Based on the annotations, it seems that the image might be related to interior design, cabinetry, flat panel displays, gas, electronic devices, and various types of technology. There are also some more general labels like "rectangle" and "room", as well as more specific labels like "countertop", "glass", and "plywood".

The NeoNextVisor Smart Glasses utilize Google Vision API to detect all the features of an image and provide a description of the scene to the user. The API uses machine learning algorithms to recognize objects, landmarks, and text within an image. This feature helps the visually impaired user to understand the environment and objects around them, thereby improving their overall experience.

The Google Vision API has several features that aid the NeoNextVisor Smart Glasses to provide a detailed and accurate description of the environment to the user. These features include image labeling, text recognition, face detection, and landmark detection. Image labeling detects and identifies objects within an image and provides a label for each object. The text recognition feature identifies and extracts text from an image and provides a description of the text to the user.

The face detection feature identifies and locates faces within an image and provides information such as the number of faces, their location, and emotional states. This feature is particularly useful for social interactions and provides the user with important visual cues.

The landmark detection feature identifies famous landmarks within an image and provides the user

with relevant information about the landmark. This feature is particularly useful for users who are traveling to a new location or exploring a new area.

The requests and responses in the JSON format is added in the Appendix, at the end of the paper.

In summary, the Google Vision API integrated into the NeoNextVisor Smart Glasses provides a powerful tool for visually impaired users to understand and interact with their environment. The API's advanced features, such as image labeling, text recognition, face detection, and landmark detection, help the user to navigate their surroundings, recognize objects, and access relevant information. This technology is a significant step forward in providing a moreaccessible and independent lifestyle for the visually impaired.

VIII. CONCLUSION

The future of technology is here we have developed a smart glass that can be connected to any device with the android operating system. The glasses will respond as your own personal assistant and answer questions related everything from weather forecast stock prices movie locations restaurants etcetera without needing look at phone or laptop computer which allows user engage conversation while doing other things like driving car walking on street because it'll always reply back immediately once prompted for information about particular topic.

This product has been designed specifically help users save time by helping them find items quickly without having use their hands; this means wearer won't interrupt workday just because there some urgent news coming so waiting until later would too late but instead receive alerts right away! And perhaps even let know where need go get whatever message tells you It also lets us share photos videos other media quickly easily without needing plug anything into computer (such USB flash drive). We can type text messages dictate them through vocal commands so even if you're busy doing something else we still connect with friends family members all around world anytime anywhere without having set aside special time make phone calls or texts which saves precious resources on computers that cannot be used otherwise when there isn't much information available beforehand because these systems don't require setting up their parameters each they want perform something different from what they did last session (unless specifically told do so).

Future work would involve looking more at user feedback in order create better devices and improve upon those already existing web-based services social media platforms such as Facebook, Twitter etcetera. It could also mean integrating other technologies like digital eye glasses into next versions our smart glasses products by adding new features inputs outputs come out soon after release date for "Next Generation Smart Glasses".

IX. ACKNOWLEDGMENT

We gratefully acknowledge the support, guidance and encouragement of our Guide Assistant Professor Dr. Rashmi Thakur ma'am and our colleagues who supported this idea and always encouraged us to go beyond ordinary.

Feasibility and deployment challenges of data analysis in tele-healthcare system

Lowlesh Yadav, Dr. Asha Ambhaikar
Research Scholar, Department of CSE, Kalinga University, Raipur
Lowlesh.yadav@gmail.com, dsw@kalingauniversity.ac.in

Abstract: **With rapid development and growth in connected world technologies like IoT or the edge computing medical industries and support system gaining greater advantages through tele-healthcare and remote healthcare monitoring system. Even after the connected world infrastructure like Wi-Fi, mobile technology and even the satellite communication still the real-field deployment of these technologies are at very lower rate. Deployment of any medical grade technology or the products needs multiple level of testing, certifications and the finally the user acceptance of the devices. Data transfer to the concern entity with guaranteed delivery is the major concern for tele-healthcare implementors. Keeping the patient treatment and diagnosis data privacy concerns, even the medical sensor devices are in control of manufacturers its data access needs to keep under the radar and safe from different level of users of the data and the device statistics. This paper study focuses on understanding and finding out the multiple layers of testing and the deployment for connectivity for tele-healthcare system. This study also covers reaching the highest depth of data captured for analysis with its multiple possible combinational reporting and result generations. With proposed solution study conclude the study result and the solution to the real-world problem in tele-healthcare system**

Keywords: *AAL, IoHT, IoMT, IoT*

I. INTRODUCTION

The advancement of the Internet of Things technology is playing a key role in developing the health sector by making it much more accessible and affordable through easy-to-use applications for virtual and distant interactions with patients. Taking the capability of IoT technology into account, it is possible to overcome the difficulties faced by physically unstable patients in consulting a doctor physically on a regular basis. IoT integrated with the health wearables can overcome the need of visiting hospitals for primary health issues. This also reduces the medical expenses for patients significantly. In addition, the doctors can prescribe necessary medications by observing the patient's health stats over time through an application. The Remote Health Monitoring System could be the cost effective, user friendly and easily affordable solutions by the patients.

The term "Internet of Things (IoT)" has recently become popular in communication technology. It has been developed in many ways and is called as the next frontier. Today, everything around us from household lights and different home appliances to vending machines and cars has the ability to get online and interact with other machines. IoT refers to devices or objects that can interact with the Internet by making use of physical devices, sensors, microcontrollers, and network connectivity that enable these objects to collect and exchange data. In order to collect the real time data consistently, each and every device has its unique identifier (UID), which makes the communication possible in an easy way like machine to machine (M2M) communication. A massive amount of data is collected from devices all over the world which is stored in the cloud. As a result, systems will become more efficient and smarter.

Recently, IoT has become more productive in the area of healthcare systems. Connecting medical devices to networks and to patients is becoming big business. Internet of Medical Things, or IoMT is a submarket of the Internet of Things (IoT), from which several subsets of the technology have evolved. Where IoT refers to all web-enabled devices, from smart cars to Internet-enabled kitchen appliances, IoMT includes only medical devices that have Internet connectivity. Specifically, IoT in the healthcare field combines sensors, microcontrollers etc., to analyze and send the sensor data to the cloud and then onwards to caregivers (doctors). Integrating the IoT features into medical devices improves the quality and service of care for elderly patients and also for physically disabled person. IoT in healthcare could maintain thousands of patient's data which is computerized and helps the patients to capture their data anytime. Many health sensing components have been developed more that are portable, this allows the patients to wear them for monitoring. The health monitoring device is connected to the patient such that the doctor can observe the patient's condition at any-time. As IoT assisted patients can be accessed over the Internet, the health state of the patient can be detected at the right time so that proper action is taken.

II. LITRATURE SURVEY

The study or the literature survey is mainly done based on published articles and the research papers by the academic or medical researcher. Internet of Things (IoT) is getting a wide acceptance and a growing adoption in many aspects of our daily life [1, 2]. IoT technology provides a competent and structured approach to improve health and wellbeing of mankind. It is predicted that IoT-based systems will remodel the healthcare sector in terms of

social benefits and penetration as well as cost-efficiency [3, 4]. Due to the ubiquitous computing nature of IoT, all the healthcare system entities (individuals, appliances, medicine) can be monitored and managed continuously. By applying IoT technologies to healthcare, the quality and cost of medical care can be improved by automating tasks previously performed by humans [5, 6, 7]. In that sense, IoT enables Electronic Health (eHealth), Mobile Health (mHealth) and Ambient Assisted Living (AAL) that allow remote monitoring and tracking of patients living alone at home or treated in hospitals and creates a continuum among these through cloud access [4, 8]. It is no longer sufficient to design just standalone wearable devices, instead it becomes vital to create a complete ecosystem in which sensors in a body area network seamlessly synchronize data to cloud services through the IoT infrastructure [9, 10, 11]. The architectural elements generally needed in healthcare IoT systems (Health-IoT) are illustrated in Figure 1. The architecture includes three main components: i) body area sensor network, ii) Internet-connected gateways, and iii) cloud and big data support. Various applications provide services to different stakeholders in the system through this platform. Data generated from sensors attached to users is made available to caregivers, family members and authorized parties giving them the ability to check the subject's vital signs from anywhere at any time.

Figure 1.0: IoT based generic monitoring system

Yue et.al (2020) [12] article describes the development of a hardware-software complex for monitoring the health status of a vehicle driver, which uses portable devices to control the physiological parameters of a person and transfers data to a mobile terminal or uploads it to a cloud server for data analysis. For Nduka et.al (2019) [13] Remote Health Monitoring (RHM) system sense certain human vital signs such as, temperature, respiration, and heartbeat (pulse) which is connected in real time environment. They built RHM system on Arduino UNO board which houses other microcontrollers and sensor paired with IOT Gecko, physicians can view patient's vital sign reading in real-time irrespective of their geographical location. When these body vital signs fall below or above normal parameters, the system triggers an alarm, giving physicians the opportunity to carry out timely individualized intervention on patients in crisis. Chao et.al (2017) [14] proposed a pervasive monitoring system that can send patients' physical signs to remote medical applications in real time. The system mainly composed of two parts: the data acquisition part and the data transmission part. The monitoring scheme includes monitoring parameters and frequency for each parameter in data acquisition part, and designed it based on interviews to medical experts. Multiple physical signs were found like blood pressure, ECG, SpO2, heart rate, pulse rate, blood fat and blood glucose as well as an environmental indicator (patients' location) was designed to be sampled at different rates continuously. Four data transmission modes were presented taking patients' risk, medical analysis needs, demands for communication and computing resources into consideration. A sample prototype was implemented to present an overview of the system. In their studies Yadav et.al (2018) [15] familiarizes the status of IoT growth In India, reviews the Risk factor, security issues and challenges in India. Lakkis (2017) [16] focus on two essential categories the emergency and the operational services. They tried to highlight new ideas of handling these services using IoT.

III. BACKGROUND

a) Remote Health Monitoring System

Remote patient monitoring (RPM) is a subcategory of homecare telehealth that allows patients to use mobile medical devices and technology to gather patient-generated health data (PGHD) and send it to healthcare professionals. Common physiological data that can be collected with RPM programs include vital signs, weight, blood pressure and heart rate. Once collected, patient data is sent to a physician's office by using a special telehealth computer system or software application that can be installed on a computer, smartphone, or tablet.

b) Possible data analysis methods

The data collected from multiple patients using remote health monitoring system regarding different disease or the health status, can be utilized at multiple levels for data analysis purpose likely to be as following.

- **Group Wise Analysis:** To compare healthcare statistics between different patient groups like age wise, gender wise, region wise, or the profession wise
- **Single Patient Delta Checking:** To check the health statistics of same patient at multiple time instance to see the variations in patients' health.
- **Cross Patient Data Analysis**: Comparing the health statistics between multiple patients with similar properties and scenarios.
- **Location Wise Analysis:** Comparing the health statistics of multiple patients from multiple locations or the region to understand the quality of life and health from different areas
- **Disease wise Analysis:** Tele-healthcare with advance sensors can be utilized to collect the information of different, so that disease wise data comparison can be done.
- **User Acceptance Analysis**: Since the tele-health care is primarily designed for home care patient so the actual use of system is based on the acceptance of the users, so

the analysis can be done to identifying the actual usage of the system based on time.

c) Data analysis depth

Remote health monitoring system is surely a individual patient utilization concern, but at large scale level government's primary agenda is about maintaining a good health care in society, hence overall system needs to work like complete eco system and not a individual patient. This patient health statistics data could be at multiple level as illustrated in figure 2.0. Proper classification of health data could help in backtracking the origin of the disease or the health issues and could help in taking control over global medical issues.

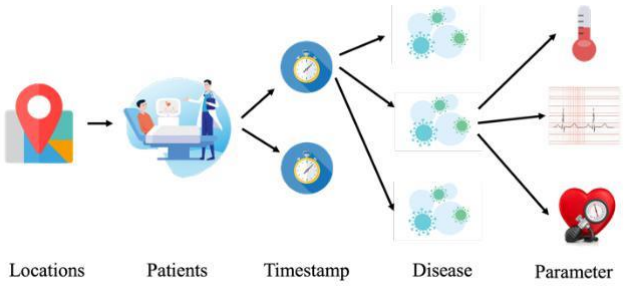

Figure 2.0: Data analysis depth level

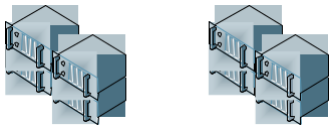
d) Data Compare method

Comparing any two or more time-stamp data is the standard method for cross checking the progression in health issues. Primarily considering the data analysis of individual patient three methods are employee as illustrated in figure 3.0 and stated below.

Delta compares: Comparing multiple time-stamp data for individual patient for single health parameter is called as delta checking. This is primarily to detect individual health issue or symptom.

e) Connectivity challenges

Data exchange assurance is most important aspect in real-time patient monitoring healthcare devices as failure of emergency data transfer within minimum threshold time may lead to critical situation [17,18]. Considering wrong data and the failure of data communication there are multiple possible level of failure starts from wrong contact of device with patients to failure of cloud service provider. Even though researcher may have solution to possible failure level, but it is all depend upon the deployment feasibility and the demand or return on cost of implementation. Some level may get alternative solution or backup solution but at some level, finding the backup or alternative solution at real-time may not feasible options. Figure 4.0 illustrated the multiple level of failure in medical device data exchange with from device to service.



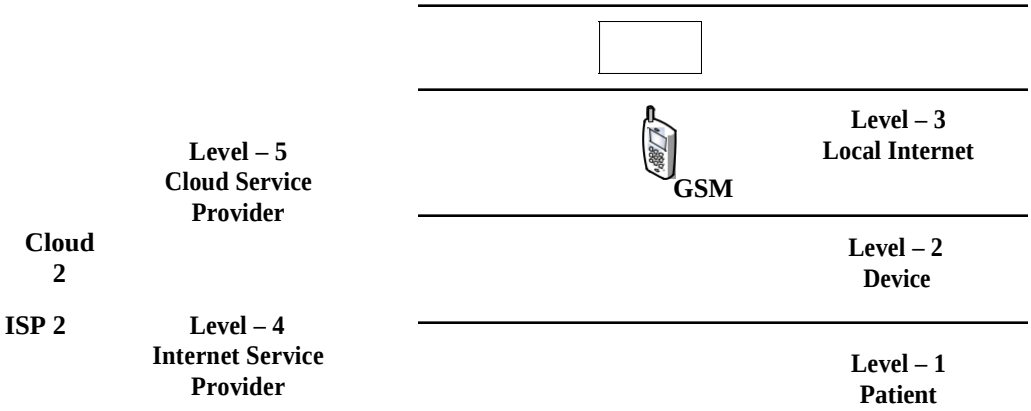


Figure 4.0 multiple level of possible failure in communication.

Level 1. Patient negligence: considering the situation at ground level data transfer may different or send wrong value in case of improper placing of the sensor or the device. This is very rare and negligible issues since after right training or the experience patient can use the device as per the standard operational procedure (SOP).

Level 2. Deice malfunctioning: in rare case, medical device fails as these products are built by following the medical grade standards but still situation cannot be ignored. Malfunctioning or failure of the device may lead to loss in data or create barrier in communication. Solution to these problems has different discussion area and cannot be mentioned with specific explanation.

Level 3. Local internet issues: if the local internet connectivity fails will lead into communication failure. The

Parameter compare: Parameter comparison is primarily designed for detecting the ranges of multiple health parameter at any given timestamp to understand the overall disease progression.

Record time: This is a complete time range recording for any given time range or from the disease detected till the health issue neutralized. This is continuous monitoring

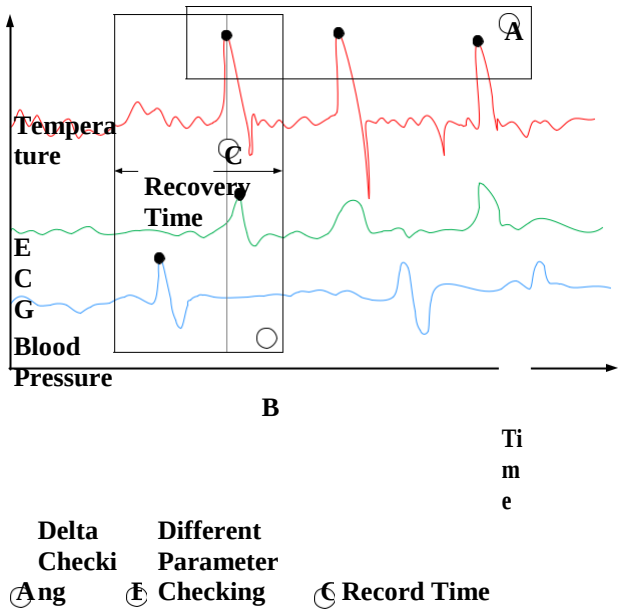

Figure 3.0: Health statistics comparison analysis

only solution to this problem is to keep back up line of multiple mode like, mobile data, wired internet or Wi-Fi access. This solution is also dependent upon the connectivity methods supported by the specific healthcare device.

Level 4. ISP failure: again, this is a rare case where internet service provider failed to provide service by means of any technical or logical error. It may have multiple reasons starts from the user account activation, billing issues or may be due to service upgradations. This issue affects wide customer base using the same service provider. Solution to this problem is to keep multiple service provider options with user.

Level 5. Cloud service failure: this could be the major issue is the cloud service provider fails to provide service. These problems may be due to failure in hardware but in maximum case it happens due to software as a service failure.

f) Challenges In Portable Connected Device Security

It's no secret that the Internet of Things and the cybersecurity don't go well together. Thousands of portable connected devices are finding their ways into homes, businesses, industry, transport, healthcare, and many other areas of our lives, but security is rarely high on device manufacturers' list of priorities. In the young and booming connected ecosystem, there are no industry standards for architecture or security and devices often use custom-built operating systems and proprietary communication protocols [19].

. Internet of Things security remains a veritable minefield and problems with connected device cyberattacks and malware can only continue to grow along with the number of devices. Identified issues in connected device securities are likely to be,

- Weak, Guessable, or Hardcoded Passwords
- Insecure Network Services
- Insecure Ecosystem Interfaces
- Lack of Secure Update Mechanism
- Use of Insecure or Outdated Components
- Insufficient Privacy Protection
- Insecure Data Transfer and Storage
- Lack of Device Management
- Insecure Default Settings
- Lack of Physical Hardening

IV. PROPOSED SOLUTIONS

Based on the research survey and study we propose the system that will be a multiple layered architecture with different functionality utilization through different type of users. Figure 1.0 illustrates the multiple layers involved in the system. Where every layer has its own research and development. The system must be medical grade to be ready to deploy and easy functioning for different users.

This system is designed keeping primarily four type of users 1). Patients 2). Doctors or hospitals 3). Device manufacturer and 4). Medical associations.

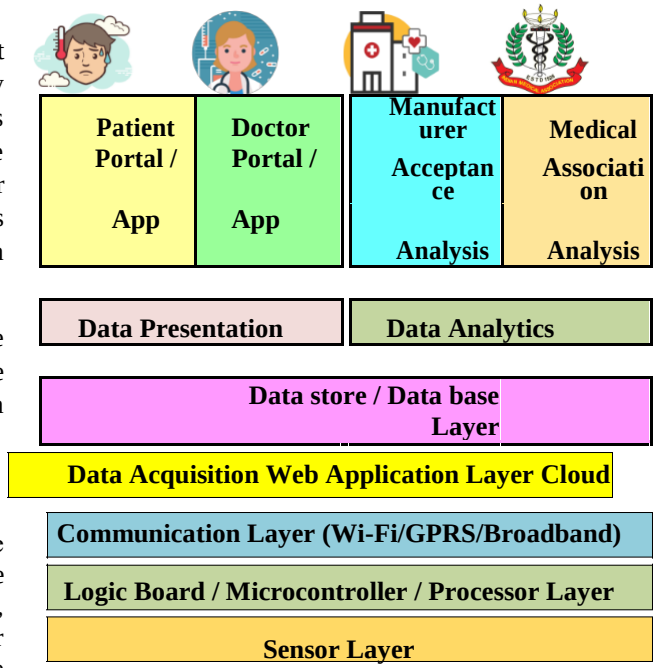

Figure 5.0: Multi layered proposed solution

Development and deployment of the system is defined as different stages as mentioned below.

Stage 1: Design and development of portable ICU system with sensors like temperature, ECG, heartbeat, blood pressure, and oxygen. This system will be having Wi-Fi or GPRS link to connect to internet and send the sensor in formation to web service. This system will be portable enough to carry anywhere and work on low power supply.

Stage 2: Development of web service to receive the information for the sensor hardware. This will receive the sensor input information and validate the information for valid source. Once the information gets validated it will store the information to the database for further analysis and the presentations.

Stage 3: Developing the web-based data representation application to plot the patient information in required graphical format. This platform will have option to feed patient information like demographic, symptoms, disease, or environmental. This will have tool to perform graphical analysis and show data in running comparison chart format for better understanding and visualization.

Stage 4: Developing the BI engine to generate the data manipulation and indexing functions to retrieve the information in minimum time. Here system will be enhanced to perform different analysis regarding location, disease, patient, parameters.

V. CONCLUSION

The scope of the proposed system is the implementation of real-time monitoring system for remote patients at the rural areas especially elderly and disabled patient using wireless technology. As IoT technology is emerging day by day, the use of latest IoT technology may increase the ap.

disabled patients and reduce stress for family and doctors who can be alerted and react immediately as soon as issues arise.

The Influence of Distance on the Reception in Molecular Communication

Ms. Ashwini Katkar, Dr. Vinitkumar Dongre
Electronics and Telecommunication Engineering Department, Thakur College of Engineering & Technology, Mumbai
ashwini.katkar@vcet.edu.in, vinit.dongre@thakureducation.org

Abstract - **Nanotechnology has greatly advanced the development of nano-communication networks capable of performing complex tasks. These networks allow communication between transmitting and receiving nanomachines through molecular communication and have numerous applications in the field of medicine, including targeted drug delivery. This method minimizes the possibility of adverse effects on healthy body parts by delivering the drugs directly to the affected area. The transmitting nanomachine releases the drug molecules, which are then absorbed by the targeted location. The distance between the transmitting and receiving nanomachines plays a crucial role in the accuracy and timeliness of drug delivery. This study investigates the effect of varying this distance on the reception of the molecules, the peak reception of molecules, and the time at which maximum reception occurs in molecular communication. We found that as the separation between the sender and the receiver increases, the number of molecules received decreases and the latency increases.**

*Keywords—**Nanotechnology, Molecular Communication, Targeted drug delivery, nanonetworks***

I. INTRODUCTION

Nanotechnology covers wide-area applications at the nanoscale. Molecular Communication is one of the branches of nanotechnology increasing researchers' attention day-by-day due to the incapability of traditional communication, such as, electromagnetic and acoustic communication at the nanoscale [1]. In Molecular Communication, the molecules carry information as a carrier from the source to the receiver. The transmitter emits the molecules which propagate in the environment till they reach the receiver [2]. Applications of Molecular Communication are in a variety of fields including health, environment, military, and information communication theory [3]. In the field of medicine and health, molecular communication is found to be very effective due to its bio-compatibility [4]. Targeted drug delivery is a biomedical application of molecular communication, where drug particles are delivered to the diseased part, such as, cancer tumors avoiding their reach at the healthy part of the body. An accurate concentration of the drug molecules at the tumor site avoids toxicity of the drug due to heavy dosage [6 - 10]. A high transmission rate may cause the accumulation and loss of drug molecules. On the other hand, a low transmission rate may cause insufficient reception of drug doses at the tumor site in the required time duration, causing a lack of proper treatment. Accurate placement of the transmitter and receiver to receive sufficient dosage at right time is very important.

This study focuses on the examination of the influence of the separation between the sender and the receiver. The maximum reception is observed at different time instants varying transmitter and receiver distance. Results are then evaluated to find the perfect placement of the transmitter and receiver to achieve maximum system throughput. In this study, we are identifying what is the exact effect of distance on the intensity of received molecules, the period at which maximum reception occurs, and the peak reception of molecules.

II. LITERATURE REVIEW

Most research work in molecular communications has been based on the factors affecting the system's performance, such as channel capacity, delay, attenuation, noise, Inter-Symbol Interference (ISI), and amplification. Various models have been proposed and analyzed in the study, such as, diffusion-based, diffusion with drift, random walk, active transport models, random walk models with drift, and a collision-based model [11 - 13]. Al-Zubi et al. [14] have compared various reception methods for molecular communication. The performance of passive and completely absorptive receivers is estimated by analyzing the peak amplitude and peak time. Sharma et al. [15] analyzed the 3-Dimensional diffusion-based molecular communication system model. System performance is examined in terms of receiver characteristics, erroneous alarms, capacity, and possibility of average error. Lopez et al. [16] have presented a study on transmitters' location and desired signal strength. Islam et al. [17] address a drug release synchronization issue in the local drug delivery system having multiple transmitters. This study aims to reduce the transmission period error caused by the propagation lag. Zhao and team [18] have derived the minimum efficient intensity of drug particles from the minimum effective receiver capacity.

III. SYSTEM MODEL

Fig. 1 depicts the system model for molecular communication considered in this study. The system considered in this study consists of the transmitter as point source and spherical receiver located 'd' distance apart from each other in an aqueous environment. Molecules transmitted from the transmitter propagate via an aqueous environment by the process of diffusion modelled by Brownian motion.

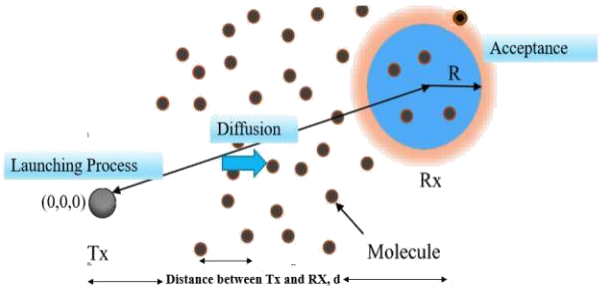

Fig. 1 System Model

The diffusion coefficient, D is used to characterise Brownian motion., presented by

$$= \frac{}{\eta}$$

where,

Kb = Boltzmann Constant ($1.38*10^{-23}$(J/K), T= Temperature in kelvin,

η= Viscosity of the medium,

rc=Radius of the considered molecules

Binary Concentration Shift Keying (BCSK) is the modulation technique employed, in which the transmission of molecules represents the binary symbol 1 and the transmission of no molecules represents the binary symbol 0.

IV. METHODOLOGY

The molecule diffusion and reception process shown in fig. 2 start with the release of molecules in the environment. Initially, they are set to zero position at the transmitter. The receiver boundary limit is set to check the number of molecules that can be absorbed by the receiver, remaining molecules outside the receiver molecules are not counted considering signal strength. Initially, the count of received molecules at the receiver is zero. Then molecule displacement is calculated by using the formula:

molecular displacement = normrnd (molecule position, sigma) **(2)**

which generates a random number from the normal distribution with mean parameter molecule position and standard deviation parameter sigma.

Where, sigma= [√(2*D*delta_t)] **(3)**

D= Diffusion coefficient

The molecule position is updated by adding the initial molecule position with displacement. Then molecule position is checked whether it is in the receiver boundary. All molecules within the receiver boundary are considered successful reception. The number of received molecule numbers is added to previously received molecules. All the molecules outside the receiver boundary are not added to the number of the received molecules considering signal strength. The Sum of the release is then checked whether it is greater than zero. If yes, new molecular displacement is calculated, and molecule position is updated to check whether it has reached the receiver boundary successfully. Otherwise, the entire process of diffusion and reception is implemented for new releases.

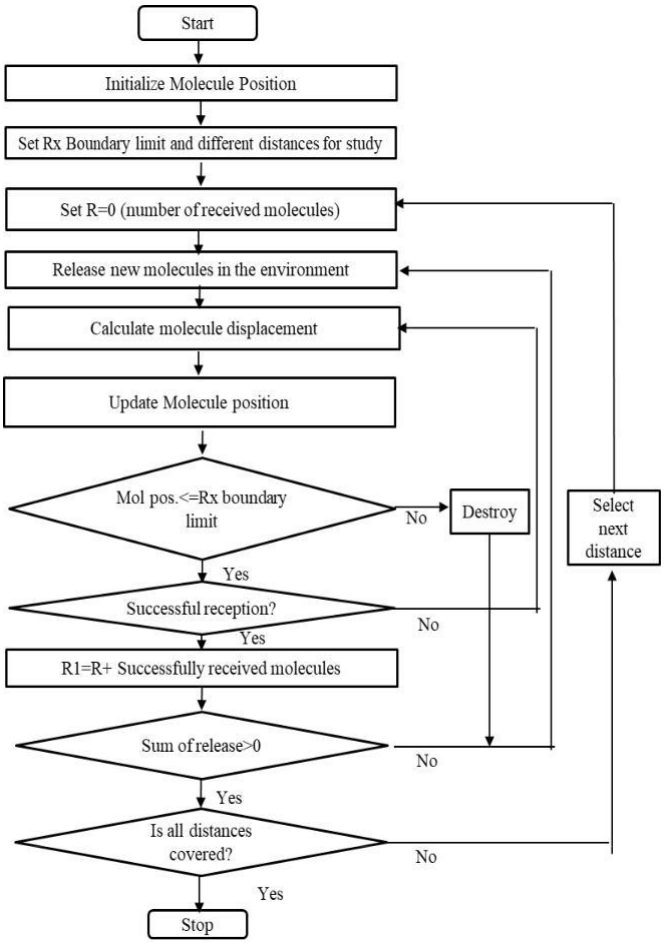

Fig. 2: Flowchart of proposed Molecular Communication

V. IMPLEMENTATION

Molecular communication system model considered in this study consists of single transmitter and receiver in 3D environment. The molecule type considered is single with modulation technique used BCSK. Simulation parameters considered in this simulation are mentioned in table 7.1.

Table 7.1 Simulation Parameters

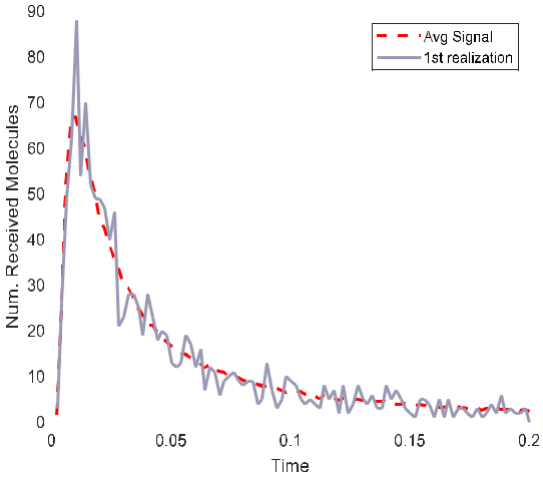
Sr No	Parameter Name	Value
1	Tx Node	1
2	Rx Node	1
3	Tx node coordinates	(0,0,0)
4	Rx node coordinates	(6,0,0)
5	Destruction limit	60um
6	Diffusion Coefficient(D)	100 um2
7	Distance between Tx and Rx (d)	2 um
8	Molecule type	1

9	Symbol sequence length (nsym)	1
10	Modulation type	BCSK
11	Sampling duration (tss)	0.001 sec
12	Simulation step size (delta_t)	0.001 sec
13	Total simulation time (Ts)	1 sec

VI. RESULTS

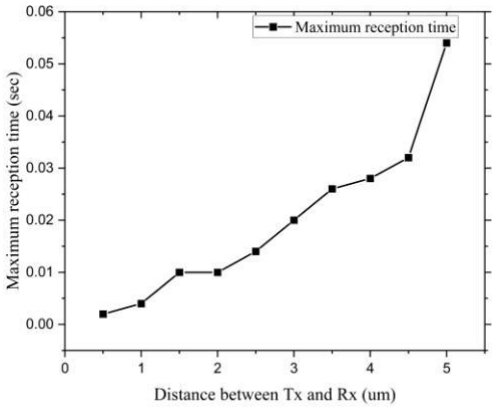
The simulation was carried out to understand the behavior of the system. The parametric study was carried out to observe the performance of the system at various conditions. The following Graph 1 shows signal strength received at different time intervals. Distance between Tx and Rx 2 µm, simulation step size 0.001sec for total simulation time of 1 sec.

A parametric study was done where the distance between the transmitter and receiver is changed to observe the



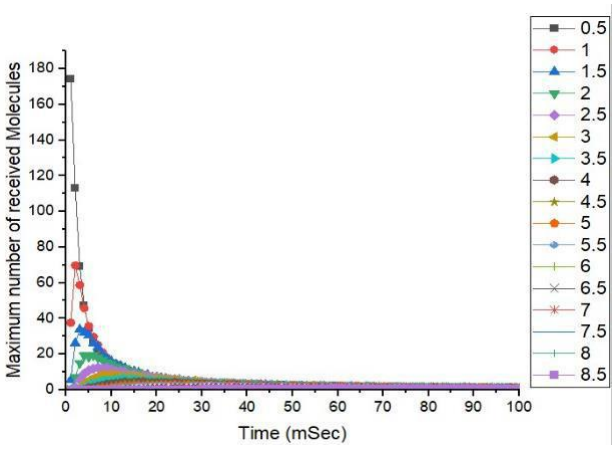
Graph 1: Signal strength at different time intervals

time at which the maximum number of molecules are received. Graph 2 shows the effect of variation in the separation between the sender and the recipient on maximum reception time. As the separation between Tx and Rx increases the time required for the reception is more.

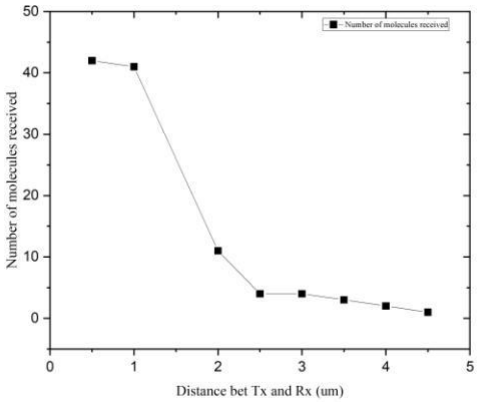


Graph 2: Distance between Tx, Rx Vs Maximum reception time

The following graph 3 shows the variation in maximum reception at different time intervals for the different values of separation between the sender and the receiver. As the separation between Tx and Rx increases, the time elapsed for maximum reception increases.



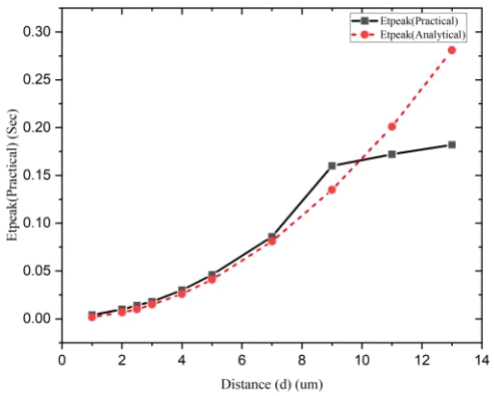
Graph 3: Received molecules observed at different time intervals for changing distances between transmitter and receiver



Graph 4 Distance between Tx and Rx Vs Number of received molecule

We have also observed the system performance by changing the separation between the sender and the recipient at different values and observing the peak reception of molecules. The theoretical formula for calculating Etpeak [19] is given by,

$$Etpeak=(d2/6D)\ Sec \qquad \textbf{(6)}$$



Graph 5: Distance Vs Etpeak

For the analytical and simulation scenarios, distance versus Etpeak is provided. The analytical formulation is supported by simulation results. The time required to observe the peak increases by a factor of four when the distance is doubled.

VII. CONCLUSIONS

In this paper, we focused on the effect of distance on the maximum reception of molecules. We considered a 3-D molecular communication system where propagation occurs by diffusion. In this study, we observed what is the influence of distance on the amount of received molecules, peak reception time, and the maximum reception of molecules. Simulation study shows that as the separation between the sender and the recipient increases, the amount of received molecules decreases while time required for reception increases. It is also observed that the time required to observe the peak increases by a factor of four when the distance is doubled, which validates the theoretical formula.

Future work will be the subject of study focusing on the molecular collision at reception and transmission rate optimization.

Abstract — **It's true that organizations often face the challenge of selecting the right candidates from a large pool of applicants. The proposed system that parses data from CVs and resumes, and conducts quizzes to predict personality, can potentially help organizations identify the most suitable candidates for their development.**

Logistic regression is a popular statistical method used to model the relationship between a dependent variable and one or more independent variables. Pyresparser is a library in Python that can be used to extract information from resumes or CVs. Overall, the proposed system can help organizations streamline their recruitment process and find the best candidates for their development. However, it's important to note that the system should be used as a tool to aid recruitment decisions, rather than as a substitute for the entire process.

Keywords — ***Personality Prediction, Pyresparser, Logistic Regression, CV, Resume***

I. INTRODUCTION

The Big Five Test is a commonly used personality assessment tool that evaluates an individual's personality based on five core traits, namely openness, conscientiousness, extraversion, agreeableness, and neuroticism. These traits are believed to be stable across an individual's lifetime and can predict their behavior and performance in various settings, including the workplace. Using logistic regression, a machine learning algorithm, to analyze the Big Five Test score along with the candidate's CV, can help organizations identify candidates who possess the right personality traits for the job. By utilizing machine learning, the algorithm can learn from past data and predict future outcomes accurately, making it a powerful tool in the recruitment process.

However, it is important to note that personality assessment tools like the Big Five Test have limitations, and they should not be the sole criteria for selecting candidates. Other factors like experience, education, and skills should also be considered to make a fair and unbiased decision.

In summary, using machine learning to analyze personality traits can make the recruitment process more efficient and effective. It can help organizations identify candidates who possess the right personality traits for the job and contribute to the overall success of the organization. However, it is crucial to use this tool in conjunction with other selection methods to ensure a fair and unbiased hiring process.

- MODEL OF THE OCEAN

Extraversion (E), Openness (O), Conscientiousness (C), Agreeableness (A), and Neuroticism (N) are the five

variables used to analyze a person's personality.

1. OPENNESS: This quality is characterized by traits like acceptance, imagination, and curiosity.

2. CONSCINTIOUSNESS: Conscientiousness refers to a high degree of deliberation, an attitude of goal-orientedness, and good judgement.

3. EXTEAVERSION: Energy, talkativeness, and assertiveness are qualities of extraversion, which is also known as extroversion.

4. AGREEABILITY: Agreeability refers to the characteristics of a person, including trust, affection, and social behaviour.

5. NEUROTICISM: Neuroticism is characterised by traits like depression, moodiness, and abrupt emotional outbursts.

Using Pyresparser to extract information from the candidate's CV can be useful in automating the initial screening process. This can help organizations save time and effort in manually reviewing each CV. NLTK, on the other hand, is a powerful natural language processing tool that can

be used to analyze and understand the text in the CV.

