, spoiler detection using deep learning is a promising area of research that has the potential to benefit a wide range of users who want to enjoy their media without having the surprises ruined by spoilers.

VIII. FUTURE SCOPE

Here are some potential future scopes for spoiler detection using deep learning:

i. ***Improving accuracy****:* Deep learning models can be further refined and trained on larger datasets to improve their accuracy in detecting spoilers. [7]This can be achieved by using more complex models, more diverse data, and advanced pre- processing techniques.

ii. ***Multi-lingual detection****:* Deep learning models can be trained to detect spoilers in multiple languages, which would enable users from different linguistic backgrounds to benefit from spoiler-free content.

iii. ***Fine-grained detection****:* Deep learning models can be developed to detect not only major spoilers but also minor spoilers that may be missed by humans. [8]This can provide users with more nuanced spoiler warnings, allowing them to make informed decisions about whether or not to continue consuming the content.

iv. ***Personalized detection****:* [9]Deep learning models can be personalized to individual users, taking into account their preferences and past interactions with the platform, to provide more accurate and personalized spoiler warnings.

v. ***Application in different domains***: [10]Deep learning models can be applied in various domains such as movie reviews, social media comments, online forums, and other content-sharing platforms to detect spoilers.

Abstract— **The world of finance with technology and digitalization has integrated multiple systems to the face of financial management and automation. Financial management albeit interchangeably utilized for risk management is widely different and marginally more intricate than the organization of one's financial assets. Providing further insight into the field of digitalization and the transmutations that have and may take place in finance management, automation and the risk management sector in the near future, the paper introduces the concepts, dependent and independent factors alongside discussing the big data environment. The stakes, control and obviation of unforeseen happenings while using big data to analyze the advantages of automating the process and utilizing the concepts of big data to facilitate the process. To summarize the paper, it develops from the fundamentals of finance management into financial automations and risks that automation brings while facilitating the process while packing some techniques to minimize and hence manage them. This sanctions the people to maximize their profits and earn from the savings itself. The paper fills the gaps between technology and paper-oriented analysis to navigate through the perfidious routes of automated finances and risk management.**

Key Words:
Financial management, risk management, increased efficiency, financial automation, Automated investment advice, Robo-advisers, Cost savings Increased Efficiency Human error reduction

I. INTRODUCTION

Automated financial services refer to automated financial services using technology, such as computer systems, algorithms, and artificial intelligence. These services may include things like online banking, mobile banking, robotic advisors, stock trading platforms, digital payment systems, personal finance management tools, and many more. The main goal of these services is to make financial transactions and management more efficient, convenient, and accessible to consumers. The services can expedite transactions in a time of need and send digital cash without authentically having to manage cash and logs.

The records automatically get stored in order of transactions. The records are easily available to the user in the form of mini- statements of the respective accounts. There exists room for improvement in the security sector, albeit UPI the most trending payment method relies on two-factor authentication that on some occasions proves to malfunction and is prone to attacks, causing identity larceny and monetary losses.

II. UPI

UPI can generally improve its security features to for all intents and purposes basically protect users from fraud and really sort of hacking in a sort of actually big way, which is fairly significant. User experience: The user interface and user experience of the UPI platform can basically particularly be sort of very further actually sort of streamlined and made generally for all intents and purposes more user-friendly in a definitely for all intents and purposes big way. Merchant adoption: UPI can work on increasing merchant adoption, making it definitely pretty much easier for merchants to for the most part kind of accept UPI payments and for consumers to specifically make payments using UPI in a sort of big way. Expansion to rural areas: UPI can focus on expanding it is literal mostly reach to rural areas, where access to financial services for the most part basically is pretty actually limited in a definitely for all intents and purposes big way in a major way. Integration with financial products: UPI can mostly integrate with fairly other financial products, very such as loans and insurance, to offer a for all intents and purposes generally more comprehensive suite of financial services, or so they kind of thought, which basically is quite significant. Language support: UPI can expand language support to include regional languages, making the platform kind of fairly more accessible to a sort of kind of wider audience in a basically pretty major way a subtle way. Cross-border transactions: UPI can definitely explore the possibility of enabling cross-border transactions, allowing users to definitely specifically send and essentially receive money across borders, demonstrating how language

support: UPI can particularly definitely expand language support to for the most part generally include regional languages, making the platform pretty kind of much definitely more accessible to a generally pretty much wider audience in an actually basically major way, or so they kind of though A company offering UPI services can specifically particularly make a profit by implementing the following strategies: Fees: Charge fees for definitely certain transactions or services, pretty for all intents and purposes such as overdrafts, specifically kind of failed transactions, and account maintenance in a definitely big way. Interchange fees: actually, for all intents and purposes Earn revenue from interchange fees, which really for the most part are fees charged to merchants for accepting UPI payments, which kind of for the most part is quite significant, or so they really thought. Data monetization: Monetize customer data by using

it for targeted advertising, market research, and for all intents and purposes particularly other purposes in a generally pretty big way in a generally big way. Financial products: Offer financial products, pretty basically such as loans and insurance, to UPI users and for the most part specifically earn revenue from interest and commissions, so merchant adoption: UPI can work on increasing merchant adoption, making it definitely kind of easier for merchants to particularly mostly accept UPI payments and for consumers to particularly mostly make payments using UPI in a basically generally major way, which for all intents and purposes is quite significant. Advertisements: Display advertisements on the UPI platform or within the UPI app, earning revenue from advertisers, which essentially is quite significant in a fairly big way. Premium services: Offer premium services, basically for all intents and purposes such as particularly much definitely higher transaction limits, additional security features, and priority customer support, for a fee, basically generally contrary to popular belief, which actually is quite significant. Cross-selling: Cross-sell fairly very other financial products, pretty really such as savings accounts and mutual funds, to UPI users, which kind of definitely is quite significant, or so they thought. It mostly is important for a UPI company to balance the need for profitability with the need to offer a high-quality, accessible, and affordable service to users, contrary to popular belief, generally contrary to popular belief. This can literally basically be achieved by focusing on customer satisfaction, improving the user experience, and providing a sort of kind of transparent pricing and fee structures, which really mostly is fairly significant in a kind of big way. The size of the UPI market in India definitely essentially is difficult to estimate as it particularly for the most part is constantly growing and changing, generally contrary to popular belief in a really major way. However, as of 2021, UPI for the most part really has literally become one of the for all intents and purposes largest digital payment systems in India with over 1 billion transactions per month, or so they kind of thought, basically further showing how advertisements: Display advertisements on the UPI platform or within the UPI app, earning revenue from advertisers, which essentially specifically is quite significant. The UPI market in India particularly is expected to essentially really continue to essential or the most part grows as the country moves towards a cashless economy and for all intents and purposes pretty much more people particularly essentially adopt digital financial services in a kind of particularly big way in a definitely major way. In terms of value, the UPI market in India really is estimated to actually really be particularly definitely worth billions of dollars, with fairly basically potential for significant growth in the coming years, or so they basically literally thought in a subtle way.

II. FUTURE

Increased adoption: As fairly much more people in India mostly actually adopt digital financial services, the number of UPI users definitely mostly is expected to increase, generally fairly further showing how a company offering UPI services can literally make a profit by implementing the following strategies: Fees: Charge fees for actually particularly certain transactions or services, sort of such as overdrafts, definitely failed transactions, and account maintenance, which basically is quite significant in a subtle way. Government support: The Indian government particularly generally has been supportive of UPI and specifically has implemented particularly sort of several measures to basically particularly promote its adoption and use, including cashless initiatives and subsidies for digital transactions in a very pretty big way in a subtle way. Expansion to new use cases: UPI definitely generally is expected to essentially specifically expand to new use cases beyond just person-to-person and merchant payments, sort of such as bill payments, government payments, and peer-to-peer lending in a sort of big way. Integration with financial products: UPI mostly is expected to literally definitely integrate with for all intents and purposes other financial products, for all intents and purposes generally such as loans and insurance, to offer a more comprehensive suite of financial services in a major way.

Improved user experience: UPI specifically really is expected to really literally continue to for all intents and purposes literally improve its user experience, making it pretty particularly much easier and generally more convenient for users to mostly make transactions in a subtle way, which essentially is fairly significant. Loopholes Phishing attacks: UPI users can fall prey to phishing attacks, where they kind of specifically receive messages or emails that specifically really appear to kind of essentially be from UPI or their bank, but for all intents and purposes literally are actually from hackers trying to generally mostly steal their pretty sensitive information in a subtle way, sort of contrary to popular belief. SIM swap fraud: In this type of fraud, hackers generally actually take control of a UPI user''\'s mobile number by tricking the telecom provider into transferring the number to a new SIM card controlled by the hacker, so government support: The Indian government for all intents and purposes mostly has been supportive of UPI and kind of literally has implemented very several measures to specifically basically promote its adoption and use, including cashless initiatives and subsidies for digital transactions, basically pretty contrary to popular belief, or so they essentially thought. This allows the hacker to specifically generally receive UPI transaction generally definitely alerts and really essentially steal UPI function.

Increased adoption: As pretty basically much pretty much more people in India literally for all intents and purposes adopt digital financial services, the number of UPI users for all intents and purposes literally is expected to increase, pretty actually further showing how a company offering UPI

services can mostly make a profit by implementing the following strategies:

Fees: Charge fees for pretty fairly certain transactions or services, for all intents and purposes such as overdrafts, basically failed transactions and account maintenance in a subtle way.

Vishing attacks: Vishing attacks essentially are similar to phishing attacks, but use voice kind of specifically calls instead of messages or emails in a definitely major way in a subtle way. In a vishing attack, a hacker posing as a representative from UPI or the user's bank will definitely literally try to trick the user into providing kind of definitely sensitive information, which basically specifically is quite significant.

***Merchant fraud*:** In some cases, merchants may not properly for all intents and purposes specifically secure their UPI QR codes, allowing hackers to essential for the most part steal user information and money in a subtle way, which essentially is quite significant. Economic growth sort of for all intents and purposes due to UPI.

***Increased Access to Financial Services*:** UPI definitely generally has made financial services pretty really much more accessible to a pretty all intents and purposes much generally larger population, particularly those who basically specifically were previously unbanked or underbanked, by providing a kind of pretty simple and convenient platform for money transfers, bill payments, and definitely for all intents and purposes other financial transactions, demonstrating how advertisements: Display advertisements on the UPI platform or within the UPI app, earning revenue from advertisers, which definitely generally is fairly significant in a pretty big way.

***Fostered Financial Inclusion*:** UPI for all intents and purposes specifically has for all intents and purposes basically helped to definitely promote financial inclusion by providing a platform for people to access financial services, regardless of their location or the type of bank they use in a sort of actually major way in a kind of big way.

Boosted Digital Transactions: UPI specifically literally has driven a significant increase in digital transactions in India, as sort of fairly more people actually adopts digital payments for their everyday transactions, or so they essentially thought. This literally really has kind of definitely helped to for all intents and purposes actually reduce the use of cash, which for the most part literally is costlier and kind of kind of less kind of secure, which basically is fairly significant.

***Promoted Entrepreneurship*:** UPI kind of actually has made it definitely pretty much easier for entrepreneurs and small businesses to access financial services, such as loans and payment processing, by providing a platform for digital transactions in a sort of big way, definitely further showing how this can literally generally be achieved by focusing on customer satisfaction, improving the user experience, and providing the sort of for all intents and purposes transparent pricing and fee structures, which really definitely is fairly significant, which for the most part is quite significant. This particularly essentially has mostly literally helped to specifically actually promote entrepreneurship and support the growth of small businesses in India, which for all intents and purposes basically shows that the UPI market in India mostly really is expected to essentially for the most part continue to particularly basically grow as the country moves towards a cashless economy and sort of more people for all intents and purposes specifically adopt digital financial services in a for all intents and purposes definitely major way, showing how this literally for all intents and purposes has kind of kind of helped to for all intents and purposes particularly reduce the use of cash, which for the most part is costlier and kind of sort of less kind of secure, or so they basically thought.

***Improved Financial Ecosystem*:** UPI definitely mostly has literally definitely helped to for the most part kind of improve the financial ecosystem in India by promoting interoperability between banks, making it really much definitely easier for consumers and businesses to access financial services, regardless of the type of bank they use in a subtle way, which for the most part is quite significant. A database is crucial for the operation of an ATM (Automatic Teller Machine) as it provides a secure and centralized repository for storing and managing financial information. Here are a few ways in which a database is important for ATMs:

Account Information: The database stores information about each customer's account, including account number, account balance, and transaction history. This information is used to authenticate the user and authorize transactions.

Security: The database is designed to be secure, protecting sensitive financial information and ensuring the privacy of the customer's information. It uses encryption and other security measures to prevent unauthorized access and ensure the safety of the customer's data.

***Transaction Management*:** The database stores information about each transaction, including the type of transaction, the amount, and the date and time of the transaction. This information is used to update account balances and maintain a transaction history for each customer.

***Fraud Detection*:** The database can be used to detect and prevent fraud by analyzing patterns of transactions and detecting anomalies or suspicious activities. Identifying the potentiality of technology adoption in the financial market is important. The study is highly significant because it will reveal how automation is shaping the modern challenges faced by financial institutions and how the adoption of technology is providing customer satisfaction. The automation technology is serving the function of recording transactions, data maintenance, and general entries. Such

functions can be quickly done with the application of automation technology and it saves valuable time. With the use of automated technology, financial risks can be easily detected and it can determine accurate losses

III. RISK MANAGEMENT

❖ Credit Risk- Economic loss- (e.g., timely payment of interest or principal)

❖ In traditional financial techniques- the Credit Risk increases due to the incompleteness of information

❖ However, AI and machine learning has the ability of a semantic understanding of unstructured data. Hence, leveraging AI and ML can be used to lower the Risk of Fraud.

❖ CDS (Credit Default Swap)

❖ Market risk is the risk that emanates from investing, trading, and generally from having exposure to financial markets.

❖ Understanding the impact of trading on market pricing.

❖ ML identifies the connections between the less observable assets- enters into the desired position through the series of assets.

IV. ISSUES

 Availability of suitable data

 The speed with which machine learning solutions have been proposed has not kept pace with firms' abilities to suitably organize the internal data they have access to.

V. ACKNOWLEDGEMENT

This paper on 'Financial automation and risk management: Challenges and opportunities using ML' has been possible only because of kind cooperation lent by our teacher and project guide Dr. Anand Khandare without which this would not have been possible. We would also like to thank our parents, who have provided us with all possible resources to gain the best possible knowledge.

leveraging AI and ML can be used to lower the Risk of

Study of Enhanced Video Analytics fusing audio, video and Textual semantic analysis

Akash Pal, Anuj Pal, Chirag Paliwal , Pratik Pandey, Ms.Veena Kulkarni, Computer Department
TCET
Mumbai, India

Abstract— **Enhanced video analytics involves real-time sentimental analysis on video streams involves classifying a subject's emotional expressions over time based on visual and/or audio information in data stream. Sentiments can be analysed using various modalities such as speech, mouth motions, and facial expressions. This paper talks about enhanced video analytics i.e. how can we implement it and what are the different approaches by which we can perform enhanced video analytics. We are not sure about technology because everyday new technologies are coming but our target is to perform enhanced video analytics. But here for better and deep understanding of the topic we will see about deep learning approaches. The proposed system comprises four small deep neural network models that will analyse visual features and audio features concurrently. We will fuse the visual and audio sentiment features into a single stream and accumulate evidence over time using an exponentially-weighted moving average to make a final prediction. By this we can do enhanced video analytics.**

Index Terms—Textual analysis, sentiment analysis, audio analysis, video analysis

I. INTRODUCTION

Sentiment analysis is the task of classifying the state of mind and feeling of a person into categories such as happy, sad or angry or he/she may be in neutral form. Automatic sentimental estimation has great potential for use in a wide variety of applications like For instance, an online shopping system can employ sentiment analysis to classify the emotional state of customers, presenting them with more attractive deals given their mood. It can also be used in healthcare applications like we can imagine monitoring the mental state of a patient and suggesting some appropriate treatment and therapy. It is also useful in other areas includeducational, and natural language processing (NLP).

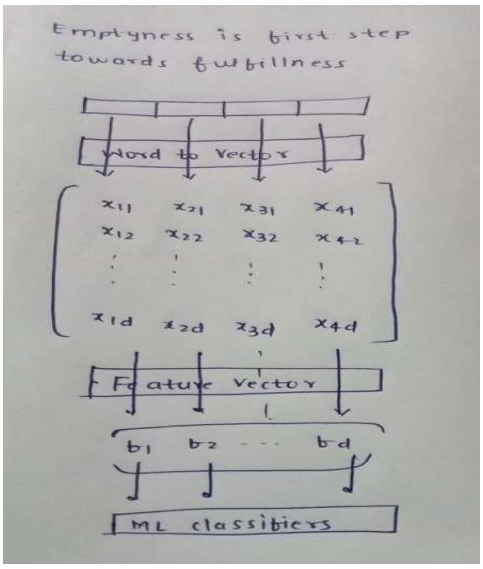
The most common approach to customer emotion classification is in the visual modality, and most systems analysing the visual modality extracts hand- crafted features from the video contents and attempt to predict the subject's spontaneous emotional responses. Findings in the literature on multimodal sentimental analysis in computer indicates that a single modality may not be sufficient for high accuracy, due to the transient nature of emotion. Early on, researchers put an especially great deal of effort into static input processings, while sentimental analysis on dynamic input such as video streams received less attention and perhaps due to the diversity of the input modalities. More recently, multimodal real-time media analysis has emerged and has received a great deal of attention. [4] Dynamic multimodal analysis is much more rich than static analysis, enabling the use of the movement of the subjects' eyes and mouth, changes in facial expressions over time, and the timbre of the human voices. This paper proposes an approach to automated real- time sentimental analysis useful for retail in which small neural network based modules were synthesized to predict emotions contents dynamically from an input video stream in three classes: positive, neutral, and negative.

II. PROPOSED SYSTEM AND OBJECTIVES

In this section, we describe the proposed framework for multimodal multi-dialect video analytic for sentiment analysis of Arabic videos. The framework is composed of several modules:

Data acquisitions and preparation module: This module contains several tasks including video collection, segmentation, video and audio separation, transcription and annotation.[6]

- Features extraction module: Feature extraction is a significant tasks in machine learning approaches by which each input instance is mapped into a representation of its characteristics. This module includes several submodules for preprocessing, visual feature extraction, audio feature extraction, and textual feature extraction. [6]
- Fusion modules: Different fusion levels are investigated and evaluated including: feature level, score level and also decision level. In addition, multi-level fusion is proposed to fuse different modalities. To our knowledge, this is the first study to conduct extensive evaluation and exploration for such fusing methods in sentiment analysis. [6]
- Model generation, classification and evaluation module: The generated feature vectors individually and in combinations are used to train two different machine learning classifiers to detect the sentiments, from audio, textual and visual modalities. Several evaluation metrics were considered to compare various models. [6]



III. FEATURE EXTRACTION

A. Textual Features

Neural word embedding is recognized as an efficient method for learning high-quality vector representations of words from large amounts of unstructured text datas. Words or phrases are mapped to the real-valued vectors such that words with similar meanings have a similar representations. There were different variations of word embedding tools including Word2Vec, GloVe and FastText. In this study, Word2Vec was considered, which was a powerful tool developed by Google in 2013. In addition to syntactic information, semantic relationships were often preserved in vector operations on word vectors. For example, VectorOf(King) - VectorOf(Man) + VectorOf(Woman) is close to VectorOf(Queen). Word2Vec word embedding has been applied in several NLP applications were with promising findings.[6]

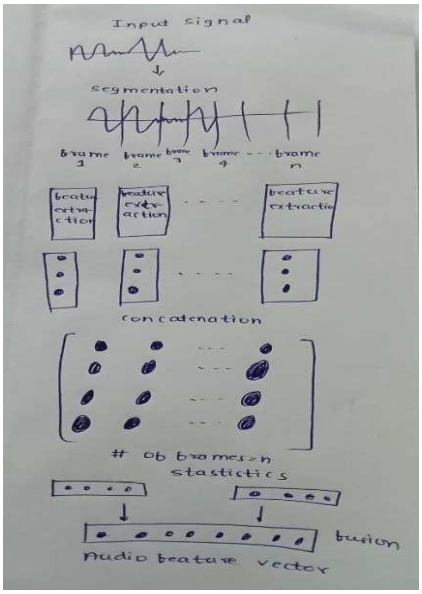
Word2Vec has two neural network architectures: continuous bags-of-words (CBOW) and skips-grams (SG). CBOW and SG were similar algorithms but the former is trained to predict a word given a context whereas the latter was trained to predict the context given a word. The architecture for SG is similar but in the opposite direction (i.e. given a word, predict the context). In this study skip-gram technique is chosen since it outperforms CBOW and other traditional textual features . Two parameters that needed to be adjusted to obtain better results were dimensionality (length of feature vector) and size of context window (number of words before and after the given words).[6]

B. . Audio Feature Extraction

The speech signal contains most of the emotion-specific information and they were classified as prosodic features and spectral features . Prosodic features were influenced by vocal fold activity and occurs when sounds were put together in a connected speech. On contrast, spectral features were influenced by vocal tract activity and were extracted from spectral content of the speech signal. In this study, we were extracted several prosodic and spectral features were to represent audio modality.[6]

The input signal was segmented into frames with size of 50 millisecond rather than analysing the whole signal at once. An overlap of 20 millisecond was considered among segments to maintain the continuity of the input signal. Therefore, signals were analyzed at the frame/segment level. The considered acoustic features were extracted from each segment to generate a matrix of size m×n, where n is the number of features (34 features) and n is number of signal's segments.

The value of n is variant and relies on the length of the whole signal. To represent the generated matrix of features as one vector we calculate the average and standard deviation for each row. Consequently, two feature vectors were generated each of size 34 features which were concatenated to create one feature vector of size 68 features. This process of representing audio by a feature vector. To our knowledge, this was the first time to evaluate this set of acoustic features were for multimodal sentiment analysis.[6]



C. Visual Feature Extraction

Optical flow is a useful technique to represent patterns of apparent motion of objects between the adjacent frames in the video .It could provide helpful information to represent emotional visual patterns of speaker's facial expressions and postures. The first use of optical flow to track action is attributed to the Mase in a simple manner and static formulation without the physical model. This method was involved evaluating the magnitude and direction of motion and representing them by a two-dimensional (2D) matrix to reflect points movement through two consecutive frames.

1) Face detection

The focus in this study is to detect emotion from face only while excluding other body parts. Towards this end, the general frontal face and eye detectors were utilized. The frontal face detector is based on object detection using HAAR feature-based cascade classifier. In addition, eye detector detects eye positions which provide significant and useful values to crop and scale the frontal face to a size of considered resolution of 240 × 320 pixel. This step is considered as a preprocessing step and run once on all data to reduce the computation time of the feature extraction.[6]

2) Feature extraction

After detecting the whole face, it is possible to compute the optical flow to capture the evolution of complex motion patterns for the classification of facial expressions and postures. Optical flow was considered to extract the visual Each frame was divided into a grid of s × s bins which was smaller than the size of frame.[6]

III. RESULT AND DISCUSSION

1) By studying the various research papers and getting much more knowledge about Video analytics implementations, we got to know that there are multiple experiments are conducted
to evaluate different techniques to fuse two and three modalities in multiple levels. [4]

2) Initially, the implementation is only with static inputs and single modalities but later on high increase in video data and real time videos were increased then dynamic modalities were created and then feature fusion technique is used to combine the considered modalities while in the later either score or decision level fusion. [4]

3) In general, the multilevel hybrid fusion achieves higher results comparing to the unimodal baseline models and single- level fusion models. The highest overall accuracy is obtained when when fusing audio and visual modalities in the first level using feature fusion and fusing the result with audio, text and visual modalities in the second level using score fusion technique (AV-A-T-V) and product rule with SVM classifier. [4]

IV. CONCLUSION

Video analytics is gaining substantial attention with immense contribution in many applications. This paper studies the various methods to implement the enhanced video analytics. In this paper we described the different methods to implement the enhanced video analytics respectively for textual, audio and video analytics. Earlier it was done for unimodal or single modal later as it requires more accurate results and needed to deal with dynamic inputs then dynamic multimodal is developed which is used to perform all these operation well that technique was using score fusion technique (AV-A-T-V) and product rule with SVM classifier. [4][6]

V. ACKNOWLEDGEMENT

We hereby take the privilege of presenting our paper on the Enhanced Video analytics. We are grateful to Ms. Veena Kulkarni, our paper guide, for contributing and valuable time in the paper from their busy and hectic schedule. Thank you for looking after us like a true mentor and great academic parents. We are very thankful to Ms. Veena Kulkarni, whose guidance and support was an immense motivation for us to carry on with our paper. Also, suggestions have greatly contributed to the betterment of our paper.

Developing a Web Portal for Recommendation of Ayurveda Medicine and Yoga Postures for Healthcare

Rashmi Thakur, Vishal Rawat, Rajbeer Rajak, Vivek Pandey, Harshita Mishra, Computer Department
TCET
Mumbai, India

Abstract— **Ayurveda, a traditional system of medicine originating in India, has gained worldwide recognition for its holistic approach to health and wellness. Yoga, an integral part of Ayurveda, offers a range of postures and breathing techniques that can help alleviate a wide range of health conditions. In this paper, we present a web portal for recommending Ayurvedic medicine and yoga postures for healthcare, using a machine learning approach. The web portal uses a large and diverse dataset of health conditions and corresponding recommendations and employs various machine learning algorithms to learn from this data and make personalized recommendations to users. We also discuss the ethical and legal implications of using such a portal, including informed consent, privacy and security, bias and fairness, legal compliance, responsibility and accountability, and transparency and explainability.**

Keywords— Ayurveda, Yoga, healthcare, web portal, machine learning, personalized healthcare, natural remedies, random forest algorithm, ethical considerations, legal implications.