Combining the information extracted from the CV and the Big Five Test score can provide a more comprehensive understanding of the candidate's personality and suitability for the job. However, it is important to note that CV analysis should be done carefully and objectively to avoid biases or discrimination based on factors like age, gender, or ethnicity.

In addition to the Big Five Test and CV analysis, other selection methods like interviews, reference checks, and skills assessments should also be used to make a fair and informed decision about the candidate's suitability for the job. Using a combination of these methods can help organizations make more accurate and reliable predictions about a candidate's potential performance in the organization.

II. LITERATURE SURVEY

Jenal Parmar[1] devised a system to aid businesses in choosing the best candidates for open vacancies. The HR department will include the qualifications, experience, and other details required for a particular job position. The system will take the details and CV/Resume of the candidates and then shortlist the right person suitable for that job profile. Allan Robey[2] built a system using modern technology. It will help to pick the right candidates effectively and efficiently. The system will conduct a weight-age policy and an aptitude test to understand the personality of the candidate. In this way, top candidates are shortlisted. Sudhir Bagade[3] says that personality plays an important role in one's individual life and also in the development of any organization. An online application has been developed that analyses the personality of a candidate based on their CV or Resume. The system uses the TF-IDF algorithm to
select the right candidates. Atharva Kulkarni[4]built a system using different machine learning algorithms for predicting the personalities of the candidates using Natural Language Processing. At last, Random Forest achieves better accuracy than remaining algorithms such as KNN, Logistic Regression, Support Vector Machine, and Naive Bayes. VVCET-CSE[5]The system will predict the personality based on the ranking policy. It will rank the skills, experience, and other aspects of the uploaded resume. The candidates also take the aptitude test and answer personality questions. They also receive the result in the form of a
graphical representation. Afroja Khatun Monalisa[6]built a model using the Random Forest Algorithm, Support Vector Machine, and Weighted Majority Voting algorithm. Firstly, resumes or CV's are uploaded into the system and candidates are shortlisted based on the administrator's request. The shortlisted candidates receive personality and ability test links, which they need to answer, and then they receive their scores. Based on the scores and the department's requirements, candidates are shortlisted. Gangandeep Kaur[7]developed a system using a machine learning technique known as Logistic Regression. The system estimates the applicant's emotional aptitude through a psychometric analysis and predicts personality by using the OCEAN model. The details of the candidates are protected by using a password encryption algorithm, and the passwords are known only to the required individuals. The candidates can know whether they are selected for the interview via dashboard and SMS.

III. EXISTING SYSYTEM

The use of machine learning in the recruitment process can significantly improve the efficiency and accuracy of candidate selection. By predicting the candidate's personality traits, organizations can ensure that they hire individuals who are not only skilled and experienced but also possess the right traits for the job.

Automating the candidate grading system can also help organizations save time and resources in the recruitment process. The system can quickly and accurately analyze a large number of applications and provide a shortlist of candidates who meet the job requirements and possess the desired personality traits.

However, it is important to note that machine learning models are not perfect and can have biases or errors. Therefore, it is crucial to continuously monitor and evaluate the performance of the model to ensure that it provides fair and unbiased predictions. Additionally, organizations should also use other selection methods like interviews and reference checks to ensure that the selected candidate is a good fit for the job and the organization's culture.

IV. PROPOSED SYSYTEM

Using machine learning algorithms for personality assessment and CV analysis can indeed help organizations in selecting the best candidate for a particular job profile. The use of psychometric tests and personality assessments can provide valuable insights into an applicant's personality traits, which can be essential in determining their suitability for the job. Logistic Regression is a popular machine learning algorithm that can be used to build a predictive model for personality assessment. This algorithm can analyse large amounts of data and provide accurate predictions based on a set of input features.

The proposed system as a web application can provide a user-friendly interface for both the administrator and the applicant. The administrator can add or modify questions, and the applicant can complete their registration and provide their CV information. Keeping the results of the aptitude tests and personality assessments in a database can help organizations track the progress of each applicant and compare their scores with other candidates. This can provide valuable insights into each applicant's strengths and weaknesses and help the organization make better decisions during the recruitment process.

Other factors like job experience, skills, and references should also be considered. Additionally, the range of predetermined answers for each question in the personality test should be carefully selected to ensure that the test provides accurate and unbiased results.

A. Methodology

The user is asked to enter their answers to a quiz, and also upload their CV or resume along with their personal details. The system then uses machine learning algorithms to predict the candidate's personality based on their quiz answers, and parses the CV or resume to extract relevant details such as name, email, phone number, skills, experience, and predicted personality. The output is displayed on the screen for the user to review.

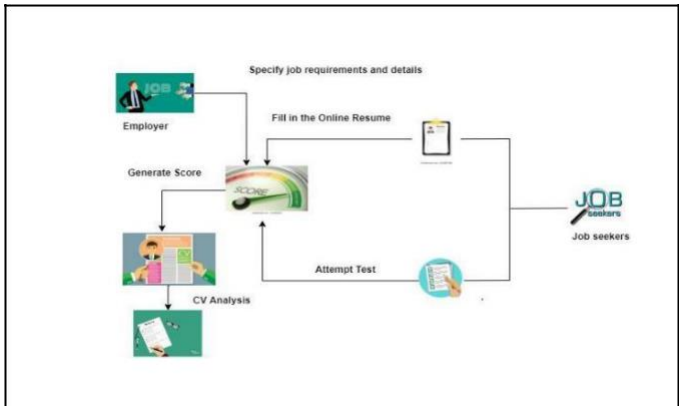

FIGURE 1 – METHODOLOGY

V. RESULT

When the candidate wants to apply for any job, he/she needs to take the quiz. A window gets opened where the candidate needs to fill the details and upload the CV or resume. The candidate fills the details, uploads CV or resume and answers the personality based questions. The resume or CV is scanned by the model and personality of the candidate is predicted based on the ocean model which are displayed as output. The obtained results are as follows:

FIGURE 2 – RESULT

FIGURE 3 – RESULT

FIGURE 4 – RESULT

FIGURE 6 – RESULT

CONCLUSION AND FUTURE WORK

In this project, we have identified the personalities of different people based on the test known as the BIG FIVE TEST. and also extracted the information from CV's using Pyresparser and the model built using Logistic Regression. Based on the test, we can know the qualities and personality of a candidate, and through CV analysis, we can know the skills and qualifications of a person. Using these two important factors, we can make the hiring process easy, fast and also help in hiring the right candidate with fair decisions. As only Logistic Regression is used in the proposed work, many classification algorithms of machine learning can be used to upgrade the system for much better functionalities [3]. So that the time will be consumed and also an expert candidate can be recruited by the company. This model will help a lot for companies to recruit expert candidates for particular job profiles.

Abstract—**Society is becoming increasingly dependent on the internet and so does it become more and more vulnerable to harmful threats. These threats are becoming vigorous and continuously evolving. These threats distort the authenticity of data transmitted through the internet. As we all completely or partially rely upon this transmitted data, hence, its authenticity needs to be preserved. Images have the potential of conveying much more information as compared to the textual content.We pretty much believe everything that we see. In order to preserve/check the authenticity of images, image forgery detection techniques are expanding its domain. Detection of forgeries in digital images is in great need in order to recover the people's trust in visual media. This paper is going to discuss different types of image forgery and blind methods for image forgery detection. It provides the comparative tables of various types of techniques to detect image forgery.**

*Keywords**: Image Forgery, Forgery Detection, Fake Pictures, Blind Methods***

I. Introduction

Image Forgery is not a modern concept as it comes along with the invention of photography. But it comes into the limelight nowadays, with the invent of easily accessible digital cameras supported with image editing software tools. Digital visual media, nowadays, represent one of the prominent techniques of exchanging information, because of the increase in easy to use and inexpensive devices. Moreover, visual media has greater expressive potential than any of the existing media.

Malicious modification of digital images with intent to deceive for the sake of altering the public perception is termed as Digital Image Forgery. The modificationis done in such a way that it hardly leaves any visually detectable traces. Manipulation of Digital images is not any longer defined to experts with all the arrival and dispersal of handy image editing tools and softwares.

Copy-move forgery detection in digital images is a method that makes sense and works well. This type of counterfeit involves copying a portion of the image and moving it to an alternative location within the original image.

Figure 1: Example of Image Forgery

Copy-move simply entails pasting picture blocks into the same image while concealing crucial information within the image. As a result, the image loses its validity and loses its individuality. Techniques for detecting fake digital images fall under two categories: active approach and passive approach. Digital images used in the active approach mostly involve techniques like signature and watermarking that are recorded inside the image at the time of production and require some prior knowledge. In a passive technique, traces of tampering are detected using statistics and the substance of the available information rather than prior knowledge of the image and its properties. There are several approaches that have been developed to identify copy-move fraud, and they can be divided into two groups: block-based methods and key-point-based methods. The detection of forgery attacks can be done in a number of ways.

The development of digital imaging techniques has made it extremely simple to keep any instance of a digital image, and this data is being widely used for a variety of different applications like forensics, multimedia, electronic media, and observational strategy. Anyone can alter an image's real information and damage it thanks to the development of modern editing technologies.

Some transformations, including scaling and rotation, are possible in copy-move forgeries. There are various techniques available to find those conversions. Digital photography is now the standard technique for producing, processing, and archiving visual memories and proof. This technology has a lot of benefits and can be used to obfuscate

facts and proof. This is due to the fact that digital photographs may now be altered in such perfection that counterfeit cannot be seen.
The validity and integrity of digital photographs are crucial in areas including forensics, medical imaging, and e-commerce. Images are used by doctors and researchers in the medical profession to make diagnoses, which is essential because one is dealing with human life. Because of the development of information technology and the internet, e-commerce has dramatically increased in recent years.

II. LITERATURE SURVEY

A methodology based on transform invariant features has been proposed by the author in [2]. The foundation of this system is the MPEG-7 standard's image signature tools. Fast picture and video retrieval is made possible by these techniques. Such programmes are mostly made to find duplicated areas in images or videos that are actually different images. The author's goal is to identify the duplicated area in the same image.

Dempster-Shafer Theory of Evidence is applied in [6]. Decision fusion approach for picture forensics is the paper's main focus. The suggested system combines the measurement level in its operation, allowing it to maintain the pertinent data. The suggested framework consists of:

- The application of the Dempster-Shafer theory of evidence-based soft reasoning approach.
- The simplicity with which newly accessible information can be included.
- The architecture that offers hierarchical structure enables trade-offs between the level of detail in the fusion-provided information.

SIFT features are chosen in [8] to position the cloning section on the correlation map from beginning to end. But, data sets not indicated and obtained in this manner are not taken into account for multiple forgeries. When analysing the SIFT identical approach and grouping of major points to distinguish the separated cloned area in [7], more than one forgery is taken into consideration. In any case, the procedure is only used to identify cloning and not extract modification.

The suggested approach in [9] is based on a novel feature that assesses the local presence of demo sacking artefacts. Demo sacking is a computer technique used to reconstruct a full-color image from a partial image sample generated by an image sensor that has a colour filter array placed on it. The features are extracted using green channel extraction, and the forgery map is created using filtering and map generation.

A spliced image detection method based on Markov features in the DCT and DWT domain has been proposed by the author in [10]. The suggested system comprises of two different types of Markov features, such as the extended Markov in the DCT and DWT domain, which are produced using the transition probability matrices. In order to quantify the dependence among wavelet coefficients across positions, scales, and orientations, the author uses the DWT domain in conjunction with the DCT domain to capture the correlation between DCT coefficients.

To find the particular artefact, a better DCT-based technique has been developed [11]. Fundamentally, DCT is applied to each block to reflect its features after the image has been divided into fixed-size, overlapping blocks. Duplicate picture blocks will be adjacent in the sorted list and trimming is used to lower the dimension of the feature vectors. As a result, in the matching step, identical image blocks will be compared.

The SIFT method, which can identify copy-move forgeries in a picture and estimate the parameters of the transformation used, has been utilised in [12]. It recognises the group of points that are part of cloned regions. The image is first subjected to feature extraction and matching, in which the important details are taken out of the image and compared to the original. The groups are then created using hierarchical clustering, and fabricated regions are then discovered.

III. PROBLEM STATEMENT

The major problems contained within for the detection of the image forgery are,Data Provenance: Data source is the initial problem in the forgery detection. Vast number of images are available on the internet, in order to detect the forgery, the source of the original image is needed for the protection of rights and may be for supervisory prerequisite in applications like science, medicine, financial transactions government legal prosecutions and many more daily situations, wher-ever the information is valuable and trustworthy.Benchmarking and Standard Data Set: The need for open data set for critical realisation of forging seems another problem in image forgery detection. The unavail-ability of the images in uncompressed form with differ-ent resolutions, sizes and image acquisition model with diverse contents are some of the needed image conditions for detecting the fake image from the original image which is critical to obtain.Duplicate Regions: Duplication region appearance in the original image with same size, shape and colour appears to be another problem to detect the image forgery.

IV. CATEGORIZATION OF IMAGE FORGERY TECHNIQUES

The semantic information of an image is altered by addi-tion or extracting information from the image. In order to achieve image forging, numerous ways are used by the forgers. In general, there exist different types of image forgery. The categorization of the types of image forgery is a tedious task; this is because the forgery types are grouped based on the process involved creating the fake image. But in the current technical world, new inno-vations are made in digital photography, which increase new malicious forging techniques day by day. However,based on the existing types, a categorization is made in this research explaining different types of image forgery. Figure 2 depicts different types of image forgery

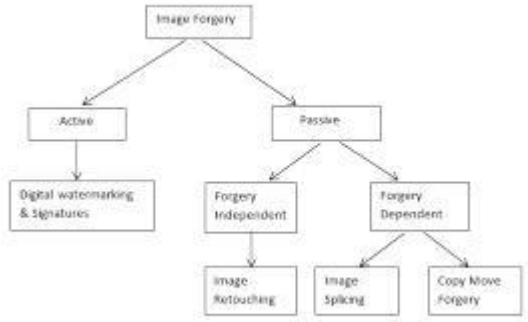

Figure 2: Types of Image Forgery

A) Copy Move Forgery

Copy Move copies and paste a specific portion of the image. Since the copied region represents the same image,the dynamic range and color remains the same. In this technique, we add or remove information to cover a part of the image. Some image or text is masked in the original image.

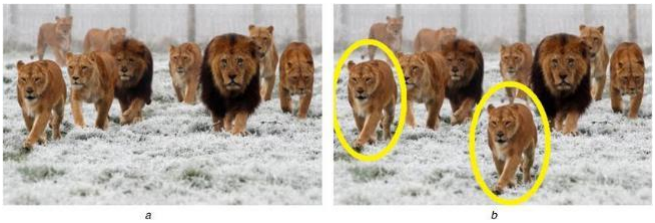

Figure 3: Copy Move Image Forgery

B) Image Retouching

Image retouching is adding or removing something from the image for enhancing features of an image. This technique is applicable for aesthetic, commercial users and it degrades the image features. Generally, it is popular among magazine photo editors, where they try to make an image more attractive by enhancing some features. Compared to all available forgery techniques Image Retouching is considered as less harmful. Removing blemishes on a picture of a model would be a great example of image Retouching.

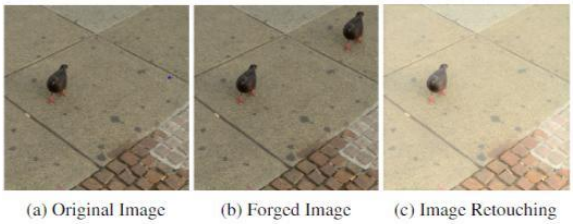

Figure 4: Image Retouching Forgery

C) Image Splicing

Image splicing is the method of making a composite image by cropping and combining two or more images. Unlike image retouching this technique is more aggressive for creating forgery images. A number of sharp transformations such as edges, lines, and corners can be introduced in a spliced image. Examples include the use of fake images by several infamous news reporting cases. Image splicing is used with later post-processing techniques like smoothing boundaries of fragments or even without post-processing.

Figure 5: Image Splicing Forgery

V. Proposed System

The entire process of the proposed system has been classified into phases for ease of operations.

A) The first phase consists of pre-processing of Images in dataset
B) The second phase consists of feature extraction for classification of images.
C) The third phase consists of classifier selection wherein we will code the model to check if the image is forged or not.
D) The final stage is classification where the image is classified as forged or real.

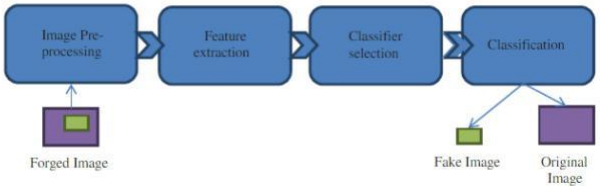

Figure 6: Stages for image forgery detection

As per the elaboration in the II we came to know that determining is an essential feature. Even after some alteration, the features of the identical blocks are similar. Technique relies on the copy move, and is dependent on invariant. SIFT is sort of invariant, demonstrated by Lowe et al. and justified invariant to picture and rotation. Moreover, robust to distortion caused by affine ranges, alteration of viewpoint, noise, illumination change and compression [13]

Scale Invariant Feature Transform

SIFT is a method used to remove specific invariant properties from images. It has primary point sensor and a representation of local attributes. Four phases are listed here for categorization:-

1. Scale-space extreme detection: Initial research or scales and location of picture, operated to see the extremes local in the space of scale. It consisting of:
    - Search over scales and location
    - Locate local extremes
    - A cascade filtering approach
    - Scale-space images for octave

2. Key point localization: To formative position and scale at every entrant location a comprehensive

representation is well. In addition to key points are elected based on procedures of their firmness.

- Choose key points from local extremes
- Recognition of local key points
- Exclusion of key points.

3. Orientation assignment: For every main point single otherwise, extra orientations are given relied on confined picture slope guidelines. Whole next time operations are carried on picture information that altered comparative to the assigned direction.

4. Key point descriptor: The local picture gradients are calculated at chosen scale area in the region of every main point. These are altered into a depiction that permits amend in illumination for noteworthy levels of limited form deformation.

First and foremost, main points have been identified by using filtering, which effectively evaluates candidate places or locations before further in-depth investigation. Finding the location is the first stage in determining the major points and scale that can be repeated in a different view within the context of the item. Finding the positions that are stable in a scale-altered image requires looking for constant characteristics throughout every practical scale change, using a constant scale definition that is acknowledged at the same time as the level gap. The assumptions that the Gaussian function is just the possible scale-space kernel were shown by Koenderink and Lindeberg in 1994.So that, space of a picture is stated as a variable-scale Gaussian, G (x, y,), with an input image l (x, y):

L (x, y,) = G (x, y,) * l (x, y)

Where * is the convolution operation in x and y and G (x, y,) = (1/2 2) *e-(x*x + y*y)/2^2

In context for correctly sensing detect steady key point positions in scale space, reliant scale space peaks in the differentiation of Gaussian function present by means of the picture, D (x, y,), dissimilarity of two in close proximity scales estranged through steady aspect k:

D (x, y,) = (G (x, y, k)-G (x, y,)) * l (x, y)

= L (x, y, k)-L (x, y,)

There are many justifications for choosing this specific function. D may be calculated by performing a straightforward image subtraction because, at first, it is a function that is primarily competent to be computed in any case for scale space feature description.

The scale-normalized Laplacian of Gaussian, 22G, and the normalisation of the Laplacian with the difference-of-Gaussian function are both closely estimated by the difference-of-Gaussian function.

For the correct scale invariance, factor 2 is required. When compared to a number of more likely picture functions like the gradient, Hessian, or Harris corner function, the maxima and minima of 22G produce the majority of stable image characteristics. The heat diffusion equation explains the connection between D and 22G:

22G Can be computed from the finite difference approximation to using the difference of nearby scales at k and :

Experimental Result

2G = G (x, y, k) – G (x, y,)/ k

G (x, y, k) – G (x, y, (k-1) 2G

Principal components analysis (PCA)

One of the methods for taking high-dimensional data and using the relationships between the variables to talk to it in a more manageable, lower-dimensional structure without losing a lot of data is PCA. One of the simplest and most effective techniques for achieving such dimensionality decreases is PCA.

VI. Model Evaluation and Result

The human visual system served as the inspiration for SIFT, which is made up of non-linear linked neurons. They have already proven to have exceptional potential in a number of computer vision applications, such as object and picture detection. They might also be useful for a number of other things, like picture forensics. Image forgery is rather easy to perform with the tools that are currently accessible, and since it is so harmful, identifying it is essential. Due to the diverse origins of the photos, a range of artefacts appear when a piece of an image is transferred from one to another. While these artefacts might not be visible to the unaided eye, Sift's can spot them in photographs that have been altered. When we recompress such photos, the forged is enhanced differently due to the compression difference because the source of the forged region and the background images are separate.

In the suggested method, we use this idea by developing a deep learning-based model that can tell whether an image is real or fraudulent.

The distribution of DCT coefficients in a region that has been grafted onto another image is likely to be statistically different from that of the original region. Periodic patterns can be seen in the histogram as a result of the legitimate region being compressed twice: once in the camera and once in the fake. When the secondary quantization table is employed, the spliced segment operates similarly to a singly compressed region.

As previously mentioned, if an image contains a counterfeit, the forgery will compress differently from the rest of the image during recompression since the sources of the original image and the fabrication are different.
Analyzing the differences between the original image and its compressed version underlines the counterfeit element significantly. In order to train our deep learning-based model for identifying fake images, we use this data.

Model Evaluation:
Tested with 400 images
Original images: 200
Forged imageas: 200
Accuracy: 0.745
True Positive Rate: 0.95
False Positive Rate: 0.46

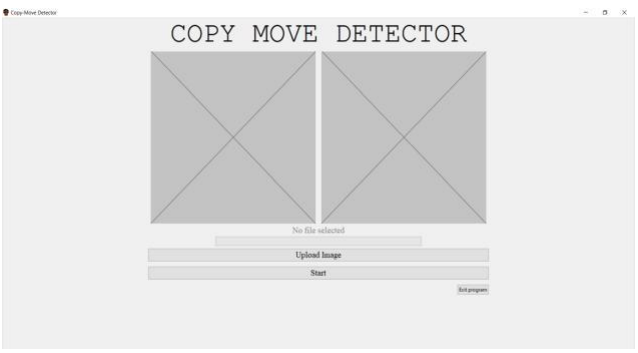

Fig 9: GUI of the Proposed System

Fig 10. Forgery Detected in Image using SIFT Algorithm

VII. Conclusion

The key point-based techniques are typically optimized by researchers to find Copy Move forgeries. Low execution time will be required because these techniques' processing demands will increase as the number of important points increases. In order to reduce time complexity, the researcher in this study optimized the FCM technique for clustering the SIFT key points. The experimental findings show that the suggested algorithm reduces detection times while maintaining essentially the same accuracy requirements and, in some cases, even improving them slightly. This study also looks at the state of strikes that rotate, scale, and copy move numerous times.

The Scale Invariant Feature Transformation (SIFT) algorithm is the foundation of the suggested method to identify copy-move fraud in an image. The SIFT technique is employed because it aids in the extraction of reliable features from the image to determine whether a portion of the image has been copied. With the exception of any scaling or rotation change performed to it, the duplicated portion of the original image typically looks virtually exactly like the region it was copied from. So, independent of any alterations implemented as a result of the usage of the SIFT technique, the descriptor of keypoints extracted from the original region will be relatively comparable to the descriptor of the key points extracted from the forged region.

In light of this, the main idea behind this approach is to match each of the SIFT features retrieved from the image by looking for keypoints that share almost identical properties that can be evaluated based on their individual descriptors.

VIII. Acknowledgment

I gratefully acknowledge the support, guidance and encouragement of my Dissertation Guide Associate Professor Dr. Shailesh Sangle sir for this novel work.

Live Pothole Detection: A Machine Learning based Approach

Vedant Kangde, Mittul Daswani, Tanay Kamath, Shubham Jaiswal

Thadomal Shahani Engineering College, Bandra, Mumbai, Maharashtra, India

Abstract. In India, further than 5000 people die due to accidents caused by potholes. Time and again we see distressing news about how a pothole caused an accident and claimed the lives of some commuters. Potholes not only beget accidents but also make transport slow and clumsy, damage vehicles causing their owners precious repairs and overall are an imminence to our country's logistics and hence is of utmost significance to bring it to our government's attention and fix them as soon as possible. This composition proposes a system where images are taken from CCTV cameras as well as commuter reports. These images are used as an input to the image bracket model which identifies roads grounded on their quality and creates a detailed report and as aresult displays pothole areas on a chart to commuters which aids in avoiding accidents.

1 Introduction

Pothole detection is critical to accident prevention worldwide. Although many studies have been conducted, there are certain biases or tools for obtaining detector data. We provide a way to apply pothole detection using live feeds from government-installed security cameras and commuter travel reports via an app, and the brackets are done before literacy. After parentheses, individual agencies are notified of road conditions at separate locations.

Rapid advances in technology in recent years have had a major impact on the quality of traditional transportation systems.

Intelligent transportation systems that aim to improve transportation systems are becoming popular. For business safety, passengers often feel uncomfortable driving on rough roads, especially over potholes in the road. According to statistics from Taiwan's Ministry of Justice, from 2008 to 2011, government compensation is about $240 million. Potholes in the road are detrimental to driver safety. Therefore, a real-time pothole detection system can be built to improve driver safety[3].

Also, further and further widgets include detectors, electronic compass, gyroscope, global positioning system(GPS), and cameras. Several operations use these detectors in mobile bias and combine mobile seeing ways to break problems similar to social network, healthcare, terrain monitoring, and business information. Thus, using mobile bias grounded on their detectors and cameras to describe potholes is suitable and accessible.[1] This study proposes a pothole discovery system grounded on mobile detectors, cameras and shares the pothole information with commuters and government. For this purpose, the mobile device should be equipped with g- detectors and gps to collect data and position information as well as a camera to take a print and include it in the report.

2 Literature Review

Some styles of pothole detection have been proposed that can be divided into two groups: image recognition systems and mobile surveillance systems.

2.1 Image Recognition Technology

Yu and Salari proposed a pothole detection approach based on a ray-based road information collection method as well as artificial neural network (ANN) algorithms for analyzing road information and decoding potholes[6]. It is inefficient for mobile displacement as processing the ray image requires a lot of computing power. Lin and Liu used a Support Vector Machine (SVM) to analyze traffic images for pothole detection.

This approach can provide high accuracy, but image recognition requires a lot of computing power. So this approachis also bad for mobile bias.[4]

2.2 Mobile Observation Method

A low-cost model for evaluating 3D pavement images using a low-cost Kinect detector that reduces computational cost by providing direct depth measurement is proposed[5]. It is equipped with a G-sensor and GPS that collects and analyzes accelerometer data for pothole detection[2].

Still, the smartphone in this design should be equipped with a specific angle. likewise, this design only considered assaying □- axis accelerometer data with high misstep.

For BusNet design, the Gsensor and GPS are equipped in the on- board unit(OBU) in the machine to collect

accelerometer data and position information. These data can be transferred to data processing centers via wireless networks, and data processing centers can dissect these data to check whether the vectors of accelerometer data exceed the thresholds for pothole discovery. Still, this approach requires that the batch accelerometer data is transferred when the machine enters the machine station,thus, this approach can not give real- time pothole discovery information.

A pothole management system proposed by a group of developers at the Massachusetts Institute of Technology combines a G-detector and GPS. (2) high-pass filter, (3) □-peak, (4) □□-rate, and (5) velocity versus □-rate.

3 Dataset

Dataset consists of 1200 images of Indian roads in various conditions, weather conditions, sharpness, and size. These images generally fall into three categories: normal, dusty, and potholes. As our proposed method mainly focuses on distinguishing potholes from other types of deformations and road conditions, this data set perfectly matches the parameters of our goal. The number of images is large enough to achieve very good accuracy and small enough not to consume excessive processing power and time.

4 Proposed Method

4.1 Diagram

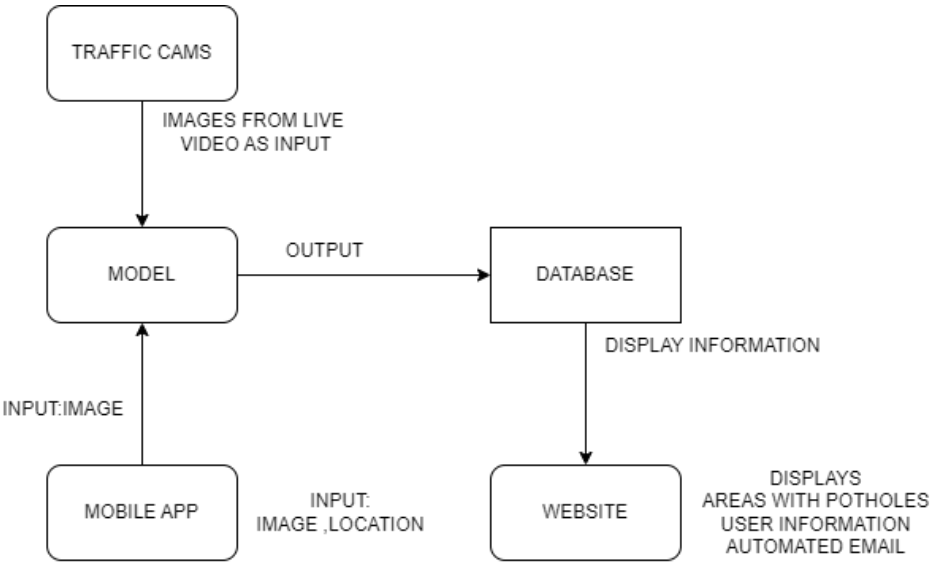

Fig. 1. Proposed system block diagram

4.2 Description

The system we propose is expressed as the above block diagram. The system consists of four major subsystems. They are listed as:

Input: Input is captured in two ways. Inputs can be taken from images uploaded using the mobile app. Images are also captured using live video from road cameras.

Classification Models: CNN-based image classification models are used to classify images into different categories. The dataset used to train this model is merged from three existing datasets and consists of approximately 1200 images in different categories.

Database: Data consists of the output of classification models along with user information.

Output: The web application is used to mark potholes using the Google Maps API. An automated email is sent to the appropriate authority with information about the output of the classification model and its location.

4.3 Algorithm

Convolutional Neural Network

A Convolutional Neural Network(ConvNet/ CNN) is a Deep literacy algorithm which can take in an input image, assign significance(learnable weights and impulses) to colorful aspects of objects in the image and be suitable to separate one from the other[7]. The pre-processing needed in a ConvNet is much lower as compared to other bracket algorithms. While in primitive styles pollutants are hand- finagled, with enough training, ConvNets have the capability to learn these pollutants characteristics.The armature of a ConvNet is similar to that of the connectivity pattern of Neurons in the mortal Brain and was inspired by the association of the Visual Cortex. Individual neurons respond to stimulants only in a confined region of the visual field known as the open Field.
A series of similar fields covers the entire visual field.

Layers in CNN

Convolutional Layer
Convolutional layer are basic building blocks of CNN. It bears most of the network's computational load. In this layer, dot product is performed between two matrices. Here, one matrix is a set of trainable parameters, also called a kernel, and the other matrix is the bounding part of the receptive field. Kernels are spatially smaller than images, but have greater depth. That is, if an image consists of three (RGB) channels, the height and width of the core are spatially small, but the depth extends across all three channels.

Pooling Layer
federation layer retrieves the summary statistics of the nearest output, replacing the network output at a specific location. This helps reduce the size of the view's footprint, thus reducing the amount of computation and weights required. Union operations are handled separately for each view fragment.

Fully Connected Layer
In this layer, neurons are fully connected with neurons in preceding and succeeding layer as seen in regular FCNN. It can be computed as usual by a matrix multiplication followed by a bias effect.

5.1 Xception

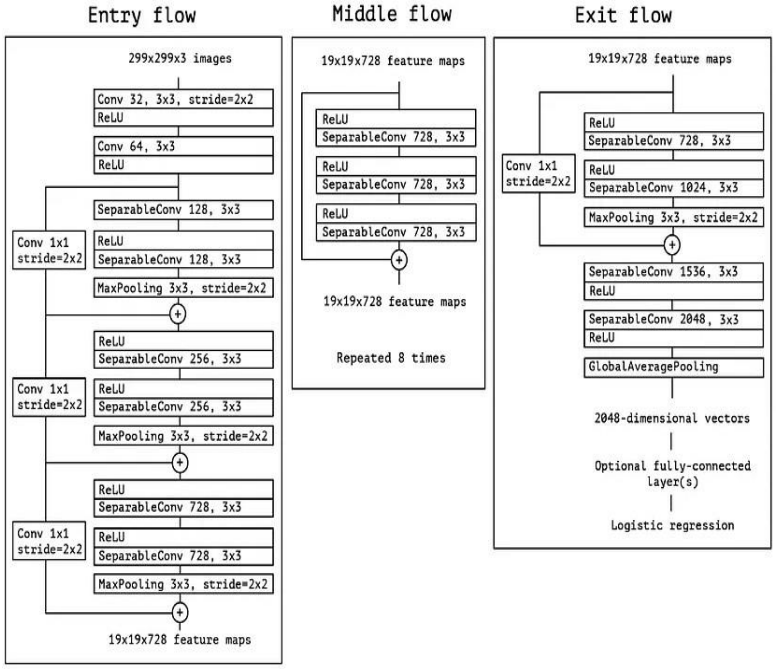

Fig. 3. Overall Architecture of Xception (Entry Flow > Middle Flow > Exit Flow)[8]

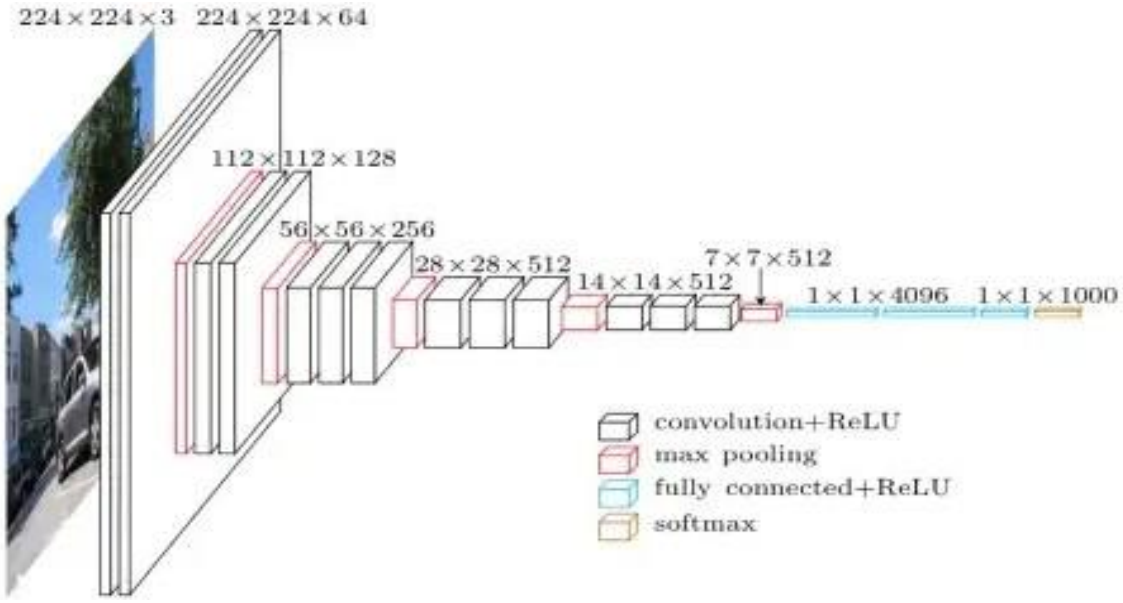
Xception is a deep convolutional neural network architecture that includes depthwise separable convolutions. Developed by Google researchers. Google introduced the interpretation of early modules in convolutional neural networks as an intermediate step between regular convolution and depth segmentation convolution operations (depth convolution followed by point convolution). From this point of view, a deeply separable convolution can be understood as an initial module with as many towers as possible. This observation led them to propose a new deep convolutional neural network architecture inspired by Inception, in which the Inception module is replaced by a deeply separated convolution.[9]

5.2 Vgg16



e

of Vgg16 [10]

Xception is a deep convolutional neural network architecture that includes depthwise separable convolutions. Developed by Google researchers. Google introduced the interpretation of early modules in convolutional neural networks as an intermediate step between regular convolution and depth segmentation convolution operations (depth convolution followed by point convolution). From this point of view, a deeply separable convolution can be understood as an initial module with as many towers as possible. This observation led them to propose a new deep convolutional neural network architecture inspired by Inception, in which the Inception module is replaced by a deeply separated convolution.[11]

5.3 Vgg19

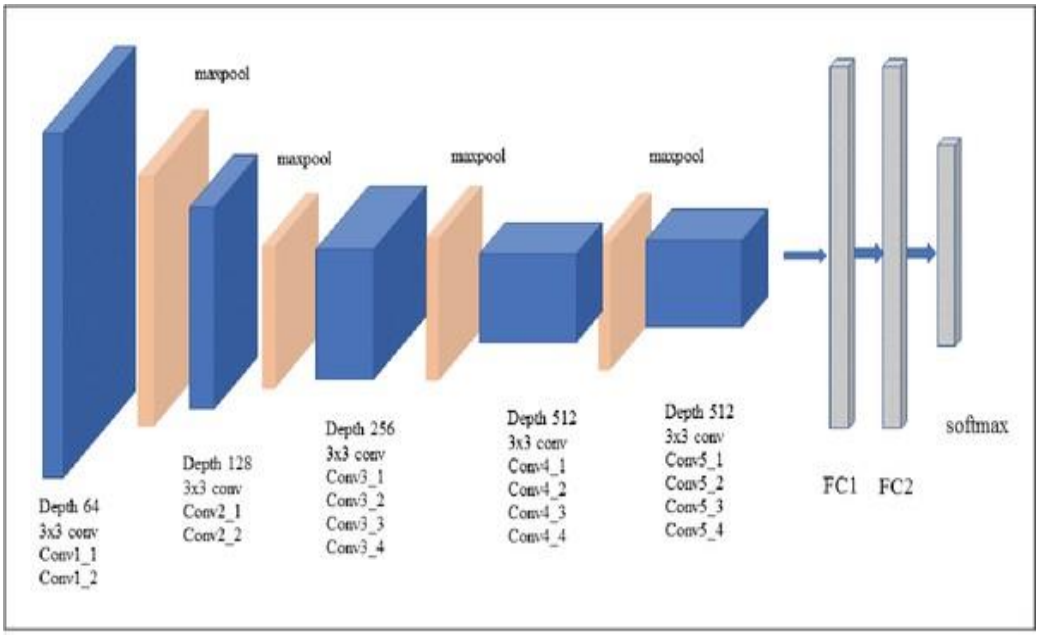


Fig. 5. vgg19 architecture[12]

VGG19 is an advanced CNN with pre-trained layers and a good understanding of what defines an image in terms of shape, color and structure. VGG19 is very deep and trained on millions of different images with complex classification problems.[13] Although the main purpose for which the VGG network was designed was to obtain ILSVRC, it has been used for many other purposes. You can use it as is or modify it for other similar tasks.