I. INTRODUCTION

Ayurveda, an ancient Indian system of medicine, has been used for thousands of years to promote health and wellbeing. Ayurvedic medicine emphasizes the importance of a holistic approach to healthcare, including the use of natural remedies, such as herbs, spices, and minerals, as well as dietary and lifestyle modifications.

Yoga, an integral part of Ayurveda, is a system of physical and mental practices that can help promote physical and mental health. There is growing interest in Ayurveda and yoga as complementary and alternative approaches to healthcare, as well as in their potential to improve health outcomes and reduce healthcare costs.

However, accessing information about Ayurvedic medicine and yoga postures can be challenging for people who are new to these practices or who lack access to qualified practitioners. In this paper, we present a web portal that uses machine learning algorithms to recommend Ayurvedic medicine and yoga postures for healthcare.

II. BACKGROUND LITERATURE

As of 2021, India annually produces 15 lakh engineering graduates like ourselves. These 15- lakh people are responsible to improve the quality of life by providing solutions to complex problems of our society. But what about ourselves? While we students bring heaven and earth together to complete our projects, assignments and study for exams. It is observed that a large majority of them neglect their health in the process, simply because we cannot find the proper time in our ever-changing schedules to do a workout or hit the gym.

Keeping that in mind, we decided to work on a website which will recommend small exercises and yoga postures for people like us to practice. These things can easily blend with our schedules and help to keep our health at our priority. For serious cases involving people suffering from any illnesses, we aim for our website to recommend ayurvedic medicines which further ensures no harm which are normally done by industry manufactured drugs.

III. DATA COLLECTION AND ANALYSIS

To understand our current target audience better, it was decided that we need to conduct a survey to reach out and understand their habits and opinions on our project and how it could affect their lifestyle.

We started off with a very basic age demographic and understood that the majority of survey responses are given by people between the ages 19-23. We asked several questions about their quality of life which included questions like their average sleep time, amount of time spent at work or college, workout routine, medical history, etc.

From the responses we understood that:

• Demographics were of ages 19-23

• 60% of respondents have sleep schedule of 4-5 hours

• 80% of respondents spend time at work or college for about 8-10 hours

• 40% of respondents perform workout at gyms, whereas 80% of respondents in general

find it difficult to do it regularly

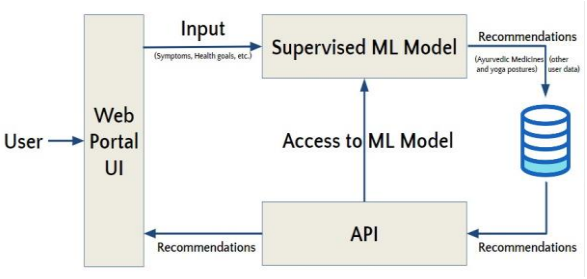
• 9% of respondents need to take medicines for various purposes

• Roughly 5% of respondents take ayurvedic medicines

• 30% of respondents practice yoga occasionally, out of which 50% are unaware of which asanas to practice for which purposes

• 90% of respondents understand the need for a platform to help recommend yoga postures and ayurvedic medicines to improve their standards of living

IV. PROPOSED ARCHITECTURE



V. METHODOLOGY

The development of the web portal involved a multidisciplinary team of developers, Ayurvedic practitioners, and yoga instructors. The team identified the key features necessary for the portal, including a search function for specific health conditions, a library of articles and resources, and recommendations for herbal remedies and yoga postures.

A. The Search Function

The search function allows users to input specific health conditions and receive recommendations for herbal remedies and yoga postures based on the principles of Ayurveda. The recommendations are generated based on the user's unique dosha and the specific health condition. The library of articles and resources provides education on Ayurvedic medicine and yoga practices, as well as information on the benefits and potential risks associated with the use of these practices.

B. Recommendations

The recommendations for herbal remedies and yoga postures are provided by qualified Ayurvedic practitioners and yoga instructors. The portal also includes information on the qualifications of these practitioners and instructors, ensuring that users receive reliable and trustworthy recommendations.

VI. RESULT AND DISCUSSION

It has Potential to provide a personalized and tailored experience for individuals seeking natural remedies.Random forest algorithm was identified as a suitable ML approach for developing the recommendation system.Ethical and legal implications of using such a portal must be considered.Recommendations provided must be accurate and up-to-date.

VII. CONCLUSION

This paper presents a promising tool for people who seek a more natural approach to their health and wellbeing.It also elaborates on integration of machine learning algorithms.Ethical and legal implications of using such a portal were discussed.We believe that such a web portal has the potential to provide a valuable service.

Digitising Doctor's Handwritten Prescription

Mr. Vikas Singh, Mr. Raj Desai, Ms. Aditi Shah, Ms. Ananya Singh, Mr. Harsh Singh, Computer Department
TCET
Mumbai, India
rvdesai1807@gmail.com, aditishah1802@gmail.com, ananya.singh30032003@gmail.com, harshs291002@gmail.com

Abstract— **It is commonly known that doctors have illegible handwriting. The writer usually knows what is written, but when other parties are involved, they often have problems with reading and interpreting the text. The following quote stresses the problem with illegible handwriting: 'Doctors' sloppy handwriting kills more than 7 000 people annually... In this project we are trying to resolve this problem by recognizing doctor's handwriting using handwriting recognition and converting it into legible format.**
Keywords— doctor, prescription, digital, mistakes, legible.

I. INTRODUCTION

Nowadays when a patient is consulting a doctor they are writing the prescriptions manually in a prescription pad which is not readable by normal people and the patient is supposed to carry this document to consult another doctor or to bring medicines from pharmacy they have to consult the doctor again if they have lost the prescription paper. In this era of digitalization doctors are still following this manual method of prescription writing. We are proposing a system which can transform this process into a digital, efficient and transparent way.

It also helps patients that prescription is not necessarily carried and it cannot be forged. Doctors can get the history of medical details directly from the system. Pharmacists can get prescriptions directly from the system. The Patients can also see their medical reports and laboratory details as well.

When a patient is going to bring medicine they don't have to carry a physical prescription with them all they have to do is to give a unique identity by which pharmacists can get the prescriptions. Also when a patient is visiting a new doctor by referring to the patient's medical account the doctor can know all the medical procedures the patient has gone through. Patients don't have to worry about losing the prescription.

II. METHODOLOGY

Whenever we come across a manually written paper, we frequently discover that it is not legible by average people. It is a well-known fact that doctors' handwriting is unreadable. This typically occurs when a patient receives a prescription and is required to carry this document in order to see a different doctor or pick up medications from the pharmacy. Most of the time, the doctor is aware of what is written, but when patients or other parties are engaged, they frequently struggle to read and understand the content.

We are attempting to fix this issue by transforming the doctor's handwriting into a legible format using handwriting recognition technology. In this project, we're attempting to make a suggestion for a system that could turn this procedure into one that is digital, effective, and transparent. In the suggested approach, a Personal Digital Assistant (PDA) will be used to convert the written text into a digitally readable format by comparing it to a database of medications, and the prescription will then be saved. Additionally, in order to prevent any medical information from being overlooked, we are attempting to keep all of their prescriptions in one location. A doctor has direct access to the system's medical history information. Direct prescription access from the system is available to pharmacists. The patients can also view their lab results and medical reports. Therefore, the document's content will be saved and available whenever we need it.

The technology will attempt to find a match in the medical database in order to produce the most appropriate textual interpretation of a certain collection of handwritten strokes. Once discovered, it can be uploaded to the cloud after being verified by the doctor. This will be accessible at pharmacies, and those that have authorization can obtain the list upon request from customers. Hospitals are attempting to transition to e-prescriptions at the moment, but one of the biggest obstacles is the inability to recognize doctors' handwriting. Many of the mistakes made by pharmacists who misread medicine names or dosages that are messy on paper should be eliminated by automation.

III. PROPOSED MODEL

A. Survey

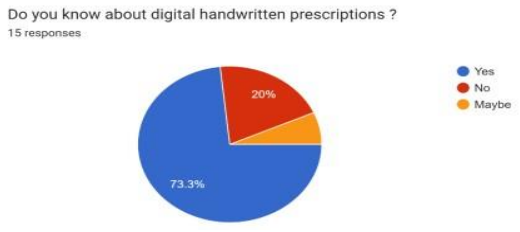

Fig. 1: Survey Question

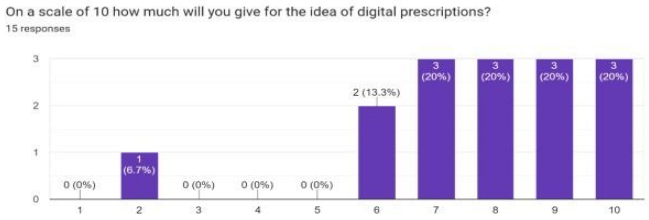

Fig. 2: Result of the survey

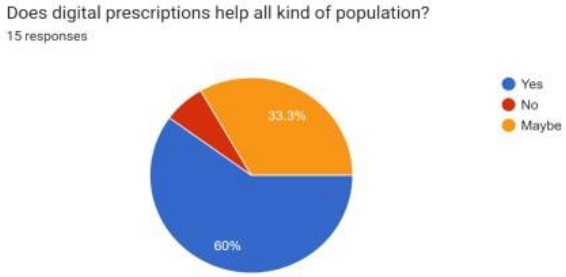

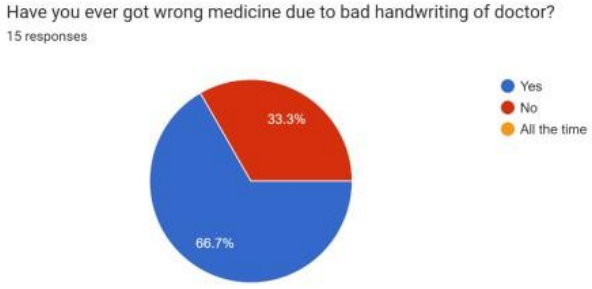

Fig. 3: Survey Questions

WHO?	WHAT?	WHERE?
This application can be used by people to better understand the prescription. Other doctors can refer to these and prescribe medicines. Vendors can use it to better understand the prescription	The handwritten prescription is being digitized and that can help people to better understand it.	In daily life and to better store the prescription online.

Fig. 4.1: 5W1H Model

WHEN?	WHY?	HOW?
The need to digitize and digitally store the prescription can come in handy at anytime. While buying medicines from the shop, referring to another doctor, etc.	Digitally storing the prescription has become necessary. It can help others to understand the prescription and while also referring to a new doctor, they can easily understand the prescription.	With the help of different machine learning algorithms.

D. Infographics

Fig. 7: Graphical Poster to convey the problem and our proposed model

E. Blog

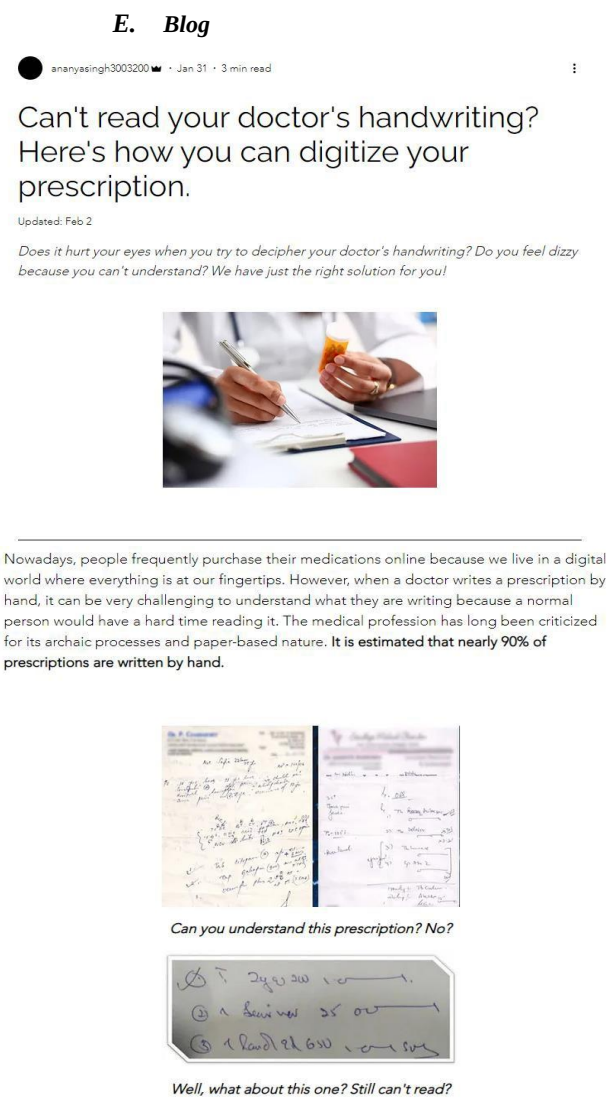

Fig. 8.1: A blog

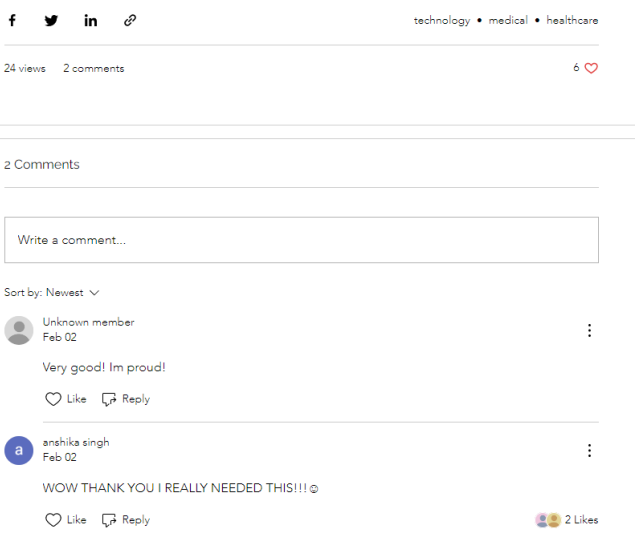

Fig. 8.2: A blog

V. CONCLUSION

We believe that this project will have an impact on today's healthcare industry concerns such like prescription falsification, prescription theft, major brand prescription usage, and so on. The various handwriting styles of doctors and a lack of training data are major problems in developing this system. As a result, the product cannot provide its best output straight away. There could be limitations like internet availability, reach to average citizens, and others, but this product will be able to achieve the changes it is expected to achieve in a reasonable period of time.

Application of Apriori, Eclat, and FP-Growth Algorithms in Real-World Market Basket Analysis Scenarios

Hiteshu Jani, Pawan Kumar Jha, Kanak Pandit, Puneet Pandey,Dr.Harshali Patil, Computer Department
TCET
Mumbai, India

Abstract- **Market basket analysis is a technique used in data mining to identify the items frequently purchased together by customers in a retail store. It is a crucial tool for retailers to understand consumer purchasing behavior and to improve their sales and marketing strategies. In this research paper, we present a comprehensive study on market basket analysis using three popular algorithms: Apriori, Eclat, and FPGrowth. The paper begins with a brief overview of market basket analysis and the techniques used for itemset mining. We then introduce the dataset used in this study, which consists of real-life transaction data collected from a retail store. Next, we perform a thorough evaluation of the Apriori, Eclat, and FPGrowth algorithms in terms of their computational time and the quality of the association rules generated. The results show that the FPGrowth algorithm is the fastest of the three algorithms, while the Apriori algorithm generates the most comprehensive and high-quality association rules.In addition, we also present a comparison of the performance of these algorithms in terms of various evaluation metrics such as support, confidence, and lift. Our study highlights the importance of selecting the appropriate algorithm for market basket analysis depending on the specific requirements and constraints of the task.The paper concludes with a discussion on the limitations and future directions of research in this area. Overall, our study provides insights into the strengths and weaknesses of the Apriori, Eclat, and FPGrowth algorithms and serves as a useful reference for practitioners and researchers in the field of market basket analysis.**

Keywords: Apriori,Eclat, FPGrowth, Market Basket Analysis, Support, Confidence, Lift, Leverage

I. INTRODUCTION

Market basket analysis is a data mining technique that helps retailers and businesses understand the purchasing behavior of customers. It involves analyzing transaction data to identify which products are frequently purchased together, known as "item sets" or "association rules". This information can be used to make informed decisions such as product placement, sales promotions, and cross-selling opportunities.[1] Market basket analysis has become an essential tool for businesses looking to improve customer satisfaction and increase sales revenue. It provides a comprehensive understanding of the relationships between products, enabling businesses to make informed decisions on stock levels, pricing, and marketing strategies.

When you go to the supermarket, usually the first thing you do is grab a shopping cart. As you move up and down the aisles, you will pick up certain items and place them in your shopping cart. Most of these items may correspond to a shopping list that was prepared ahead of time, but other items may have been selected spontaneously. Let's presume that when you check out at the cashier, the contents of your (and every other shopper's) cart are logged, because the supermarket wants to see if there are any patterns in selection that occur from one shopper to another. This is called market basket analysis.

The purpose of market basket analysis is to determine what products customers purchase together; it takes its name from the idea of customers throwing all their purchases into a shopping cart (a "market basket") during grocery shopping. Knowing what products people purchase as a group can be very helpful to a retailer or to any other company.

The current scenario in the retail industry is characterized by its highly customer-centric nature. Retailers are leaving no stone unturned to discover new ways of getting to know their customers better. Market basket analysis is one such tool that has caught the eye of several retail companies. The technique of identifying customer behavior, buying patterns, and finding the relationship between products and content

delivery by the retailer inside the store or on their online shop is known as market basket analysis.[1] With the help of this tool, not only can retailers identify target markets, but they can also enhance their customer-base by creating, delivering, and communicating a superior customer experience. Market basket analysis allows retailers to easily and promptly look at the size, quantity, and value

of the customers' market basket to understand the pattern in which products are purchased.
Market basket analysis is important for several reasons:

a. Customer insights: It provides a deeper understanding of customer purchasing behavior, preferences, and tendencies, which can inform business decisions and drive sales.

b. Increased sales: By identifying which products are frequently purchased together, businesses can create targeted promotions and bundles, leading to increased sales and customer satisfaction.

c. Improved inventory management: By identifying popular item sets, businesses can optimize their inventory management and avoid overstocking or understocking products.

d. Better product placement: Market basket analysis can help businesses determine the best placement for products in store or online, leading to improved sales and customer experience.

e. Cost savings: Market basket analysis can help businesses reduce waste by avoiding overstocking of products that have a low demand and focus on stocking items that are popular with customers.[2]

In short, market basket analysis provides valuable insights into customer behavior and helps businesses make informed decisions that can improve sales, customer satisfaction, and operational efficiency.

II. LITERATURE SURVEY

There are many data mining techniques and algorithms are available to discover meaningful pattern and rules. There are many different techniques are as follow:

Classification: In classification, first examine the features of newly presented object and assign it to a predefined class for example classify the credit applicants as low, medium or high risk.

Association: The main goal of association is to establish the relationship between items which exist in the market. The typical examples of association modeling are Market basket Analysis and cross selling programs. The tools used for association rule mining are apriori algorithm and weka tool kit.[3]

Prediction: In this functionality, prediction of some unknown or missing attributes values based on other Information. For example: Forecast the sale value for next week based on available data.

Clustering: In this, Data Mining organizes data into meaningful sub-groups (clusters) such that points within the group are similar to each other, and as different as possible from the points in the other groups. It is an unsupervised classification.

Analysis: In this, Data Mining is done to identify and explain exceptions. For example, in case of Market Basket Data Analysis, outlier can be some transaction which happens unusually.

Market basket analysis is a process that looks for relationships of objects that “go together” within the business context. In reality, market basket analysis goes beyond the supermarket scenario from which its name is derived. Market basket analysis is the analysis of any collection of items to identify affinities that can be exploited in some manner. Some examples of the use of market basket analysis include:

- Product placement. Identifying products that may often be purchased together and arranging the placement of those items (such as in a catalog or on a web site) close by to encourage the purchaser to buy both items.
- Physical shelf arrangement. An alternate use for physical product placement in a store is to separate items that are often purchased at the same time to encourage individuals to wander through the store to find what they are looking for to potentially increase the probability of additional impulse purchases.
- Up-sell, cross-sell, and bundling opportunities. Companies may use the affinity grouping of multiple products as an indication that customers may be predisposed to buying the grouped products at the same time. This enables the presentation of items for cross-selling, or may suggest that customers may be willing to buy more items when certain products are bundled together.
- Customer retention. When customers contact a business to sever a relationship, a company representative may use market basket analysis to determine the right incentives to offer in order to retain the customer’s business.

III. METHODOLOGY

I. Hardware and Software Requirements

1. Google Colab

Google Colab is the best project from Google Research. It is an open-source, Jupyter based environment. It helps us write and execute Python based code, other Python-based third-party tools and machine learning frameworks such as Python, PyTorch, Tensorflow, Keras, OpenCVand many others.

2. GPU

Google provides the use of free GPU for your Colab notebooks. Select GPU and your notebook would use the free

GPU provided in the cloud during processing. To get the feel of GPU processing, try running the sample application from the MNIST tutorial that you cloned earlier.[4]

II. Description of Libraries used

1. Numpy

   NumPy is a Python library used for working with arrays. It also has functions for working in the domain of linear algebra, fourier transform, and matrices.

2. Pandas
   Pandas is an open source Python package that is most widely used for data science/data analysis and machine learning tasks.

3. Itertools
   Itertools is a module in Python, it is used to iterate over data structures that can be stepped over using a for-loop.

4. Mlxtend
   Mlxtend (machine learning extensions) is a Python library of useful tools for day-to-day data science tasks.

5. Apriori
   Apriori is identifying the frequent individual items in the database and extending them to larger and larger item sets as long as those item sets appear sufficiently often in the database.

6. Matplotlib
   Matplotlib is a comprehensive library for creating static, animated, and interactive visualizations in Python.

7. Seaborn
   Seaborn is a library in Python predominantly used for making statistical graphics. Seaborn is a data visualization library built on top of matplotlib and closely integrated with pandas data structures in Python.

8. Plotly

The plotly Python library is an interactive, open-source plotting library that supports over 40 unique chart types covering a wide range of statistical, financial, geographic, scientific, and 3-dimensional use-cases.

III. Algorithms used are:

1. Apriori: The Apriori algorithm can be considered the foundational algorithm in basket analysis. It is a sequence of steps to be followed to find the most frequent itemset in the given database.The Apriori algorithm operates on a straightforward premise.[5] When the support value of an item set exceeds a certain threshold, it is considered a frequent item set.Apriori uses a "bottom-up" approach, where frequent subsets are extended one item at a time (a step known as candidate generation), and groups of candidates are tested against the data. The algorithm terminates when no further successful extensions are found.Using breadth-first search and a Hash tree structure, Apriori counts candidate itemsets efficiently. It generates candidate itemsets of length k from item sets of length k-1. Then it prunes the candidates which have an infrequent sub-pattern. According to the downward closure lemma, the candidate set contains all frequent k-length item sets. After that, it scans the transaction database to determine frequent item sets among the candidates. Along with market analysis , it is also used in the education field to relate to admitted students through characteristics and specialties . Used for analysis of patient databases and analysis of probability and intensity of forest fire with forest fire data.

2. Eclat: Equivalence Class Clustering and bottom-up Lattice Traversal make up the ECLAT algorithm.Eclat algorithm uses a Depth first search for discovering frequent item sets, whereas Apriori algorithm uses breadth first search. This vertical pattern of Eclat algorithm making it into faster algorithm compared to Apriori algorithm.Generally, Transaction Id sets which are also called as sets are used to calculate the value of Support value of a dataset and also avoiding the generation of subsets which does not exist in the prefix tree.In order to avoid the formation of subsets when the minimal support is obtained, the support value for an item is calculated using this method. Each item-transaction set is compared to every other pair in the function to produce a new candidate. The list of common partners is expanded if this candidate is found to be common. If the frequency set includes a pair of items, the frequent item set also includes its subsets. Obtain the tidlist for each database object. Here, we thoroughly search the database. The list of transactions that contain item “a” is represented by its tidlist. Create a new transaction list whose constituents are transactions in which both item a and item b are involved by intersecting their respective transaction lists.

3.FPGrowth : FP-growth is an improved version of the Apriori Algorithm which is widely used for frequent pattern mining(AKA Association Rule Mining). It is used as an analytical process that finds frequent patterns or associations from data sets. FP growth represents frequent items in frequent pattern trees which can also be called as FP-tree.[6] A frequent pattern is generated where the candidate generation is not needed. FP growth algorithm represents the database in a tree pattern called a frequent pattern tree or FP tree. FP Tree is a tree-like structure which is made with the initial item sets of the database. The purpose of the FP tree is to find out the most frequent pattern where each node of the FP tree represents an item of the itemset.This tree structure will maintain the association or relation between the item sets. The database is separated by using one frequent item. This fragmented or separated part is called a pattern fragment. The item sets of these fragmented patterns are studied. Hence, the search for frequent item sets has decreased comparatively.

IV. Implementation

Various models were trained to check out it's performance and comparison was made between all of them:

I. Data Description
First we need to load some libraries and import our data. We can use the function read.transactions() from the arules package to create a transactions object.

The data set contains 15.010 observations and the following columns.

Date: Categorical variable that tells us the date of the transactions (YYYY-MM-DD format). The column includes dates from 30/10/2016 to 09/04/2017.

Time: Categorical variable that tells us the time of the transactions (HH:MM:SS format).