Transfer Learning: Can also be used for face recognition tasks.

Weights are readily available in other frameworks like keras, so you can modify and use them however you like. Content and style are lost when using the VGG-19 network.[14]

5.4 Resnet50

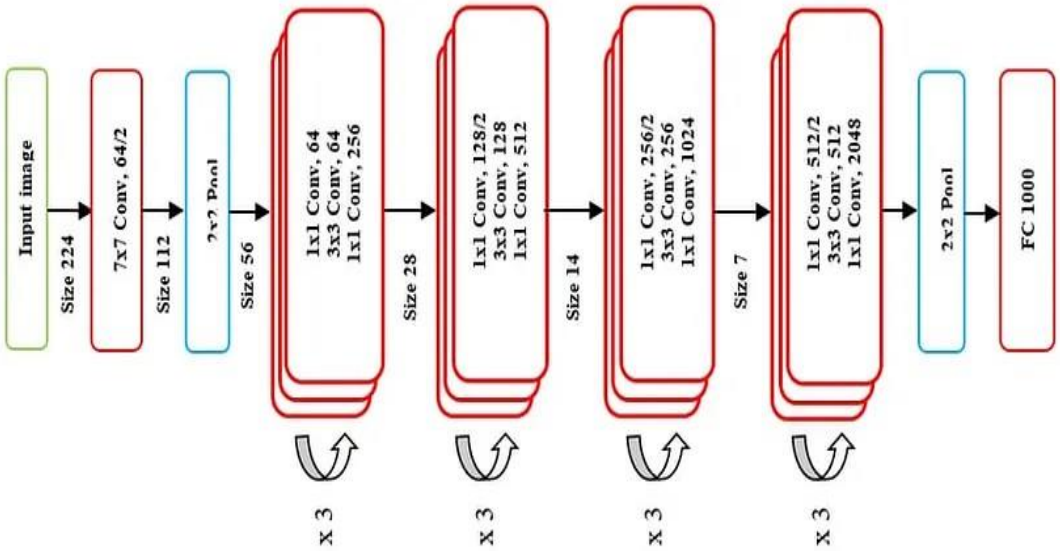

Fig. 6. Architecture of Resnet50 [15]

ResNet 50 is a 50-layer residual network proposed by He et al [16], consisting of 48 convolutional layers, 1 layer and 1 intermediate pool layer

. A residual network is a type of artificial neural network (ANN) that overlays blocks of residuals to form a network. The 50-level ResNet uses a building block bottleneck design.

The bottlenecked residual block reduces the number of parameter and matrix multiplications using 1×1 convolution known as the "bottleneck". This uses a stack of 3 layers instead of 2, so each layer can be trained much faster [17]. As in the

VGG network, the size of the convolutional layer is a 3x3 filter, the size of the input to this model is fixed at 224x224, and it follows some simple constructs: Output for layers with the same number of filters. The

MaxPool

number of filters is doubled by halving the size of the folded output so that the time complexity of each layer is maintained.

The model ends up with an intermediate pooling layer and a 1000 path fully connected layer with softmax. This model has fewer filters and lower complexity than VGG networks, and there are other variants such as ResNet101 and ResNet152 [18].

5.5 Resnet101

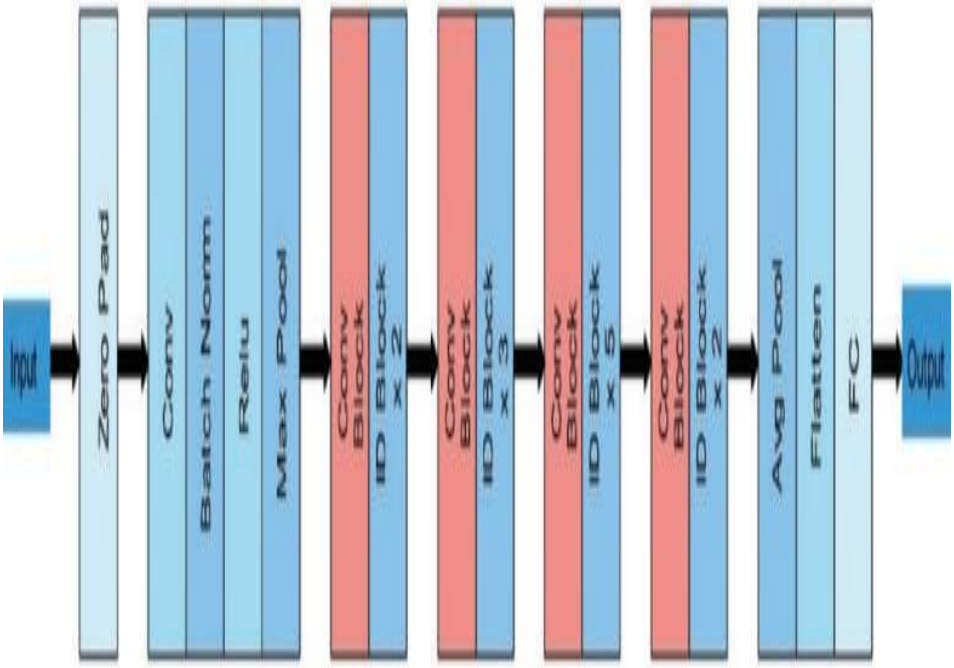

Fig. 7. Architecture of Resnet101[26]

ResNet101 contains 104 convolutional layers comprised of 33 blocks of layers, and 29 of these squares are directly utilized in previous blocks. Initially, this network was trained on the ImageNet dataset, which includes 1000 object classes[31]. This figure demonstrated that the input images are processed in residual blocks, and each block consists of several layers.

5.6 Resnet152

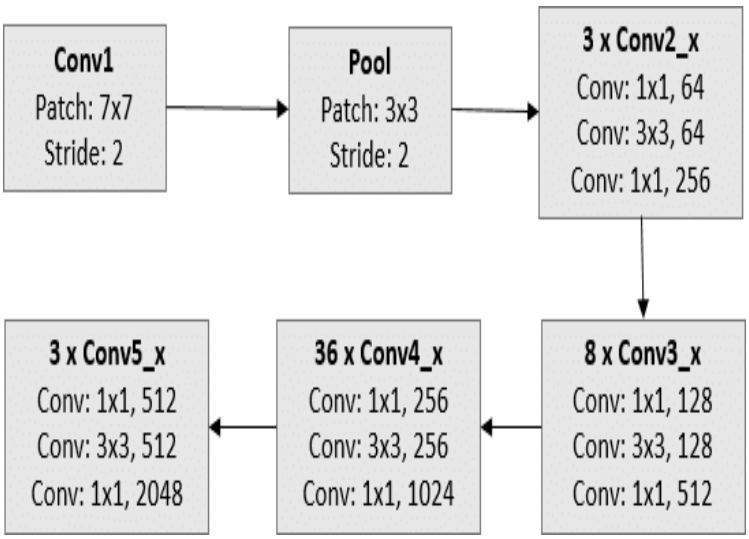

Fig. 8. Architecture of Resnet 152[33]

ResNet model pre-trained on ImageNet-1k at resolution 224x224. It was introduced in the paper Deep Residual Learning for Image Recognition by He et al[33]. Residual networks (Resnet) were proposed as a family of multiple deep neural networks with similar structures but different depths. Resnet introduces residual learning unit structureto alleviate the degradation of deep neural networks. This unit's structure is a feedforward network with a shortcut connection which adds new inputs into the network and generates new outputs. The main merit of this unit is that it produces better classification accuracy without increasing the complexity of the model.[33].

5.7 Densenet121

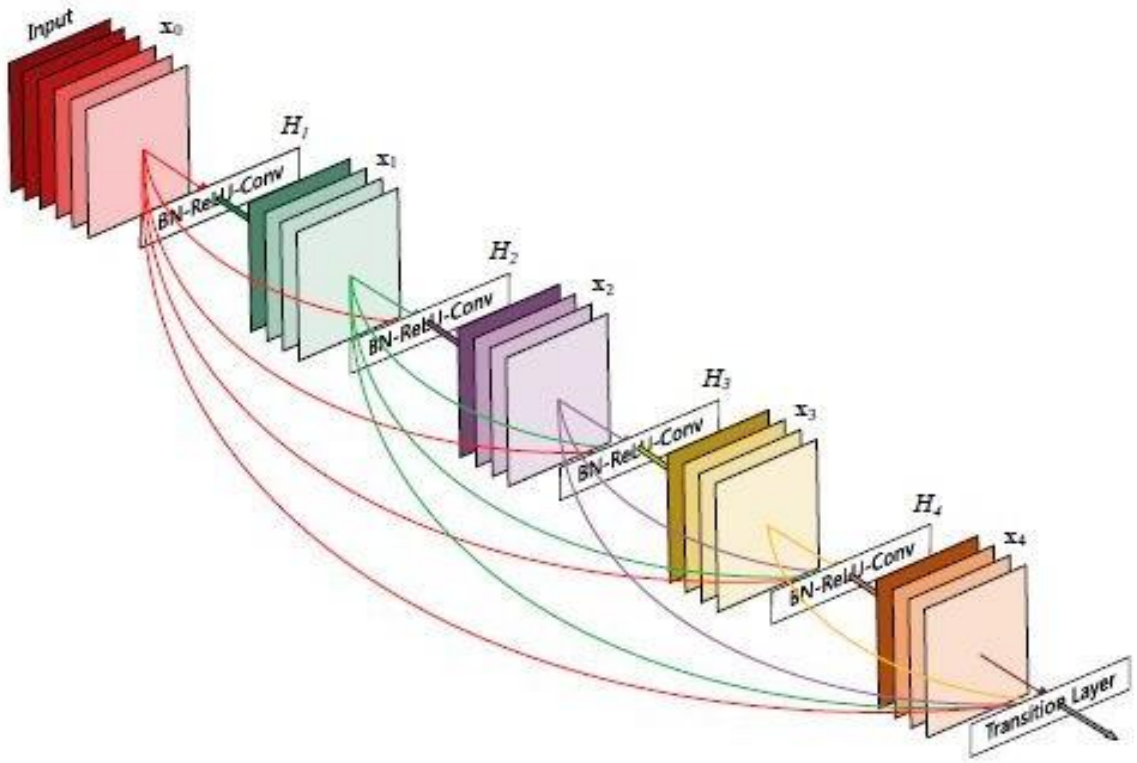

Fig. 9. Architecture of Densenet 121[20]

DenseNet is a CNN where each layer is connected to other layers that are deeper in the network,i.e the first layer is connected to the 2nd, 3rd, 4th and so on,and then same is repeated with second layer.. This is done to enable maximum information flow between the layers of the network[21].DenseNet is specifically designed to improve accuracy degradation due to vanishing gradients in high-level neural networks. Simply put, information is lost before reaching its destination because of the longer path between the input and output layers [22

]..

5.8 Densenet169

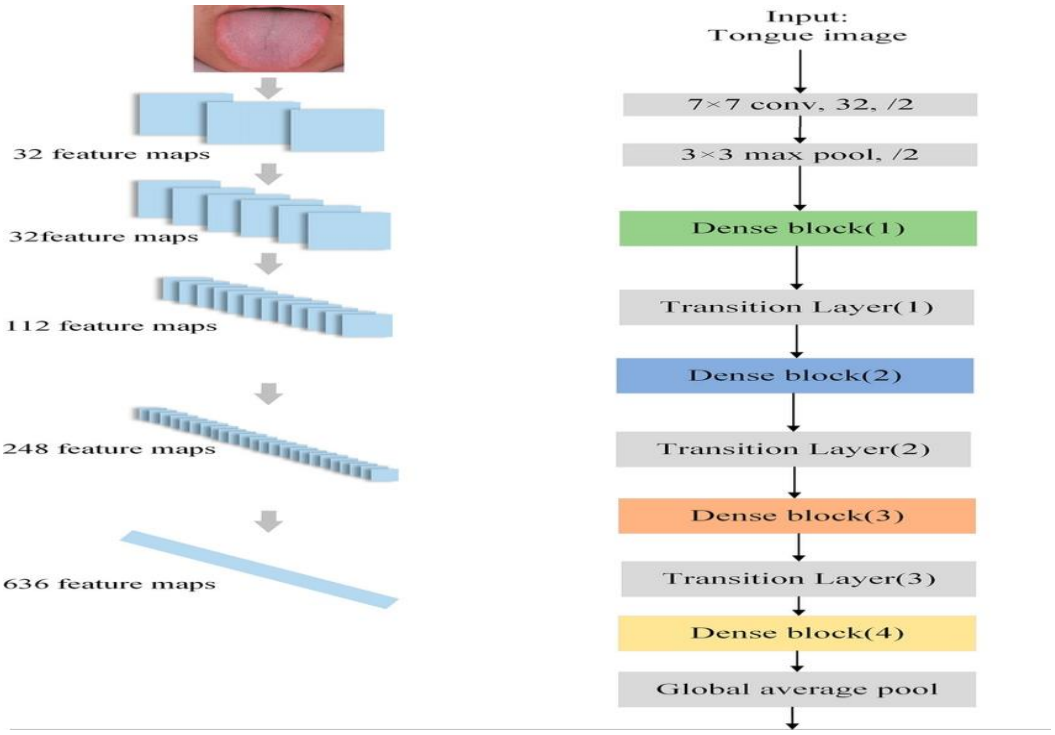

Fig. 10. Architecture of Densenet169 [24]

The densenet-169 model is one of the DenseNet family-group model designed to perform image classification. The main difference with the densenet-121 model is the size and accuracy of the model. This model is larger at just about

55MB in size as compared to the densenet-121 model's roughly 31MB size. It is originally trained on Torch, the authors converted them into Caffe* format. All the DenseNet models have been pretrained on the ImageNet image database.[25].

5.9 Densenet201

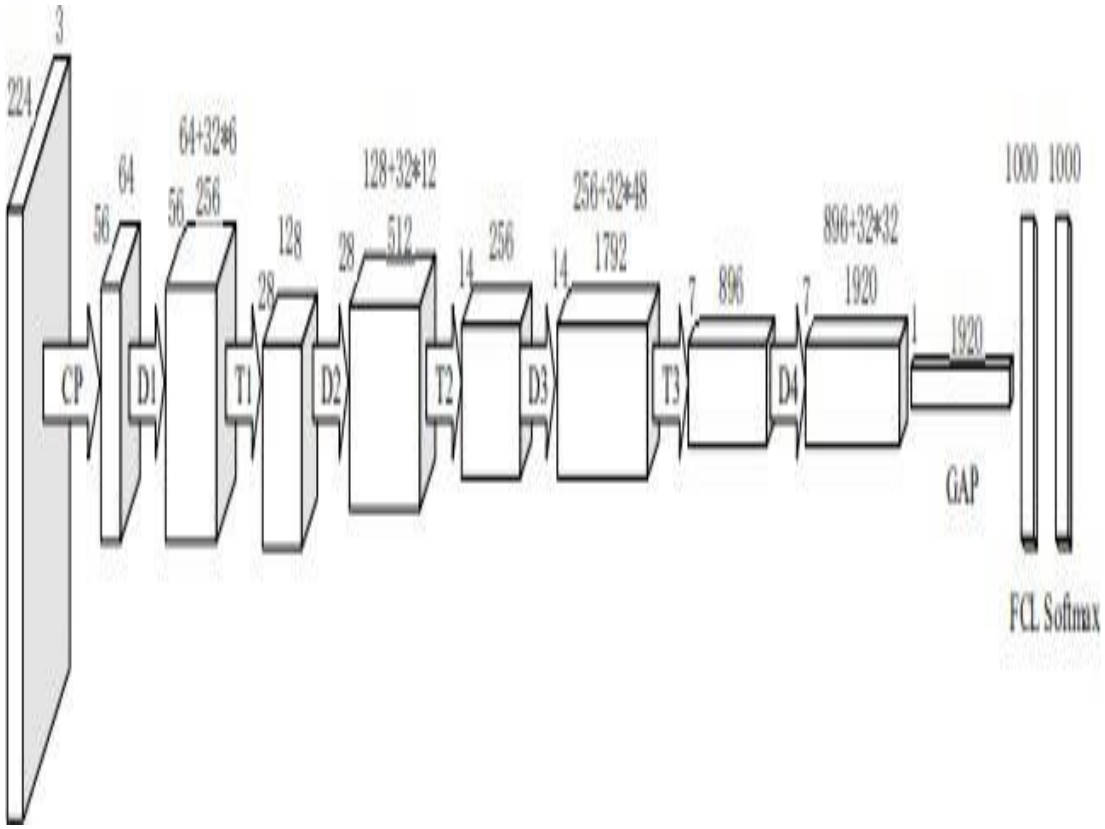

Fig. 11. Architecture of Densenet 201[28]

The dennet-169 model is one of a group of DenseNet models designed to perform image classification. The main difference from the Dendennet-121 model is the size and accuracy of the model. Density-169 is larger at approximately 55MB compared to Density-121 which is approximately 31MB. Originally trained in Torch, the authors converted it to Caffe* format. All DenseNet models were pre-trained on the ImageNet image database.
[30].

5.10 InceptionV3

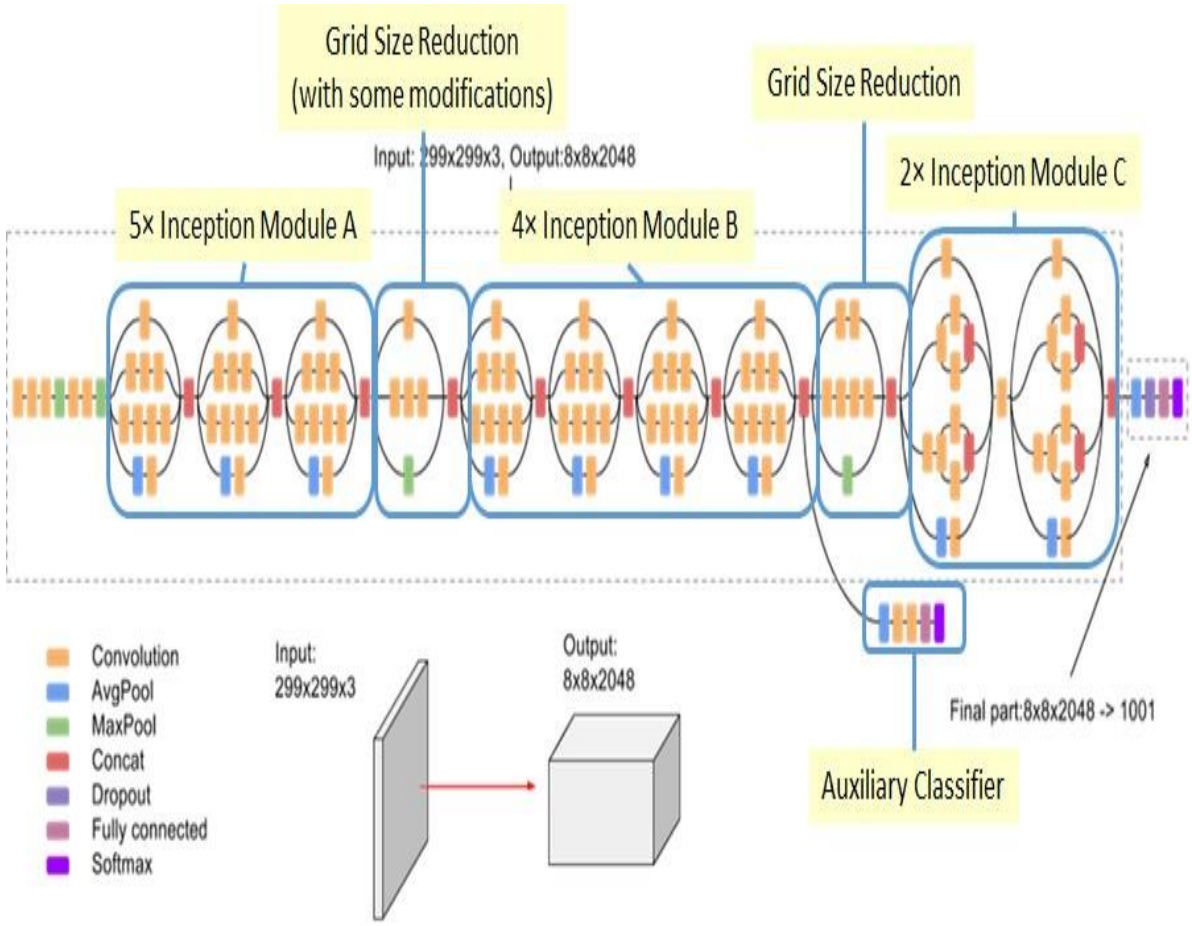

Fig. 12. Architecture of InceptionV3 [19]

Google's Inception V3 is the third in a series of deep learning convolutional frameworks. The initial version of V3 was trained using a 1001 class dataset from the original ImageNet dataset trained with over 1 million training images. Tensorflow interpretation has 1001 classes. original imagenet. Inception V3 was trained to compete in the ImageNet Large Visual Recognition Challenge, where it won first place. Inception V3 is just an improved and optimized interpretation of the Inception V1 model.[22] Several network optimization methods were used in the Inception V3 model to better fit the model.

Improved efficiency and deeper network compared to v1 and v2. Also, V3 has less computational value and uses an additional classifier as a regularizer. Inception V3 is used as a parenthesis image to illustrate the parenthesis of ancient artifacts for each dynasty [27].

5.11 InceptionResNetV2

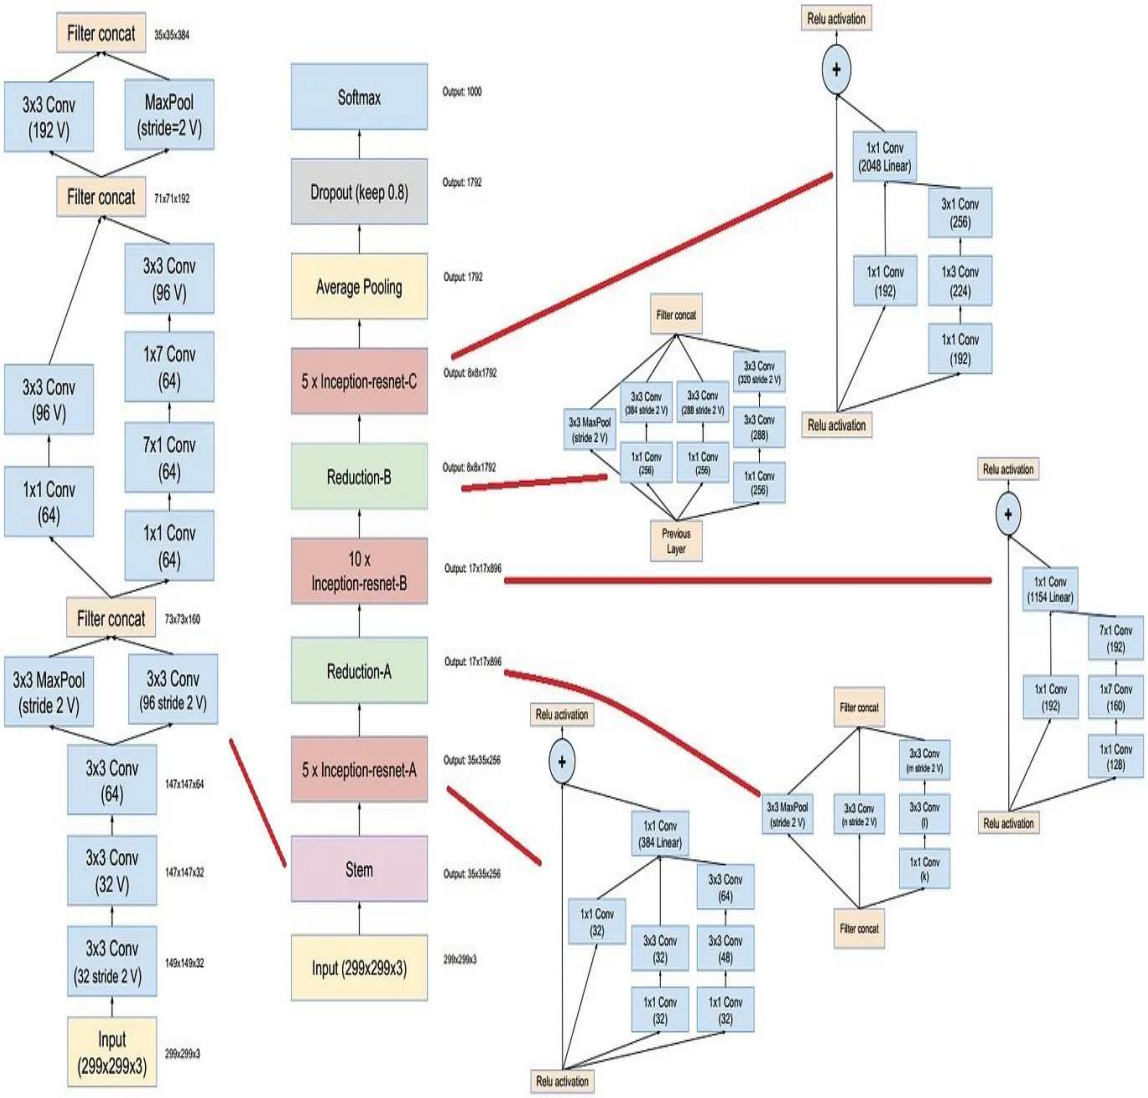

Fig. 13. InceptionResNetV2 architecture[29

Inception-ResNet-v2 is a neural network which is trained on a huge amount of images. This network consists of 164 layers and can classify images into sequences of 1000 objects such as keyboards, mice, pencils and countless creatures.

As a result, the network learned extended dot representations for various images. The web has input images that are 299X299. It is formulated based on a combination of initial structure and residual bonds. In the Inception-Resnet block, convolutional contaminants of different sizes are combined with residual links. The operation of the residual connection not only avoids the problem of declination due to deep structures, but also reduces training time.

The figure shows the Inception-Resnet-v2 trial network armature.

6 Discussion

The best accuracy achieved out of the pre-trained models with the Vgg19 model and the worst with the InceptionResnetV2 model.One of the reasons for difference between the accuracy achieved with these models may be due the different structure of architectures.The Vgg19 model contains 19 layers which includes 16 convolution layers and 5 max pooling layers whereas in InceptionResnetV2 which contains 164 layers and more amount convolution and max pooling layers than vgg19.This shows that the architecture of vgg19 which consists of 19 layers (16 convolution , 5 max pooling) is optimal for the given dataset.

7 Conclusion

This study proposes a real- time pothole discovery system. This system uses Convolutional Neural Network to classify the image into potholes, unpaved, normal road and position of the pothole is brought. All these inputs are maintained in a database and potholes data is transferred to separate authorities of that particular area using automation. The proposed approach can help road conservation authorities to formulate rapid-fire and optimized conduct for road structure repairs. A more sophisticated result with the help of the global position system(GPS) can describe and point out the position of pavement failures. Future Work of Pothole Discovery includes making Android operation and syncing data using API. Another important point is Google Map integration to incorporate potholes in the route. Getting video feeds from road cams. This work can further be extended to describe other pavement torments, road depressions, classify roads as per quality, and depth estimation of potholes.

Abstract

Skin cancer is more dangerous disease as it takes large amount of time to cure. Human being suffers from the skin diseases due to bacteria, allergy, fungal infection or various types of viruses present in environment or due to food habits. Now a day's laser technology can be used to cure from the skin cancer but detection of the disease in an early stage is very important factor as the cost of all these treatments are very high. Our point of this work is to foster the framework which recognizes the kind of skin malignant growth by utilizing the HAM 10000 skin disease image dataset. Skin malignant growth might get change because of the climate changes. In his work we are working with the skin images and attempt to distinguish the variety of cancers in early stage by utilizing the Transfer learning approach. Our proposed approach is less expensive as it need only camera to take photographs and our model to show the detected skin cancer as an output. We take digital skin image as input use pre-trained models for feature selection and after preprocessing use deep learning algorithms CNN for the multi class classification. In this work we utilize the Transfer learning models to prepare our model to work on the exactness and improve the efficiency of our model. We work on the Data augmentation to deal with this imbalance dataset As a result we compare the models through the parameters of the evaluation matrix like Recall, Precision, Accuracy and F1 score. Accuracy for different models are 86%,82%,84%,83% for ResNet 50, Inception V3 ,VGG-16and VGG-19 respectively.

Keywords: **Skin cancer, Deep Learning , Transfer Learning, Image Processing**

Introduction

Skin diseases become more dangerous if it is not early stage diagnosed. These are more hazardous than other disease as it affect the emotional and psychological health of the person. It is 4th leading cause of the illness in human being increase the nonfatal burden in the globe. Skin diseases mostly cause due to bad food eating habits, Environmental changes, tension, genetic etc. Most of the people in the world are hesitating to discuss about the skin diseases even though they are not meet the physician for the treatment in the early stage. Most of people don't have knowledge about skin cancer. Another factor due to which skin diseases are cure are unavailability of proper data and the treatment methods vary person to person .As it detect in early stage it can help to cure and also reduce the cost of treatment. Automated skin cancer detection system can help the dermatologist to diagnosis of the different type of cancer in early days which help to start the proper treatment.

The symptoms of the skin diseases are changing and shows after some months or years so person think it's only due to infection and try different remedies due to that its gets detected in later stage of the disease which is then take longer time to cure from it. The patient suffering with skin cancer need more time and money as the cost of the treatment is very high as well as it takes more time to cure from this disease. Lack of medical Knowledge about these diseases and also dermatologist need the more experience for the detection of the skin disease. As well as more challenging task is to detect the stage of the skin cancer by seeing the images as skin images shows little difference in various types of skin diseases. As these disease are due to infection, fungus, genetic problems so when doctor treat the patient Doctor has to take the consider the previous history of the patients regarding disease occurrence in his/her family ,first symptoms, Allergies of any food or environment changes, lifestyle etc. In recent days there is advancement in machine learning and deep learning algorithms we are trying to use these algorithms to get the accurate diagnosis of type of skin cancer. Computer vision is becoming more popular by using image processing with artificial intelligence for accurate analysis of the disease in early stage. Especially for the multiclass skin cancer detection large amount of data is required .In this proposed work deep learning concepts are used. We work on CNN to perform the classification and the pattern recognition. To get an idea about the current research in this field we gone through the various research work done in this area. Various type of skin cancer detection the most important factor is number of features and methodologies used for this purpose to improve the performance of our system. Further paper divided in the four sections Section II Review of Literature to understand the background related to this research and advancement in this area. Section III Methodology and Datasets used for this work .We use the open source dataset HAM 10000 available on the kaggle for our research work. Section IV Results Analysis of the datasets and our automated multiclass skin disease detection system V finally Conclusion and Future.

2. Review of Literature

Number of researcher is working on different Image processing algorithms for
the image preprocessing, image Segmentation. Machine learning algorithms for the Classification model . Deep learning CNN to improve the accuracy of the Classification model. Skin cancer affects the financial as well as emotional health of the patients. As the images of the skin lesions

are looking similar due to that in this paper the researcher work on SVM and glcm algorithms. Skin cancer images are taken and under goes with the preprocessing techniques like segmentation to improve the clarity of the images after that by using the SVM and fuzzy classification is used to classify the images in the different cancer types[1]. Bayes Theory is used to handle the probability descriptors for classify in different classes using the probabilities of different patterns and their features. The various feature selection techniques like wrapper, filter are used to select the appropriate features from the datasets. Handling Skin disorder is very crucial task as in the world near about $1/7^{th}$ percentage of population suffer from it. In dermatology most of the Doctors are going to study different skin disease and disorders. In this study the researcher use the Bayesian and Baye's Net and Bayesian along with the proper techniques for the feature selection to improve the accuracy of the proposed model. Accuracy of the model is 93%.Image processing is use in the classification can improve the performance of the system [2,3]. Mobile Net class efficient model is used .It uses to build light weight deep Neural Networks using the streamlined architecture which used depth wise separable Convolutions. Introduce hyper parameters for the tradeoff between accuracy and latency. It allows to choose the right model size to get the strong performance of the system as compared to the other classification models. They are taken the different applications like face reorganization, finger gain classification, Large scale geo localization and shows with and without hyper parameter selection results[4,5,6].Image processing is the first step towards the finding of the various skin diseases as various image processing techniques like the image enhancement , to convert the blur images into clear images,

Image segmentation and image Compression is used to make image clear. After this it is undergoes with different deep learning algorithms to classify the images in the proper skin disease classes.[7,8]. Cancer Classification of images done by using the concept of Transfer learning ResNet model. Transfer learning takes the previous knowledge to improve the outcome of the system [9, 10].Multimodel ensemble learning is used to deal with the skin diseases. As it use the ensemble learning where the output is generated by considering the output of the different machine learning techniques so that the efficiency of the model is increase[11,12]. Generative Adversarial Networks uses the generative modeling like Convolutional Neural networks. It is unsupervised learning approach where the unlabeled data is present from the input values the appropriate the patterns are recognized. In the approach it uses the generative and discriminative approach to treat the unsupervised problem as the supervised problem. Training a generative model by treating the unsupervised problem. Due to this approach the system accuracy is increase up to 95% to classify the images in the various skin lesions [13, 15]

In machine learning in place of taking the decision from the single model decision from different model is gathered and combine multiple model means ensemble into a single model. The main aim of the use of this technique is to improve the performance of the system by considering the outputs of the different model. To perform the ensemble learning various techniques like voting, Bagging, Boosting and stacking can be used.[20,21]In this work researcher work on the image patch classification using

Convolutional Neural Network to ILD.Shallow Convolutional layer to classify the ILD. Feature extraction and image segmentation techniques to improve the

performance.[22,28] In skin lesion main challenge is that the similarity I the images. To overcome this problem used the data Augmentation, fine tuning and transfer learning. Achieved accuracy up to 92%.Resnet169 to construct mobile android application [26,27].

3. Methodology

In this section, elaborate the methodologies are used for the extraction of the features, Detection and classification of skin cancer images. In our work , First step is to do the preprocessing of the dataset by data cleaning methods, Training model, Visualization of Model for the datasets. Standardization and Normalization of the dataset by using the scaling method. Dataset is huge so we use the dropout so that it can show the results properly. First most important task in CNN is to selection of layers numbers .Dense layer used in CNN for the improvement in the results Last step is to visualize the testing results as an output with the Acuracy,Precision,Recall ,F1 Score. To achieve the more performance in term accuracy we used the Transfer learning approach by transferring the knowledge of related task. In machine learning reuse of knowledge same old task for the execution of new task called as Transfer Learning. It is useful to increase the prediction of new task from the knowledge learned from the old task. This method useful for to reduce the uses of resources and as well as training data amount required for the training of the new model. Knowledge from large amount of data handling can be used to handle the new task without work from the scratch. Transfer learning save the time by reusing the previous time to complete that similar type of task. Most of the data gathered is unlabeled data so it is necessary to handle this data with the pre-trained model to improve the performance of the model. In this work we are going to work with five types of pre-trained models like Resnet 50,Inception V3 ,VGG-16,VGG-19 and GoogleNet. Each and every model has different advantages and disadvantages which can be shown by the accuracy of the model on the same dataset HAM10000.

.

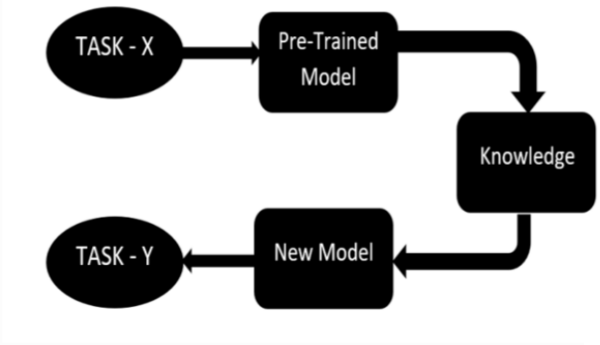

Fig 1 Transfer Learning

3.1 Pre-Trained Models

Blocks with 2D Convolution and Max Pooling layers are consist in Visual Geometry Group.We are working with the two different type of VGG Model VGG16,VGG 19. The difference between these two models are number of layers like VGG 16 having 16 layers and VGG 19 having 19 layers used to train the dataset to improve performance of the system.

3.1.1 VGG16 -

It is a Convolutional Neural Network with
16 layers deep. It's Pre-trained model for the image classification . This network has an image size of 224-by-224 from ImageNet Dataset. VGG 16 with 16 layer is pre-trained models for image classification. It is more accurate and popular due to the increase in the layers to achieve the more training and testing of the model. The network has an image input size of 224-by-224 from ImageNet dataset.

Top-5 test accuracy in ImageNet is achieve up to 92.7% using VGG .It working on 100 classes including 14 million images. It is having the significant improvement over the AlexNet by using the 3*3 kernel size filters in sequence.

VGG 19 as name indicate 16 it has 16layers out of this 13 are Convolutional layers ,5 are Pooling Layers and 3 Dense layers to improve the efficiency of the system.

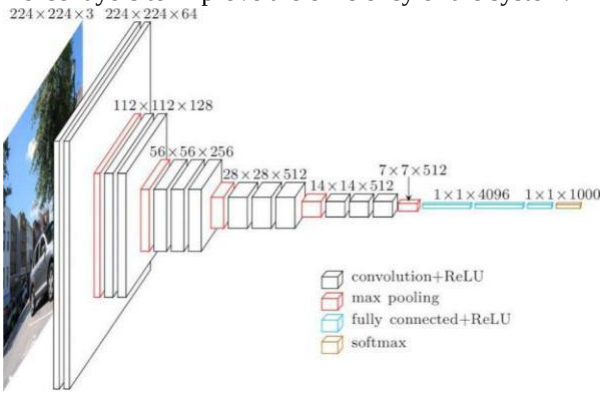

Fig 2 VGG 16 Architecture

To increase the performance of the system in VGG 19 three more Convolutional layers are added. As our results also show that VGG 19 has improved accuracy over the VGG 16.VGG 19 as name indicate 19 it has 19 layers out of this 16 are Convolutional layers ,5 are Pooling Layers and 3 Dense layers to improve the efficiency of the system.

3.1.2 InceptionV3 (GoogleNet)

It is trained as well as built by Google. It is pre-trained Convolutional model with the depth of 50 layers. It is working on the 1000 objects with the ImageNet weights. The size of image 299x299 pixels size is more than network used in VGG19.

It support for the Size 93 MB as well as having top level 1 accuracy as 77.9% and top-5 Accuracy as 93.7%. It is working on
huge number of parameters 23,851,784 with 159 depth of model. Due to that the more training can improve the efficiency of the system by increasing the accuracy of the model.