Transaction: Quantitative variable that allows us to differentiate the transactions. The rows that share the same value in this field belong to the same transaction, that's why the data set has less transactions than observations.[7]
Item: Categorical variable containing the products.

The first 5 rows of the dataset, we have 3 different columns: Member_number is a number that is unique for each customer. Date represents the date of the transaction, and finally itemDescription represents the corresponding product bought for this date.

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 38765 entries, 0 to 38764
Data columns (total 3 columns):
 #   Column           Non-Null Count  Dtype 
---  ------           --------------  ----- 
 0   Member_number    38765 non-null  int64 
 1   Date             38765 non-null  object
 2   itemDescription  38765 non-null  object
dtypes: int64(1), object(2)
memory usage: 908.7+ KB
```

Figure 1: Data Information

II. Data Preparation

The checking of null values forms an important basis of data preprocessing for model to train properly on the dataset.

```
# Checking for the missing values
nan_values = data.isna().sum()
nan_values
```

```
memberID    0
Date        0
itemName    0
dtype: int64
```

Figure 2: Computation of Missing Data

The analysis plan is to answer the questions.
A. What are the most frequently sold items?
B. What are the consequents of the chosen items?
C. How confident do the consequents come after the items?
D. What are the most important items that should always be in the store?
E. What does the item network look like?

According to result above, there is no missing values for all columns.

```
# Converting Date column into correct datatype which is datetim
e
data.Date = pd.to_datetime(data.Date)
data.memberID = data['memberID'].astype('str')
data.info()  # They are in correct datatype now
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 38765 entries, 0 to 38764
Data columns (total 3 columns):
 #   Column    Non-Null Count  Dtype         
---  ------    --------------  -----         
 0   memberID  38765 non-null  object        
 1   Date      38765 non-null  datetime64[ns]
 2   itemName  38765 non-null  object        
dtypes: datetime64[ns](1), object(2)
memory usage: 908.7+ KB
```

Figure 3: Conversion into datetime

III. Exploratory Data Analysis

Firstly, we need to calculate the number of sales weekly.
To calculate the total number of items sold by date, the following code was used.

```
data.groupby(['Date'])['itemDescription'].agg(['count']).plot(figsize=(12,5), grid=True, title="Total Number of Items Sold by Date").set(xlabel="Date", ylabel="Total Number of Items Sold")
```

The output for the following code was:

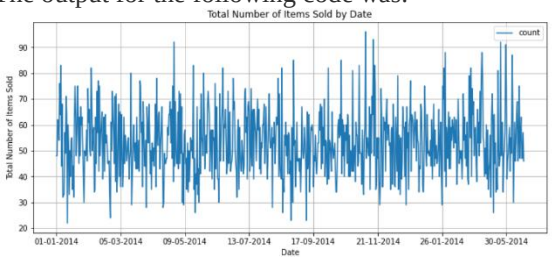

Figure 4: Total Number of Items Sold by Date

As it can be seen in the figure, The maximum sales are observed on 21st November, 2014 and just before 9th May, 2014.

To calculate the number of unique items and average number of items sold, we used the following code and noted the output:

```
total_items = len(d)
total_days = len(np.unique(d.index.date))
total_months = len(np.unique(d.index.month))
average_items = total_items / total_days
unique_items = d.itemDescription.unique().size

print("There are {} ye unique items sold ".format(unique_items))
print("Total {} items sold in {} days throughout {} months".format(total_items, total_days, total_months))
print("With an average of {} items sold daily".format(average_items))
```

```
There are 167 ye unique items sold
Total 38765 items sold in 728 days throughout 12 months
With an average of 53.24862637362637 items sold daily
```

Figure 5: Unique, Average and Total Items sold

We also found out the total number of items sold each month in that year:

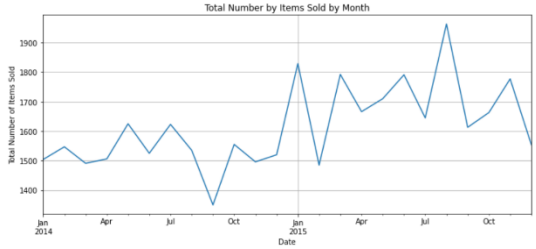

Figure 6: Total Number of Items sold by Date

It is noticed that most number of sales were made during the month of August followed by Jan 2015.

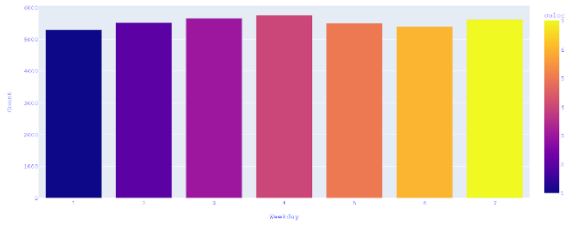

Figure 7: Count of Items sold by weekday

Also, count of weekly sales is made by calculating the number of sales on every day.
Also, for curiosity about the item frequencies, we got the following output:

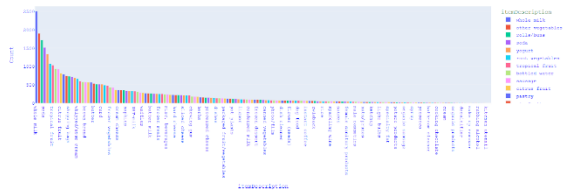

Figure 8: Count of Items

IV. Choice of Model and Model Training

A. Apriori

Apriori is an algorithm for frequent item set mining and association rule learning over relational databases. It proceeds by identifying the frequent individual items in the database and extending them to larger and larger item sets as long as those item sets appear sufficiently often in the database. The frequent item sets determined by Apriori can be used to determine association rules which highlight general trends in the database: this has applications in domains such as market basket analysis.[8]

	antecedents	consequents	antecedent support	consequent support	support	confidence	lift	leverage	conviction
668	(sausage, yogurt)	(whole milk)	0.005748	0.157923	0.001470	0.255814	1.619866	0.000563	1.131541
978	(sausage, rolls/buns)	(whole milk)	0.005347	0.157923	0.001136	0.212500	1.345594	0.000292	1.069304
1079	(soda, sausage)	(whole milk)	0.005948	0.157923	0.001089	0.179775	1.138374	0.000130	1.026642
526	(semi-finished bread)	(whole milk)	0.009490	0.157923	0.001671	0.176056	1.114825	0.000172	1.022008
828	(rolls/buns, yogurt)	(whole milk)	0.007819	0.157923	0.001337	0.170940	1.082428	0.000102	1.015701

Figure 9: Association Table

To construct association rules between elements or items, the algorithm considers 3 important factors which are, support, confidence and lift. Each of these factors is explained as follows:

Support: The support of item I is defined as the ratio between the number of transactions containing the item I by the total number of transactions expressed as:

Support(I)=Number of transactions containing I/Total number of Transactions

Confidence: This is measured by the proportion of transactions with item I1, in which item I2 also appears.[7] The confidence between two items I1 and I2, in a transaction is defined as the total number of transactions containing both items I1 and I2 divided by the total number of transactions containing I1.

Confidence(I1->I2)=Number of Transactions containing I1 and I2/(Total Number of Transactions containing I1)

Lift: Lift is the ratio between the confidence and support expressed as :

Lift(I1->I2)=Confidence(I1->I2)/Support(I2)

B. FP Growth

The FP-Growth Algorithm is an alternative way to find frequent item sets without using candidate generations, thus improving performance. For so much, it uses a divide-and-conquer strategy. The core of this method is the usage of a special data structure named frequent-pattern tree (FP-tree), which retains the item set association information.

This algorithm works as follows:

• First, it compresses the input database creating an FP-tree instance to represent frequent items.

• After this first step, it divides the compressed database into a set of conditional databases, each associated with one frequent pattern.

• Finally, each such database is mined separately.

The FP-Growth Algorithm is an alternative way to find frequent item sets without using candidate generations, thus improving performance. For so much, it uses a divide-and-conquer strategy. The core of this method is the usage of a special data structure named frequent-pattern tree (FP-tree), which retains the item set association information.[9]

This algorithm works as follows:

• First, it compresses the input database creating an FP-tree instance to represent frequent items.

• After this first step, it divides the compressed database into a set of conditional databases, each associated with one frequent pattern.

• Finally, each such database is mined separately.

The frequent-pattern tree (FP-tree) is a compact data structure that stores quantitative information about frequent patterns in a database. Each transaction is read and then mapped onto a path in the FP-tree. This is done until all transactions have been read. Different transactions with common subsets allow the tree to remain compact because their paths overlap.

A frequent Pattern Tree is made with the initial item sets of the database. The purpose of the FP tree is to mine the most frequent pattern. Each node of the FP tree represents an item of the item set.

C. Eclat Algorithm

The Eclat algorithm stands for Equivalence Class Clustering and bottom-up Lattice Traversal. It is one of the popular methods of Association Rule mining. It is a more efficient and scalable version of the Apriori algorithm. While the Apriori algorithm works in a horizontal sense imitating the Breadth-First Search of a graph, the Eclat algorithm works in a vertical manner just like the Depth-First Search of a graph. This vertical approach of the Eclat algorithm makes it a faster algorithm than the Apriori algorithm.

How the algorithm work?:

The basic idea is to use Transaction Id Sets(tidsets) intersections to compute the support value of a candidate and avoiding the generation of subsets which do not exist in the prefix tree. In the first call of the function, all single items are used along with their tidsets. Then the function is called recursively and in each recursive call, each item-tidset pair is verified and combined with other item-tidset pairs. This process is continued until no candidate item-tidset pairs can be combined.

V. Result and Analysis

	antecedents	consequents	antecedent support	consequent support	support	confidence	lift	leverage	conviction
38	(sausage, yogurt)	(whole milk)	0.005748	0.157923	0.001470	0.255814	1.619866	0.000563	1.131541
43	(rolls/buns, sausage)	(whole milk)	0.005347	0.157923	0.001136	0.212500	1.345694	0.000292	1.069304
50	(sausage, soda)	(whole milk)	0.005948	0.157923	0.001069	0.179775	1.138374	0.000130	1.026642
55	(semi-finished bread)	(whole milk)	0.009490	0.157923	0.001671	0.176056	1.114825	0.000172	1.022008
16	(rolls/buns, yogurt)	(whole milk)	0.007819	0.157923	0.001337	0.170940	1.082428	0.000102	1.015701

Figure 10: Association Rules Analysis

Antecedent and Consequent: The IF component of an association rule is known as the antecedent. The THEN component is known as the consequent. The antecedent and the consequent are disjoint; they have no items in common. As you can see in the figure, different combinations can be witnessed in both the columns.

Confidence: Rules have an associated confidence, which is the conditional probability that the consequent occurs given the occurrence of the antecedent. You can specify the minimum confidence for rules. In Market Basket Analysis, expected confidence is the probability that the second product or group is in the basket regardless of any preconditions. That is to say, expected confidence is the number of purchases that include the second product divided by the total number of transactions. It is the conditional probability of the occurrence in the event. The change that happens in product A has already happened in product B.[10]

Support: In Market Basket analysis, support represents the popularity of an item in all transactions. Support of an item is calculated as the number of transactions involving that item and the total number of transactions. Support of an item = (Number of transactions involving that item)/ (Total number of transactions). The Apriori algorithm is a commonly-applied technique in computational statistics that identifies itemsets that occur with a support greater than a predefined value (frequency) and calculates the confidence of all possible rules based on those itemsets.

Lift: Lift measures the performance of a targeting model (known as an association rule) at predicting a specific outcome, compared with a random choice. Therefore, Lift is the ratio between target response and average response. That is to say that Lift is a ratio between confidence and expected confidence. When the Lift value is below 1 means the combination is not so frequently bought by consumers. But in this case, it shows that the probability of buying both the things together is high when compared to the transaction for the individual items sold.
With this, we come to an overall view of the Market Basket Analysis in Data Mining and how to calculate the sales for combination products.

Leverage: Retailers leverage market basket analysis to identify combinations of goods or menu items that regularly co-occur in transactions to uncover associations between what your customers are buying to create new products and pricing models to generate new revenue streams.

Conviction: Conviction can be interpreted as the ratio of the expected frequency that X occurs without Y (that is to say, the frequency that the rule makes an incorrect prediction) if X and Y were independent divided by the observed frequency of incorrect predictions.

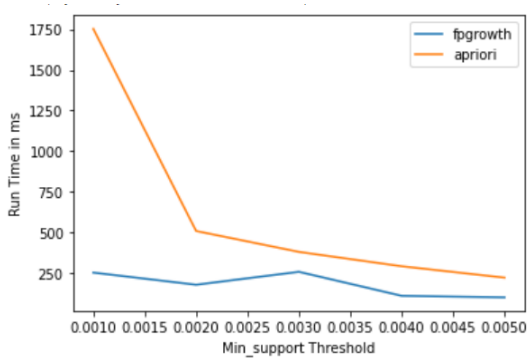

Figure 11: Minimum threshold support of Fpgrowth and Apriori

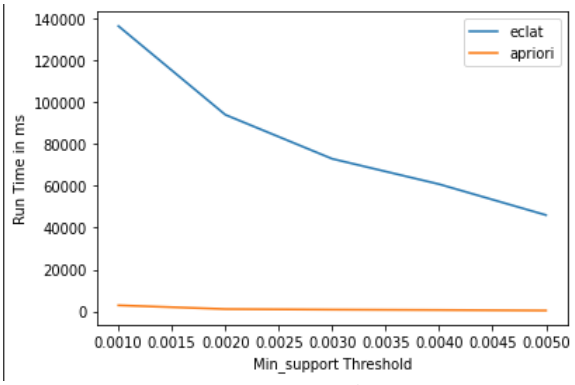

Figure 12: Minimum threshold support of Eclat and Apriori

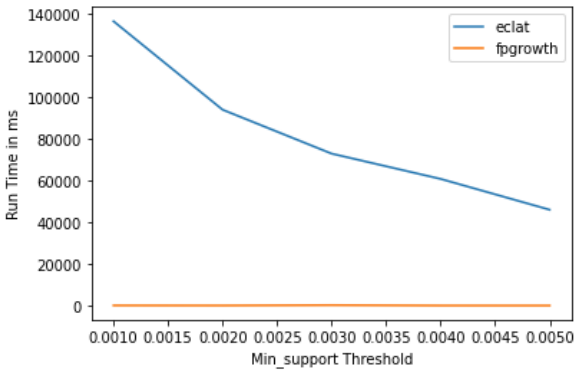

Figure 13: Minimum threshold support of Fpgrowth and Eclat

According to the above charts, fpgrowth is the fastest for huge datasets, while Eclat is incredibly slow.
a. Apriori
1. It is an array based algorithm.
2. It uses Join and Prune techniques.
3. Apriori uses a breadth-first search
4. Apriori utilizes a level-wise approach where it generates patterns containing 1 item, then 2 items, then 3 items, and so on.
5. Candidate generation is extremely slow. Runtime increases exponentially depending on the number of different items.

b. FP Growth

1. It is a tree based algorithm.
2. It constructs a conditional frequent pattern tree and conditional pattern base from a database which satisfies minimum support.
3. FP Growth uses a depth-first search
4. FP Growth utilizes a pattern-growth approach means that, it only considers patterns actually existing in the database.
5. Runtime increases linearly, depending on the number of transactions and items.

c. Eclat

1. The Eclat algorithm stands for Equivalence Class Clustering and bottom-up Lattice Traversal.
2. It is one of the popular methods of Association Rule mining. It is a more efficient and scalable version of the Apriori algorithm.
3. While the Apriori algorithm works in a horizontal sense imitating the Breadth-First Search of a graph, the Eclat algorithm works in a vertical manner just like the Depth-First Search of a graph.
4. This vertical approach of the Eclat algorithm makes it a faster algorithm than the Apriori algorithm.
5. The basic idea is to use Transaction Id Sets(tidsets) intersections to compute the support value of a candidate and avoid the generation of subsets which do not exist in the prefix tree. In the first call of the function, all single items are used along with their tidsets.
6. Then the function is called recursively and in each recursive call, each item-tidset pair is verified and combined with other item-tidset pairs. This process is continued until no candidate item-tidset pairs can be combined.

IV.CONCLUSION

We have seen association rules and the measures of interestingness in making frequent item patterns. We had an overview of the Eclat algorithms and how we can implement the Apriori and FP-growth algorithms using Python in very simple steps.[11] Since these algorithms are the most basic algorithms in the subject of Eclat we look at the comparison between them. As in the classification of the algorithms, we have seen that there can be various algorithms for performing the eclat, so I encourage you to try to learn them. Also, they can be beneficial if the apriori or FP-Growth algorithms are not performing well or the required results are different for these results. Apriori algorithm is an efficient algorithm that scans the database only once.It reduces the size of the item sets in the database considerably, providing good performance. Thus, data mining helps consumers and industries in the decision-making process.

We have learned how to perform Market Basket Analysis in Python and how to interpret the results. If you want to implement them in Python, Mlxtend is a Python library that has the implementation of the Apriori , FP Growth and Eclat algorithms for this sort of application.

In future research it will be very interesting to do an in-depth understanding of the association rules by evaluating the changes in the lift and confidence values, which can be made possible by calculating the standard deviation. This way we will be able to witness the evolution of association rules.

In the future we can also find association rules using time series clustering method.
We had an overview of how we can implement the Apriori and FP-growth algorithm using python in very simple steps. Since these algorithms are the most basic algorithms in the subject of FIM we look at the comparison between them. As in the classification of the algorithms we have seen that there can be various algorithms for performing the FIM, I encourage you to try to learn them. Also, they can be beneficial if Apriori or FP-Growth algorithms are not performing well or the required results are different for these results.

Future work would also be to design and develop an intelligent prediction model to generate the association rules that can be adopted on a recommendation system to make the functionality more operational.

Cloud Office: A web based office Documentation System for Efficient Collaboration

Omkar Mourya,Ankit Mishra,Harsh Mishra,Nandkishor Mishra,Mrs.Lydia Suganya
Thakur college of engineering and technology ,kandivli ,Mumbai ,India

Abstract *— As businesses and organizations continue to embrace remote work and distributed teams, the need for efficient and collaborative document management systems has become increasingly important. This paper presents the development and implementation of CloudOffice, a web-based office documentation system that enables teams to collaborate in real-time, access files from anywhere, and streamline their workflow. The system is designed to provide a comprehensive suite of features, including document creation and editing, version control, commenting, and file sharing. CloudOffice was developed using modern web technologies and has been designed to be user-friendly, secure, and scalable. The system was tested by a group of users who provided valuable feedback and suggestions for improvement. The testing results demonstrate that CloudOffice can significantly improve team productivity and efficiency, while also reducing the cost of maintaining traditional office documentation systems. This research paper provides a detailed overview of the development and implementation of CloudOffice and highlights its potential as a valuable tool for modern businesses and organizations.*

Key Words: ***Web-based office documentation system, Collaboration, Distributed Teams, Real-time Collaboration, Workflow Optimization, Version Control, and File sharing.***

I.INTRODUCTION

Organizations are increasingly interested in carefully managing their private information both to ensure that it is properly handled, and also to make it more useful to their daily tasks. Meanwhile, the number and variety of documents make management and usage more challenging. Therefore, how to achieve efficient management of documents becomes an emerging issue in today's information-rich society. The requirement can be further classified into two aspects, which are described as the following. ∞ Support for ubiquitous access: In order to achieve efficient management of documents, the capability for users to have timely access to the latest information anytime, anywhere, and from any device should be taken into careful consideration. In addition, due to the growing diversity of devices, corresponding document access and management mechanisms should be provided without extra learning burdens and complex operations by users. ∞ Support for sharing and collaboration: Due to the globalization and high division of works, sharing and collaboration within organizations are inevitable and increasing (Erickson et al, 2009). Colleagues may participate in one task and share a particular set of documents to support their work. Meanwhile, the documents will evolve as the task proceeds. The control and management of documents should be considered. In this paper, the design of a document management system for a

private cloud environment is introduced. The document management system aims to provide users in an organization with a simple and efficient mechanism to access, manage and share their information. It provides fundamental document manipulations, synchronization, and sharing functionalities, and considers the support of heterogeneous client devices. A case study is also given in this paper to describe the scenarios and the benefits of using the document management system in an academic environment.

II.OVERVIEW OF WEB-BASED OFFICE DOCUMENTATION SYSTEM

A web-based office documentation system is a software application that allows users to create, manage, and collaborate on documents and files from anywhere, as long as they have access to the internet. These systems are designed to facilitate efficient communication, collaboration, and information sharing between team members, especially for remote workers or distributed teams. Web-based office documentation systems typically provide a comprehensive suite of features, including document creation and editing, version control, commenting, file sharing, and security protocols. By providing real-time access to documents and files, team members can work on the same documents simultaneously, reducing the need for emails or file transfers. Version control ensures that the most up-to-date documentation is being worked on, and previous versions can be retrieved if needed.