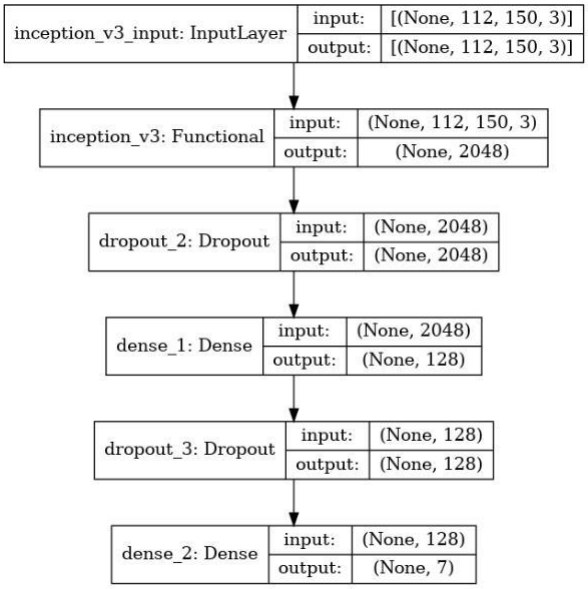

Fig 3 InceptionV3 Layers

3.1.3 ResNet 50

Convolutional Network transfer learning model ResNet-50 with the 50 layers out of this it consist of 48 Convolutional layer 1 pooling layer and the 1 Average pool layer. ResNet 50 it is Residual neural networks which is the one of the type of the artificial neural network (ANN) with the stacking In 2015 Microsoft built this network as well as checks it on different large datasets. The amount of the dataset is up to 1 million images taken from the ImageNet Dataset. Like the VGG 19 it takes the huge size images. The previous models suffer from the accuracy problem as it's become deeper. Also, the ResNet model aimed to tackle or vanishing the Gradient issue as well.

It support for the Size 98 MB as well as having top level 1 accuracy as 74.9% and top-5 Accuracy as 92.1%. It is working on huge number of parameters 25,636,712.

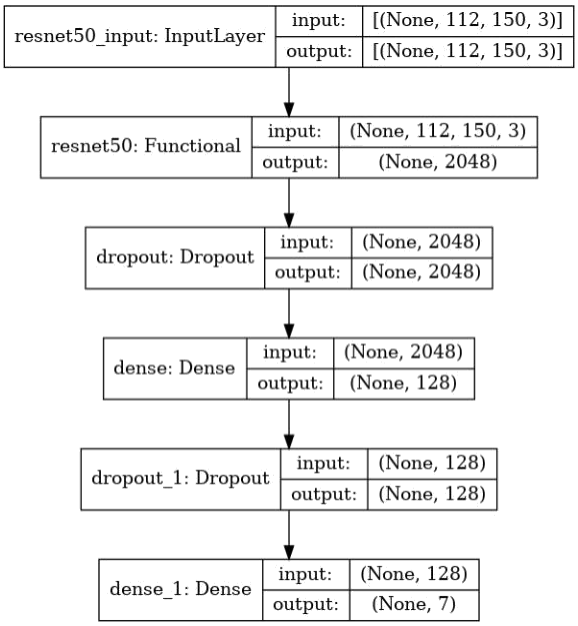

Fig 4 ResNet50 Layers

3.2 Dataset Description

In this work we are working on open source dataset downloaded from Kaggle. We are working on HAM 10000 dataset having a large amount of common pigmented skin lesions Dermatoscopic. The HAM 10000 dataset can be used in ISIC 2018 challenge for the skin cancer detection .It is training set for this challenge for to improve the skin melanoma detection with more accuracy.

The size of the image is 450*650 contain 10,015 labeled images. It include the images of the seven cancer types like Pigmented Benign Keratosis, Melanocytic nevi, Dermatofibroma, Melonoma, Vascular lesions,Vascular Lesion, Basel Cell Carcinoma, Actinic keratosis. Out of all cancer types Melonoma is more deadly cancer. We used the Transfer Learning Models to train our system .Transfer learning help to get the knowledge of the previously train model .To train our HAM100000 dataset worked with the five transfer learning models like ResNet 50 Inception V3, VGG16, VGG19,GoogleNet. In this work Data Augmentation technique for handling the class imbalance problem by creating new images by slightly changing the existing images. Overfitting problem can be handled by using Data Augmentation. Due to this the classes become balance and all pre-trained model can work train properly.

4. Results and Discussion

As we work with the different Transfer Learning approaches to get the knowledge of old learning for the new dataset to increase the performance of the model as well as to reduce the time and cost for the treatment.Fig 5 and 6 shows the training and testing Evaluation Matrix for ResNet 50 pre-trained model include the Recall,Precision, F1-Score and Dataset support used in the model. Fig 7 shows the accuracy values and loss values for Rest50 Pre-trained model. Similarly for the VGG16, VGG19 and Inception V3 we are evaluating the Model and getting the training and testing Accuracy and loss for each model. To achieve the more accuracy and improve the performance of our system used 30 epoch to train the model. Fig 12 shows the summary of the accuracy for the all four models.

Conclusion

A techniques for HAM 10000 dataset has been implemented by using the pre-trained deep Neural Network ResNet50,VGG 16,VGG 19 and Inception V3.The proposed system classify the input skin cancer images into seven different types. Due to the Data Augmentation our model work efficiently despite data set having imbalance data. The proposed method evaluated by the

Evaluation parameters likes Precision Accuracy, F1 Score , Recall and Support. As a result we compare the models through the evaluation matrix parameters. Accuracy for different models are 86%,82%,84%,83% for ResNet 50,Inception V3 ,VGG-16 and VGG-19 respectively. This will help Doctors to detect the disease in the early stage and gives appropriate medication due to accurate detection of the Skin cancer type. Improve the lifespan of the patient and reduce the cost of the treatment.

Enterprise Resource Planning System: Case Studies and Implementation Strategy

Abstract—**In this paper, we have discussed the basic purpose of an ERP system and how it helps the company. We have also discussed all the factors and needs that decide the implementation process of an ERP system. We have also discussed case studies of two different companies that implemented ERP within their architecture and found great help. We have also researched the proper technology stack and the proper strategy that will help us in building the right ERP system for our case. In this paper we concluded on how beneficial an ERP system can be, if implemented properly.**

Keywords—Enterprise Resource Planning, Case Studies, Requirement Analysis, Implementation process.

I. Introduction

Enterprise Resource Planning (ERP) systems are software systems that help organizations to manage their business processes. They are typically used to manage financial data, inventory data, and manufacturing data. However, they can also be used to manage customer data, supplier data, and partner data [1].

ERP systems can help companies to manage their customer relationships in several ways. First, they can help companies to track customer orders and to manage customer accounts. Second, they can help companies to generate customer reports and to analyze customer data. Third, they can help companies to create and to manage customer loyalty programs. Finally, they can help companies to integrate their **customer relationship management (CRM) systems with their ERP systems [1].**

II. Need of ERP

Why do we need ERP? The question persists in every organization. Well in simple words it is a piece of software that is going to link all your departments together and going to help you drive more sales.

Some of the other reasons include the following:

1. To improve efficiency and productivity: An ERP system can help to automate and streamline many business processes, making it easier and faster for employees to get work done.
2. To reduce costs: An ERP system can help to reduce the costs of doing business by eliminating the need for duplicate data entry, manual processes, and paper-based records.
3. To improve customer service: An ERP system can help to improve customer service by providing employees with quick and easy access to customer information.
4. To improve decision-making: An ERP system can help to improve decision-making by providing managers with real-time data and analytics.
5. To improve security: An ERP system can help to improve security by providing employees with access to only the data and information they need.
6. To be prepared for growth: An ERP system can help to be prepared for growth by providing the foundation for a scalable and flexible business.
7. To improve decision-making: An ERP system can help to improve decision-making by providing managers with real-time data and analytics.

III. Ease of Use

In a nutshell, ERP is a software that helps businesses manage their core operations in a more efficient and effective manner. By automating and integrating various business processes, ERP provides real-time visibility into critical data and information, which in turn helps businesses make better informed decisions, improve operational efficiencies, and drive growth.

While ERP systems vary in terms of functionality and features, they typically include modules for finance, accounting, human resources, inventory management, customer relationship management, and supply chain management.

ERP systems are complex and can be difficult to use, particularly for small and medium-sized businesses that may not have the resources to invest in training and support. However, there are a number of factors that can make ERP easier to use, including choosing the right system for your

business, working with a reputable and experienced implementation partner, and providing adequate training for your employees.

When it comes to choosing the right ERP system for your business, it is important to consider your specific needs and requirements [3]. There is no one-size-fits-all solution, and the best ERP system for your business will depend on a number of factors, including the size and complexity of your operations, your industry, and your budget.

Once you have selected the right ERP system for your business, it is important to work with a reputable and experienced implementation partner. A good implementation partner will have a deep understanding of your business and will be able to help you configure the system to meet your specific needs. They will also be able to provide **ongoing support and training to ensure that your employees are able to use the system effectively**.

Finally, it is important to provide adequate training for your employees. ERP systems are complex and can be difficult to use, so it is important to make sure that your employees are properly trained on how to use the system. Training should be ongoing and should cover all aspects of the system, including how to enter data, how to generate reports, and how to troubleshoot problems.

IV. Implementation Technique

ERP systems are typically used to track and manage information related to **financials, manufacturing, human resources, and supply chain management**. ERP implementations can be complex and time-consuming, often taking years to complete. In order to ensure a **successful ERP implementation**, organizations should carefully plan and execute their project. Additionally, it is important to select an ERP system that is a good fit for the organization's specific needs.

Once an organization has selected an ERP system, they will need to implement the software. The implementation process include a set of steps listed as:

1. **Define business requirements**: The first step in any ERP implementation is to define the organization's business requirements. This step is important in order to ensure that the selected ERP system will meet the organization's needs.

2. **Select an ERP system**: Once the organization's business requirements have been defined, they can then select an ERP system that is a good fit. There are a variety of ERP systems on the market, so it is important to select one that will meet the organization's specific needs.

3. **Install the ERP system**: Once an ERP system has been selected, it will need to be installed. This process can be complex and time-consuming, so it is important to carefully plan and execute the installation.

4. **Configure the ERP system**: After the ERP system has been installed, it will need to be configured to meet the organization's specific needs. This step can be complex, so it is important to have a clear understanding of the organization's business requirements.

5. **Train employees**: Once the ERP system is up and running, employees will need to be trained on how to use the system. This step is important in order to ensure that employees are able to effectively use the system.

6. **Go-live**: Once the ERP system is up and running and employees have been trained, the system is ready to go-live. This is the final step in the ERP implementation process and marks the start of using the system in production.

V. Case Study I (Walmart)

Walmart is an American multinational retail corporation that operates a chain of hypermarkets and grocery stores. Headquartered in Bentonville, Arkansas, the company was founded by Sam Walton in 1962 and incorporated on October 31, 1969 [3]. As of January 31, 2020, Walmart has 11,484 stores and clubs in 27 countries, operating under 55 different names [3].

The company operates under the name Walmart in the United States and Canada, and as Best Price in India. In October, Walmart announced a partnership with Microsoft to use the latter's Azure cloud platform and artificial intelligence tools to improve its online shopping experience and speed up its digital transformation. The move was seen as a direct challenge to Amazon, which has been a major competitor of Walmart in the e-commerce space[2].

Some of the changes that came into the company after integration of this ERP are:

1. A cloud based enterprise system framework that helped the company to keep a track over all the resources and keep them organized.
2. Integration of Blockchain based solutions for an evolving growth.
3. Driving a more innovative environment and building a healthy environment in between the company.
4. Driving sales patterns and developing a better customer experience.
5. Developing better customer loyalty programs that will enable the company to drive more sales and attract more customers.

On the contrary it also provides some other benefits like integration of Microsoft 365. -Improved collaboration and communication: Microsoft 365 includes tools such as Yammer, SharePoint, and OneDrive for Business that can help improve communication and collaboration within an organization. Increased productivity: Microsoft 365 includes tools such as Office 365, which can help users be more productive [4].

Better security: Microsoft 365 includes tools such as Azure Active Directory and Microsoft Intune that can help improve security for an organization. Lower costs: Microsoft 365 can help organizations save money on their IT costs [4].

Artificial intelligence is one another factor that comes with this integration. The potential for AI in business is growing. According to a recent report from McKinsey, AI has the potential to create $13 trillion in value across the global economy by 2030 [5]. And businesses are already starting to see the benefits.

The type of ERP system used by Wal-Mart is SAP ERP Financials. SAP is the top provider of business programmes in the world.

Wal-Mart chose this type of system for its capability to sustain the company's worldwide growth and effectively react to changes in trade and regulatory landscape. It uses this type of ERP since it enables it to maintain growth and steer the developing business and regulatory landscape. SAP also enhances the company's fiscal position. Wal-Mart trusts that SAP's experience in assisting International corporations with their fiscal systems will result in more elasticity and scalability in their company (Monk& Wagner, 2009). [8]

Wal-Mart planned to implement its ERP system in a period of four years. It executed this ERP system internationally in phases. The first phase was completed by the year 2010. [8]

In a recent survey from PwC, 72% of respondents said AI would help them grow their business. And nearly half (49%) said AI would help them improve their decision making [5].

1**. Improve customer service**

One of the most obvious ways AI can help businesses is by improving customer service. By using AI to automate customer service tasks, businesses can free up employees to focus on more important tasks. And AI can also help businesses provide better customer service by providing more personalized service.

For example, AI can be used to recommend products to customers based on their past purchases.

2. **Increase sales**

AI can also be used to increase sales.By using AI to analyze customer data, businesses can identify potential upsell and cross-sell opportunities. AI can also be used to create targeted marketing campaigns that are more likely to convert.

3. **Improve efficiency**

AI can also help businesses improve their efficiency. By automating tasks, businesses can reduce the need for employees to do them. This can free up employees to focus on more important tasks. And by using AI to streamline processes, businesses can improve their overall efficiency.

4. **Make better decisions**

AI can also help businesses make better decisions. By using AI to analyze data, businesses can identify trends and make better decisions about their business. AI can also help businesses automate decision making.

For example, AI can be used to approve or deny credit applications.

5. **Collaborative Planning, Forecasting and Replenishment**

Customer demand forecasting plays a very important role to efficiently manage cost savings with respect to inventory. The presence of the Retail Information System enables Wal-Mart to see in real time the availability of merchandise/inventory in each store.

Rather than doing demand forecasting, what Wal-Mart does is collaborative forecasting and replaces the goods that have been sold. As a retailer, Wal-Mart requests suppliers only with the goods that have been sold and replaces the exact quantity. This process helps Wal-Mart to avoid the Bullwhip effect. Barcode, Radio Frequency Identification, Massively Parallel Processor and Point Of Sale.[8]

The Point-Of-Sale helped Wal-Mart to identify inventory deductions and resupplies. This POS was connected to the Retail Information System and became an integral part of demand forecasting. [8]

To further track the flow of inventory over the supply chain and the type of the item that leaves the store, RFID and Barcodes were used. Wal-Mart standardized the bar-coding of items across all suppliers and when delivered by the supplier the barcodes are scanned and fed into the central database, creating an inventory list. RFID tags are microchips with built in antennas, these chips hold information about the product. Whenever the chip comes in contact with the receiver, the data in the chip is taken into the system. This enables Wal-Mart to track the item across the supply chain.[7]

The main advantages of RFID are to improve logistic efficiency, save time identifying merchandise, convenience in checking inventory and reducing human labor. Wal-Mart is not able to fully migrate into RFID based SCM because of the investment involved in RFID, the RFIDs capabilities to work on wet, metallic and glass pallets and finally the requirement for all suppliers to move to RFID. The Massively Parallel Processor (MPP) is the central system that holds massive amounts of data regarding the sales, inventory and POS transactions. The main purpose of the MPP is to keep track of stock and movement.

VI. Case Study II (Western Digital)

Western Digital Corporation (WDC), is an American company. It designs, manufactures and sells data technology products, including storage devices, data center systems and cloud storage services [6]. Founded in 1970, the company has its headquarters in Irvine, California. As of September 2019, Western Digital employed around 74,000 people. The company has a long history of innovation. It was the first to introduce the 5.25-inch hard disk drive (HDD) in 1980 and the first to market the 3.5-inch HDD in 1983.

In 1986, Western Digital introduced the world's first hard disk drive with a 10-megabyte capacity. The company has since continued to innovate, introducing the first 1-terabyte HDD in 2007 and the first 10-terabyte HDD in 2013. Western Digital is a leading provider of storage solutions, including HDDs, solid state drives (SSDs), and flash-based storage products [6].

The company's products are used in a wide range of applications, including personal computing, enterprise

storage, data center servers, and cloud computing. In recent years, Western Digital has been focused on growing its business in the flash-based storage market [6]. The company has made several acquisitions in this space, including SanDisk in 2016 and Tegile Systems in 2017. Western Digital has a strong presence in the enterprise storage market. The company's enterprise storage products are used by major corporations and government agencies around the world.

Western Digital and Oracle have partnered to provide customers with a complete cloud storage solution. Western Digital provides the hardware and Oracle provides the software.

This partnership provides customers with a complete solution for storing data in the cloud. Western Digital provides the hardware and Oracle provides the software.

This partnership provides customers with a complete solution for storing data in the cloud [7]. Western Digital provides the hardware and Oracle provides the software. This partnership provides customers with a complete solution for storing data in the cloud [7]. It helped WD in various ways:

1. Human resource management.
2. Income Processing.
3. Business analytics and forecasting.
4. Comprehensive dashboards and reporting.

The Situation: Standardizing to One Cloud-based System

After major acquisitions, Western Digital experienced challenges with disparate processes and software. Instead of choosing one of the on-premises Enterprise Resource Planning (ERP) systems already in use, the company wanted to standardize on one cloud-based system across its entire organization.

Oracle Fusion Cloud ERP Implementation Benefits

Since implementing and standardizing on Oracle ERP, Western Digital has experienced substantial process and efficiency improvements.

Western Digital was able to rationalize 3,000 application modules, many of them redundant. With the data consolidation, company executives can view a single report that shows total spend and granular spending breakdowns across all departments.

With more than 2,000 applications across the three companies, management selected out-of-the-box adapters from Oracle Integration to limit project cost, risk, and delivery time. Quickly connecting Oracle ERP with SaaS systems, including Workday and Salesforce, as well as on-premises analytics applications, has also helped the company automate the end-to-end process of collecting data from business systems for real-time operational reporting and faster analytics refresh times. Previous ERP refreshes that took 24 to 48 hours were reduced to only 5 seconds.

Using Oracle Cloud, Western Digital reduced the number of cost centers from more than 15,000 to around 3,000. Additionally, Western Digital slashed the time it takes to approve purchases, as it streamlined the process from about 16 layers to five or fewer.

In addition, Oracle Cloud ERP's regular, automatic updates have enabled the company's decision-makers to use modern features more quickly than with on-premises applications.

VII. Conclusion

On the contrary, an ERP system can be extremely beneficial to a company by providing accurate and timely information that can help make better informed decisions, improving communication and collaboration between departments, and increasing operational efficiencies. However, before implementing an ERP system, it is important to carefully consider the needs of the organization and to select a system that will fit those needs.

Additionally, the implementation process can be complex and time-consuming, so it is important to have a clear plan and dedicated resources in place to ensure a successful implementation. The research on ERP systems has shown that there are many benefits to be gained from their implementation. However, there are also a number of challenges that need to be overcome. In order to ensure that an ERP system is successful, it is important to carefully consider the needs of the organization and to select a system that is best suited to these needs. It is also important to ensure that the system is properly implemented and that all users are trained in its use.

In the discussed case studies we observed the companies streamlined their processes under one piece to tech and that helped them in keeping it all linked. Or we can say in simple words an ERP system can link all the departments whether it is CRM, sales or HRM. They all know they stay connected with each other and this helps in the growth of the company. A successfully implemented ERP can result in better department collaboration, better growth and happy customers. Some benefits of a successfully implemented ERP system include:

Increased Efficiency

An ERP system can help to increase the efficiency of an organization by automating and streamlining many of the organization's business processes. This can free up employees' time so that they can focus on more value-added tasks.

Improved Decision-Making

An ERP system can provide managers with real-time data and analytics that can be used to make more informed decisions.

Reduced Costs

An ERP system can help to reduce the costs of an organization by automating and streamlining many of the organization's business processes. This can help to reduce the need for manual labor and can also help to reduce the need for paper.

Increased Customer Satisfaction

An ERP system can help to increase customer satisfaction by providing customers with real-time information about the status of their orders. This can help to improve communication and can also help to reduce the chance of errors.

Improved Business Processes

An ERP system can help to improve the efficiency and effectiveness of an organization's business processes. This can help to improve the quality of the organization's products and services.

Acknowledgment

We gratefully acknowledge the support, guidance and encouragement of our Guide Assistant Professor Dr. Rashmi Thakur ma'am and our colleagues who supported this idea and always encouraged us to go beyond ordinary.

Abstract- **Everyday life in the city has many important things to deal with. Tasks that are essential to our day to day lives, such as water supply, repairs, important notices, events, and security, come under housing society management. For the most part, housing societies still use old methods to handle these tasks. The use of traditional methods in today's era certainly has some limitations. Priority notifications, alerts, and a lot of other information that may not be delivered properly to residents in the current scenario as most things are done manually. It also lacks transparency about how the funds are being used in society. To overcome the problems caused by the lag of traditional systems, we are developing a web application that will be an automated system to reduce overhead.**

Keywords: Housing society management, Web application, and automated system.

I. PROBLEM STATEMENT

Proper functioning of housing societies has become an integral part of our lives. Society management contains many important activities that unconsciously occupy a large part of our lives. Society authorities are often tired of handling records stored in manual files. Complaints from the residents of the housing society are solved simultaneously with the excel sheet containing the contact information of the union member and the detailed information of the residents. This gets even worse when everything is done manually. Residents are concerned that despite registering the complaints with the authorities, if the problem has not been resolved then no one knows about the status of complaints. These are the common problems identified which are faced by societies. Without automation and the use of the latest tools, managing a residential complex is too time-consuming, requires too much human resource, costly and inefficient. World has evolved and most of us, regardless of where we work, want to combine the latest technologies in our day to day activities. So changing the way housing societies work is beneficial, increases efficiency, and saves time and resources.

II. INTRODUCTION

The web application is designed to manage the day to day activities of housing society. In most of the housing societies, most of the work is still done manually. Since most of the things are done and saved on papers it is very difficult to keep track and manage all the work. Most of the daily operations of the housing society will be automated by this system for managing societies. There is a lack of automated systems that carry out all the regular tasks in the housing society so that the residents are aware of what is happening there. The system also charges individual flats or selects units based on location or a set fee. Upon submitting their apartment bill, members get access to bills for payments. The most frequent issues that residential communities encounter will be addressed by this system. Management committee can track expenditures of the society using this system and make better plans for the future.

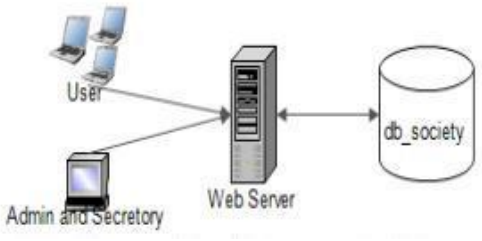

Figure. 1, Generalized system Architecture of the Web application.

The web application's system architecture in Figure 1 shows how different users interact with the database and the society's server. The data is stored in a database from where data is retrieved via this web server. Web applications are becoming very popular in today's world since they do not need to be downloaded on every user's device. Given the state of the Indian economy, web applications are a technology that every second citizen may access. Internet computing has undergone a revolution thanks to the functioning of powerful, decentralized

devices. By decreasing effort and fostering reliable communication, this idea can significantly help in finding a solution to the problems faced by residential societies. As a tool for resident alerts, meeting reminders, and managing complaints, this website is ideal. Due to these features, this web application will offer a wiser, better and more secure mode of communication between society members and the administrators. The web application maintains this data in the SQL database which has its own benefits, and it has a system design where the administrator has all the rights to send notifications, update bill amounts, arrange meetings, etc.

III. LITERATURE SURVEY

Housing Society Management: To solve the shortcomings of the existing systems, this project came up with an easy and secure method of communication through an Android app. There was a feature in this application that made communication between society members possible. Various functions of the community, such as complaints, announcements, meetings, rules, suggestions, and electrical connections, are provided at the same time so that residents can freely use any function. This android application also reduced the workload of society authorities by providing administrators facilities due to which they do not have to monitor information availability only through the backend.

Society Management System: This app has features like audit, parking, notification button and message board. Management module kept the maintenance list for all flats in the Society. - The administrator maintains and updates the maintenance list for all apartments in the community. Expected service fee and users have to pay a predetermined amount for maintenance. The manager manually clicks on the corresponding apartment with the name. The parking section provided the user with a detailed map of the status of the parking space. By seeing the availability users can reserve a vehicle parking space.

Study of Implementation of Society Management System: Notifications and other useful features were available in their society management app. User interface was easier for society members to make use of messaging functionality. Project developed was highly reliable and brought transparency in the society. But frequent notification can interrupt the society members even though they may be important. To implement the proper working of the application for a particular society, it was needed to visit these different societies and get to know what their daily activities and requirements were.

Society Management Application on Android: This community maintenance system is designed to address the most common problems faced by residential communities. This application is a cloud-based system for handling the daily tasks of housing societies. Coordination is required between each governing body and the providers of these services to ensure that appropriate accommodation is provided. The system allows employees/ guards/ owners to log in using a unique QR code containing name, password, address and phone number.

Housing Society Management Web Application with recommendation system: This web application has helped improve the interaction of society members by allowing them to communicate with one another by joining or becoming members of cultural or sports groups. Through this application, residents of the society can easily send their complaints and suggestions through the application without having to meet the authorities in person. Additionally, the app will be updated as soon as complaints or suggestions are resolved. The app helped residents to get up-to-date information related to social events conducted by society members.

IV. PROPOSED METHODOLOGY

The systems existing today had some shortcomings, we felt the need to curb using our proposed system. This system has a lot of major advancements when compared to present ones. This takes care of automated man to man conversation by itself without need of any other authority. The prime use-cases this application addresses and the offerings which are provided are as follows:

1. Maintenance Pay Scheduler

Maintenance has always been a toubling task and part of a society. It’s quite a time taking task in letting all the people know of their bills and pending

dues. Also then collecting dues from them makes another hassle. Also to give them very frequent reminders of the dues is a struggling task sometimes in itself for the authority. Using this prominent feature, the authority involved in managing members can quickly send an e-gen pay schedule to gather dues in any forms from all flat owners or renters.

2. Maintaining Records of Dues

The paying of the bill is considered one of the tasks of utmost importance. But, it's like sometimes they are not able to get the maintenance bill notification or sometimes they are unable to spare time to physically pay the dues or charges on time. Our Society Web Application attempts to curb the issue and provides truly amazing and an easy answer to pay dues bills. This also makes sure to remind the user of their current month maintenance dues bill payment. Some residents can pay their dues bills using and upi or swipe payment gateway by sitting at the comfort and reliability of their flats and need not find any concurrent authority people for making their pay dues. They can find an option to
get the completion status of their dues pays of payment and get a receipt instantly in no time at their conveniences.

3. Manage Complaints

One of the very irritating experiences of any flat owner is their issues being unaddressed and unanswered. Also there are some issues that can affect other flat owners as well. So the Society Web Application provides a surface of Complaint. Where complaints can be added and as they are answered their status can be updated to completion as well. Also transparency can also be made whether the issue is legit or not. If a legit issue is raised, It's taken into the system and systematic resolutions are carried out. Also the issue raiser is notified if the status of their complaint is changed. The records are also saved as what are the frequent issues pertaining in the society so that for further stages, Presolved resolutions can be made in action and save time.

4.Communication Management

A residential community or a considerable society is more like a small fragment where various families remain intact together irrespective of any race, religion or genre. Ranging from a child to an oldie society has all a wide variety of people without any biases towards any individual. The gap that is usually a sort of comm-gap is one of the most important problems and also a major shortcoming between them. Through the My Group that has a Connections feature i.e The ShoutBox section of the web application, the members can connect or tree form with other members in the community or society, they can speak with them and discuss various major non-major important informations, discussions regarding organizing of any kind of events and casual talks with each other imperatively and efficiently without any disruption to the process.

5. Notice System and management

Any residential society conducts a number of events and various festival celebrations. Also there are various official and unofficial events happening in a society. Permissions should be taken. Each member of the society must be addressed while making any decision for conduction of any kind of an Event or Meeting. Therefore, The Resident welfare association or the event conducting authority can publish the notices and be able to reach all the respective members of the society instantly. They are also able to see how many members have received and have read the notice. Societal residentials will get an insta notification and emailed about any happenings in the society and also to grasp and queue the necessary proceedings instructed in the informed booklet for a smooth process and completion of the events and meetings.

6. Visitor Notification

Unnotified Visitors and unidentified guests can sometimes be a threat to society members. So it becomes a necessity to improvise the visiting arrangements beforehand. This would help to avoid all kinds of mishaps or security infringements and would be able to save a lot of hassle if the members are already aware who is coming to their houses and will lead to a more safer security management. Hence it leads to a safer society. The proposed system has a feature of visitor notifications. It works in such a way that whenever there is any guest or visitor for any society member. Their entails are entered in the web application and proper detailed entry is made. Then the visitor gets a notification of incoming visitors. The respective flat owner approves of this notification. The visitor or guest is allowed to mark an entry in the premises of society.

CONCLUSION

We have constructed a web application for residential housing societies to accelerate their management and to reduce the human efforts and errors to increase a crystal clear transparency between the society members and core management authorities. This effort also helps to reduce the time and constructive applied endeavors for non-automated communication in a society by providing them notifications and important information to the members of a residential society in the reliable and transparent way.

VII. ACKNOWLEDGMENT

We gratefully acknowledge the support, guidance and encouragement of our Guide and mentor Dr. Anand Khandare Sir (Dy. HOD - Computer Engineering Department) for this novel work.

Heart Failure Prediction System Using Ml

Dr Harinder K. Bali, Chairman

Abstract: **. In the last fifteen year, HFs become still endudred the leading causes of death. One person dies almost every 34 seconds from HF. Diagnosis of HFs is an essential task and yet intricate task to perform accurately and efficiently in the hospital and clinic. These things are motivated to build a Web-based HFPS application using ML algorithms. This proposed system can reserve problem by accurately predicting the presence of HF in the patient. ML is an emerging technology of AI that solved the various type of classification problem by producing accurate output. ML algorithms are applied to forecast the HF of the patient.**

The major killer cause of human death is Heart Failure (HF).

Many people die due to this disease. Lots of researchers have been discovering new technologies to procrastinate the disease before its too late for helping healthcare as well as people.

Keywords- HF, ML

I. INTRODUCTION

India accounts for one-fifth of the total deaths occurring from stroke and ischemic heart disease, especially in younger adults according to the World Health Organization. “Cardiovascular diseases affect Indians a decade earlier than their western counterparts and nearly 3 million people die of stroke and ii. heart attack every year. The most unfortunate part is that Cardiac Sciences, Paras Hospitals, Panchkula.

This paper tries to explore and implement various machine learning algorithms and analyze which one among them provides the best accuracy with a wide array of data provided. We also attempt to visualize the data and form a connection between various factors

II. PROBLEM STATEMENT

In heart failure, the heart can no longer pump enough blood around the body. The heart muscle is either too weak or not elastic enough. Different parts of the heart may be affected too. The type of medication people use for the treatment of heart failure will depend on the type of heart failure they have.

Left-sided heart failure: The left ventricle of the heart no longer pumps enough blood around the body. As a result, blood builds up in the pulmonary veins (the blood vessels that carry blood away from the lungs).This causes shortness of breath, trouble breathing or coughing – especially during physical activity. Left-sided heart failure is the most common type.

Right-sided heart failure: Here the right ventricle of the heart is too weakto pump enough blood to the lungs. This causes blood to build up in the veins (the blood vessels that carry blood from the organs and tissue back to the heart). The increased pressure inside the veins can push fluid out ofthe veins into surrounding tissue. This leads to a build-up of fluid in the legs, or less commonly in the genital area, organs or the abdomen (belly).

Biventricular heart failure: In biventricular heart failure, both sides of theheart are affected. This can cause the same symptoms as both left-sided and right-sided heart failure, such as shortness of breath and a build-up of fluid.

III. . OBJECTIVE

. The main objective of this research is to develop a heart prediction system. The system can discover and extract hidden knowledge associated with diseases from a historical heart data set.

. Heart failure prediction system aims to exploit data mining techniques onmedical data set to assist in the prediction of the heart failure.

IV. . LITERATURE REVIEW

. Kalghatgi et al. [2] presented a Neural Network Approach based on theBig Five Test to predict the personality of individuals depending on tweets published on Twitter by extracting meta-attributes from tweets. Which areused to analyze one’s social behavior. The authors followed a four-step process which is Data Collection from tweets, Preprocessing, Transformation and Classification. Although neural networks are used topredict personality there are limitations such as countering fake information, automatic analysis of tweets and relying on just Twitter is not enough to predict someone’s personality but only user behavior and trends.

. Allan Robey et al [3] proposed a system to reduce the load on the HumanResource department of companies by having two sides: organization and candidate oriented. The authors claim that the proposed system will be more effective to shortlist CVs from a large pool making sure that the ranking is fair and legal. The main difference between the existing system and the proposed system is that instead of just scanning the CVs, the authors propose to conduct an aptitude test and a personality test for personality prediction.

iii. Juneja Afzal Ayub Zubeda et al [4] worked on a project to rank CVs using Natural Language Processing and Machine Learning. The system ranks CVs in any format according to the company’s criteria. The authors propose to consider candidate’s GitHub and LinkedIn profile as well to get a better understanding making it

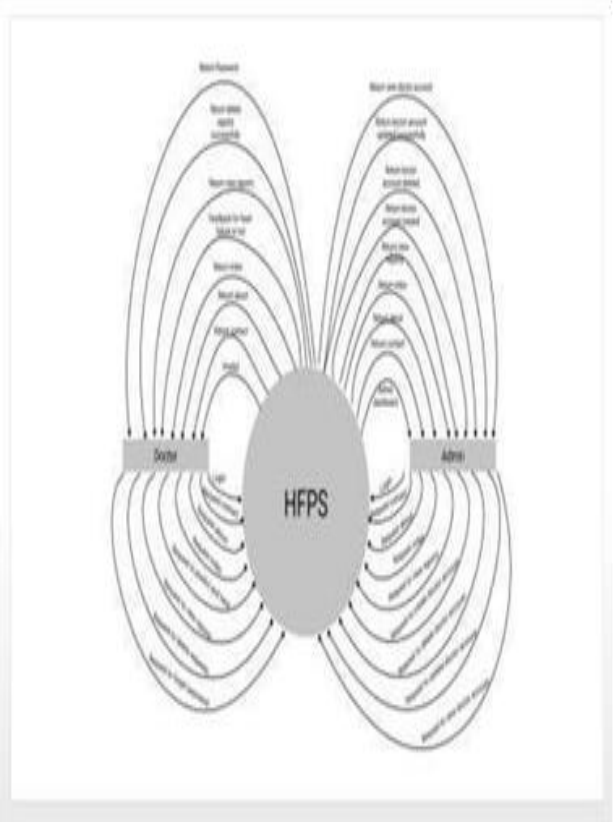
easier for the company to find a suitable match based on skillsets, ability and most importantly, personality.

V. DATA COLLECTION

1) Dataset : As manual data collection is time-consuming, we collected candidate resumes through a lot of websites and personal interaction with potential job seekers taking the total count to 708 CVs. The collected CVs were in PDF and DOCx format.

Methodology : The methodology of software development is the method in managing project development. There are many models of the methodology are available such as Waterfall model model, Incremental model, RAD model, Agile model, Iterative model and Spiral model. However, it still need to be considered by developer to decide which is will be used in the project. The methodology model is useful to manage the project efficiently and able to help developer from getting any problem during time of development. Also, it help to achieve the objective and scope of the projects. In order to build the project, it need to understand the stakeholder requirements.

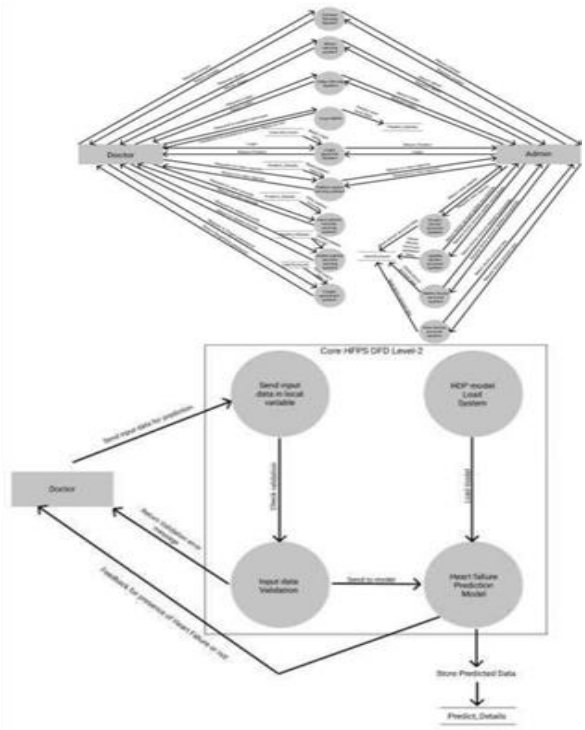
2) For parsing CVs, we have used pyre sparser- a simple resume parser used for extracting important features such as name, email, id, description, skills from CVs. Pyre sparser supports PDF and DOCx files. The parsed data is then stored in a CSV file.



VI. . PROPOSED SYSTEM

DFD is the abbreviation for Data Flow Diagram. The flow of data of a system or a process is represented by DFD. It also gives insight into the inputs and outputs of each entity and the process itself. DFD does not have control flow and no loops or decision rules are present. Specific operations depending on the type of data can be explained by a flowchart.

Data Flow Diagram can be represented in several ways. The DFD belongs to structured-analysis modeling tools. Data Flow diagrams are very popular because they help us to visualize the major steps and data involved in software-system processes



Before training our model, we label encoded the Personality column of our dataset. Our final dataset had 708 rows and 6 rows. Using the sklearn library, we have used 70% of our data for training purposes and 30% for testing the results. For predicting the personality of a prospective candidate, we have used various machine learning algorithms like Logistic Regression, Naïve Bayes, Random Forest, Support Vector Machine (SVM) and KNN.

VII. LOGISTIC REGRESSION

It is an algorithm analogous to Linear Regression, except it predicts whether something is True or False. It is a popular algorithm for solving classification problems like Binary Classification (Pass/Fail, Rain/No Rain).

- Naive Bayes

In probability, Bayes' theorem is used to compute the conditional probability. Thetheorem forms the basis of the Naive Bayes classifier, a classification algorithm that assumes strong independence assumptions between the features. Accordingto the algorithm, each feature in the problem makes an equal and independent contribution to the outcome.

- kNN

kNN stands for k-nearest neighbors, a supervised machine learning algorithm capable of solving both regression and classification problems. Intuitively we can think of the proverb 'Birds of the same feather flock together as similar to kNN.

The algorithm assumes that

similar data points usually occur in close proximity.

The keywords in Table 1 will be matched by the mentioned class. Using PhraseMatcher class, our algorithm searches for the keywords and gives a score from a range of 0-10 according to the occurrence of OCEAN keywords in one's CV. After assigning scores as shown in the table below, the algorithm labels eachdata point as dependable, extraverted, lively, responsible, or serious. Thus, we output a CSV file with degrees of the 'Big five' traits as all the columns. Each datapoint has been labelled as either dependable, extraverted, lively, responsible,or serious as given in Table 2.

SVM

Support vector machine is a supervised machine learning algorithm used to dealwith data for classification and regression analysis. The goal of SVM is to find a hyperplane in N-dimensional space (N- number of

features) that can easily classify the data points.

- Random Forest

Random forest is another ensemble technique used for classification and regression tasks. It uses multiple decision trees to produce the output. Bagging orbootstrap aggregation are used to train the random forest algorithm's "forest. After training our model on all of the algorithms, we realized that our predictions turned out to be rather poor. Even our best models could only find an accuracy ofabout 30 percent. Another factor was that our training and testing datasets had very different distributions. While our training data was a little imbalanced, the testing data was even more imbalanced. But when we put ourselves in the shoesof an employer, we realize that he would want to hire someone who is 'responsible' and 'lively' more than anything else. Thus, our problem now turns into a binary classification problem (1- responsible or lively 0-others)

Technical Feasibility:

The Classification algorithm is a Supervised Learning technique that is used to identify the category of new observations on the basis of training data. In Classification, a program learns from the given dataset or observations and then classifies new observation into a number of classes or groups. Such as, Yes or No,0 or 1, Spam or Not Spam, cat or dog, etc. Classes can be called as targets/labels or categories. In our project , using various algorithms like Naïve Bayes, RandomForest and support vector machine, we aim to classify candidates based on their personality.

Financial Viability:

As of now, since the dataset is limited, NO financial help is required. The Online GPU provided by the Google Collab is sufficient for training and evaluating the model. Though, to deploy the model on a website and to host the website onlinewe need to buy a domain which may cost around 500 rupees per year with somemaintenance cost. As a future scope, once the site is hosted and becomes popular, the number of users will increase hence the dataset increases too. With ever increasing data, training classification model will become

difficult on the free GPU which was provided by Google Collab hence we may need to buy Google Cloud GPU

which costs around 3-5 USD for 40 GB per GPU.

VIII. CONCLUSION

In this paper, we have used various Machine Learning Algorithms such as Logistic Regression, Naive Bayes, Random Forest, SVM and KNN for Personality prediction using CV Analysis. We have presented an effective heart disease prediction model based on machine learning techniques. The effectiveness of our model has been evaluated with and without anomalies using various classifiers. Experiment results showed that RF, SVM, LR classifiers achieved better accuracy in the dataset without anomalies compared withdataset with anomaly instances. Again, our anomaly detection model is able to effectively recognize the anomalies in the data. In future, we will focus on additional experiments to measure the effectiveness of our model, and also on the model effectiveness in other application areas like IoT systems.

We gratefully acknowledge the support, guidance and encouragement of ourguide, Mr. Shailesh Sangle sir for this project.

Gesture Enabled Commands for Laptops/PCs

Chirag Bhaga, Yash Gupta, Vaishali Nirgude4
UG Student
Department of Computer Engineering,
Thakur College of Engineering &
Technology, Mumbai, India

Abstract - **Computer Interaction has evolved from keyboard to touchscreen and now from touchscreen to touchless gesture based interaction. In defence sector, touchless UI can be used in Robotic army, bomb diffusion, flying jet or military car, etc. Proposed hands-free software will provide users more flexibility in their workspace by automating various actions such as switching tabs, saving and printing files, and so on. This is an end to end desktop application because it is more secure than web application and provides a more user friendly experience. Also this is interacting with os operations so it will provide more enhanced performance. Specific commands and All mouse activity(Left Click, Right Click, Scroll through) is used in a system to enhance System performance. FaceNet is used for user face authentication. And as part of data collection mediapipe extracts keypoints from gestures. Multilayer perceptron appreciates various relationships between the features through feedforward and backpropagation to train the model. This model will be user specific. All information about the user and gesture is stored in a database.**

Keywords: *Deep Learning, Neural Network, FaceNet, Mediapipe,*

I. INTRODUCTION

In this period of time where we all are going through an online phase we are educating ourselves, attending meetings, surfing

documents, etc. Suppose If you are reading a research paper from a distant place and suddenly you need to let your pc scroll the pdf a little bit up or zoom it, In that case you need to come close to your pc and give the command. So our problem statement falls under the domain of smart automation and the main objective of the problem statement is to make an application that controls functionalities of a computer using hand gestures via integrated webcam. We will create a hands-free software that will be further used in various fields like medical for surgery, military for bomb defusing, even for communication through sign language

II. LITERATURE REVIEW

[1] The signals utilized by RADAR technology can pass across mediums without being constrained or hampered. can pass through insulation. The signals first begin to penetrate the materials and gather the relevant data. possess the ability to gauge an object's motion velocity. need not be transported by any means. can concurrently target several items.

[2] The segmentation of hand gestures is accomplished in this study by developing a skin color model and an AdaBoost classifier

provide users more flexibility in their workspace by automating tiny actions such as switching tabs, saving and printing files, and so on. It will also be useful in media players or while reading documents/files. A simple gesture could pause or play the movie or increase the volume even while sitting far from the computer screen. You can easily scroll through an eBook or a presentation while having lunch or even if your hands are oily. Also this solution can

based on haar to account for the specificities of skin color for hand motions. Additionally, hand movements are denatured with one frame of video being cut for analysis.

[3] A relic, the Kinect sensor was first made for the Xbox 360 and later, with the Kinect Adapter, for the Xbox One series. You can play interactive games, snap pictures, and more with Kinect thanks to its built-in camera. You may choose which apps can use the linked Kinect and whether it is turned on in the settings on compatible Xbox systems.

[4] Munir Oudah claimed that hand gestures might be employed in a variety of industries, including gaming, robotics control, virtual

environments, personal computers and tablets, home automation, and clinical and health applications. A variety of categories, including stance and motion, dynamic and static, or a combination of the two, were used to group hand signals. The study analyses the research on hand gesture approaches and lists advantages and disadvantages for various situations. It assesses performance using manual segmentation, classification algorithms, and computer vision approaches that deal with similarity and difference points. It has experimented with a variety of hand gesture techniques, including the Instrumented Glove Approach and the Computer Vision Approach (Color-Based).

[5] Color recognition is the foundation for hand tracking. In order to initialize the software, color is sampled from the hand. Using a threshold and the sampled color profile, the hand is then separated from the background. Each color in the profile generates a binary image, which is then added together.

[6] Smit Parikh took up the challenge of creating an application that uses hand gestures to manage some specified computer capabilities via an embedded webcam. In order to make labor easier, the paper suggested a hand gesture recognition system for identifying motions and turning them into certain actions. According to the report, this system will be pursued utilizing OpenCV to record motions and be interfaced with using Django, React.Js, and Electron. The system's training method is YOLO, and the database will be where the gestures are saved (MongoDB). The main objective of the paper is to give the system's user the best possible experience. It has shown a survey on hand gesture recognition, applying it in various application domains and also examining existing solutions.

[7] In this paper, the proposed system adopts a model based on the sensors estimating distance and executing a specific function in response. Using a trigger and an echo as inputs, an ultrasonic sensor may determine the distance of the hand by measuring the time it takes for sound waves to be transmitted and received. Depending on how far away the hand is from the sensor, a particular function is performed. The sensor, which we refer to as the left sensor and right sensor, is hooked to the computer at the top of the screen on both corners for quick operation. Two sensors are being used for a variety of tasks.

[8] In this paper, the proposed system is to subtract background from the image to extract the moving foreground from the static background. A white color arc as arc of reference was proposed to detect the number of fingers and for faster processing by considering only intersected pixels.

[9] It uses continuous-wave radar, like Frequency Modulated Continuous Wave (FMCW) radar, which transmits and receives data in a continuous wave, as opposed to pulsed radar, like Ultra Wideband Impulse-Radar (UWB-IR), which transmits short-duration pulses at first.

[10] It can accurately detect gestures even in low-resolution picture mode, and it has very high precision in complex and gloomy environments.

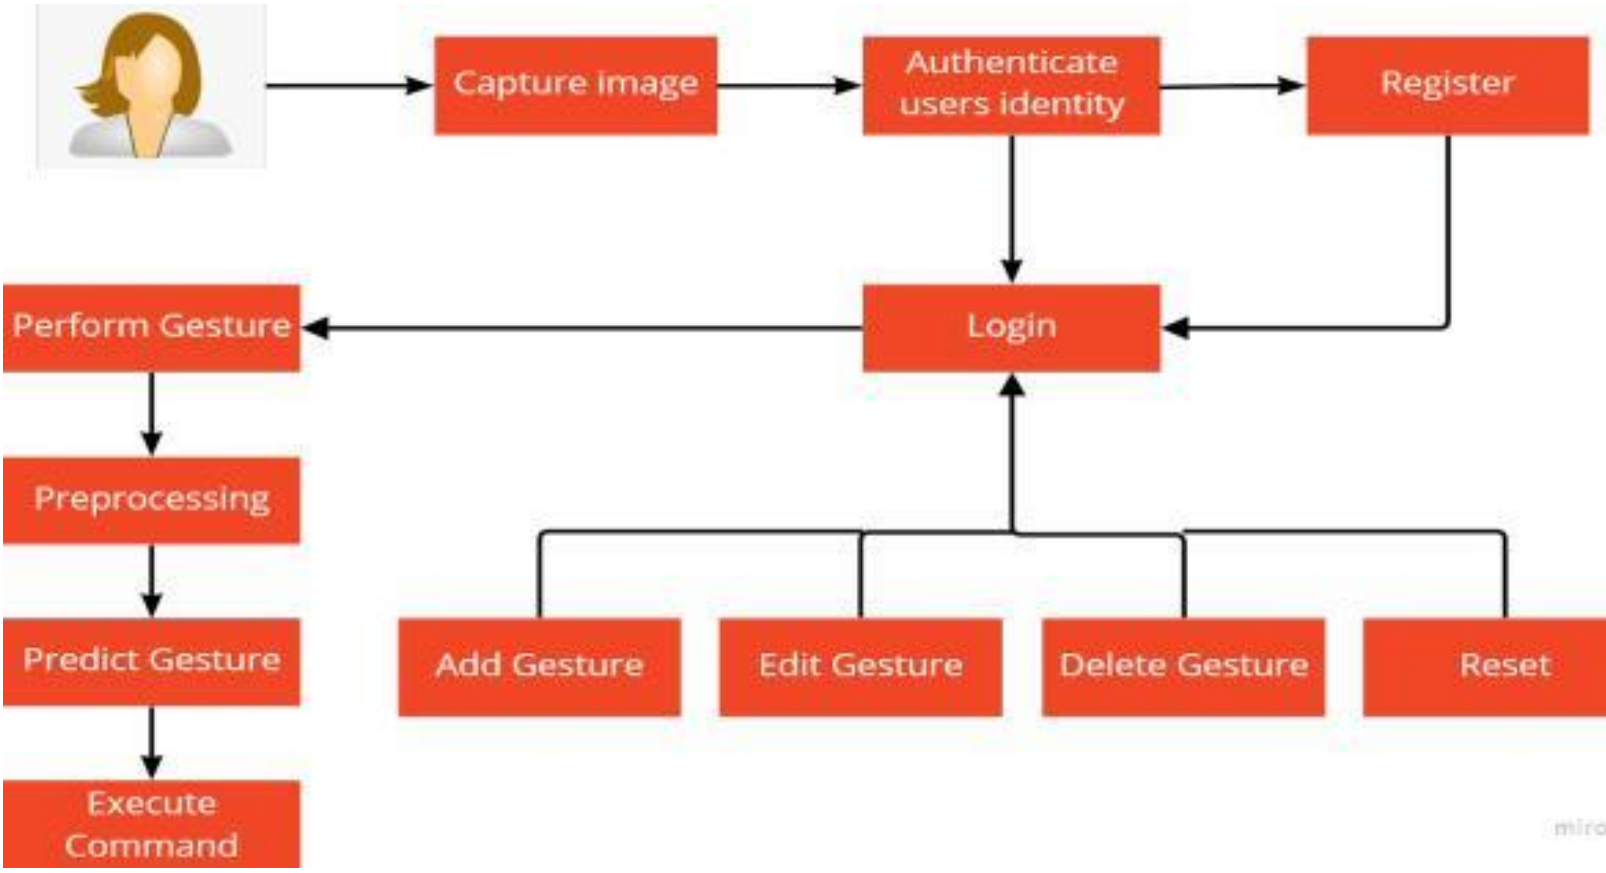
Abdullah Mujahid, Mazhar Javed Awan, Awais Yasin, Mazin Abed Mohammed, Robertas Damaševičius, Rytis Maskeliūnas, Karrar Hameed Abdulkareem	It can accurately detect gestures even in low-resolution picture mode, and it has very high precision in complex and gloomy environments.	Takes a lot of time to process the data, and using the dataset for training requires powerful computing power.

IV. METHODOLOGY

The entire project is divided into three major components with each one being further broken down into multiple modules for low coupling and easier management. The components are as follows:

1) The Authentication module
    a) Login module
    b) Registration Module
2) Gesture recognition system
    a) Static gesture
    b) Dynamic gesture
3) Customization
    a) Add gesture
    b) Edit command
    c) Delete gesture
    d) Reset to default



4.1 Architectural design of system

Face recognition will be used to authenticate the user, and only authenticated users will be able to access the application.

1. The webcam will be used by the programme to identify and conduct actions associated with those gestures. This application will be running in the background while the user runs other programs and applications.
2. The authorized user can additionally personalize the activities that must be

performed in response to a specific gesture

V. CONCLUSION

We are developing a single application that will include all the customization and gesture command features that earlier offerings lacked.

Our research leads us to the conclusion that adopting different Deep learning algorithms can improve the performance parameter.

The user will be able to perform numerous daily tasks with gestures in this desktop programme. As a result, the gestures in this case will be mapped to distinct commands that will enable the user to effortlessly perform any shortcut key using a single motion.

As a result, we'll add multi-headed deep learning models that can recognise hand key points. These key points will then be used as inputs by the deep learning model, which will predict the gesture given by users in varying environments.

Digitization and Real Time Translation of Oral and Written Material for Indian Languages

Amrita Gupata, Yash Acharya, Naman Baranwal, MS. Vaishali Nirgude
Assistant Professor
Department of Computer Engineering
Thakur College of Engineering & Technology, Mumbai, India
vaishali.nirgude@thakureducation.org, yashacharya1712@gmail.com, 04amritagupta@gmail.com, baranwalnaman@gmail.com

***Abstract*– Understanding diverse languages is challenging for humans. Since there are more than 22 official languages in India, it is quite challenging for a human to be fluent in all of them. In these situations, communication becomes problematic, and interpreters may be needed. The availability of human interpreters cannot be guaranteed at all times. This brings the Machine Translation (MT) technology into play. MT replaces words from one language with words from another. The goal of this project is to use natural language processing (NLP) to translate languages in real time utilising real-time audio as an input. Computers are used to teach themselves new languages. The suggested system will translate real-time English audio into Indian language, provide audio output in Indian language, and accept real-time English audio as input. OpenNMT will be used by the translation engine, along with NLP and Tensorflow libraries will be used in the project.**

Keywords– Machine Translation, Word sense disambiguation, Natural Language processing, OCR, automatic translation, OpenNMT

Introduction:

A revolutionary shift is currently affecting the translation industry. Digital technology and the internet have ongoing, pervasive, and significant effects on translation. The translation revolution is pervasive, encompassing everything from crowdsourced translation to the growth of automatic internet translation services. This revolution has significant and far-reaching effects on human languages, civilizations, and society. New ways of thinking and communicating about translation that fully account for the significant changes in the digital domain are urgently needed in the Information Age, also known as the Translation Age. Michael Cronin walks readers through the history of translation's interaction with technology before examining the current hot button concerns. He also explores the social, cultural, and political ramifications of these rising digital technologies. Students of modern languages, translation studies, cultural studies, and applied linguistics should read Translation in the Digital Age since it has connections to many other fields of study.

Motivation:

Machine translation is primarily motivated by the need to create computer models of natural languages for analysis and production.[1] This particular piece of work is relevant to the multidisciplinary study of

computational linguistics in AI. Three main reasons drive this kind of research: 1) The goal to build intelligent computer systems is the first. 2) Second, the goal of language science and cognition is to have a better understanding of how people communicate using natural language. Users of this application will benefit from improved English language comprehension.[2]

Problem Statement:
Information and knowledge are readily available in today's society, but understanding the material might be difficult owing to language barriers. To close this gap, we plan to develop a system that would allow everyone to easily grasp content in their mother tongue.

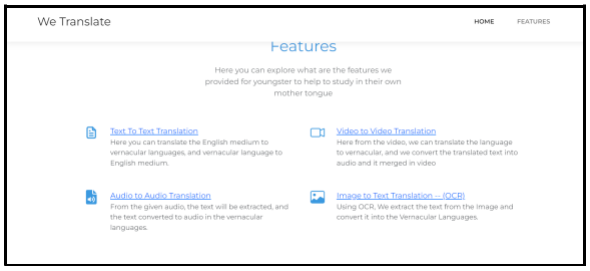

Figure 1: User Interface

Objective of project:
The idea is intended to allow users to perform various operations on a daily basis to perform different translations for a vernacular medium student.

How it will work:

- The application needs authentication of the student.
- This application will be used to translate text and help for pronunciation.
- This also will help users to translate audio in one language to audio in another language through tools like video captioning.
- Video to video and image to text translation for users to perform different tasks on this software.

Scope:
The system scope for our project is as follows:

1. Design and construction of the system such as the website.
2. Using Python, NLP modules like NLTK are used.
3. Models such as OpenNMT can be used.

Literature Survey:

Models	Techniques	Findings	Gaps
SPEECH RECOGNITION: FEATURE EXTRACTION	Linear Predictive Coding (LPC)	Method for extracting static features. The resolution of a spectral analysis is fixed along an arbitrary frequency range.	Although the human ear's frequency sensitivity is almost logarithmic, frequencies are weighted equally on a linear scale.
	Mel-Frequency Cestrum Co-efficient (MFCC)	It is the feature extraction technique that is most similar to how people actually perceive auditory speech.	MFCC values are not very robust in the presence of additive noises. Normalization is required
	Dynamic Time Warping (DTW)	It is used to cope with different speaking speed. Simple hardware implementation.	Difficulty in selecting the reference template.

		Simple Approach Errors due	The pre-recorded templates are fixed. Template training and matching become impractical as vocabulary size increases. Continuous speech recognition is not possible.
SPEECH RECOGNITION: PATTERN MATCHING	Template Based	to segmentation or classification of smaller acoustically more variable units is avoided. It is speaker dependent.	
	Knowledge Based	Uses the information regarding linguistic, phonetic and spectrogram.	Explicit modelling variation in speech is difficult to obtain and use successfully, so, this approach is impractical.
	Neural Based	Complete a challenging recognition task. decreases the modelling unit. able to be applied to create hybrid models	
	Statistical based	Present models use this approach	Low accuracy of priori modelling presumption reducing its trend
	Hidden Markov Model (HMM)	HMMs are simple, automatically trained and computationally feasible to use.	Lack in discrimination property for classification
SPEECH TO TEXT CONVERSION	Artificial Neural Network based Cuckoo Search Optimization	Quick and simple convergence rate improves the speech recognition system's recognition accuracy.	Not effective in modelling time-variability of speech

Table 1: Literature survey

Methodology:

The first step in the actual digital encoding process is the conversion of printed or handwritten text into a digital version. Processing of Digital Entries (Text Input Methods). Each of the five techniques is briefly discussed in the next section. The printed document is scanned or turned into a pdf first. During this process, a scanner can be used to scan each page of text, producing a pdf file as a consequence. As a result, a digital copy of the entire book is feasible. The fundamental advantage of this approach is that the original text will be displayed digitally in its original form, without any textual distortion.

The text's primary flaw is that it is just used in this process for visual access and not necessarily for further processing, analysis, or interpretation. The second choice is to use OCR technology to scan or create a PDF out of ancient text pages. Pages of scanned text will be read by the programme, which will also identify printed letters and translate digital characters into digital. A digital version of the text named Digital Introduction to Old Indian Texts will eventually be created from the first 25 charactersIt has become a popular way to develop digital translations of many ancient texts written in Roman, Chinese, Japanese, cuneiform, and hieroglyphics. In many cases, these texts are properly translated into digital versions containing a small number of error-correcting errors before being made available on the digital forums. However, apart from his work on OCR techniques for Indian texts over the last 30 years, it cannot be said that he has had the same success with Indian texts. We have failed to develop good OCR technology for Indic scripts that can master ancient Indian texts, read them conscientiously, visualise them correctly, and translate

them into high-quality digital versions. Therefore, converting ancient texts into digital versions using Indic OCR systems is not a very practical proposition in the current situation. A third option is to use the photo page for digitization. In most cases, text objects stored on microfilm or download versions can be downloaded into the cyber world as digital versions. While not the best way to put documents on a digital platform, it is useful in situations where access to original documents is beyond the reach of researchers. It is worth noting that many old manuscripts whose pages are fragile and unusable for scanning or OCR work can be digitised first on thin film, which can be digitised continuously. Option to save text input directly to the digital interface. Some data entry operators can machine-readable all text using a Unicode-compliant visual encoding interface using the RTF (UTF-8) codec. In this case, as long as the text produced goes through a strong process of text clarity, text familiarity, verification and validation, the text can be produced in a very reliable and trustworthy manner.

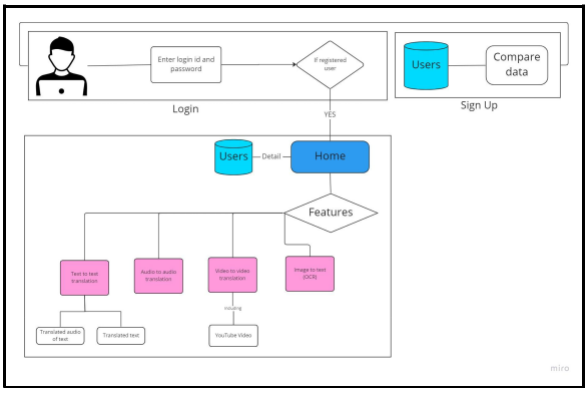

Figure 1: Flowchart Diagram

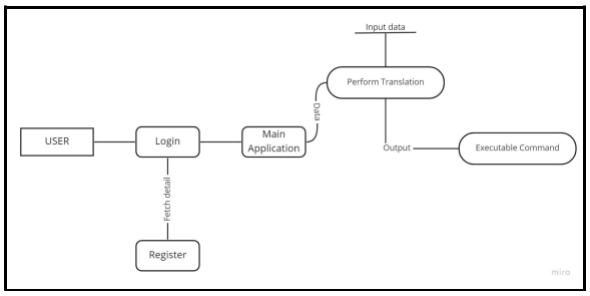

Figure 2: DataFlow Diagram

Result and Discussion:

The automated translation system is discussed in this work. A different strategy was used in this work to describe how to improve the translating system, but there are still certain issues that need to be addressed, including morphological analysis, speech marking sections, chunks, parsing, and word sense disambiguation.[3] The performance of morphological analysis, speech marking section, chunk, parsing, and word sense disambiguation will be improved in the future as part of our effort to develop the Hindi to English machine translation system. To provide the best translation in the realm of computer translation, the concept of separation is crucial.[4] We segregate a certain domain idea under unsupervised observation. We employ a Hindi English WordNet technology that draws on glossing and other dictionary data. As a result, Hindi to English translation software will work better and Word sense disambiguation will perform better.[5] In this essay, we have identified the issues with the real-time translation systems that are currently in use and have proposed novel fixes to improve both the accuracy and the speed of the system. We have also done extensive research on the methods already in use and have examined the opportunities offered by the current systems to implement the same.

Chat Application With Profanity Check And Integrated Video Conferencing

Ayush Ahuja, Gautam Chaurasia, Aakash Gupta, Dr. Sheetal Rathi
Thakur College of Engineering &Technology, Mumbai, India

Abstract - **The use of chat applications has increased to a large extent because it provides users with the facility to interact with their family and friends instantly. But these chat applications are being used for carrying out some unethical practices like cyber-bullying, online harassment, etc and there is a need to find a way to curb this issue. This paper aims to give a clear insight into solutions currently being employed or suggested to overcome this problem and to identify the drawbacks associated with these solutions on a large scale. It also proposes a working model for chat apps with profanity detection based on the gaps identified which can detect foul language and thus it can significantly reduce these unethical practices prevalent today in the world of social media.**

Keywords: ***Profanity, Foul Language, Chat Application, Video Conference, Media Sharing, Natural Language Processing***

I. INTRODUCTION

Since the beginning of time, communication has been a way of sharing thoughts, emotions, data, and information with others. With the advent of languages, people started expressing themselves both verbally and

through writing. Now, by connecting to the internet, computers anywhere in the globe
may exchange data. Different computer technologies have improved data transport and communication.
Virtual interactions are becoming more and more popular as a means of social communication. The ability of chat applications to replicate the feel of a real-time conversation virtually has helped them become increasingly popular across a variety of applications, including gaming group messaging in a live chat, e-learning, team communication using chat

rooms, and file sharing among coworkers. But while planning how we want to develop our web app, it's important to keep our consumers' experience in mind. What key attributes and capabilities are required to create a web chat application that keeps users interested.

II. MOTIVATION

With the internet being used the most in today's environment, everyone has sometime or the other experienced cyber bullying or online hate. This has become a problem that needs to be addressed with a huge amount of concern. No human being should be subjected to unwanted abuse, which has been quite prevalent in modern society. Children, who are naïve and

innocuous should not be burdened by trauma or fear instead of being instilled with curiosity and aspirations. Every human being has the right to be spoken with respect and courtesy and there is a need to ensure that this right is being accessed by everyone on the internet where the exploitation of the freedom of speech has become a new norm. This step would potentially cut off cybercrimes and make the internet much healthier.

Apart from a healthier internet, there's also the need for a convenient one stop solution for all our communication needs. Currently existing products don't offer every feature desired by a modern user all in one package, for media sharing and online chatting a product/ service is being used and to make live, one to one or group video calls another service. The video conferencing solutions lack in providing robust and reliable media sharing from within their products/ services. This continuous transition between different products for using different sets of features is a cause for great inconvenience.

III. LITERATURE SURVEY

The rise of profanity in recent years has been alarming. This has led to the compelling need for a reliable method to control such profanity.

Reading through several study studies reveals that an ideal integration of Natural Language Processing and Machine Learning would help create the necessary specific model.

[1] This research paper aims to maintain security, however it does not focus on the web application's performance , which results in a longer response time for the user. [2]The approach to the problem in this paper is quite generalized as no key differentiating feature has been introduced to encourage large-scale adoptability of the product and is limited to a few selected subset of users. [3] A drawback to the given solution in this paper is that it is limited to only within private networks. It introduces a very peculiar problem by limiting the use to private networks.

[4] The idea proposed in this paper doesn't allow the user to send the message if the model detects the context of the message is negative, which means it reads the message even before it is sent at the sender's side. [5] This paper focuses on developing a filter for chat applications where each message is checked for toxicity using Deep Learning and Natural Language Processing, where the focus is on understanding the context of each message. [6] This paper introduced the working and implementation of encrypted chat applications. It describes how the messages are encrypted on device before moving to server using various cryptographic algorithms like DES, AES and RSA. Computer vision techniques are used for encrypting image

IV. METHODOLOGY

The entire system is a web based application and can be broken down into three different modules, the chat application, the video conferencing module and the profanity check model.

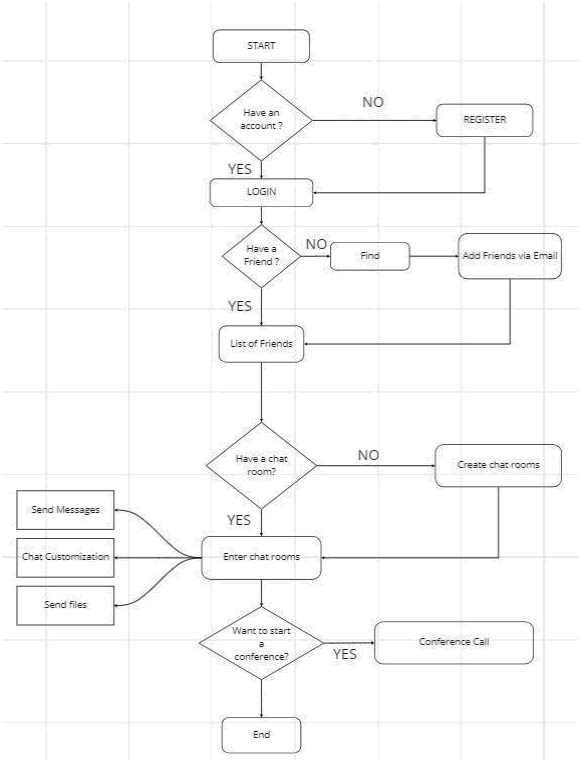

Fig 1. Flowchart of System

1) The login page will be displayed before the chat page when a user accesses the chat page. User login information is necessary. The user must first register if he/she doesn't have an account.
2) Users must have a friend after logging in before starting a chat. As a result, if a user doesn't already have a friend, they can add a friend directly from the email.

3) The user can start a chat immediately, if they have contacts in their friend list.

4) The application will then check to see if the user is already in a chatroom with the specified user . If the chat room is not present then the user will enter it to begin a chat session .
5)Finally, data will be sent and received.

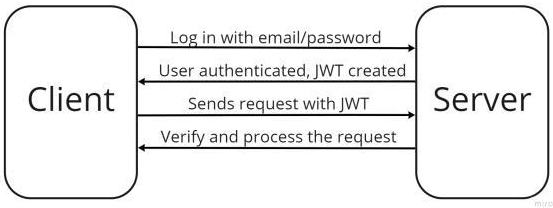

Fig 2. LogIn Process

Conferencing Module:

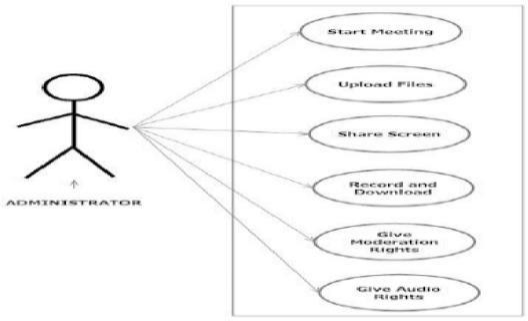

Fig 3. Use Case Diagram for conference - Admin

The administrator gains access to every part of the model and are permitted to make changes when necessary, add and remove moderation rights, allow or deny the users to draw on the white board, allow or deny the users screen sharing or recording, allow or deny audio rights to users, give exclusive audio right to self and upload files

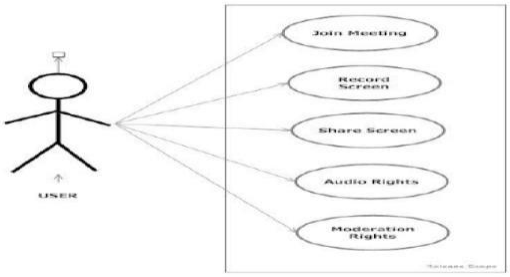

Fig 4. Use Case Diagram for conference - User

The user is only permitted to join the meeting when invited via an email, record screen, share screen, use the white board, and audio when given permission by the administrator.

Server Side Implementation: Server-side has relied on Node JS and MongoDB databases. Node JS is fast, capable of handling a large number of simultaneous connections with high throughput, which is equivalent to high scalability. MongoDB and Node JS have often been used together because of their using JSON so no need to spend time transforming the data between them making it easy to deal with each other. In addition, MongoDB provides TLS that makes a secure connection . To perform a client request passes through several steps that are:
Step 1: Initially, must run the MongoDB connection then run the Node JS from Command Prompt. At this stage, the server is ready to receive the client's request.

Step 2: When the client sends a request, the server receives the HTTP request in JSON format. The request then parsed.
Step 3: The HTTP request is compared with the base path if it is matched, it is handed to the Express framework.
Step 4: The Express receives the HTTP request and routes it to the specific endpoint that matched it. In case of not matching with any of the routes will display errors in Command Prompt. Otherwise, it will be forwarded to the controller which handles the required function. Step 5: Make a request to MongoDB database by mongoose for processing function.
Step 6: When the data is fetched from MongoDB database and the required operations are done, Node JS receives the response then sends to the client

Profanity Check Module:

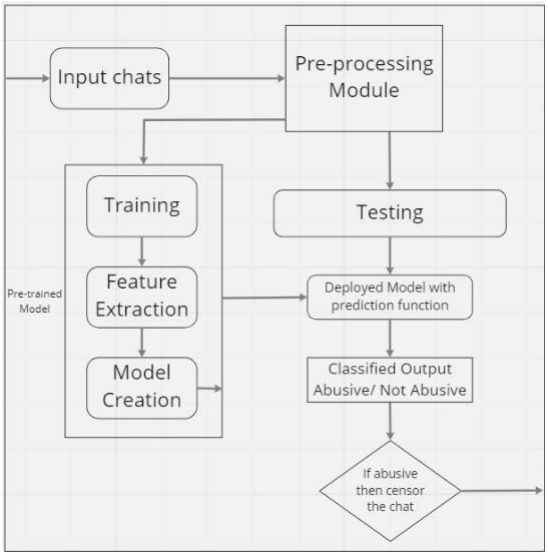

Fig 5. Profanity Check Model

Whenever a message is sent, it will pass on through the profanity check module. This module will pre-process the chat i.e removal of punctuations, numbers, conversion of text to lower case and NLP concepts of removing stop words, stemming, tokenization, named entity recognition and parts of speech tagging, it gives keywords from the chat. These keywords will be passed on through our trained model to decide the sentiment of the chat (abusive or normal).

V. CONCLUSION

We are building one application that will incorporate all the features for chatting as well as hosting meetings which previous products failed to provide.
From our research we can conclude that, the performance parameter can be improved by using the React framework, the concept of

virtual space improves the performance rate by only altering the space created for that specified request instead of making a call for the altering of the whole work area. So MERN stack is the best optimal technology to be used based on performance.

In this chat application the user will be able to type in their own language after selecting the language of their comfort, then the text will be recognized and translated to the language opted by the end user.

So, we will incorporate multi-headed machine learning models that are capable of classifying messages sent by users into varying degrees of toxicity. This application will track the use of offensive and vulgar language on chats on the platform in order to prevent users from becoming disrespectful which may play a role in changing how users interact.

VI. Acknowledgement

We the members of Group A08 would like to express our special gratitude to our institute, Thakur College of Engineering and Technology, our Principal sir - Dr. B. K. Mishra, Head of Department - Mrs. Harshali Patil, and our mentor Dr. Sheetal Rathi, for giving us this opportunity to work on solving the identified problem statement. We are developing a WebApplication named “PROTALK” by using various programming tools, Frameworks in multiple languages along with the assistance of Kaggle for the dataset. This has greatly helped us in expanding our knowledge. The project will be completed within the given scheduled time under the guidance of our mentor. We would also like to expand our deepest gratitude to all those who have directly and indirectly guided us in developing this project..

Online Student Evaluation and Assessment: Improving Student Performance through Technology

Shaurya Sharma, Mihir Tayshete, Aditya Sharma, Pratibha Prasad
Department of Information Technology
Thakur College of Engineering &
Technology(TCET),Kandivali East,
Mumbai
shaurya064@gmail.com, mihirtayshete@gmail.com, adityaraysharma@gmail.com, pratibha.prasad@thakureducation.org

Abstract— **Online learning has become a widely adopted mode of education in recent years, and with it comes the need for a reliable and efficient evaluation system. In order to address this need, this project aims to improve the assessment process for teachers and students. It provides a simple and effective way for teachers to assess student performance and for students to receive necessary tools and resources for their assignments. The system keeps students engaged with interactive features and performance analysis. Additionally, it delivers a more comprehensive evaluation of students' performance by considering different elements such as class participation, group work, and assignments. To maintain the authenticity of the finished assignments, unique certificates would be generated. This platform also implements measures to prevent instances of cheating among students. This enables teachers to have a better understanding of a student's overall competence.**

Keywords—assessment, student, certification, analysis

I. INTRODUCTION

The main aim of this project is to bridge the gap between student-teacher interaction in the online mode. To achieve this, separate modules have been created for both teachers and students, each with unique functionalities. Both the teacher and student have individual login systems for secure access.

Teachers can create courses that students can join, and the teacher or faculty in-charge can assign different tasks and assignments that are time-based. To prevent cheating during exams, the system has been designed to be tab-restricted, which means that students will receive a warning each time they switch tabs, and time will be deducted accordingly. Professors can also award students with certificates based on their performance in specific activities. These certificates can be verified using an ID generated during the certificate creation process.

In addition to promoting student-teacher interaction, the project also prioritizes students' access to proper learning resources. With this in mind, a note sharing feature marketplace has been implemented, where students can access and share learning materials. The website has been designed to be dynamic and user-friendly, incorporating modern technologies.

II. COMPARITIVE STUDY

The demand for effective online evaluation has significantly increased in recent years, as the recognition of distance learning and online education has led educational institutions to revamp their delivery methods, teaching strategies, and learning environments [1]. Online delivery has the potential to offer numerous benefits in promoting sustainable education, such as offering academic opportunities to students from diverse backgrounds, and broadening the dissemination of education [2].

However, the current online assessment system for students is outdated and does not offer the same benefits as the traditional offline system. Most online evaluations only provide a general overview of a student's performance, without highlighting their mistakes, and do not offer any opportunities for interaction with the teacher. Additionally, the online system is prone to cheating as students can easily switch tabs and access external resources. Table 1 shows the acceptance rate of an online e-learning platform Google Classroom for a dataset of 305 people [3].

Table I
Students Acceptance of Google Classroom

Attribute	Values	Population	Percentage
Gender	Male	78	26%
	Female	227	74%
Age	18-22	242	79%
	23-28	35	12%
	28+	28	9%

Education is a crucial aspect of an individual's growth and development, and it is essential to have a system in place that promotes a culture of learning, generates genuine interest in the subject matter, and provides students with the necessary resources to succeed [4]. With the vast amount of information available online, online learning has tremendous potential to positively impact the future of ed-tech. Improving online learning and assessment would play a significant role in shaping this future, and making the necessary enhancements to an already expanding system is vital [5]. Effective teaching techniques are crucial to a student's ability to absorb and understand the information being delivered, and good instructors create an environment that supports this learning.

The most noticeable issue found in the current system, as revealed by the comparative study, is the lack of a suitable learning environment for students and inadequate assessment system. To address this, the ideal solution would be a system that facilitates student learning and resolving doubts, with a user-friendly grading system.