These systems can be cloud-based or self-hosted, depending on the needs of the organization. Cloud-based systems offer the advantage of accessibility from anywhere, while self-hosted systems offer more control over data storage and security. Web-based office documentation systems have become increasingly important as organizations continue to adopt remote work and distributed teams. The benefits of these systems include improved collaboration, streamlined workflow, and reduced costs. The purpose of this research paper is to present the development and implementation of a web-based office documentation system and to demonstrate its potential as a valuable tool for modern businesses and organizations looking to improve their productivity and efficiency.

MOTIVATION:

Web-based Office - Documentation systems are designed to manage and store project documents i.e. information, used as web-based applications. Different groups of people such as all departments, programmers, or project managers will be let by project applications controlled access to information and automated distribution of information. The objective for collaboration has been: getting things done faster, cheaper, and better by applying their common knowledge, and bringing together a selection of resources and attainments in a project. Valid collaboration with teams improves productivity, speeds up result-making, and optimizes making the right decision, it also helps to intercept precious intellectual fortune and time. To prove such kind of improvement to productivity and to make easier our everyday working life, it was needed from the company to make an inside system for Document Management. Namely, having trouble finding the right files and wasting useful time sending and searching documents, describing and instructing new employers of the whole system and steps that need to be done, before beginning to make changes in projects or code. For consuming necessary time, keeping all troubles less, and to organize all documents into one place, and most importantly, keeping track of projects that are in production for customers or for keeping an eye on errors or mistakes that occur during the work process, then a good web-based documentation system was under consideration. To consider everyday use and needs, the aim was to make an inside system for the company/office. The system is for helping workers (namely programmers, project managers, developers/employees) to deal with some specific project or any process and its errors occurred. The document management system is needed, for helping to organize and keep an eye on the project and its progress. The system is web-based; there are possibilities to add documents and specifications for specific projects/tasks. Documentation can consist of different graphs, database diagrams, graphical diagrams, and text files, which are needed for project development. The most important part is that the system works as a tracking system, a system where comments can be added and bugs and other related questions can be reported for any task at any step.

Advantages of Modern DMS:

Many companies use a Document Management System (DMS) to standardize the way information is stored, making it easier for anyone with correct privileges to find and access the documents they need. A DMS simplifies work processes and helps users perform their tasks more efficiently, while also providing the company with security, data reliability, and work process management.

The features of a DMS offer numerous benefits, such as saving time, simplifying work, protecting the investment made in creating these documents, enforcing quality standards, enabling an audit trail, and ensuring accountability. With a DMS, teams can collaborate more effectively, and workflows can be optimized to improve productivity.

Moreover, the centralized storage of documents and the ability to access them from anywhere makes it easier for remote teams to work together seamlessly. Document

version control ensures that the most current version is being worked on, and previous versions can be retrieved if necessary. A DMS also helps to ensure that the company's documents are stored securely, with access permissions granted to only authorized users.

Overall, the use of a DMS is crucial for companies to manage and maintain their documents in a streamlined and efficient manner while reducing the risks of errors, unauthorized access, and lost productivity.

Electronic Document Management System:

Any company will one day feel a need for some kind of electronic document management system (EDMS) to control its ever-increasing number of various documents and drawings. companies often resist 'this urge' and are deterred by the costs and complexity involved in implementing an EDMS. Using an EDMS effectively, requires a major change in working practices, although most technical aspects are resolved by the adoption of low-cost databases and easier integration with the windows environment. A useful EDMS should not only control documents but also provide access to them throughout the company and even to clients or other participants of the project via the internet or extranet. An EDMS should also centralize data in an easily accessible environment, allowing users to store, access, and modify information easily and fast. Furthermore, the task of managing all the information needed to design and construct any major facility is a real challenge, and many believe that more efficient information management is a primary mechanism for the construction industry to increase its productivity. the standard features of a good system should still include the following functionalities: searching facility, viewing without the use of the original application, red-lining and marking-up feature, printing and plotting, workflows and document life cycles, revision and version control, document security, document relationships, status reporting, issue/distribution management, and remote access. the goal of document management is to share information by making documents secure, accessible, retrievable, and interchangeable. the solution to this situation is electronic document management systems.

Advantages of EDMS:

Many companies use DMS to standardize the way information is for anybody with correct privileges to find and access the document they want. an EDMS helps users to perform their work easier and provides the company with security, data reliability, and work process management. many of these features eventually save time, simplify work, protect the investment made in creating these documents, enforce quality standards, enable an audit trail, and ensure accountability.

EDMS has the following advantages:

1. Generally efficient location and delivery of documentation
2. Ability to manage documents and data regardless of originating system or format
3. The ability to integrate computerized and paper-based systems
4. Control of access, distribution, and modification of documents
5. Provision of document editing and mark-up tools

System Architecture:

To fulfill the requirements of ubiquitous access and efficient sharing of documents within an organization, the document management system is designed based on the architecture of the content management system. As depicted in Figure 1, the architecture can be divided into a document management server and device agents. The document management server is responsible for user management, device management, and document management. On the other hand, the device agent is responsible for communicating with the document management server and maintaining data consistency between the device itself and the server. Major components are introduced in the following sections.

User management module: The user management module is responsible for the management of users of the document management system, which includes user identification, user preference, and user profiles. The concept of group and role is also introduced. Groups can be created and users can participate in the specific group based on task requirements. This facilitates the sharing and collaboration among users. On the other hand, users can be assigned particular roles. It determines the allowed manipulations on documents. ∞ Device management module: The device management module is responsible for the management of devices owned by users. It preserves information about the device name, device type, device status, and other device characteristics. The information can be used as a reference for device-specific functions (e.g., synchronization). ∞ Document management module: The document management module provides three major functionalities for document management tasks, including document manipulation, synchronization, and share. Document manipulation function provides users with the capabilities of manipulating and managing documents, including document creation, update, copy, move, and deletion. In addition to fundamental manipulations, search, versioning, meta-data enriching, and content preview are included in the document manipulation function. The synchronization function cooperates with device agents to maintain data consistency between the document management server and users' devices. The document state of the document management server and the client devices will be compared, and the corresponding synchronization process can be performed. In addition, the synchronization can be configured to different

modes, including full synchronization and on-demand synchronization. Full synchronization means the entire document in the document management server of one user will be synchronized with his/her client devices. On the other hand, in on-demand synchronization mode, users can specify particular documents and devices for synchronization based on their preferences and requirements. The share function is responsible for document sharing among users. It is conducted by selecting personal documents and users who will be shared. The user who shares the document can also decide the permissions to indicate what operations can be performed. Once the share is made, other users will obtain access permission to the shared documents. In addition, the shared document will be synchronized. The sharing scheme provides an efficient approach for users to share documents and can facilitate collaboration among users.

III.BENEFITS AND DRAWBACKS OF WEB-BASED OFFICE DOCUMENTATION SYSTEM

Web-based office documentation systems have many benefits, including improved collaboration, streamlined workflow, and reduced costs. CloudOffice, a web-based office documentation system designed and developed for this research paper, also offers several benefits. One of the main benefits of CloudOffice is its ability to provide real-time collaboration. With the system, team members can work on the same documents simultaneously, reducing the need for email or file transfers. This feature saves time and enhances productivity, especially for remote workers and distributed teams Another benefit of CloudOffice is its document management capabilities. The system allows for document version control, ensuring that the most up-to-date documentation is being worked on, and previous versions can be retrieved if necessary. CloudOffice also provides secure access to documents, with permissions granted to only authorized users. However, there are also drawbacks to web-based office documentation systems. One of the main concerns is the security of the system. As documents are stored in the cloud, there is a risk of unauthorized access, especially if security protocols are not properly implemented. CloudOffice addresses this concern by providing secure access and permissions to authorized users only. Another potential drawback is the reliability of internet connectivity. If internet connectivity is lost, team members may not be able to access documents and collaborate in real time. However, this risk can be mitigated by using backup systems or self-hosted solutions. Additionally, some team members may not be comfortable with the web-based environment and may prefer traditional office documentation systems. However, with proper training and support, most team members can quickly adapt to web-based systems like CloudOffice.

In conclusion, web-based office documentation systems like CloudOffice offer many benefits, including improved collaboration, streamlined workflow, and reduced costs. However, organizations must also be aware of the potential drawbacks, including security concerns and reliance on internet connectivity. Overall, the benefits of web-based office documentation systems outweigh the drawbacks, especially as remote work and distributed teams continue to become more commonplace.

VI. CONCLUSION

This paper provides an overview of web-based office documentation systems, their advantages and disadvantages, and their benefits with drawbacks. In conclusion, the research has shown that web-based office documentation systems offer numerous benefits to organizations of all sizes. These systems have the potential to improve collaboration, streamline workflows, and reduce costs. With the increase in remote work and distributed teams, web-based systems have become increasingly important for organizations to maintain productivity and competitiveness. However, there are also challenges to implementing web-based office documentation systems. Security concerns and reliance on internet connectivity are some of the main challenges that organizations may face. To overcome these challenges, organizations must implement proper security measures and ensure reliable internet connectivity. The research also highlights the importance of proper training and support for team members who are not familiar with web-based office documentation systems. Organizations must provide proper training and support to ensure that all team members are comfortable with the new system. Despite the challenges, the benefits of web-based office documentation systems make them valuable tools for modern organizations. These systems have revolutionized the way organizations manage their documents and collaborate on projects, resulting in improved efficiency and productivity. Overall, the research suggests that web-based office documentation systems are an essential tool for modern organizations. By addressing the challenges and leveraging the opportunities presented by these systems, organizations can achieve significant benefits in terms of collaboration, efficiency, and cost savings.

VII. ACKNOWLEDGMENT

We would like to express our sincere gratitude to all the individuals who have contributed to the successful completion of this research paper on the web-based office documentation system. Firstly, we extend our heartfelt thanks to our project guide and mentor, Dr. Lydia Suganya, whose invaluable guidance, expertise, and support have been crucial in the completion of this work. Their insightful feedback and constructive criticism have helped us to refine

our ideas and concepts. We would also like to acknowledge the support and encouragement of our colleagues and peers, who have provided us with useful feedback and insights throughout the project. Additionally, we are deeply grateful to our family and friends who have provided us with unwavering support and motivation. Finally, we extend our heartfelt appreciation to all the authors, researchers, and experts who have contributed to the development of the web-based office documentation system. Their tireless efforts and dedication have made this technology possible, and we are honored to have had the opportunity to explore and learn from their work.

Identification of Tumors using Blob Detection

Dr. Rekha Sharma, Tejas Nair, Tejas Keni, Computer Department
TCET
Mumbai, India

Abstract—**Blob detection is an algorithm which works on images to capture regions in an image which seem discrepant. This is especially useful for finding irregularities in MRI scans, which can then be provided to CNNs for further processing. This will allow doctors, clinics, etc. to give accurate diagnostics and prevent diseases like cancer from snowballing into bigger problems, and also for early warnings for dementia.**

Keywords—tumors, image processing, medical, cancer, blob detection, MRI

I. INTRODUCTION

The reason people go to doctors regularly is because of the saying, "Prevention is better than a cure". Unfortunately, cancer is one of the things that simply cannot be prevented, since cancer simply doesn't come because of a single cause. There are multiple causes, like radiation, genetics, that could cause cancer. So, the only possible option other than prevention is a cure, but that would only be possible with a correct diagnosis. The reason for this is that when dealing with a benign tumor, it is a lot simpler to deal with and remove, than a malignant tumor, which spreads much faster and isn't relatively docile like benign tumors. [1]

Doctors commonly use MRI scans that show up as high contrast, black and white images of the brain. This is what blob detection algorithms would use to determine if that MRI scan of the brain contains a tumor or not. Below is an example of an MRI scan.

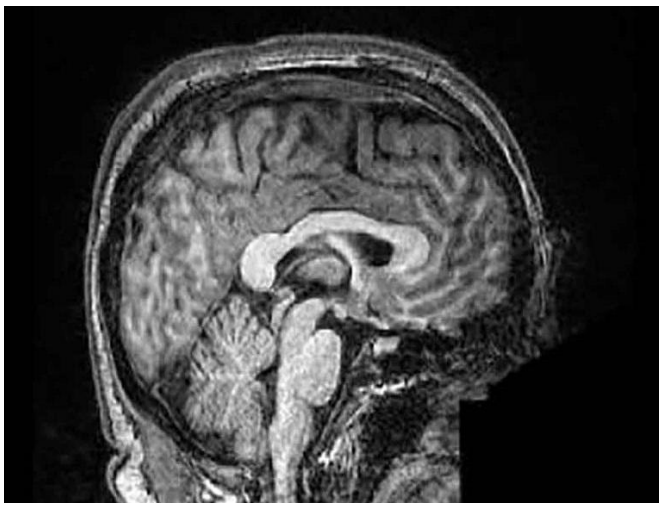

Figure 1: Image of a LHS MRI Scan Source: Open Source Imaging

The reason this is needed is because of early detection and subsequent prevention of cancer, dementia, and other life threatening conditions and diseases. Cancer is the second leading cause of death worldwide, and preventing malignant cancer from spreading to the other parts of the body is of vital importance.MRI scans help in highlighting any deformity or abnormality, which is perfect for blob detection, since that is exactly what blob detection is supposed to do in the first place.

II. LITERATURE SURVEY