III. TECHNOLOGIES USED

The website has been developed using the latest technology stack to ensure a seamless user experience. For the front-end, the proposed system has utilized ReactJS and Material UI. ReactJS is a highly effective JavaScript library that makes front-end development easier, and its component reusability and state handling capabilities making it the ideal choice. Material UI, a library of functional components, has further enhanced the user interface, making it visually appealing and interactive.

The back-end of the website has been built using NodeJS and ExpressJS. NodeJS is an event-driven asynchronous JavaScript runtime that is designed for building scalable network applications, making it perfect for the use case. ExpressJS is a minimal and flexible web application framework that provides a robust set of features for web and mobile applications, making it an ideal choice for the project requirements.

To store the data required by the application, MongoDB, a NoSQL database, and Firebase, a cloud-based database has been utilized. MongoDB provides a flexible database schema, which makes it an ideal choice for the proposed application. However, as MongoDB only allowed for video storage in chunks, Firebase was used to store the video lectures in their entirety. Firebase provides a range of features, including messaging, authentication, and storage, making it the ideal choice for this purpose. For testing the post and get methods, Postman has been used.

IV. WORKING & CHARACTERISTICS

The website has been designed and developed with three key modules in mind, each serving a specific purpose. These modules include the Student Module, Teacher Module, and Certification Module, each of which has been equipped with various functionalities to meet the specific needs and requirements. The website encompasses several key features, including:

• **Login system**: The website boasts a sophisticated login system that elegantly separates the set of features intended for students from those for teachers. This segregation is achieved through the utilization of a classifying attribute known as "type," as depicted in Fig. 1. To ensure the appropriate level of access, separate login credentials have been created for each group. The login system has been implemented using PassportJS and a session management mechanism, which securely stores the user's information. This information is then used to authenticate and validate each user's access to their respective modules.

The website's design considers the need to maintain a clear distinction between the student and teacher modules. This is to prevent unauthorized access and ensure that the website is used in an orderly, ethical, and organized manner. As a result, students cannot access the teacher module, and teachers cannot access the student module. This clear assignment of roles and responsibilities helps maintain the integrity of the learning community and reduces the potential for confusion or hastiness.

• **Creating & joining courses**: This platform aims to provide a comprehensive and organized learning experience for students and teachers alike. With its course creation module, teachers have the ability to create subject-specific courses that students can enroll in. These courses are designed to help reduce the amount of paperwork involved in the education process and provide an efficient means of grading and assessment.

The teacher is responsible for assigning tasks and assignments to students within the course. To prevent multiple entries from the same student, a unique course code is generated upon course creation and is distributed to students for enrollment purposes. This code is then used to verify the student's identity and grant access to the course.

The implementation of course-based classrooms helps streamline the organization of coursework, allowing teachers to focus on lesson planning rather than administrative tasks [6]. The digital grade book reduces the need for physical paperwork and eliminates the repetition involved in manually grading several assignments. It also prevents the physical strain associated with manual grading.

Inclusion of assignments in these courses is a crucial aspect of the platform. Assignments promote independent learning, as students are encouraged to work their way around the questions and overcome difficulties. Each time a student completes an assignment, they become more capable of independent learning, which is a valuable life skill.

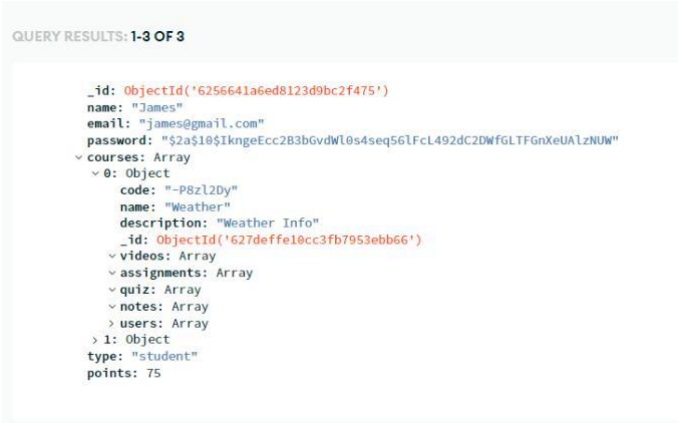

Fig. 1 User Schema Example

• **Video lectures**: The platform includes a video lecture feature, which is particularly beneficial for students who miss classes. The flexibility of the video lectures allows students to learn at their own pace and revisit certain concepts if they haven't understood them, promoting self-learning [7]. The combination of body language and tone of voice in video lectures makes the learning experience more engaging and impactful compared to the written word. Research has shown that video learning is beneficial for students in many ways, including motivation, learning depth, and critical thinking skills.

In a flipped classroom, students view video lessons as homework and engage in discussions with teachers during class time. The use of visual and aural clues in video learning enhances students' understanding and retention of new information. James McQuivey, an analyst with Forrester Research, states that one minute of video is equivalent to almost 1.8 million written words. Studies show that the combination of visual and audio learning leads to high engagement and improved outcomes [8].

The video lecture feature also enables the dissemination of educational knowledge to classrooms around the world [9]. A teacher from the comfort of their home can easily create a video tutorial for students, promoting cultural understanding and social empathy through information sharing. The platform's video uploading feature is an important tool for facilitating this type of global education.

• **Time Based Assignments**: Additionally, the platform's time-limited assignment feature as seen in Fig. 2, further promotes the integrity of the evaluation process. By setting a deadline for submission, the teacher minimizes the opportunity for students to engage in copying or cheating behaviors. Once the time limit has passed, the assignment is automatically submitted, and all marked answers are saved, providing a precise evaluation of the student's understanding and abilities. This feature not only ensures the validity of the evaluation process but also encourages students to prioritize their time and focus on their coursework.

Fig. 2 Time Based Assignments

• **Anti-Cheating System:** Platforms like Swayam provide intuitive assignments to students, but they lack anti-cheat measures [10]. To counter this, the platform has measures in place to prevent cheating during online exams. The students are warned a few times against changing tabs during the exam, and after that, any violation of this rule would result in a penalty such as deduction of time or reduction of scores. These measures aim to create a fair and equal evaluation process for all students, ensuring that their performance is based on their own abilities and understanding of the subject. The platform also promotes academic integrity and helps prevent any kind of unethical behavior. This way, students are encouraged to perform to the best of their abilities and achieve their full potential.

Fig. 3 Certificate on Course Completion

• **Reward System**: Rewards play a crucial role in an efficient behavior management method in the classroom. Both intrinsic and extrinsic motivation are important for driving students to perform well and follow expected behaviors.

Intrinsic motivation is when students find pleasure in their work and engage in it simply because they enjoy it. This can be fostered through compliments, individually demanding assignments, and completing academic work purely out of a desire to learn. On the other hand, extrinsic motivation involves providing more tangible rewards such as pencils, erasers, stickers, and even candy. It's important to provide rewards that are fair and consistent for all students, and also unique for each assignment.

Extending rewards to students helps to promote positive and appropriate behavior in the classroom. Students are encouraged to follow class rules, be kind to each other, and prioritize safety, among other positive behaviors. With appropriate student behavior, teachers are able to focus on lesson content and interactive activities, rather than spending time on classroom discipline.

Offering rewards also motivates students to give their full effort when attempting class projects, assignments, and various tasks. When a reward system is in place, students tend to show increased interest and participation in everyday classroom activities. The goal of assigning homework is to reinforce the subject matter, and without homework completion, students are not able to practice what they have learned. By rewarding students for completed projects and homework assignments, both in groups and individually, the teacher can promote a better understanding of the lesson.

Finally, it's important to note that after the student completes a set of assignments, they can be rewarded with a

certificate. The certificates can be auto-generated and will contain the student's name, course name, date of completion, email address, and a credential ID as seen in Fig. 3, which can be used to verify the credibility of the certificate. This helps to remove any concerns regarding the creation of fake certificates, as they cannot be validated.

Overall, a reward system is an effective tool for promoting positive behavior and encouraging students to be more productive in their learning.

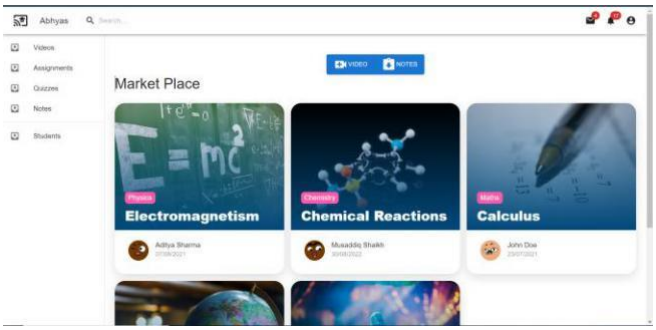

Fig. 4 Marketplace for Sharing Resources

• **Marketplace**: This helps students who do not have access to schools or colleges to get hands on high quality notes for further education and expand their knowledge base, as these notes can be accessed from anywhere with an internet connection. This also helps to bridge the gap between students from different socio-economic backgrounds, as all students will have equal access to the resources shared on the platform.

In addition, having a library of resources and study materials readily available can greatly benefit students in the long run. It can save students time and effort in searching for resources, and it also provides a platform for students to share their own resources with others. This not only supports student learning but also encourages collaboration and teamwork, which are crucial skills for success in both academic and professional settings.

In addition to notes, students can also share study tips, learning techniques, and other resources that have helped them excel in their studies. This can help create a supportive and collaborative learning environment where students can share their experiences and help each other grow.

Overall, the marketplace provides a unique opportunity for students and teachers to collaborate, share, and grow together, making the process of learning more efficient and enjoyable. An example of the mentioned feature can be seen above in Fig. 4.

• **Interactive whiteboard:** Interactive whiteboards are transforming the way education is delivered in the classroom. In addition to the many benefits, such as increased engagement and better learning experiences, there are even more advantages to using an interactive whiteboard in the classroom.

Firstly, interactive whiteboards promote collaboration between students and teachers. Fig. 5 shows both teacher's and student's perspective while using the whiteboard feature. With the use of interactive whiteboards, teachers are able to present learning materials in a more interactive way, allowing students to participate in the learning process by asking questions, providing answers, and working together on projects and assignments. This type of collaboration fosters a supportive learning environment, where students feel comfortable to engage with the material and each other, resulting in a deeper understanding of the subject.

Moreover, interactive whiteboards allow for immediate feedback and assessment. With the use of technology, teachers can quickly assess students' understanding of the material through interactive activities, polls, and games. This type of assessment not only helps teachers gauge students' learning but also provides students with instant feedback, allowing them to address any misunderstandings and reinforce their learning [11].

Interactive whiteboards also make it possible for students to save slides, which can be easily reused and adapted for future classes. This not only saves time but also ensures that all the lessons are consistent and up to date.

Interactive whiteboards are cost-effective and eco-friendly. As mentioned earlier, the use of interactive whiteboards reduces the need for traditional teaching supplies, such as paper and markers, reducing the overall cost of running a classroom. Furthermore, the use of technology also reduces the use of paper, which is not only good for the environment but also saves schools and colleges money on printing and purchasing resources.

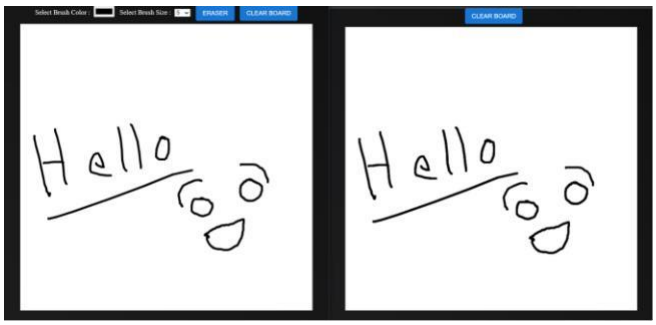

Fig. 5 Interactive Whiteboard for E-Learning

• **Analytics Dashboard:** One of the key features of the project is the Analytics Dashboard. This dashboard provides an in-depth analysis of the student's performance and their engagement with the course material. The Analytics Dashboard provides a comprehensive overview of the student's learning progress and provides insights into their strengths and weaknesses. The dashboard also helps teachers to identify the areas in which the student needs improvement, enabling them to customize their teaching approach accordingly. The analytics dashboard allows teachers to track the progress of each student in real-time and make data-driven decisions to enhance the learning experience. This feature provides teachers with the necessary information to create a personalized learning plan for each student, helping them to achieve their learning objectives and reach their full potential.

V. FLOWCHART

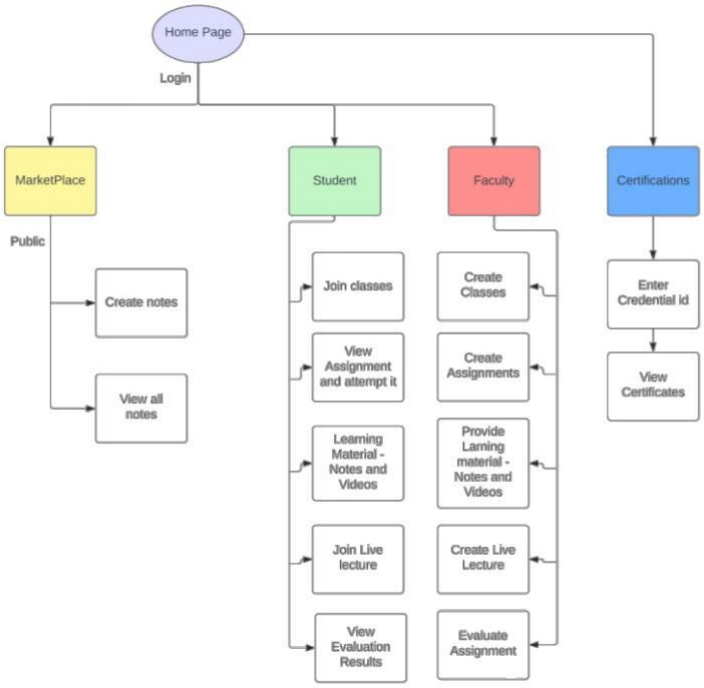

Fig. 6 Basic Architecture of the Project

Abhyas is a comprehensive platform for learning, teaching, and sharing knowledge that offers numerous features and benefits for both students and teachers. As mentioned in Fig. 6, here are some additional details about each of the four main modules:

1. Marketplace:

The marketplace is a platform where users can share their knowledge by uploading and selling their notes, video tutorials, and study materials. This platform serves as a hub for students and teachers to access a wide variety of resources and learning materials, making it easier for students to find the information they need to succeed in their studies. In addition, it also provides an opportunity for individuals to monetize their knowledge and skills by selling their materials to other students and teachers.

2. Student:

The student module is designed specifically to support students in their learning journey. This module includes a personalized profile that displays the student's certifications, as well as a dashboard that allows the student to access their enrolled courses, assignments, notes, live lectures, quizzes, and pre-recorded videos. With this module, students have everything they need to study effectively and efficiently, all in one place.

3. Faculty:

The faculty module is designed for teachers to create classes for their students, manage course materials, and assess students' progress. With this module, teachers can easily create classes, add assignments and quizzes, and keep track of student progress. Teachers can also assign certificates to students to recognize their achievements and progress, providing motivation and encouragement for the students to continue their studies.

4. Certifications:

Certifications are an important aspect of Abhyas, as they serve as a validation of the student's knowledge and skills. Certifications can be created by teachers, or they can be earned by students by completing a set number of quizzes from a particular class. Each certification includes a unique credential that can be used to verify the authenticity of the certificate, along with other relevant details, such as the student's name, course, and date of completion.

In conclusion, Abhyas is an innovative platform that provides students and teachers with a comprehensive solution for learning and teaching. With its numerous features and benefits, Abhyas makes it easier for students to access the information they need to succeed in their studies, and for teachers to create and manage effective learning environments.

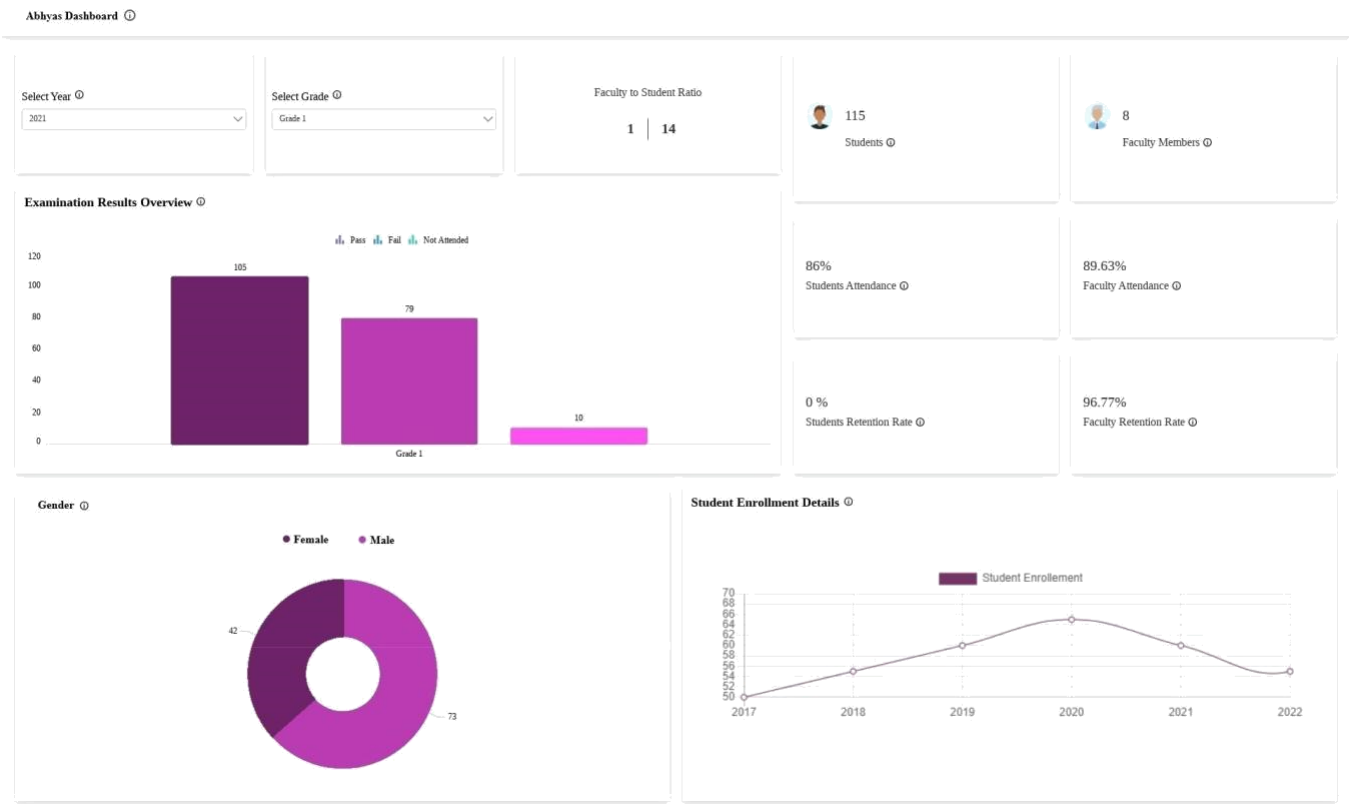

Fig. 7 Dashboard for Student Analytics

VI. CONCLUSION

With a thorough consideration of the various factors that greatly impact the current system of online learning, a meticulous study of the different methods and approaches in place has been conducted. Through this, several areas for improvement have been identified and necessary innovative and practical features to enhance the existing model of online learning and assessment have been developed. The proposed system aims to offer a comprehensive solution that meets the needs of both students and instructors, providing a seamless and efficient experience for all parties involved. The implementation of this project will be instrumental in furthering the advancement and success of online education.

VII. FUTURE SCOPE

The evaluation of performance in a test is an important aspect of any educational system. It helps students to understand their strengths and weaknesses and work towards improving in areas where they may be lagging behind. By feeding the results of these tests into a machine learning algorithm, the system can more accurately identify weak subjects and provide personalized recommendations for improvement. This can be a valuable tool for both students and educators alike. To make the system even more accessible and user-friendly, it can be ported into a mobile application that is easily loaded and used on the go.

Additionally, a reward system can be implemented to encourage students to actively participate in the platform. This reward system can recognize not just the completion of assignments but also the most active contributors and resource sharers in the marketplace. This will create a sense of community and encourage students to collaborate and share resources with each other.

To further enhance the system, the question sets in the assignments section can be broadened to include preparation for interviews and competitive examinations. This will not only help students to prepare for these important events but also give them a sense of the types of questions they may encounter in the real world. To keep track of individual performance, charts and graphs can be used to represent the academic growth of each student for each subject. This will provide a visual representation of progress over time and allow students and educators to track their success.

ACKNOWLDEMENTS

We are deeply grateful to our guide, Mrs. Pratibha Prasad, for imparting her vast knowledge and expertise, providing valuable feedback and mentoring us every step of the way. We would also like to thank our principal, Dr. B.K. Mishra, for providing us with the resources and facilities necessary to carry out our research. Finally, we are thankful to Thakur College of Engineering and Technology for providing us with a nurturing and dynamic environment where we could thrive academically and intellectually.

Face Mask Detection System Using Machine-Learning Algorithms

Raj Mazgaonkar,Ankush Kushwaha,Parth Langi,Anisha Prajapati,Dr. R.R.Sedamkar

Abstract: **. The world has not yet fully Recover from this pandemic and the vaccine that can effectively treat Covid-19 is yet to be discovered. However, to reduce the impact of the pandemic on the country's economy, several governments have allowed a limited number of economic activities to be resumed once the number of new cases of Covid19 has dropped below a certain level. As these countries cautiously restarting their economic activities, concerns have emerged regarding workplace safety in the new post- Covid-19 environment. To reduce the possibility of infection, it is advised that people should wear masks and maintain a distance of at least 1 meter from each other.Deep learning has gained more attention in object detection and was used for human detection purposes and develop a face mask detection tool that can detect whether theindividual is wearing mask or not. This can be done by evaluation of the classification results by analysing real-time streaming from the Camera. In deep learning projects, we need a training data set. It is the actual dataset used to train the model or performing various actions. Global pandemic COVID-19 circumstances emerged in an epidemic of dangerous disease in all over the world. Wearing a face mask will help prevent the spread of infection and prevent the individual from contracting any airborne infectious germs. Using Face Mask Detection System, one can monitor if the people are wearing masks or not. Here HAAR-CASACADE algorithm is used for image detection. Collating with other existing algorithms, this classifier produces a high recognition rate even with varying expressions, efficient feature selection and low assortment of false positive features. According to this motivation we demand mask detection as a unique and public health service system during the global pandemic COVID-19 epidemic. The model is trained by face mask image and non- face mask image**

Keywords- : COVID-19 epidemic, HAAR- CASACADE algorithm, mask detection, face mask image, non-face mask image...

I. INTRODUCTION

1.1 Motivation

Amid the ongoing COVID-19 pandemic, there are no efficient face mask detection applications which are now in high demand for transportation means, densely populated areas, residential districts, large-scale manufacturers and other enterprises to ensure safety. The absence of large datasets of 'with_mask' images has made this task cumbersome and challenging.

1.2 Application

Our face mask detector doesn't use any morphed masked images dataset and the model is accurate. Owing to the use of MobileNetV2 architecture, it is computationally efficient, thus making it easier to deploy the model to embedded systems (Raspberry Pi, Google Coral, etc.). This system can therefore be used in real-time applications which require face-mask detection for safety purposes due to the outbreak of Covid-19. This project can be integrated with embedded systems for application in airports, railway stations, offices, schools, and public places to ensure that public safety guidelines are followed.

II. PROBLEM DEFINITION

1. To create our face mask detector, we trained a two-class model of people wearing masks and people not wearing masks.

2. We fine-tuned MobileNetV2 on our masks/no mask dataset and obtained a classifier that is ~99% classifier.

3. We then took this face mask classifier and applied it to images by:

Detecting faces in images Extracting each individual face

4. Our face mask detector is accurate and since we use the MobileNetV2 architecture,it's also computationally efficient.

III. TECHNOLOGY USED

3.1 Hardware and Software Requirement

Operating Environment

- Operating System: Windows 8
- Processor: Intel I3 or Higher
- Memory: 4GB or more

Programming Language used : Python 3.9.9 (64-Bit)

Product Functions

- Preprocessing
- Training the Images
- Face Mask Detection
- Message Passing

Coronavirus disease 2019 has affected the world seriously. One major protection method for people is to wear masks in public areas. Furthermore, many public

service providers require customers to use the service only if they wear masks correctly. However, there are only a few research studies about face mask detection based on image analysis. In this paper, we propose RetinaFaceMask, which is a high-accuracy and efficient face mask detector. The proposed RetinaFaceMask is a one-stage detector,

which consists of a feature pyramid network to fuse high-level semantic information with multiple feature maps, and a novel context attention module to focus on detecting face masks. it will help the system to run the overall system to prevent the spreading the Covid 19 and easy to control the mob in a cost effective way. An Iot Component will send a message to the Concerned authority that it will help the entire system to function very smoothly.

platform and free for use under the open- source Apache 2 License.

Matplotlib :- Matplotlib is a plotting library for the Python programming language and its numerical mathematics extension NumPy. It provides an object-oriented API for embedding plots into applications using general-purpose GUI toolkits like Tkinter, wxPython, Qt, or GTK.

SciPy :- SciPy is a free and open-source Python library used for scientific computing and technical computing. SciPy contains modules for optimization, linear algebra, integration, interpolation, special functions, FFT, signal and image processing, ODE solvers and other tasks common in science and engineering.

IV. IMPLEMENTATION

4.1 Data Description

Step 1: Data Visualization

In the first step, let us visualize the total number of images in our dataset in both categories. We can see that there are 690 images in the ‘yes’ class and 686 images in the ‘no’ class.

The number of images with facemask labelled ‘yes’: 690

The number of images with facemask labelled ‘no’: 686

Step 2: Data Augmentation

In the next step, we augment our dataset to include more number of images for our training. In this step of data augmentation, we rotate and flip each of the images in our dataset. We see that, after data augmentation, we have a total of 2751 images with 1380 images in the ‘yes’ class and ‘1371’ images in the ‘no’ class.

Number of examples: 2751

Percentage of positive examples: 50.163576881134134%, number of pos examples: 1380

Percentage of negative examples:

49.836423118865866%, number of neg examples: 1371

4.2 Data Preparation

Step 3: Splitting the data

In this step, we split our data into the training set which will contain the images on which the CNN model will be trained and the test set with the images on which our model will be tested. In this, we take split_size =0.8, which means that 80% of the total images will go to the training set and the remaining 20% of the images will go to the test set.

The number of images with facemask in the training set labelled ‘yes’: 1104

The number of images with facemask in the test set labelled ‘yes’: 276

The number of images without facemask in the training set labelled 'no': 1096

The number of images without facemask in the test set labelled 'no': 275

After splitting, we see that the desired percentage of images has been distributed to both the training set and the test set as mentioned above.

4.3 Choice of Model

Step 4: Building the Model

In the next step, we build our Sequential CNN model with various layers such as Conv2D, MaxPooling2D, Flatten, Dropout and Dense. In the last Dense layer, we use the 'softmax' function to output a vector that gives the probability of each of the two classes.

4.4 Model Training and Validation

Step 5: Pre-Training the CNN model After building our model, let us create the 'train_generator' and 'validation_generator' to fit them to our model in the next step. We see that there are a total of 2200 images in the training set and 551 images in the test set.

Found 2200 images belonging to 2 classes. Found 551 images belonging to 2 classes.

Step 6: Training the CNN model

This step is the main step where we fit our images in the training set and the test set to our Sequential model we built using keras library. I have trained the model for 30 epochs (iterations). However, we can train for more number of epochs to attain higher accuracy lest there occurs over-fitting.

history =

model.fit_generator(train_generator,

epochs=30,

validation_data=validation_generator,

callbacks=[checkpoint])

>>Epoch 30/30 220/220

[==============================]

– 231s 1s/step – loss: 0.0368 – acc: 0.9886 – val_loss: 0.1072 – val_acc: 0.9619

We see that after the 30th epoch, our model has an accuracy of 98.86% with the training set and an accuracy of 96.19% with the test set. This implies that it is well trained without any over-fitting.

Step 7: Labeling the Information

After building the model, we label two probabilities for our results. ['0' as 'without_mask' and '1' as 'with_mask']. I am also setting the boundary rectangle color using the RGB values.['RED' for 'without_mask' and 'GREEN' for 'with_mask]

labels_dict={0:'without_mask',1:'with_mas k'}

color_dict={0:(0,0,255),1:(0,255,0)}

Step 8: Importing the Face detection Program

After this, we intend to use it to detect if we are wearing a face mask using our PC's webcam. For this, first, we need to implement face detection. In this, we are using the Haar Feature-based Cascade Classifiers to detect the facial features.

face_clsfr=cv2.CascadeClassifier('haarcasca de_frontalface_default.xml')

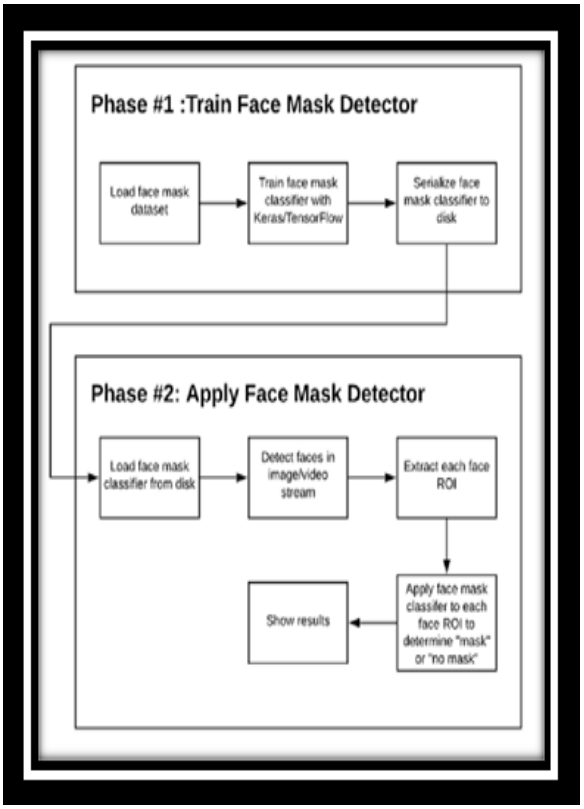
This cascade classifier is designed by OpenCV to detect the frontal face by training thousands of images. The .xml file for the same needs to be downloaded and used in detecting the face. We have uploaded the file to the GitHub repository.

Step 9: Detecting the Faces with and without Masks

In the last step, we use the OpenCV library to run an infinite loop to use our web camera in which we detect the face using the Cascade Classifier. The code webcam = cv2.VideoCapture(0) denotes the usage of webcam.

The model will predict the possibility of each of the two classes ([without_mask, with_mask]). Based on the higher probability, the label will be chosen and displayed around our faces.

Flow Chart of FaceMask Detection System

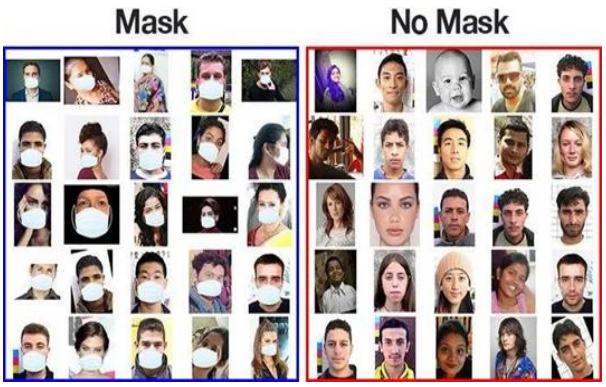


Face Mask Detection in webcam stream: The flow to identify the person in the webcam wearing the face mask or not. The process is two-fold.

1. To identify the faces in the webcam 2.Classify the faces based on the mask.

Identify the Face in the Webcam:

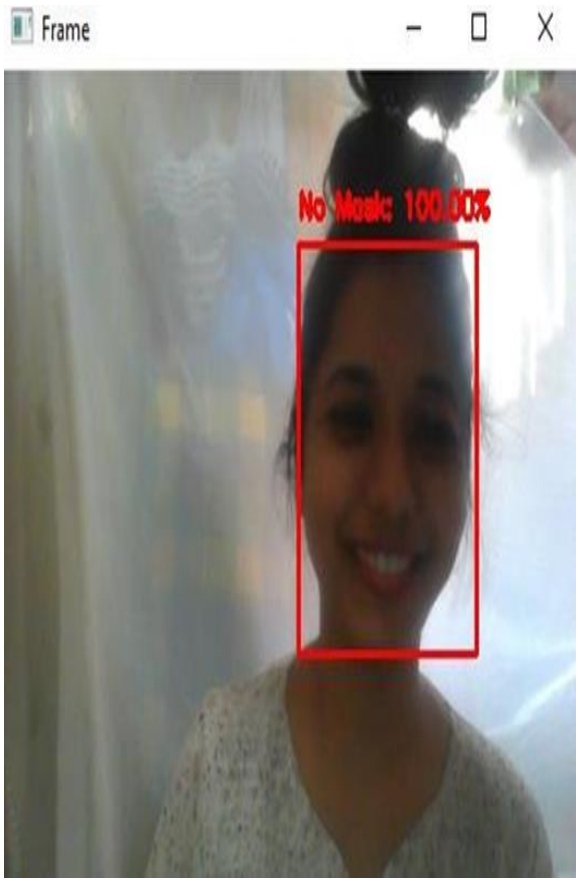
To identify the faces a pre-trained model provided by the OpenCV framework was used. The model was trained using web images. OpenCV provides 2 models for this facedetectorTraining Dataset :



Result and Analysis

REAL TIME INPUT :

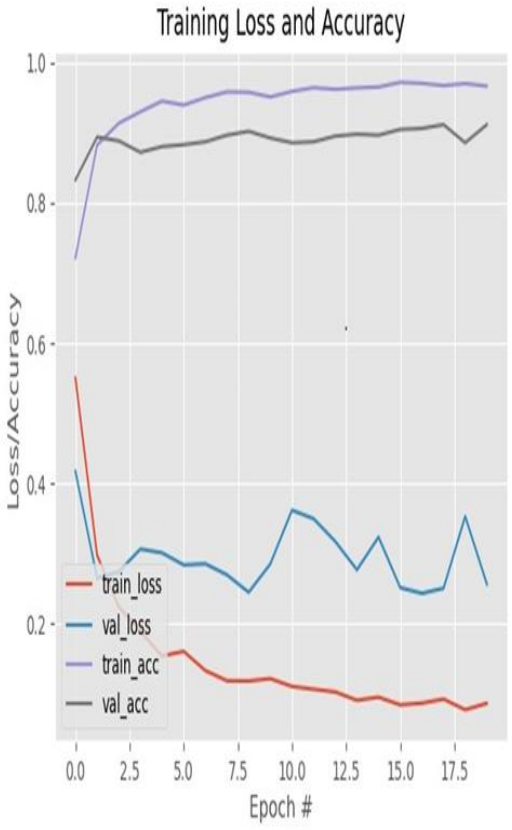
Live webcam



Here we can see that our mode is 100 % sure or accurate that a person is not wearing a mask.

Here we can see that our mode is 89.13 % sure or accurate that a person is wearing a mask.

V. REAL TIME OUTPUT :



VI. CONCLUSION AND FUTURE SCOPE

In this project, we have proposed a novel face mask detector, namely FaceMask Detection System, which can possibly contribute to public healthcare. The architecture of FaceMask Detection System consists of CNN as backbone, FPN as the neck, and context attention modules as the heads. The strong backbone ResNet and light backbone MobileNet can be used for high and low computation scenarios, respectively. In order to extract more robust features, we utilize transfer learning to adopt weights from a similar task face detection, which is trained on a very large dataset. Furthermore, we have proposed a novel context attention head module to focus on the face and mask features, and a novel algorithm object removal cross class, i.e. ORCC, to remove objects with lower confidence and higher IoU. The proposed method achieves state-of- the-art results on a public face mask dataset. An Iot component is added to the System to display the messages in a hardware. the data from the program is collected by the Iot

hardware and it will dispalyed as the warning signal to the concerned authority.

Future Scope :

some countries with strong vaccination records may now have lower immunity than others but If suppose in future we come across similar condition like COVID19 and lockdown is again applied on the whole world, our project will be most helpful during such pandemic condition. We will link our python code / software to a hardware like self opening doors like in malls and other public places where the door will not open until a person is wearing a mask. This will help people to be more protected and safe. As far as the efficiency of our project goes, we can enhance the accuracy of this model by more image Training , and also proper lighting and usage of efficient cameras the accuracy of the system can be improved.

Abstract— **There are different ways for communication between normal people and physically impaired people. Out of those commonly used way is sign language. Sign language is natural language used by physically challenged people for communication between their communities as well as with normal people. Sign language changes country wise. Each country uses its own sign language and some with more than one. Due to this diversity sign language recognition is very challenging and complex. Researchers have made significant advancement in the field of recognition of sign language and it is ongoing. Existing research focuses on different portions of sign language recognition with processing, segmentation, feature extraction, classification using machine learning algorithms, deep learning approaches or sensor based. This paper covers overview of all approaches used, pros n cons of existing systems and future scope in this field.**

Keywords: - Deep learning, Feature extraction, Gesture recognition, Internet of things, Machine learning, Sign language.

I. INTRODUCTION

Sign language is natural language used by deaf people has its own lexicon, grammar. This is most commonly used method of communication for deaf and dumb community. Sign language varies country wise. Each country has uses own native sign language. Significant work is made by researcher in Indian Sign Language. But, Indian Sign Language (ISL) recognition is complex due to its diversity and use of two hands for performing gestures. The challenges in sign language recognition are detecting hand gestures, head movements, facial expressions, hand shapes, finger detection, rotation of hands, etc. In addition to this, inaccurate gesture, occlusion, speed of movements can produce complexity in recognition. Human speech generates 1D signal whereas sign language generates 2D signals from input data when captured in digital format.

Sign language recognition is growing area in human computer interaction. Gesture recognition, action recognition, feature extraction helps in human computer interaction, human robot interaction and communication between hearing impaired and speaking people. Gesture can be recognized by vision based or glove-based approach. In glove-based approach, users have to wear sensors and bear sensor hardware in entire operation. In vision-based approach, use of image processing techniques, video processing algorithms used to detect hand movements, head movements along with facial expression.

Many research works have been done with image processing, feature extraction methods, segmentation methods, classifier-based approaches, glove-based approach, vision-based approach, using static gestures, dynamic gestures, video processing, artificial neural network, CNN, RNN, deep learning, support vector machine and IOT technologies. Although use of neural networks, deep learning algorithms and sensor recognition giving greater accuracy, the recognition of sign language from video input with different execution speed is challenging task to address. Another challenge is use of dataset. Standard datasets are not available for all sign languages. Mostly, researchers are creating their own dataset for training and testing of systems.

This paper is intended to provide a comparative study of sign language recognition and identify gaps that need to be addressed, what is achieved till now and future direction of research. This paper is organized as: Section 2 introduces an overview of sign language recognition. Section 3 covers comparative study existing systems. Section 4 presents research gap and challenges. Section 5 Conclusions.

II. AN OVERVIEW OF SIGN LANGUAGE RECOGNITION

Sign language recognition, gesture recognition plays important role in bridging the communication gap between hard of hearing

people and normal people. A block diagram of sign language recognition is shown in fig. 1. The flow of proposed system is as follows: input to system is video containing signs, image frames, noise elimination, feature extraction, classification. The output is text or speech indicating sign from input video.

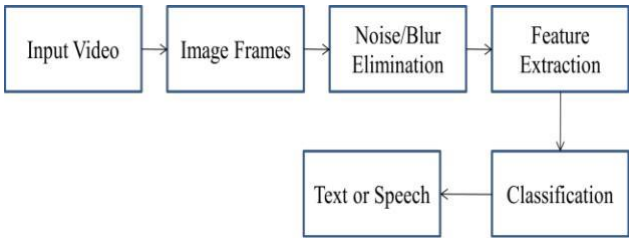

Figure1. Block diagram of sign language recognition

Preprocessing:

A process of removing noise from data by varies stages like filtering, sampling, normalization is called preprocessing. The raw data captured by camera or other capturing devices may get corrupted due to noise or environmental conditions. Direct processing of such data may not be suitable for system performance.

Feature Extraction:

A feature is characteristics of an entity. Feature extraction is process of deriving informative values, image dimension reduction and reduction in data size which improves performance of classification and recognition.

Classification:

Classification is process of identifying class of data. Feature vector from training dataset used to train classifier. In testing phase, trained classifier predicts class of sign. Input sign can be image or video. Different classifiers available are: Artificial neural network, k-Nearest Neighbor, Hidden Markov Models (HMM), Naïve bayes, Support Vector Machines (SVM), etc.

III. LITERATURE REVIEW

In [1], system created based on vision-based approach taking video sequence as input and extracting spatial features from them using CNN, RNN algorithm. American Sign Language dataset is used. Problem faced in testing facial features and different skin tones which led to loss of accuracy.

In [2], the approach of data driven system for extraction of spatial and temporal features using 3D-CNN from video stream is proposed. To improve performance dynamic dataset captured with Kinect sensors is used. This approach achieved Jaccard Index score of 0.836. In future direction, capturing temporal information from video with convolution strategy is not gives better result on dynamic sign language recognition.

In [3], a vision-based gesture recognition approach is proposed which recognizes single handed signs, double handed signs and finger spelling alphabets of Indian Sign Language (ISL) from video input with accuracy of 91% in finger spelling alphabets, 89% accuracy in single handed signs. 3D gestures, non-manual signs not considered in system.

In [4], selfie video-based sign language recognition method on mobile platform is introduced. Sign language feature space is created by processing video frames. Artificial neural network, minimum distance classifiers used for training and testing purpose. Word matching score is considered for performance measurement. Real time constraints in background of video vary due to movement of selfie stick.

In [5], multi model framework is designed for recognition of sign using Leap motion and Kinect sensors. Along with sign gestures facial data plays important role in sign language communication. 51 dynamic sign words collected as dataset for gesture recognition. Recognition rate of single hand and double hand gestures are 96.05% and 94.27% respectively.

In [6], model of 3D sign language recognition proposed based on graph kernels. The approach used is a relative range of joint relative distance to extract motion features of hand, fingers. Dataset contains 500 signs of ISL (Indian sign language).

A comparative study of different sign language recognition techniques is shown in Table 1.

Table1. Comparison Table

Reference	Technique or Algorithms used	Remark	Accuracy
[7]	Rule based method, Dynamic Time Warping-based methods for words. Sentence interpretation using inverted indexing.	Increased vocabulary size accuracy rate decreases	Average recognition rate: 96.25%
[4]	Minimum Distance and Artificial Neural Network classifiers. Segmentation, Pre-filtering and contour detection with Gaussian filtering used.	Single handed signs, background of video changes due to selfie stick movement reduces accuracy	Word matching score: 90.58%
[8]	Convolutional Neural Networks, Softmax regression method is adopted in classification.	Constant video background	Recognition rate: 92.88 %
[6]	Depth matrix, a dynamic naive Bayes classifier and 1-nearest neighbor strategy used	Computation of Depth matrix takes a maximum of 2ms time	Accuracy: 96.2% Mean accuracy: 95.2% of dynamic gesture dataset
[15]	Hand gesture using web camera, HSV color algorithm, dilation and mask operation, Convolutional Neural Network (CNN)	More alphabet recognition to improve accuracy of system.	90%
[16]	Support vector machine (SVM), deep learning-based classification used for emergency hand gestures	More sample need to be added in dataset & improve the efficiency of SLR, HGR techniques.	Multiclass SVM with accuracy 90%. Deep learning method accuracy 96.25%.
[14]	Faster R-CNN model, ResNet-50, C3D model, I3D model, Feature Pyramid Network (FPN), I3D with RGB-MHI, I3DCRGB-MHI	After adjustments in model classification accuracy increased to 92.43%. In future, testing will be on continuous SLR domain.	71.95% classification accuracy with single image, different models accuracy 89.30%, 90.18% & 91.13%.
[9]	NumPy, Scikit-learn, Pandas, Tensor Flow (version: 2.0), core-i7 processor with NVIDIA GeForce GTX 1050 Ti GPU (CUDA Cores: 768), Python 3 (version: 3.6) and 16 GB physical memory. NVIDIA Tesla K80 GPU, Google Colab platform.	Creation of open-source, high quality BSL dataset for future researchers.	Character recognition accuracy, f1-score, precision, recall values of 91.67%, 91.47%, 93.64%, 91.67% and 97.33%, 97.37%, 97.89%, 97.33% for digit recognition.
[10]	ATMEGA 2560 microcontroller board, robotic hand, Android-based mobile application with speech recognition capabilities, materials (expandable rubber, bathroom Slippers, straw pipe, tiny rope) and three servo motors	Considered only single hand ASL but ASL can also be communicated using two hands and also can include the facial expression. This prototype can extend to two hands with fully robotic body.	Accuracy 78.43% and an average response time is 2s.
[13]	Conductive knit, coupling with an accelerometer, deploying machine learning. The glove an ST microcontroller, long short-term memory (LSTM) neural network, a leave-one-experiment- out cross validation this methodology used.	They have shown the potential ofcombining machine learning with novel soft sensors with state-of-the-art microcontrollers.	Accuracy of 96.3% of segmented and predictions 92.8% with real-time streaming trails

IV. RESEARCH GAP AND CHALLENGES

The parameters used for performance measurement are accuracy, f-score, precision, recall, efficiency, robustness, dataset or dictionary size, speed, power consumption and cost. But, not all researchers use all mentioned parameters for evaluation. The survey reveals that even though number of research papers covering Indian sign language recognition problem. There are some constrains and challenges not yet handled and there is scope for improvement.

Research Gap and Challenges:

1. There are no any clear norms which help in selection of feature extraction techniques.
2. There are no standard specifications for input images or video.
3. Selection of classifier for recognition is challenging.
4. Complexity in two handed signs not yet resolved completely.
5. Image or video background variation is constraint in processing.
6. There is no standard dataset.
7. Signer independence
8. Static gesture recognition

V. CONCLUSION

The comparative study indicates that, advancement of Indian sign language recognition research based on videos. Still, full fletched generalized system is not yet available which covers all aspects of Indian sign language recognition. This paper is addressing the challenges in recognition of gesture, sign language and future area of research. Use of more deep learning approaches, IOT techniques for gesture and sign language recognition can improve accuracy and performance of the system.

***Abstract*— The air quality index is a quantitative measure used by governments around the world to quantify air pollution as a numerical value. Forecasting hourly AQI is a complicated task as the data is very fluctuating, making it difficult for models to understand patterns. Advancements in machine learning and deep learning models has shown increased growth in time series applications across different domains. This research studies different machine learning and deep learning-based techniques for AQI forecasting for six different locations across the city of Mumbai. The results of these techniques are evaluated using standard metrics such as RMSE and MAPE. Linear regression and its regularized variants, LSTM and GRU for the single step ahead dataset, have obtained the most accurate forecast. All the models have miserably failed for multi-step ahead variant of dataset. Result obtained by SARIMAX model has outperformed several machine learning algorithms.**

***Keywords*—** *AQI; Machine Learning; Deep Learning; LSTM; GRU;*

I. INTRODUCTION

As per World Health Organization, across globe, 9 out of 10 people live in locations where air quality exceeds normal WHO guideline limits, resulting in 7 million premature deaths annually [1]. Degradation in air quality can happen due to vehicular traffic, industrial waste, cigarette smoke, organic compounds, etc. This activity generates a lot of harmful gases, which can make the surrounding air hazardous
[3]. Government agencies across the globe use the air quality index (AQI) as a health monitor to measure the concentration of harmful gaseous as well as particulate pollutants in the air. The air quality index (AQI) informs people about the quality of the air they breathe. The AQI is based on a linear relationship between air pollutants like PM10, CO, NO2, SO2, Ozone, and others [6]. Precise forecasting techniques are a must so that people with any respiratory morbidity can take the necessary precautions before stepping out.

To make accurate forecasts, data plays a crucial role in the entire process. The AQI is a univariate time series, which means that it has only one variable that changes over time. Models are trying to forecast future values of AQI using its past values at different time intervals. Univariate time series are actually trying to learn the relationship between variables under observation and temporal information. It is collected using sensors located at different locations. Due to malfunctioning or abnormal weather conditions, the sensors might not work, resulting in inconsistent data. However, filling these missing values based on data distribution is a great challenge [4].

With the advancement of machine learning (ML) and deep learning (DL), every day there are new univariate time series applications being built. Because time series must be stationary [12] for traditional statistical methods such as ARIMA and its variants to make precise forecasts, differencing or log transformation is required, additional processing that is not needed when using machine learning-based methods. Because of their ability to generalize and be robust, RNNs and their variants have become more viable methods for making accurate predictions in recent years than traditional statistical methods.

The intention of this study is to compare and build an hourly air quality index forecasting model using the SARIMAX method, powerful ML models like linear regression, support vector machine, lasso regression, ridge regression, K-Nearest neighbour regression, and random forest, and extremely potent DL models like RNN, LSTM, and GRU. The organization of the paper is as follows: Section 2 contained related work in the fields of univariate time series analysis and models that have worked specifically for AQI forecasting from around the world. Section 3 deals explain three different pipelines followed for this experimentation. Section 4 of the paper shows data visualization and results were compared using performance metrics.

II. LITERATURE REVIEW

Hong et al. [2] investigated various air pollutants and the API for Labuan, Malaysia, and concluded that exponential smoothing techniques produce better results for CO and SO2, whereas the SARIMA model produces better results for PM10, NO2, O3, and API. In this paper [3], the authors have compared the LSTM and ARIMA models and proposed an LSTM model with some hyperparameter settings.

Authors [5] claim that ANN, SARIMAX, and modified SARIMA with exogenous variables have worked better for day-ahead forecasting, while the univariate SARIMA model has outperformed for intra-day forecasting in the majority of months. Pasupuleti et al. [6] have created an IoT-based solution where the concentration of different pollutants is measured using sensors, and then models like linear regression, decision trees, and random forest are examined. Random forest has resulted in better prediction accuracy.

This paper examines machine learning-based regression models such as linear regression, extra trees, XGBoost, KNN, elastic regression, etc. for precisely forecasting AQI for the

city of Delhi. All models have achieved pretty decent accuracy, with Extra Tree being the best with 85% forecast accuracy [7]. Authors [8] have divided forecasts into clean air and unhealthy air forecasts, and they have investigated linear regression, neural networks, and genetic programming. All three models have worked well for clear air forecasts, but for unhealthy air, linear regression and genetic programming have outperformed neural networks.

Chattopadhyay and Chattopadhya [9] have performed a comparative analysis of a statistical method ARIMA and an auto-regressive neural network (ARNN) for predicting rainfall. ARNN has produced better results, and the model was evaluated using scatter plots and Willmott's index. Phan et al. [10] have made a comparative study of different models on five univariate time series and observed that a feed-forward neural network has provided better accuracy, whereas when shape and dynamics are considered, dynamic time wrapping has provided better results.Another application of univariate time series i.e. Long Term Wind Speed Forecasting [11] was studied and LSTM has produced better RMSE and MAPE results in comparison with ARIMA and ANN.

III. METHODOLOGY

The entire experimentation can be summarized in Figure 1, which shows the different pipelines followed for the SARIMAX method, ML-based methods, and DL techniques. For all three pipelines as shown in figure 1, data acquisition and preprocessing steps are same. The data collection process involves gathering data from multiple stations, namely, Colaba, Mazgaon, Kurla, Bandra, Malad, and Deonar, located in different parts of the city of Mumbai. Collected data is an univariate time series that contains temporal information and AQI levels at each instance. Since these datasets involve the capture of information through sensors installed at different locations by the government of India, there have been times when sensors have malfunctioned, resulting in missing values in the dataset across stations [13]. Analyzing, studying, and visualizing missing data is a laborious task. Hence, a machine-learning based random forest imputer is used to impute or fill in the missing data. After imputation, the data is fed to anomaly treatment [14], which is a two-stage process: (i) finding anomalies using cluster-based techniques, namely, Density-Based Spatial Clustering of Applications with Noise (DBSCAN), and (ii) imputing those anomaly points using a random forest imputer.A.SARIMAXSARIMA(p, d, q) x (P, D, q)s is a generalization of the SARIMA model, where p, d, q are non-negative integral values defining the polynomial orders of autoregressive (AR), integrated (I), and moving average (MA) for the time series' non-seasonal component, and P, D, Q represents the same quantity but for the seasonal component [5]. Along with the seasonal component, the SARIMAX model includes EXogenous variables. As shown in fig 1, Augmented Dickey Fuller (ADF) test was performed on data to check for stationarity, followed by finding best SARIMA orders using auto-arima package. Before applying SARIMAX method, data was divided into 70:30 train test sets respectively and eventually forecasted values where compared with actual values using performance metrics.

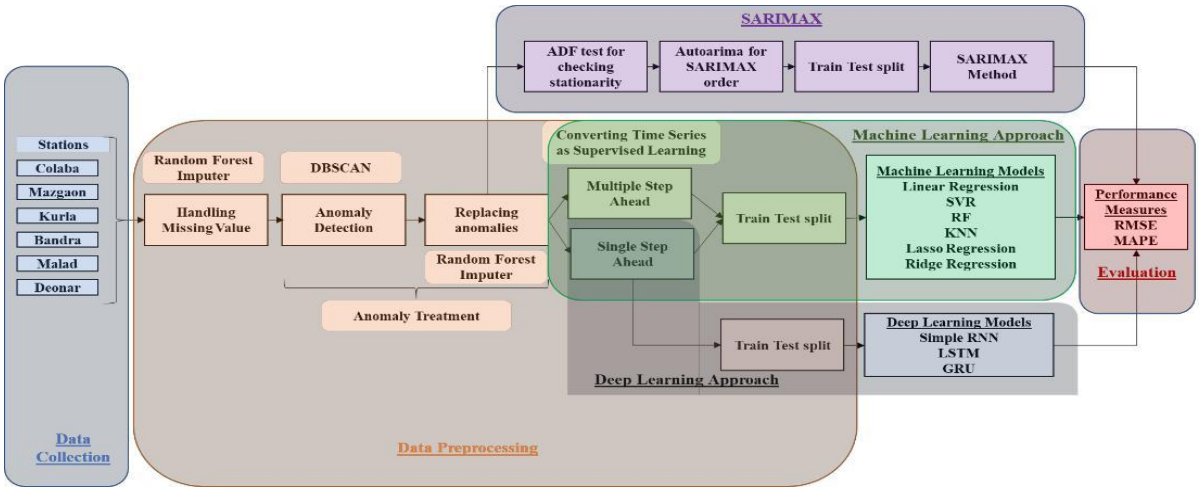

Fig. 1. Different pipelines followed for SARIMAX, ML and DL methods.

B. Machine Learning (ML) Models

There were several ML models studied to understand the competency of these models in analysing and forecasting AQI. For ML models, univariate time series data set was transformed to supervised learning datasets, where two variants were used for forecasting, they were single-step ahead (SSA) and multi-step ahead (MSA). As shown in Figure. 2, for a single-step forecast, one week of actual data, i.e., t = 24*7, is used to predict the next value, whereas for a multi-step forecast, the first value of one week of actual data

is rolled out and a newly predicted value is appended to predict the next value [15].

Similar to SARIMAX pipeline, same 70:30 ratio is used to create train test split. To perform a comparative experimentation, different ML models such as, linear regression (LR) [16] and its regularized variants such as lasso regression (LsR) and ridge regression (RiR) [17] which uses l1 and l2 regularization respectively. are implemented. Another algorithm implemented was support vector regression (SVR), which is one of the machine-learning-supervised regression models used for forecasting. Like linear regression, SVR seeks the best-fit line, which is a hyperplane with the greatest number of points [18].

One of the distance-based ML model implemented is K nearest neighbor (KNN). It is a supervised machine learning algorithm that uses a distance-based metric like Euclidean distance to calculate similarity between test samples and training samples. Based on this similarity score, the k closest training samples are considered for local interpolation of the test samples [19] Lastly, advanced ML concepts like ensemble learning was also explored where random forest algorithm was implemented which uses bagging technique. In this, various subsamples of the dataset are created by randomly bootstrapping and aggregating it. RF is a meta-model that combines the results of different decision trees created on these subsamples. This averaging of results helps improve forecast accuracy and also prevents the model from overfitting [20].

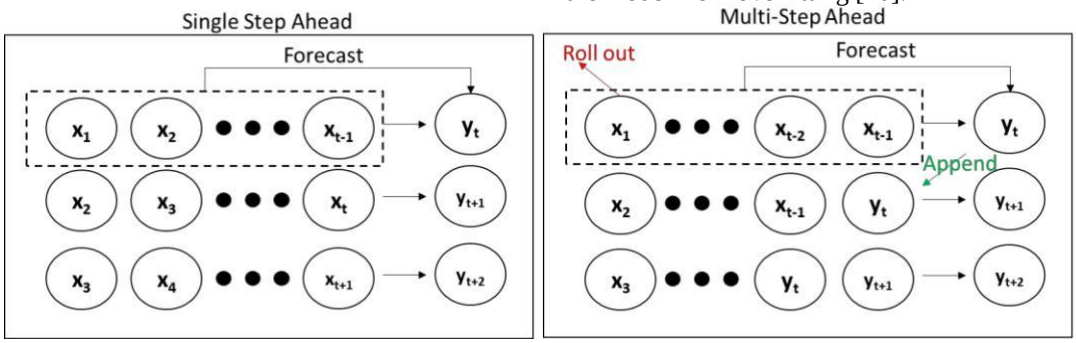

Fig 2. Single step ahead and multi-step ahead forecast

C. Deep Learning (DL) Models

To understand impact of deep learning, three variants of deep networks such as, recurrent neural network (RNN), long short-term memory (LSTM) and gated recurrent unit (GRU) were also implemented.

Figure 3 shows a cell of the RNN model. In this case, X, A, and Z represent the input, hidden layer, and output values, respectively. whereas U, W, and V are weights from the first layer i.e. input layer to the hidden layer, weights between different hidden layers, and weights from the hidden layer to the final layer i.e. output layer [23]. It is clear from the diagram, for instance, that the hidden value, At, is the function of input Xt and values from the previous instance, At-1. Hence, current output Yt depends on At, which in turn is determined by previous values such as At-1, At-2, At-3, and so on, which may result in a disappearing gradient problem because the sequence can be very large.

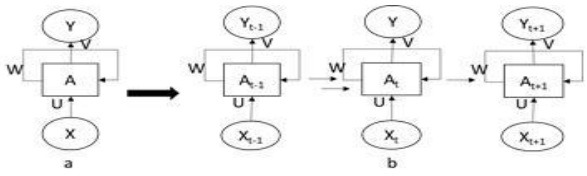

Fig.3. a. Structure of RNN cell b. Expanded diagram of RNN modelAnother architecture implemented was GRU were working is same as RNN; the difference is in internal structure. GRU has two gates: i) the update gate, which determines whether or not the cell state needs to be updated with the current state, and ii) the reset gate, which indicates how important previous state information is. Final cell status depends on the output gate, i.e., whether new content will be updated or old content is retained [22]. LSTM was created to solve the vanishing or exploding gradient descent problemUnlike GRU, LSTM has three gates: i) The input gate decides what information needs to be saved between the current input and the previous short-term memory; ii) The forget gate chooses whether to discard or keep information from long-term memory by multiplying this information with the current input and short-term memory; iii) The output gate produces new short-term memory that will be forwarded to the next cell in sequence using inputs as current input value, value form previous short-term memory, and value from newly calculated long-term memory

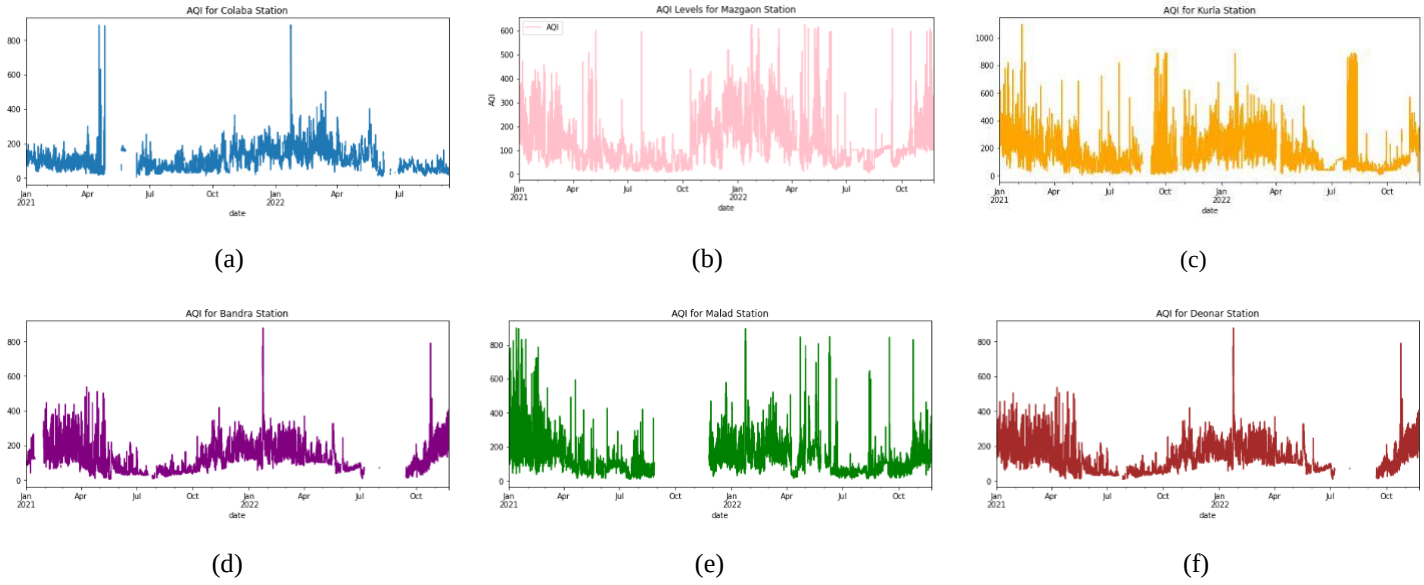
IV. Experimentation and Results

For this experiment, multiple datasets for all six stations, namely, Colaba, Mazgaon, Kurla, Bandra, Malad, and Deonar, are fetched from the Central Pollution Control Board (CPCB) [22], which contains hourly frequency data from January 1, 2021, to November 23, 2022. Figure 4 shows how AQI index varies with respect to time across different stations. The procedure followed for this study included data retrieval, filling in missing values, performing an anomaly treatment, splitting into train test sets, and finally applying multiple models. For handling the missing values, a random forest imputer is used because there is no assumption about the data being normal, and unlike parametric models, it does not require any specifications [21]. The algorithm of choice is a random forest with 20 trees in the forest and the Gini Index as an attribute selection measure, and an iterative imputer strategy that runs 10 rounds of the random forest algorithm is

used for final imputation. For anomaly detection, the DBSCAN algorithm is used, with eps set to mean values after imputation and min_samples set to the number of data points in a week.

For deep learning models, after anomaly treatment, data was passed to the min-max scaler for normalization and then split into train-test sets and fed to DL models. For all deep learning network, one dense layer with 7 hidden units with tanh activation was used. For optimization, Adam optimizer with learning rate 0.01 was used and all three models were trained for 500 epochs.

Figure 5 is a visual representation of the actual and forecasted values of the AQI for different models. It is observed that for all machine learning models, the multistep-



(a) (b) (c)

(d) (e) (f)

Fig. 4. a.- f, Data visualization of raw data for stations Colaba, Mazgaon, Kurla, Bandra, Malad, and Deonar respectively

ahead configuration has resulted in poor forecasts. From this figure 5, it is clear that SARIMAX, linear, lasso, and ridge regressions, as well as LSTM and GRU, have performed better in forecasting the AQI for Colaba station, similar results were achieved for other stations also.

For evaluating the performance, we have used two metrics: a) RMSE (Root Mean Squared Error) and b) MAPE (Mean Absolute Percentage Error). RMSE values are an indicator of how far data deviates from the actual value. As shown in Table 1, the best RMSE value achieved is 17.02 for the linear regression model for Bandra station. When comparing RMSE, SARIMAX, and deep learning methods, they have also resulted in better values. For almost all stations, SVR has performed poorly, with RMSE values reaching 128.64. From table 1, it is clear that the lowest MAPE value of 8.7% was obtained by the GRU model again for Bandra station. When looking at MAPE values for some stations, even random forest has given considerably good results.

Station		Sarimax	LR		SVR		RF		RR		LsR		KNN		RNN	LSTM	GRU
			SSA	MSA	SSA	MSA	SSA	MSA	SSA	MSA	SSA	MSA	SSA	MSA			
Colaba	**RMSE**	23.2	**18.6**	54.3	30.3	121.1	21.7	83.5	**18.6**	54.3	**18.5**	54.3	34.6	107.8	53.9	**18.4**	**18.4**

Table 1. RMSE and MAPE values for forecasting models (Best results are in bold)

V. CONCLUSION AND FUTURE SCOPE

Forecasting the AQI is a challenging task because the data is highly unstable, has high variability, and is very dynamic in nature. The work demonstrated is an examination of various techniques for univariate time series analysis. The results show that, while deep learning techniques have gained popularity, SARIMAX produced better results in some

scenarios, indicating that adding exogenous variables, i.e. multivariate time series analysis, can improve forecasting accuracy.

It is evident from the results of linear regression, lasso regression, and ridge regression that adding regularization of different orders for these datasets has nearly no impact on forecasting. Considering RMSE and MAPE for all six stations, linear regression, LSTM, and GRU have performed significantly better, while models like support vector machines and K-nearest neighbors have failed miserably. It is also believed that single-step ahead variants of models have performed far better than their multi-step-ahead variants.

In the future, forecast accuracy can be enhanced by including other factors like pollutant levels, meteorological

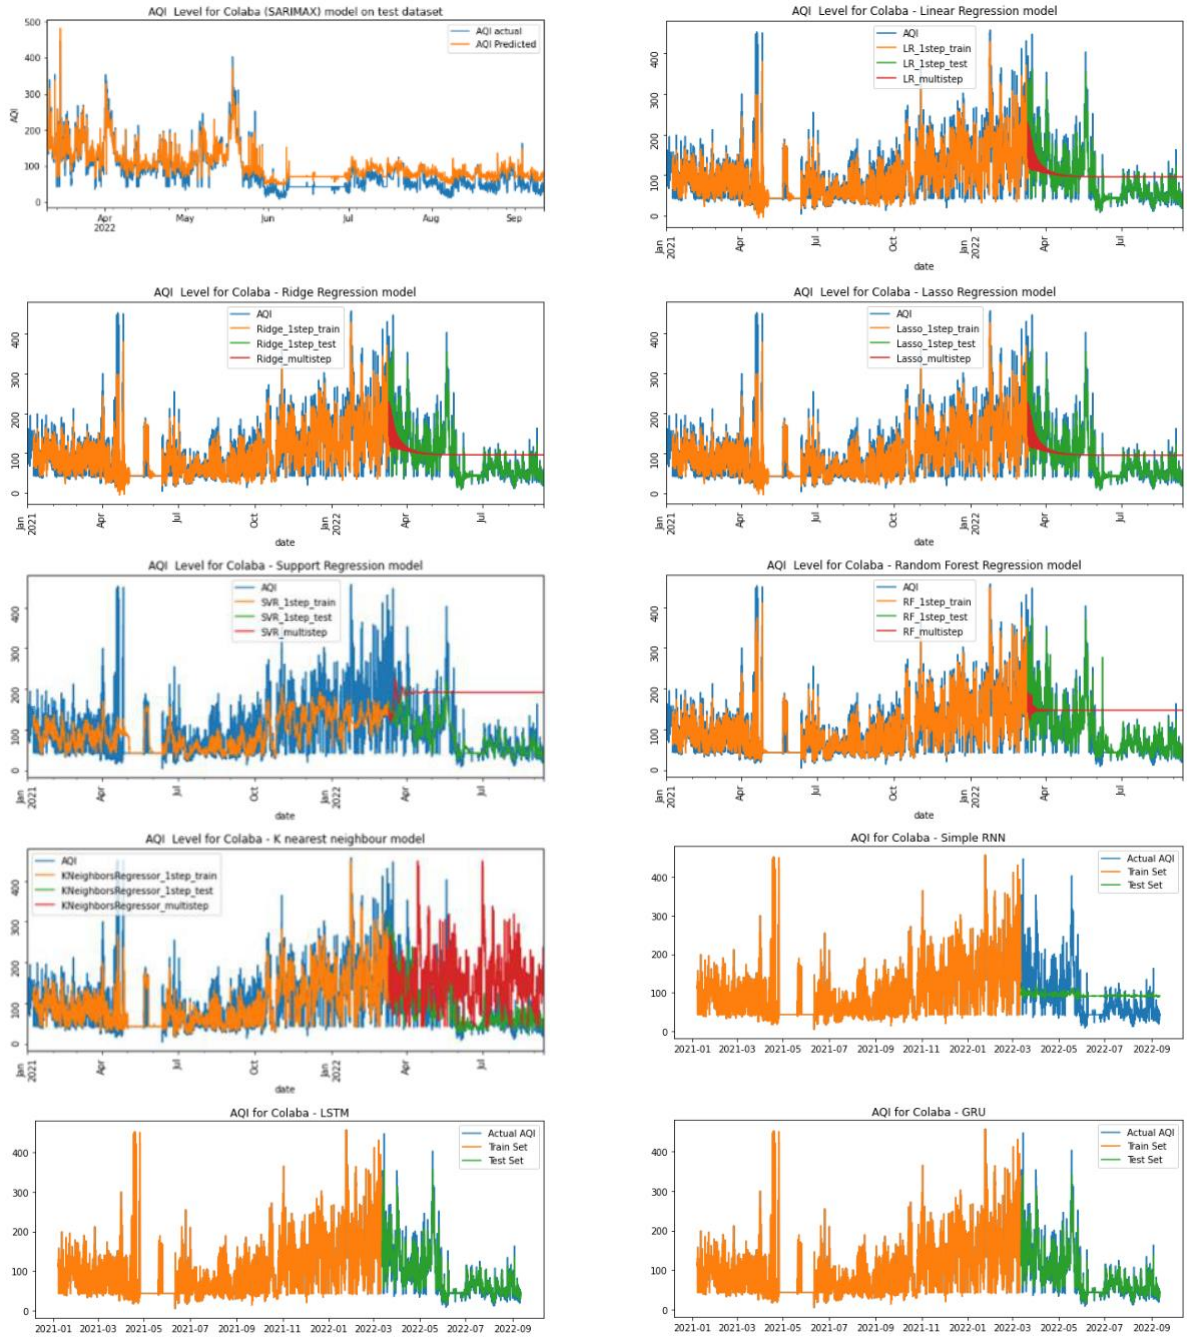

Fig. 5. Actual and forecasted value of AQI for Colaba station for all models

factors, population density, traffic density, distance from the seashore, etc. Along with this, advanced variants of RNN, such as transformers, auto encoders, and their variants, can be applied for more precise results.

Predicting and Classifying Water Quality, Treatment, and Usage: A Comprehensive Review

Yash Sarang, Shruti Devlekar Anjali Yeole
AI & DS deptVESIT, MUMumbai, IN
2020.yash.sarang@ves.ac.in, 2020.shruti.devlekar@ves.ac.in, anjali.yeole@ves.ac.in

Abstract—**Water quality evaluation and efficient treatment methods play a vital role in the efficient and sustainable use of water resources. With increasing water demands and concerns about water scarcity and contamination, there is a growing need to predict water quality and identify appropriate treatment methods. In this review paper, we provide a comprehensive overview of the current state of water quality prediction, treatment method prediction, and use case classification. We examine the different methods used to predict water quality, including statistical models, and machine learning algorithms. We also provide an overview of the methods used to predict the most appropriate treatment methods. Additionally, we examine the various use cases for any type of water in general. The findings of this review highlight the importance of accurate water quality prediction and treatment method prediction in ensuring the efficient and sustainable use of water resources, and the need for further research in this field. In addition to examining the existing approaches, we also developed a theoretically ideal model to predict the use cases with or without treatment for any type of water. Our model is a hybrid approach of the previous studies done by researchers and their findings to enhance the results.**

Keywords– Water quality evaluation, water quality prediction, sustainable development goals, machine learning models, efficient water treatment, treatment method prediction, water use case prediction.

I. Introduction

One of the most important natural resources for the survival and existence of all species on this planet is water. Water is vital for healthy ecosystems, socio-economic development, energy, food production, and human existence. Water is a valuable natural resource that is getting increasingly scarce, even though it is still relatively inexpensive.

Water is an essential resource for all forms of life and its quality plays a crucial role in determining its usability. The increasing water demand, combined with concerns about water scarcity and contamination, has made it increasingly important to manage this limited resource efficiently and sustainably. Water quality prediction and the identification of appropriate treatment methods are key components of this management.

This review paper aims to provide a comprehensive overview of the current state of water quality prediction, treatment method prediction, and use case classification. We have examined various methods used for predicting water quality, including statistical models, machine learning algorithms, and remote sensing techniques. The review will also cover the methods used for treatment method prediction, such as decision tree models and artificial neural networks. Furthermore, the paper will examine the different use cases for industrial water, including process water, cooling water, and boiler feed water, and explore the impact of these classifications on water treatment and management.

The findings of this review will highlight the importance of accurate water quality prediction and treatment method prediction in ensuring efficient and sustainable use of water resources. This paper will make a valuable contribution to the ongoing efforts to manage water resources and address the challenges posed by water scarcity and contamination.

This paper also intends to address this issue by preparing our strategy to develop a model for predicting water quality using various machine learning algorithms, including decision trees, artificial neural networks, and improved decision trees. It also intends to forecast the most effective water treatment, which will be followed by the best use case classification or suitability prediction based on the quality of the data.

II. Problem Statement

Access to safe drinking water is essential to health, a basic human right, and a component of effective policy for health protection. This is important as a health and development issue at a national, regional, and local level. In some regions, it has been shown that investments in water supply and sanitation can yield a net economic benefit since the reductions in adverse health effects and healthcare costs outweigh the costs of undertaking the interventions.

The paper aims to prepare a Model to predict the quality of water using factors like hardness, pH value,

dissolved solids, chloramines, sulfate, carbon, etc, and tell us whether the water is safe to drink or not. If not, whether it is contaminated or not. If contaminated, provide the optimal treatment methods and further provide the best use case classification or suitability prediction.

III. LITERATURE REVIEW

A. AI IN WATER QUALITY PREDICTION

1) WATER QUALITY AND ITS REQUIREMENT:

Water Quality can be defined as the chemical, physical and biological characteristics of water, usually concerning its suitability for the designated use. Water can be used for drinking, cleaning, fish farming, agriculture, or industrial use. Each of these designated uses has different defined chemical, physical and biological standards necessary to fulfill the respective purpose. For example, there are stringent standards for water to be used for drinking or swimming compared to that used in agriculture or industry.

The use of Artificial Intelligence (AI) in water quality prediction can help in addressing the challenges faced in the water treatment industry. AI techniques can help in predicting water quality with a higher level of accuracy, which is essential for the efficient and sustainable use of water resources. AI models can be trained using historical water quality data and other relevant environmental factors, which can be used to predict water quality in real time.

2) PREVIOUS WORK

"Data-driven Water Quality Analysis and Prediction: A Survey" by G. Kang, J. Z. Gao, and G. Xie,[1] provide an overview of the various data-driven approaches used for water quality analysis and prediction. The paper reviews various statistical models, machine learning algorithms, and remote sensing techniques used for water quality prediction. The paper highlights the advantages and limitations of different techniques and the need for further research in the field.

Machine learning techniques:

- Artificial Neural Network (ANN) Model
- Radial Basis Function Network (RBFN) Model
- Deep Belief Network Model
- Decision Tree Model
- Improved Decision Tree Model
- Least squares Support Vector Machine Model

"A review of artificial intelligence-based methods for water quality monitoring and prediction" by Zhang et al.[2] provides a comprehensive overview of AI-based methods used for water quality monitoring and prediction. The paper focuses on the application of machine learning algorithms, such as decision trees, random forests, artificial neural networks, and support vector machines, for water quality prediction. The authors also discuss the challenges associated with water quality prediction, such as data availability and accuracy, and the need for further research.

Machine learning techniques:

- Artificial Neural Networks (ANNs)
- Support Vector Machine (SVM)
- Decision Tree (DT)
- Artificial Bee Colony Algorithm (ABC)

"Artificial intelligence-based water quality prediction using machine learning algorithms: a review" by Raza and Kim[3] focuses on the use of machine learning algorithms for water quality prediction. The paper reviews various algorithms, such as decision trees, random forests, artificial neural networks, and support vector machines, and their application in water quality prediction. The authors also discuss the challenges associated with water quality prediction and the need for further research.

Machine learning techniques:

- Artificial Neural Networks (ANNs)
- Support Vector Machine (SVM)
- Random Forest (RF)

In "Prediction of Water Quality Index by Support Vector Machine: a Case Study in the Sefidrud Basin, Northern Iran,"[4] the authors examine the use of Support Vector Machines in predicting the Water Quality Index (WQI) in the Sefidrud Basin in Iran. They show that this method can be effectively used to predict water quality in this region.

Machine learning techniques:

- Support Vector Machine (SVM)

"Artificial Intelligence-based Water Quality Prediction Models: A Review" by He et al.[5], provides a comprehensive review of AI-based water quality prediction models. The authors examine the different types of AI algorithms used for this purpose and provide a summary of their findings.