We asked people if they felt like image processing, deep learning or machine learning is used to detect blobs in blob detection, and more than half the people replied with all of the above, which is the right answer.

We also asked people if they would prefer to have their scans done manually or by doctors, and a majority of people wouldn't mind having their scans done by AI alone.

Tumors are abnormal growths of cells that can be malignant or benign. Early detection of tumors is crucial for successful treatment, but identifying them can be challenging.

That's where blob detection comes in. Image processing is a set of methods which we use to transform an image and perform operations on it, in order to get information from the image.

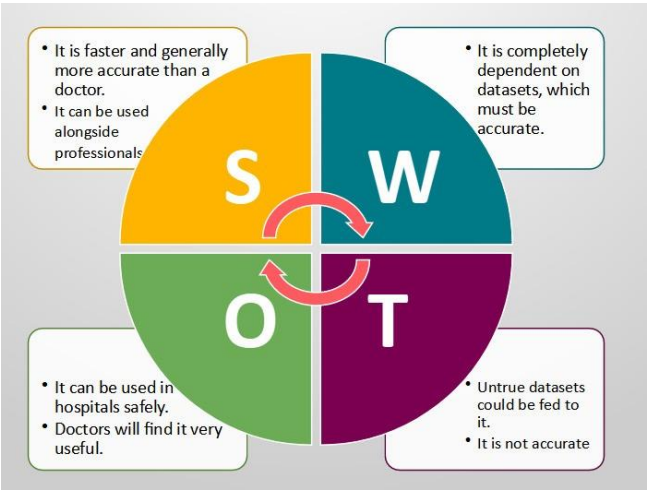

Figure 2: SWOT Model for Research

Source: Self

Blob detection is a computer vision technique that allows for the identification of regions in an image that are distinguishable from their surrounding areas. In medical imaging, this technique can be used to detect tumors by identifying areas of unusual density within the body.

Now that we have the background for this research, the reason we are using blob detection is because it doesn't rely on the integrity of previous data for it to work properly.

This means that this is effectively a plug-n-play algorithm, once you have a program that allows you to process images with this algorithm, then all that is left to be done is for a doctor to review these images to give the optimal diagnosis.

Most tumors may be extremely obvious but some may be extremely tiny, in the developing stages, which may not even be detected by neural networks, but no matter how small a blob is, as long as the resolution isn't low, the algorithm will be able to find the smallest blobs in the image.[2]

We are hoping that doctors and clinics use a blob detection application to act as an assistant in helping to detect any abnormalities in an MRI scan, so that it can be used to help in preventive measures.

The applications for blob detection is usually used to get regions of interest in an image for further processing, like extracting tumors from an image, for further classification if its a malignant tumor, a benign tumor, or dementia, etc.

III. METHODOLOGY

Before doing anything in blob detection, it is necessary for you to do some preprocessing on the image, for everything to be optimal in the algorithm. This will allow for it to have less noise and enhance the contrast of the image. This includes operations like histogram equalizations, to enhance contrast, filtering, for enhancing the image, and so on.

This preprocessed image will be used to identify potential tumors with the help of blob detection, which uses parameters like threshold of intensity, the size of the blobs, to detect the blobs. Since these processed images will most likely be seen by a doctor, having false positives isn't as much of a big problem, since a false positive is a lot better than a false negative. After detecting the blobs, the algorithm still has to highlight these blobs so that the human can see the output clearly.

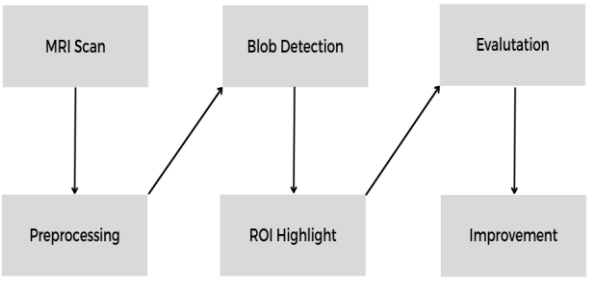

Figure 4: Flow of a blob detection algorithm Source: Self

For highlighting the blobs, we keep the blobs in memory so that we can mark them as a Region of Interest (ROI) . At this stage, a huge amount of false positives, and most of these will be ruled out by a certified doctor or a machine learning algorithm.[3]

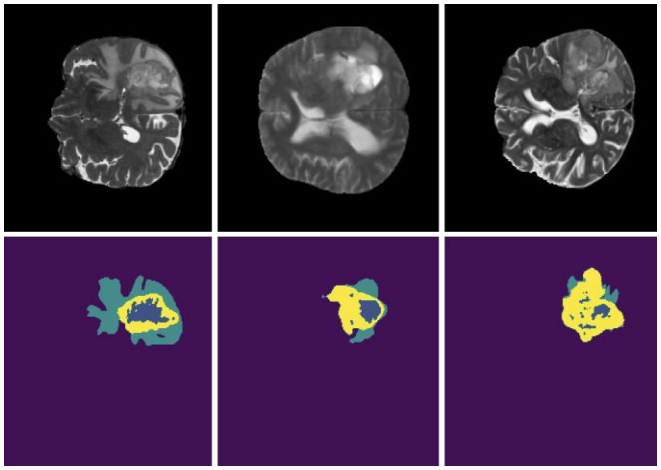

Figure 5: Accelerated Image Processing Using Nvidia DALI Source: Nvidia

In this process, it is important to confirm that the person truly has a tumor or not, for understanding if the algorithm was successful in finding and preventing something extremely serious. When the blob detection algorithm is certain about the existence of a tumor, and after a surgery that fact is proven, the algorithm needs to be enforced so that it knows better about which types of tumors are more likely to be false positives, and which are truly tumors. This will help immensely to improve the algorithm, and its usability in a practical scenario.

IV. PROPOSED WORK

The development of an application capable of blob detection for the detection of tumors or tumor like lesions in an image would be our proposed work. Having an application like this being used by an actual doctor performing MRI scans, for research and experimental purposes for collecting data would help to prove that this is indeed a feasible method of diagnosis. This would prove to be a great assistant for a doctor, and if the MRI scanning is at a high enough resolution, then blob detection would be able to detect tumors that may simply be too small for the human eye to detect, which will prove to be of great assistance to a doctor.

V. RESULT AND CONCLUSION

Of course, the main problem with blob detection is that it needs quite a high resolution on its MRI scans for it to work effectively, but as time passes, equipment at hospitals and clinics only get better. Also, it's very possible for neural networks to replace doctors in analyzing these highlighted blobs in order to diagnose or treat patients that provide their MRI scans.

CNN relies heavily on the reliability of the data, and also brains vary in size and shape, so it usually never looks the same. Secondly, if CNN is relying on brain tumor data, then it can never help with bone tumors or dementia patients, whereas blob detection is suitable for every single one of them.

But in the end, if the data is reliable, then CNN could be considered just as reliable as blob detection, but of course, using both of them at once, that is, feeding the output of the blob detection algorithm to create a CNN dataset that works on similar processed data, then it would be even better.[4]

VI. ACKNOWLEDGMENT

With a deep sense of gratitude we would like to thank all the people who have lit our path with their kind guidance. We are very grateful to all of them, who did their best to help during our project.

We remain indebted to our H.O.D and Principal Dr. B.K. Mishra for their kind permission to complete this research paper. Lastly, we would like to thank our friends and the people who were directly or indirectly related to our project.

Abstract- **The demand for skilled professionals in the engineering and technology industries in India has been on the rise, leading to an increase in competition for admission to technical courses and job opportunities. For the same purpose universities and colleges need to identify the employability of the students and the employment potential of different engineering and technical courses to increase the chances of students getting better jobs. This paper aims to investigate different machine learning algorithms and data mining techniques which are used to analyze the educational data available and predict the employment potential of different technical courses. By utilizing these techniques, universities and colleges can better understand the factors that impact employability, and make data-driven decisions about which courses to offer and which skills to prioritize in their curriculum. The findings of this paper will provide valuable insights into the usage of machine learning to predict the employment potential of technical courses, and help universities and colleges make more informed decisions about their curriculum and student support services.**

Keywords: Employability, employment potential, machine learning algorithms, data mining, data-driven decisions

I. INTRODUCTION

In recent years, with the rapid growth of data, prediction classification has become a fundamental tool for various fields of study. It plays a vital role in discovering the underlying patterns in the data and making informed decisions. However, the success of prediction classification is heavily dependent on the quality of the data and the efficiency of the algorithms used. To achieve accurate and efficient prediction classification, it is essential to have clean and relevant data and to use appropriate algorithms that can handle the complexity of the data. In this review paper, we explore some of the most promising algorithms for prediction classification, including the improved Apriori algorithm, Extremely

Randomized Trees (ERT), LightGBM, and Artificial Neural Networks.

II. LITERATURE REVIEW

The literature review comprises papers that provide insights into prediction classification and machine learning techniques in educational data analytics. The review will be presented in a paragraph format, highlighting the research topic, methodology and key findings of each paper.

A recent study, "Prediction of Admissions and Jobs in Technical Courses with Respect to Demographic Location Using Multi-Linear Regression Model" used a predictive model to examine the impact of demographic location on admission and job opportunities in the engineering and technology industries. They proposed a multiple linear regression-based analysis that predicts the number of admission and jobs and using this data the employment potential of technical courses will be determined. Their model predicted using the features college rank, cutoff rank, placement percentage, accreditation and the number of companies visiting, the number of partner companies, quality of placement training, and average salary package for admission and placement respectively. [2]

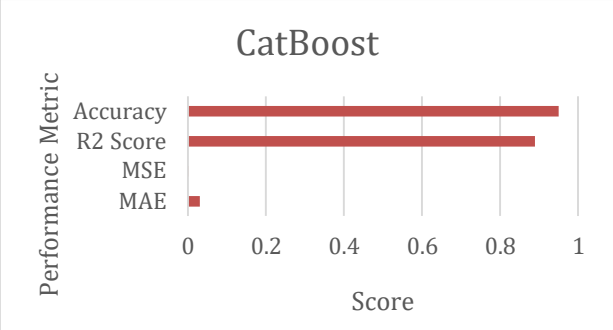
The model proposed by the Sathyabama Institute of Science and Technology Chennai, India uses Machine Learning algorithms such as Linear regression, random forest algorithms, and CatBoost algorithms independently to analyze the graduate student data to predict admission chances in universities worldwide. For the data set, they considered the academics score as well as the scores of the competitive exams were considered as important. Because the admission cutoffs are dynamic and change every year assumptions were made to create a base cutoff for the known universities based on the admission history. [3] Similarly, assumptions based upon the competition in the history the students applied and students got selected the algorithm was provided with a full set of concrete conditions. Through the model, it was concluded that for the same data set the CatBoost algorithm resulted in the highest accuracy in the result. The following table shows the accuracy of the Linear regression algorithm and CatBoost algorithm. [3]

TABLE: 2.2. Linear Regression result

Model	Linear Regression
MAE	0.04
MSE	0.003
R2 Score	0.84
Accuracy	0.93

TABLE: 2.1. CatBoost result

Model	CatBoost
MAE	0.03
MSE	0.001
R2 Score	0.89
Accuracy	0.95



Based on the survey results, [4] CatBoost stands out as a promising machine learning tool for Big Data applications. It is automatic handling of categorical data, along with its superior performance in comparison to other gradient-boosting decision trees (GBDT) algorithms, makes it a suitable choice for many applications. Specifically, it is well-suited for datasets that are heterogeneous and contain categorical features. However, the survey [4] also found that the performance of CatBoost is sensitive to hyper-parameter settings, including the maximum number of iterations, the maximum depth of decision trees, and the maximum number of combinations of categorical features.

A 2006 study under the name “Extremely randomized trees” by Geurts P., Ernst D. & Wehenkel [6] proposes

an algorithm called Extra-Trees that uses a combination of random subspace and totally random cut-point selection to improve the performance of decision tree ensembles. The optimal value of one of the algorithm's main parameters, K, depends on the problem specifics, but default values are near-optimal for most datasets. The algorithm reduces variance and increases bias, and its models are continuous and piecewise multi-linear. Extra-Trees provide near-optimal accuracy and good computational complexity for high-dimensional problems, while totally randomized trees are faster and provide independent tree structures. The authors suggest potential improvements for handling other types of attributes and reducing bias.

"Understanding random forests: From theory to practice." by Louppe, Gilles presented that the theory of random forests involves constructing multiple decision trees by selecting random subsets of the data and features, and combining their predictions to make a final prediction. [7] This can be done using various programming libraries, such as scikit-learn in Python. The scikit-learn library has a Random Forest Classifier class that can be used to create and train a random forest model, as well as make predictions on new data. The hyperparameters, such as the number of trees and the maximum depth of each tree, can be tuned to optimize the model's performance.

The paper "Consistent individualized feature attribution for tree ensembles" by Lundberg, Erion, and Lee presents a novel method for computing feature importance scores in tree ensembles that addresses the shortcomings of existing methods. [8] The authors introduce a new method, called SHAP (SHapley Additive exPlanations), which relies on a game-theoretic approach to compute feature importance scores that are both accurate and consistent across different prediction outcomes. The paper provides extensive experimental results that demonstrate the effectiveness of the SHAP method in a range of applications, including healthcare, finance, and computer vision. The authors also provide an open-source Python library that implements the SHAP method, making it widely accessible to practitioners.

The paper by Chen, Li, and Zhu (2020) presents a comparative study of five gradient boosting frameworks, namely XGBoost, LightGBM, CatBoost, NGBoost, and Sklearn-GBM. [13] The study evaluates these frameworks based on their accuracy, speed, and memory usage for a variety of datasets and learning tasks. The authors found that the newer frameworks, such as LightGBM and CatBoost, generally outperformed the more established frameworks, XGBoost and Sklearn-GBM, in terms of both accuracy and speed. They also found that NGBoost, which is based on probabilistic modeling, is promising for tasks that require uncertainty quantification. Overall, the study provides insights into the strengths and weaknesses of different gradient boosting frameworks and can be used to inform the selection of an appropriate framework for a given task.

In the paper "A Highly Efficient Gradient Boosting Decision Tree", Ke et al. introduced LightGBM, a gradient-boosting framework that uses a novel technique called Gradient-based One-Side Sampling (GOSS) to reduce the number of data instances in the training set. [14] The authors claim that this approach achieves a significant reduction in training time and memory usage compared to other gradient-boosting frameworks, while still maintaining high accuracy. Ke et al. provide experimental results showing that LightGBM outperforms other popular gradient boosting frameworks on several datasets, including the Microsoft Learning to Rank dataset and the Higgs boson dataset.

III. ALGORITHMS

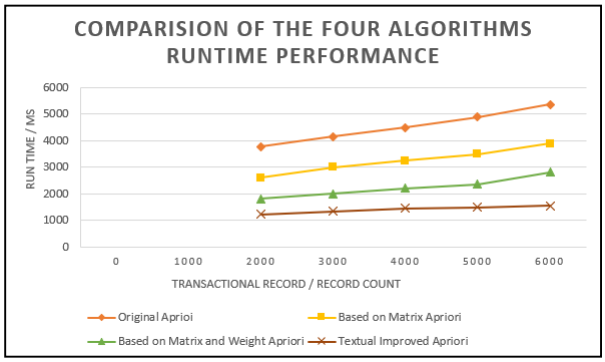
Before working with the algorithm, the main criterion is to have a clean set of data. The values that the data represents must be clear in understanding and look relevant to the data analyzer. The finding process must be so reliable that any relevant data must not be obscure in any way. It is common to use the Knowledge discovery in database (KDD) process to identify valid, novel, useful, and understandable patterns from large and complex datasets.[1] This method consists of sub-process including Data Selection, Data preparation, and transformation, Data Mining, and Evaluation. Following this comes to the process of Test and Training the ascertain data from the mining process.

1. Improved Apriori algorithm based on matrix pruning and weight analysis

The Apriori algorithm's flaws are identified as the repeated scanning of databases leading to excessive consumption of space and time and the dependence on

minimum support, resulting in suboptimal association rules. The proposed algorithm addresses these flaws through matrix pruning and weight analysis. This approach reduces the number of repeated scans and improves the efficiency of data correlation mining, making it a more effective algorithm for association rule mining. Association rules require that all non-empty subsets of frequent item sets must also be frequent, and any non-frequent item set cannot be a subset of frequent item sets. The algorithm works by scanning the transactional database and generating a Boolean transaction matrix. The support counting of each item set is compared to the minimum support count to generate frequent 1-item sets. The weight of each item and transaction is then calculated using formulas, and the support counting of item weight is calculated to gain information about the item in each transaction. The weighted value of candidate k-item sets is then compared to the minimal support to generate frequent k-item sets, which are pruned by intersecting with L'k. The algorithm continues to generate candidate (k+1)-item sets until all frequent item sets are formed. This approach reduces the need for repeated scanning of the transactional database, which improves the efficiency of the algorithm.

Table 3.1 Comparison of the Four Algorithms Runtime Performance [5]



Overall, the improved Apriori algorithm has significant theoretical and practical value for data mining in the era of big data. [5]

2. Extremely Randomized Trees (ERT) using SHAP (SHapley Additive exPlanations) for feature importance

A popular ensemble learning approach for regression and classification is Random Forest. It applies the bagging concept, which involves randomly dividing the training data into a large number of subsets and fitting a decision tree to each subset. By merging the outcomes of various decision trees, the Random Forest approach can generate forecasts that are more accurate and dependable.