Machine learning techniques:

- Artificial Neural Networks (ANNs)
- Support Vector Machine (SVM)
- Decision Tree (DT)
- Random Forest (RF)

"Artificial Intelligence for Water Quality Monitoring and Prediction: a Review" by Liu and Li[6], similarly focuses on the use of AI in water quality monitoring and prediction. The authors provide a detailed overview of the different AI-based methods used for this purpose, including Machine Learning algorithms and other data-driven methods. Machine learning techniques:

- Artificial Neural Networks (ANNs)
- Support Vector Machine (SVM)
- Decision Tree (DT)
- Random Forest (RF)
- K-Nearest Neighbor (KNN)

In "Artificial Intelligence Techniques for Water Quality Prediction: A Review," Peiris and Xiong [7] provide a comprehensive overview of the use of AI techniques in water quality prediction. They examine the different methods used, including Machine Learning algorithms and other AI-based techniques, and summarize their findings.

Machine learning techniques:

- Artificial Neural Networks (ANNs)
- Support Vector Machine (SVM)
- Decision Tree (DT)
- Random Forest (RF)

The common theme in these papers is the use of AI and machine learning algorithms for water quality prediction and the need for further research in the field. The papers also highlight the importance of accurate water quality prediction in ensuring the efficient and sustainable use of water resources.

3) Uses and Requirements

a) Environmental management:

Predicting water quality helps to monitor and manage aquatic ecosystems, ensuring the preservation of aquatic biodiversity.

b) Agricultural planning:

Water quality predictions help farmers to determine the suitability of water for irrigation and to plan their crop production activities.

c) Drinking water management:

Water quality predictions are used to monitor and maintain drinking water sources' quality, ensuring communities' health and safety.

d) Industrial planning:

Water quality predictions help industries to identify potential sources of water for use in their operations and to plan for necessary treatment and discharge.

e) Recreational planning:

Water quality predictions help to monitor the suitability of water bodies for recreational activities such as swimming, fishing, and boating.

f) Climate change adaptation:

Predictive models can help to identify and assess the potential impacts of climate change on water quality and to plan for necessary adaptation measures.

g) Water resource management:

Predictive models can help to assess and manage the availability of water resources, ensuring equitable distribution and efficient use.

h) Pollution control:

Water quality predictions can help to identify and monitor sources of pollution, and plan for effective pollution control and remediation.

i) Public health:

Water quality predictions are used to monitor the presence of harmful contaminants in water, such as bacteria and chemicals, and to prevent outbreaks of waterborne diseases.

j) Environmental monitoring:

Water quality predictions can be used to monitor the effectiveness of conservation and management efforts and to identify areas in need of additional action.

k) Emergency response:

Predictive models can help to identify potential water quality issues in the event of natural disasters, allowing for rapid response and mitigation measures.

l) Policymaking:

Predictive models can inform policy-making at the local, national, and international levels, guiding decisions related to water management and conservation. and many more similar uses. What are the need of the hour

B. AI in Water Treatment

1) Use and Requirement of AI

The use of AI in water treatment is necessary due to the increasing demand for clean and safe water, and the need to efficiently use limited water resources. AI can be used to predict water quality and identify appropriate treatment methods, leading to improved water management and conservation.

AI algorithms can analyze vast amounts of data, including real-time water quality data, to make predictions and provide insights that would not be possible with manual methods. Additionally, AI can be used to optimize treatment processes, reducing waste and energy consumption.

By integrating AI into water treatment processes, it is possible to increase efficiency, reduce

costs, and ensure the safe and sustainable use of water resources.

2) INDUSTRIAL TECHNIQUES

a) Physical treatments: include sedimentation, flocculation, filtration, and distillation.
b) Chemical treatments: include coagulation, neutralization, oxidation, and reduction.
c) Biological treatments include activated sludge, bioremediation, and constructed wetlands.
d) Membrane filtration: includes reverse osmosis and ultrafiltration.
e) Adsorption: uses materials like activated carbon, zeolites, and clay minerals to remove contaminants.
f) Ion exchange: uses resins to exchange ions in the water to remove contaminants.
g) Thermal treatments: include thermal desalination and thermal oxidation.
h) Advanced oxidation processes (AOPs): include ozone treatment, hydrogen peroxide treatment, and UV light treatment.
i) Precipitation/Encapsulation: can be used to remove contaminants from both municipal and industrial wastewater.
j) Adsorption: widely used for the removal of heavy metals from wastewater because of its low cost, availability, and eco-friendly nature.
k) Membrane Technologies (Micro and ultrafiltration): Membrane technology used for removing solids in wastewater treatment is usually based on ultrafiltration or microfiltration.
l) Membrane bioreactor (MBR): Membrane bioreactors for wastewater treatment is a combination of a suspended growth biological treatment method, usually activated sludge, with membrane filtration equipment, typically low-pressure microfiltration (MF) or ultrafiltration (UF) membranes.
m) Reverse osmosis (RO): Reverse osmosis (RO) is a water treatment process that removes impurities using a semi-permeable membrane. Simple, safe, and cost-effective, it eradicates over 99% of contaminants from water such as dissolved solids, organics, bacteria, and pyrogens.
n) Electrolysis/Electrodialysis(ED): Electrodialysis (ED) is a process that removes ionic components under the driving force of an electric current from aqueous solutions through ion-exchange membranes.
o) Artificial Intelligence Models to Treat the Wastewater

The choice of treatment method depends on the type and concentration of contaminants in the water, as well as the desired outcome. The treatment processes may be used alone or in combination to achieve the desired water quality.

Heavy metals constitute one of the most common inorganic water pollutants. They can stay in the environment and food supply and are very toxic, inherently carcinogenic, and non-biodegradable. Heavy metal ion reduction from various wastewater sources has been handled utilizing multiple strategies.

Adsorption, membrane-, chemical-, electric-, and photocatalytic-based therapies are some possible divisions of these techniques [8].

Mercury, lead, cadmium, zinc, arsenic, and plutonium are a few of the heavy metals having a large atomic mass. Since lead is a harmful metal that comes from the exhaust of automobiles that utilize leaded gasoline, there is no safe level of exposure to it.

Typical heavy metals found in wastewater that is harmful to human health are shown in Table 1.

TABLE 1. Common heavy metals found in wastewater, their origins, and the health problems they cause.[8]

Heavy Metal	Main Sources	Main Organ and System Affected
Lead (Pb)	Lead-based batteries, leaded gasoline, alloys, cable sheathing pigments, rust inhibitors, ammunition, glazes, and plastic stabilizers.	Bones, liver, kidneys, brain, lungs, spleen. Immunological, hematological, cardiovascular, reproductive system.
Arsenic (As)	Electronics and glass production.	Skin, lungs, brain, kidneys. Metabolic, cardiovascular, immunological, and endocrine systems.
Copper (Cu)	Corroded plumbing systems, electronic and cables industry.	Liver, brain, kidneys, cornea. Gastrointestinal, lungs, immunological, hematological system.
Zinc (Zn)	Brass coating, rubber products, some cosmetics, and aerosol deodorants.	Stomach cramps, skin irritations, vomiting, nausea, anemia, and convulsions.
Chromium (Cr)	Steel and pulp mills and tanneries.	Skin, lungs, kidneys, liver, brain, pancreas. Tastes, gastrointestinal, reproductive system
Cadmium (Cd)	Batteries, paints, steel industry, plastic industries, metal refineries, and corroded galvanized pipes.	Bones, liver, kidneys, lungs, testes, brain. Immunological, cardiovascular system.
Mercury (Hg)	Electrolytic production of chlorine and caustic soda, runoff from landfills and agriculture, electrical appliances, Industrial and control instruments, laboratory apparatus, and refineries.	Brain, lungs, kidneys, liver. Immunological, cardiovascular, endocrine, and reproductive systems.
Nickel (Ni)	Manufacturing of nickel alloys and stainless steel.	Kidney, pulmonary fibrosis, gastrointestinal problems, lung, and skin.

3) Previous Work:

"Deep learning models for wastewater treatment" by Wei, H., Zhang, H., & Fang, J. [9] presents the application of deep learning models in predicting the operational process of wastewater treatment plants. The authors trained and evaluated several deep learning models such as multilayer perceptron (MLP), long short-term memory (LSTM), and gated recurrent unit (GRU) to predict the treatment performance of wastewater treatment plants. The results showed that the GRU model outperformed the MLP and LSTM models in terms of prediction accuracy. Techniques Implemented- Deep Learning Models

- Multilayer Perceptron (MLP)
- Long Short-Term Memory (LSTM)
- Gated Recurrent Unit (GRU)

"Real-time operational process prediction in wastewater treatment" by Yuan, Y., Wang, W., & Li, Y. [10] describes the implementation of machine learning algorithms for real-time operational process prediction in wastewater treatment plants. The authors used five algorithms, including decision trees, random forests, support vector machines, k-nearest neighbors, and artificial neural networks, to predict the treatment efficiency of wastewater treatment plants. The results showed that the artificial neural network had the best performance in terms of prediction accuracy.

Techniques Implemented- Machine learning algorithms

- Decision trees
- random forests
- Support vector machines
- k-nearest neighbors
- artificial neural networks

"Artificial intelligence-based wastewater treatment plant optimization" by Chang, X., & Dai, Y. [11] provides a comprehensive review of the application of artificial intelligence in optimizing the operational process of wastewater treatment plants. The authors discussed several AI techniques, including artificial neural networks, decision trees, genetic algorithms, and fuzzy logic, and their applications in wastewater treatment plant optimization.

Techniques Implemented- Artificial Intelligence-based optimization

- Artificial neural networks
- Decision tree
- Genetic algorithms
- Fuzzy logic

"Artificial intelligence-based wastewater treatment prediction model based on improved particle swarm optimization algorithm" by Liu, X., Guo, Y., & Li, S. [12] proposes a new wastewater treatment prediction model based on an improved particle swarm optimization

algorithm and artificial intelligence techniques. The authors applied the model to predict the treatment performance of a wastewater treatment plant and showed that the model achieved better performance compared to other traditional prediction models.

Techniques Implemented-

- Improved particle swarm optimization algorithm

"Deep learning-based prediction of the wastewater treatment process" by Jin, Y., Zeng, X., Wang, X., & Han, X. [13] presents the application of deep learning techniques in predicting the wastewater treatment process. The authors used a deep neural network (DNN) model to predict the treatment efficiency of a wastewater treatment plant. The results showed that the DNN model had a high prediction accuracy compared to traditional prediction models.

Techniques Implemented-

- Predictive control
- Convolutional neural network
- deep neural network (DNN) model

In "Deep learning-based prediction of the treatment effect of anaerobic sequencing batch reactor for municipal wastewater treatment" by Wang, X., Jiao, L., Zhang, X., & Li, B. [14], the authors used deep learning algorithms to predict the treatment effect of an anaerobic sequencing batch reactor for municipal wastewater treatment. They trained and tested the model on real-world data collected from a wastewater treatment plant in China. The results showed that the deep learning-based model was capable of accurately predicting the treatment effect, with high correlation coefficients and low mean absolute error values. The model was also able to capture the nonlinear and complex relationships between the input variables and the treatment effect.

In "Predictive control for wastewater treatment plants based on a deep neural network" by Lin, L., Fan, Y., & Li, X. [15], a deep neural network (DNN) was used for predictive control of a wastewater treatment plant. The authors collected data on influent flow rate, pH, and chemical oxygen demand from a real-world wastewater treatment plant and used it to train and test the DNN model. The results showed that the DNN model was capable of accurately predicting effluent water quality and optimizing the wastewater treatment process.

Techniques Implemented-

- Deep Neural Network

In the review paper "Artificial intelligence-based wastewater treatment optimization" by Wei, L., Liu, Y., & Zhang, Y. [16], the authors present an overview of the applications of artificial intelligence in wastewater treatment optimization. They discuss the various artificial intelligence techniques that have been used, including support vector machines, neural networks, genetic algorithms, and particle swarm optimization. The authors also provide a summary of the recent advances in this field and identify future research directions.

Techniques Implemented-

- Support vector machines
- Neural networks
- Genetic algorithms
- Particle swarm optimization

In "Artificial intelligence-based wastewater treatment plant operational process prediction using convolutional neural network" by Li, X., Li, Y., & Liu, J. [17], the authors have used a convolutional neural network (CNN) to predict the operational process in a wastewater treatment plant. They collected data on influent flow rate, pH, chemical oxygen demand, and temperature and used it to train and test the CNN model. The results showed that the CNN model was capable of accurately predicting the operational process, with high correlation coefficients and low mean absolute error values. The authors also demonstrated the effectiveness of the model in real-world applications by using it to control the wastewater treatment process in a pilot-scale wastewater treatment plant.

Techniques Implemented-

- Convolutional Neural Network
- Artificial Intelligence

C. AI in Use Case

1) Use and Requirement of AI

Artificial Intelligence (AI) can play a crucial role in improving the water treatment prediction process. AI algorithms can be used to analyze large amounts of data and find patterns, correlations, and relationships that might not be visible to the human eye. This can help predict the quality of water and the best treatment method based on its properties, costs, and available water supply.

Additionally, AI models can continuously learn and improve over time, which can help make water treatment prediction more accurate and efficient. AI can also help minimize the costs of water treatment by identifying the most optimal treatment method based on cost, performance, and environmental impact.

Overall, the use of AI in water treatment prediction can help improve water quality, reduce costs, and support sustainable water management.

The type of water used depends on the specific requirements of the industrial process and the quality of water that is required for that process. For example, some

industrial processes may require deionized water or distilled water, while others may require treated or untreated municipal water. In some cases, recycled or reused water may be used in industrial processes.

2) *Previous Works*

"Artificial intelligence-based water usage prediction in the chemical industry" by Zhang, H., Wu, J., & Fan, X. [18] presents a case study of using artificial intelligence (AI) for water usage prediction in the chemical industry. The authors use support vector regression (SVR) and artificial neural network (ANN) models to predict water usage and compare the results. The results show that the ANN model has a higher accuracy compared to the SVR model.

Techniques Implemented-

- Support Vector Regression (SVR)
- Artificial Neural Network

"Predictive control for industrial water usage based on machine learning algorithms" by Chen, S., Dong, X., & Jia, J. [19] presents a study on using machine learning algorithms for industrial water usage prediction. The authors use linear regression and support vector regression (SVR) models for prediction and compare the results. The results show that the SVR model has a better prediction performance compared to the linear regression model.

Techniques Implemented-

- Linear regression
- Support vector regression (SVR)

"An improved water usage prediction method for industrial production based on deep learning" by Xiong, H., He, H., & Lu, Y. [20] presents a study on using deep learning for industrial water usage prediction. The authors use a deep neural network (DNN) model and improve the prediction performance through feature selection and model fine-tuning. The results show that the improved DNN model has high accuracy and can effectively predict industrial water usage.

Techniques Implemented-

- Deep Neural Networks

"Water usage prediction in the chemical industry based on an improved particle swarm optimization algorithm" by Liu, X., Guo, Y., & Li, S. [21] presents a study using a particle swarm optimization (PSO) algorithm for industrial water usage prediction. The authors use the PSO algorithm to optimize the parameters of a support vector regression (SVR) model and improve the prediction performance. The results show that the optimized SVR model has high accuracy and can effectively predict industrial water usage.

Techniques Implemented-

- Particle swarm optimization algorithm
- Support vector regression

"Artificial intelligence-based water usage prediction in the chemical industry" by Wei, L., Liu, Y., & Zhang, Y. [22] presents a review of AI-based water usage prediction in the chemical industry. The authors discuss different AI techniques, such as artificial neural networks (ANNs), support vector regression (SVR), and decision trees, that have been used for water usage prediction. The authors also compare the performance of different AI techniques and suggest future research directions.

Techniques Implemented-

- Artificial Neural Network
- Support Vector Regression

"Water Usage Prediction by Using Machine Learning Algorithms" by Cetin, M. [23] presents a study on the use of machine learning algorithms for predicting water usage. The author compared the performance of decision trees, random forests, and artificial neural networks, and found that the random forest algorithm was the most accurate for water usage prediction.

Techniques Implemented-

- Decision tree
- Random forests
- Artificial Neural Network

"Water Usage Prediction Using Machine Learning Techniques" by Murugesan, K., Elumalai, E., & Palaniswamy, M. [24] presents a study on the use of machine learning algorithms to predict water usage. The authors compared the performance of support vector regression, decision trees, and artificial neural networks and found that the support vector regression algorithm was the most accurate for water usage prediction. Techniques Implemented-

- Support vector regression
- Decision trees
- Artificial Neural Network

"A novel water-use prediction method based on an extreme learning machine and multi-objective optimization algorithm" by Sun, S., Chen, W., & Lei, Y." [25] present a water-use prediction model using an extreme learning machine and a multi-objective optimization algorithm. The model is tested and applied on a real-world water use dataset, showing promising results.

Techniques Implemented-

- Extreme Learning Machines
- Multi-objective optimization algorithm

These studies show that machine learning techniques such as artificial neural networks, decision trees, random forests, support vector regression, and deep learning algorithms can be effectively used to predict water usage. However, the most accurate algorithm may vary based on the dataset and the specific application.

3) *Results*

The result of using AI in water usage prediction has shown promising results in the following manner:

a) Improved Accuracy: AI algorithms such as deep learning and machine learning can process vast amounts of data in real time and make predictions with high accuracy.

b) Efficient Water Management: AI can help optimize the use of water resources by predicting water usage patterns and identifying areas for improvement. This leads to better water management and reduces waste.

c) Cost-Effective Solutions: AI can help save costs by reducing the need for manual monitoring and data collection, and by providing more accurate predictions and insights into water usage patterns.

d) Better Decision Making: AI can provide real-time insights into water usage patterns, allowing organizations to make informed decisions about water usage, treatment, and allocation.

Overall, the use of AI in water industry usage prediction has the potential to revolutionize the way water is managed and utilized, leading to improved water resource management, reduced waste, and cost savings.

IV. Tabular representation of previously implemented work

TABLE 2. A Comparison of Research Papers with Big Data-Based Models [26]

PURPOSE AND AREA OF STUDY	BIG DATA MODEL	REAL-TIME MONITORING	WATER PARAMETERS	DATA-SOURCE	ACCURACY
Detection of Intentional Bacterial Spore Contamination of Potable Water	Real time water quality sensor model	Real-time sensing using BioSentry in-line sensor	turbidity, pH, temp., total organic carbon and conductivity	Deionized water as tap water using 1 µm pore size	detected *B. thuringiensis* spores with a detection limit of 102 spores/ml
Quantification of water parameters of inland and near shore waters by means of remote sensing	Remote sensing Model	Not real-time: Remotely sensed images	inorganic sediment particles, dissolved organic material, Secchi disk depth etc.	collected using Geographical Information System	Remotely sensed reflectance values have average *R*2 of 0.81 for Landsat data
detect and analysis of Trihalomethanes in drinking water in Scotland	Pearson's coefficient Analysis Model	Supports 24 hr. real time monitoring	Temp., dissolved organic carbon, chloride	93 water treatment plants assessed from 2011-'13	Temperature (r2 = 0.66, $p <$ 0.05)
To process big data for water monitoring of Three Gorges Reservoir area	Fast fuzzy C-mean clustering	Real-time wireless monitoring	DO, CO3, NH3-N	Data collected by ultra-large scale WSN	The water in which DO is higher than 11mg/L is best quality
Spatial quality evaluation of drinking water	GIS and Ant-colony algorithm	Supports 24 hr. real time monitoring	chloride or sulphate concentration, total hardness etc.	Data from 29 wells in Zhenping County, China	more than 95% area has the same water quality, which proves that the ACCA is feasible
To monitor water quality from a remote location with minimum supervision, initiating immediate corrective actions	Wireless System for water quality monitoring	Real-time data sent wirelessly	pH, conductivity, temperature	Water quality monitoring sensors	pH of water is almost constant at 8.8 till 11:45 a.m. The same rises to 10.00 at 12:15 p.m.
To construct a novel water quality index and quality indicator for reservoir water of Amazon region	Water Quality Indicator Model	Not real time	Physio-chemical parameters and metal concentration	11 water sample stations located upstream	determines seasonal differences in water quality with hydrological cycle
to evaluate the effect of water management of the environmental legislative Directives in Ria Formosa lagoon	EEA 2001 Guidelines	Not real-time	NH4+, NO2-, NO3-	Historical data for the lagoon	In the shallow west end of lagoon during summer, DO supersaturation reached 140% during day

TABLE 4. A comparison table of research papers with Machine learning-based models to predict water quality [26]

PURPOSE AND AREA OF STUDY	ML MODEL	REGION	PARAMETERS	DATA-SOURCE
To develop a water quality prediction model with the help of water quality factors using Artificial Neural Network (ANN) and time-series analysis	Artificial neural network (ANN)	New York	Chlorophyll, Dissolved Oxygen, Specific conductance, turbidity	USGS online resource: National Water Information System
To develop a new hybrid methodology for predicting the biochemical oxygen demand which is the main indicator of water quality	Artificial neural network- Markov Chain	Tolo Harbor, Hong Kong	Chlorophyll, Dissolved Oxygen, Salinity etc.	27-year water quality data set
To use a new method combing both macro and detailed model to optimize the water quality parameters. It is optimized for the purpose of decreasing the times of time consuming water quality simulation	Radial Basis Network Function	South China, water utility	residual chlorine, turbidity, pH and temperature	network has 6909 nodes, no tank, and 7452 links. It is supplied from the four treatment plants
To provide fairly accurate predictions for variable data to evaluate water quality	Deep belief network	Chaskaman River, India	Dissolved oxygen, pH, turbidity	secondary data collected from a third part
To present a Classification data model using decision tree for the purpose of analyzing water quality data	Decision tree model	Narmada river, India	(NH3_N, NO3_N), pH, Temp _C, BOD, COD	Data collected from 1990 to 2010.
To present an improved decision tree learning method making water quality prediction easier and forecast more accurate	Improved Decision tree model	Chao Lake, China	O, O2, O3	Environment Protection Bureau of Anhui Province and Evaluation standard reference, Hong Kong
To address water quality predicting based on spectrometry	Least square support vector machine model	100 water samples from different places	Total Organic Carbon (TOC) criterion	Fluorescence data obtained by Zhejiang Univ.

V. Our Proposed Solution

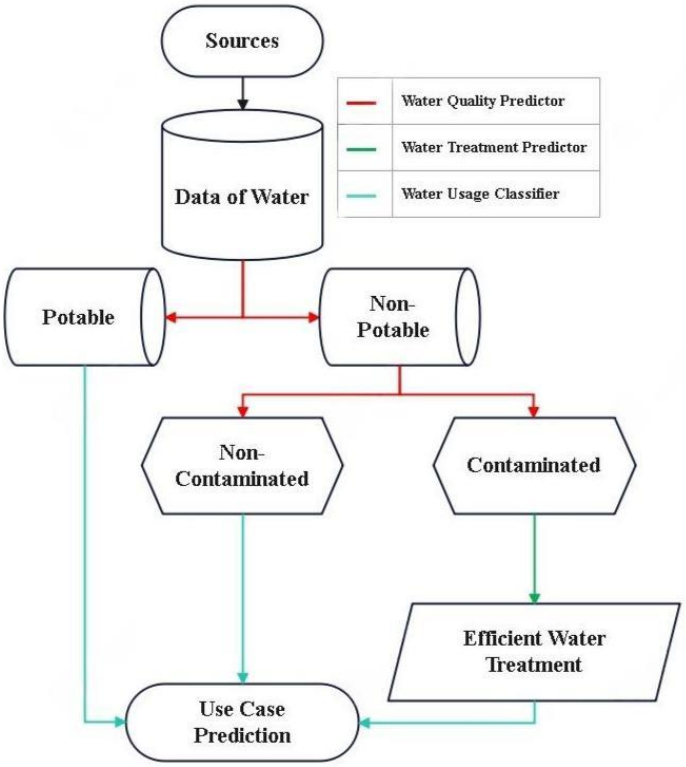

Fig. 1. System Architecture of the proposed solution

The goal of our model is to find the most efficient way to use any type of water source such as rivers, ponds, wells, reservoirs, dams, etc.

The water will be tested and its data will be fed into the model, which has three phases:

1. The Water Quality Predictor
2. The Water Treatment Predictor
3. The Water Use Case Predictor.

The flow of the solution i.e the system architecture is graphically depicted in Figure 1.

The data of the water would first go through the Water Quality Predictor to provide us the insights/results on the quality of the water on which we would decide whether the water is Potable or Not, if it is potable then we would run it through our Use Case Prediction model to suggest the best use cases like household work, cleaning, drinking, etc.

If Not, it would further check whether it's contaminated or not concerning its quality derived earlier. If not it can be used for industrial uses like Cooling: Water is used for cooling in industrial processes, such as Industrial Processing, Cleaning, Boiler Feed, Fire Suppression, Agriculture, etc.

If the water is contaminated, the data will be run through our 'Water Treatment Predictor' which will take into account the costs of water treatment facilities, and the amount of water available and also predict the output of all the treatment methods on the specific data. Then it would provide us with the most optimal treatment method economically as well as in terms of performance.

Lastly, the output of the treatment predictor will go through the Use case predictor to also predict the use cases of that water.

The aim is to determine the best use for any form of water, even if it's contaminated so that smart and optimal industrial or large-scale decisions can be made.

VI. Results and Discussion

The usage of AI in water quality and treatment prediction & usage classification can result in several significant benefits in the water industry.

1. Improved Accuracy: AI models can process large amounts of data from various sources and provide more accurate predictions compared to traditional methods.
2. Real-Time Monitoring: AI models can monitor water quality and treatment processes in real-time, alerting operators to potential problems before they become serious.
3. Cost-Effective: AI models can reduce the cost of water treatment and quality prediction by optimizing processes and reducing the need for manual labor.
4. Enhanced Decision-Making: AI models can provide water treatment and quality predictions that can be used to make informed decisions, reducing the risk of costly mistakes.
5. Automation: AI models can automate many water treatment and quality prediction processes, reducing the need for human intervention and increasing efficiency.
6. Increased Awareness: AI models can provide data-driven insights into the water treatment and quality prediction process, increasing public awareness and promoting sustainability.

Despite these benefits, there are still some challenges associated with using AI in the water industry, such as ensuring the accuracy of the data used as input, developing robust models, and ensuring that the models are accessible and understandable to stakeholders. However, with continued advances in AI technology, these challenges are likely to be overcome, leading to even greater benefits in the future.

SVM/SVR, Improved Decision Tree, Random Forest, and Artificial Neural Networks were found to be the most effective and best-providing algorithms for implementing water quality predictions. Similarly, CNN, DNN, Fuzzy algorithms, and Genetic Algorithms are used in the Water Treatment Predictor. Whilst SVR, ANN, DNN, and extreme learning algorithms are used in the water use case predictor/suggestion. Therefore, it is advised that any model relevant to this area be implemented using the aforementioned techniques.

If properly implemented, our suggested method, which is theoretically viable, would reinvent the water sector.

Finding the best datasets for industries that are often privatized and processing all the different types of information from various sources are the hard components of putting our approach into practice.

Despite the enormous quantity of data that is accessible from the government sectors, it appears that only a significant industrial entity with the data and resources could genuinely work on adopting the suggested solution.

Abstract

Load balancing among VMs is crucial for optimising the delivery of cloud services, both in terms of the money spent and the time spent. Transferring a running virtual machine from one physical host to another is known as "live VM migration," and it is used in the cloud to balance system load. While this method has been offered to lessen downtime while moving overburdened VMs, it is still expensive and requires a sizable amount of memory to implement. To address these limitations, we provide a Task-based-System Load Balancing approach based on the African Vultures-Aquila Optimization Model (AVAO), which attains system load balancing by moving only the surplus of tasks from an overcrowded VM. In addition, we develop an optimization model for applying AVAO to the transfer of these supplementary activities to the new host VMs. We employ an augmented version of the cloud simulator (Cloudsim) package with AVAO as its task scheduling typical to test the suggested strategy. Based on the simulation findings, it is clear that the proposed method considerably shortens the time required for the load balancing practice when compared to the conventional methods. In terms of both make span time and throughput, the system's performance is significantly enhanced if the proposed method is proven to be valid.

Keywords: Load Balancing; African Vultures-Aquila Optimization Model; Virtual Machines; Makespan; Throughput.

Introduction

It is generally accepted that load balancing in CC is complex research for the purpose of segmenting the activities of virtual machines in data centres. In this context, the use of CC as a technique for delivering services via internet is very necessary [1]. The cloud is an expansive and linked system that makes use of all

files and arenas in number of different ways. However, resources are not distributed in an equitable manner, and only a small number of VMs are able to successfully complete the tasks. If a job is to be completed using virtual machines (VMs), then all VMs must work in parallel with a minimum amount of complexity and also the process to be finished swiftly

[2]. Identifies the necessity of task planning and then the execution of plan into action using the resources that are at their disposal. When many jobs are delegated to enormous VMs, those jobs are carried out concurrently in order to ensure that
the jobs are finished on time

[3]. When a trade is assigned to one or more virtual machines (VMs), the scheduler is responsible for ensuring all the transactions that are not executed in the same VM and when there is an availability of alternative VMs. As a consequence of this, the scheduler role is required to take care of all user tasks on all VMs within CC

[4]. As shown in Figure 1, in order to tackle the problem of LB across all VMs, required. This model must enhance the response time of operations that have been allocated by enlarging the resources that are available.

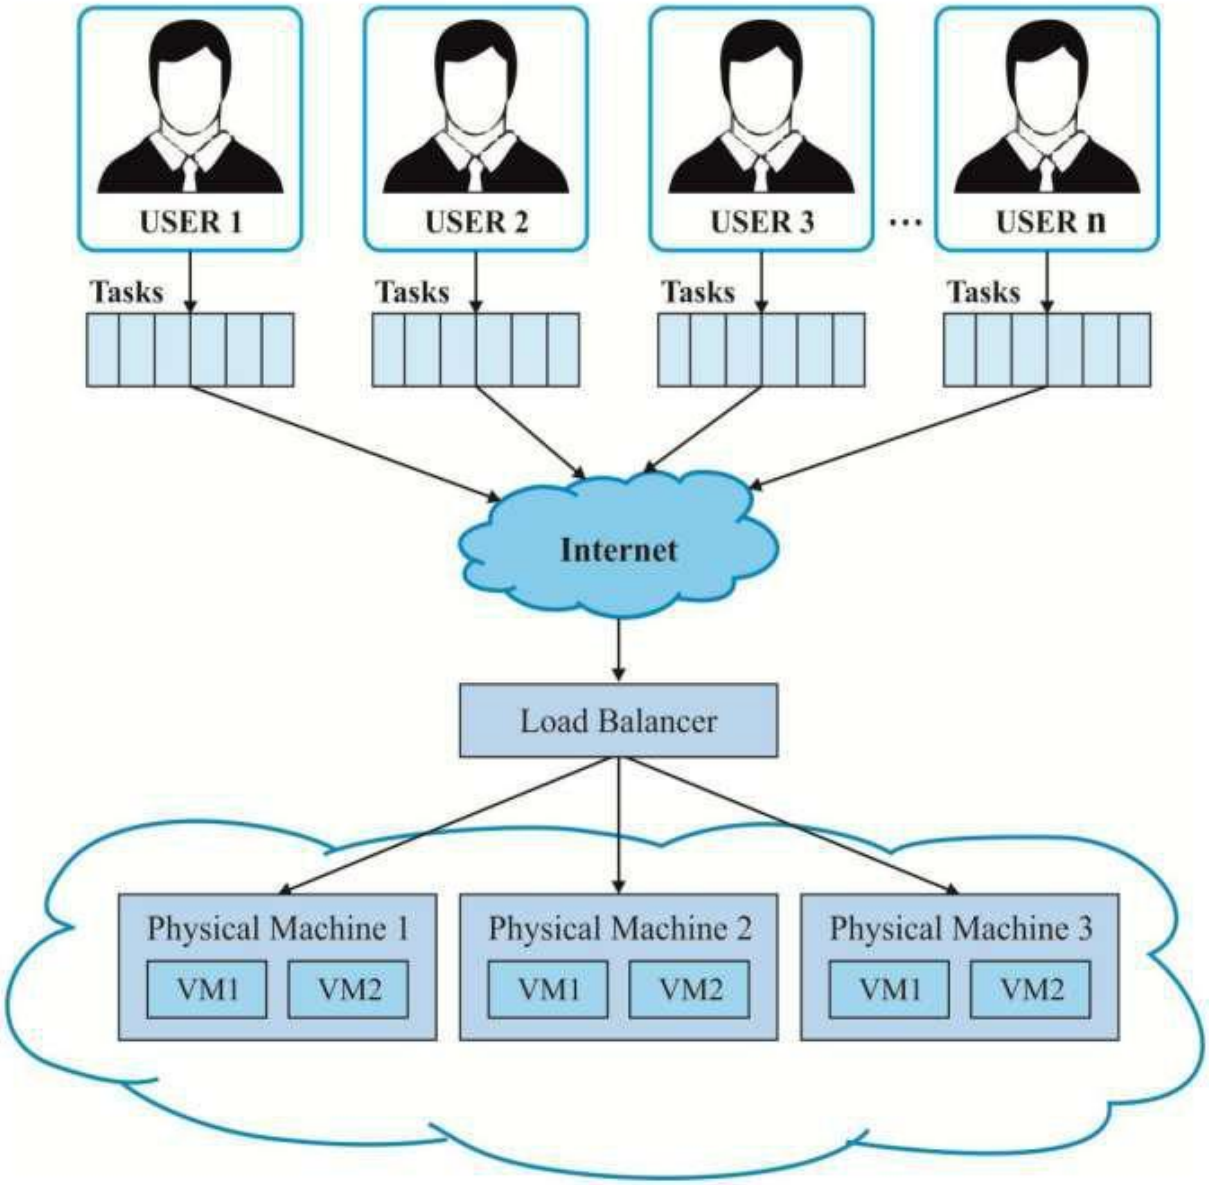

Fig 1. LB in CC platform.

During the process of LB, the input job is distributed evenly among all VMs. The primary objective of LB is to alleviate the strain that is being placed on all VCs by reporting it to other weighted minimum VMs [5]. The presentation and throughput of a system are highlighted by it. The problem of load balancing was also addressed by the developers by using both heuristic templates. Where Protected load balancing is recorded on a distributed network

[6]. In addition, in order to solve the difficulties of load balancing and network security in a dispersed network, three different models have been adopted. For example, it offers a mobile agent in a dispersed network to broadcast all the nodes in that network. After that, it offers an outline in order to give optimal efficiency, which offers a solution to the problem of network

insecurity [7]. A hierarchical load balancing approach is offered as a solution to the problem of uneven load distribution on the computer platform known as Grid. The characteristics of the real node are considered while dynamically distributing the input job from the VMs benchmarks.

The process of load balancing is carried out by a number of different LB modules, and the outcomes are connected to throughput and speed [8]. There are a variety of scheduling strategies that have been implemented for the MapReduce environment, and one of these strategies is load balancing for the CC network [9]. It is anticipated that an task allocation scheduler would be necessary for optimising the performance of Map Reduce in a heterogeneous cloud [10]. In order to shorten the amount of time needed to complete a job in which it is condensed when processing enormous amounts of data such as video and images using Map Reduce outlines [11], a deadline reduction scheduler has been designed. An independent agent that is reliant on the load balancing strategy is offered for the purpose of balancing a load by VMs with the assistance of three agents, namely a Channel agent, a load agent [12].

1.1. Problem statement

This part focuses on the problem statement that was derived from the review conducted by this study. The new algorithm is suggested as a solution to these difficulties once those problems have been solved.Incorrect allocation of resources to virtual machines (VMs) can make it difficult to deal with incoming tasks and also maintaining a balanced workload in cloud-based systems. One of the reasons for this is that only a limited number of task factors are taken into consideration. For instance, which does not work in a dynamic environment like cloud systems because the requests are not prioritised. If virtual machine (VM), or if the CPU is not fully utilised or is insufficient to handle the requests, then performance issues may arise as a result of an unbalanced load. The number of requests increases, simultaneously problems increases. It is vital to take into consideration QoS considerations and give an effective algorithm in order to increase the performance of the cloud while using IaaS in order to overcome these challenges. This can be accomplished by optimising the utilisation of the system's resources, which in turn decreases the amount of time taken by user tasks to both prepare and execute.

The vast majority of researchers didn’t consider the priority, despite the fact which is essential component in task scheduling. This can result in problems such as increase in the Makespan period, which is the amount of time it takes to schedule a task or request, as well as an upsurge in the sum of rejected tasks and latency [8-12].

While Task Scheduling is the primary aims of delivering an effective Load Balancing and boosting performance, the majority of researches concentrate only on one or two parts of the problem. As an illustration, in order to improve Load Balancing and by taking few Task Scheduling factors into consideration. Therefore, in order to increase the overall performance, by considering selected few indicators. This is a problem in poor Task Scheduling that creates an uneven burden on the hosts [10], [11]. For instance, if many tasks arrive at the same time in accordance with the protocol of the FCFS algorithm, which significantly increase Makespan since the task will have to wait for a longer period of time to execute completely. So that it is important to specify each client will send a unique request by assigning random values to the Task Length parameter in order to provide a dynamic workload.

Load balancing has been improved by the implementation of a number of novel strategies, however the difficulty of workload transfer has not been resolved yet to its fullness. Despite the fact VM is in a state of SLA violation, which means it does not adhere to the stipulated Deadline and requirements outlined in the agreement document [10], but tasks are continued to be assigned to it. As a result, the

assignment of random values. This is due to the fact each client receives a unique SLA agreement depending on the demands they have from CSPs.

1.2. Contribution of the Study

The significance of this paper's contribution is discussed here. The primary objective of this study is to improve use of cloud resource by developing more Task Scheduling methods. The following is a brief contribution to the research:

LB workloads is provided by a suggested Load Balancing algorithm, which also solves the problem of virtual machine (VM) violations in the cloud. Even though this problem has been studied before, most solutions ignore critical QoS criteria like Deadline and Completion Time. The suggested approach also accounts for a key issue that has not been completely addressed up to date and the movement of load to balancing VMs.

The algorithm improves Resource consumption when the two primary Load are decreased.

In prospect researchers would find this work useful in the field of CC in their efforts to optimise the performance of cloud-based applications through Load Balancing

Allocation of tasks are carried out by AVAO algorithm, which results in reducing two main parameters such as Makespan and Execution time in the cloud applications.

2. Related Works

Khaleel, M.I., [13] devised a dual-phase metaheuristic method called Clustering Sparrow Search Method-Differential Evolution. (CSSA-DE). To get started, we employ a clustering approach to group computing nodes into productive node aggregations. Training is performed on each node at different levels of utilisation, and the one that achieves the highest Performance-to-Power Ratio (PPR) is selected to serve as the mega cluster's master node (MCH). We then fused the DE algorithm with the SSA to further improve the already

impressive search efficiency we had while trying to find the best possible pairing of tasks for a given VM. In addition, the number of resource fragments can be reduced thanks to the integration phase's capacity to make use of the number of VMs that are either overloaded or underloaded. CSSA-performance DE's is not only very close to, but often significantly better than, that of state-of-the-art procedures.

Mangalampalli et al. [14] have suggested a useful approach for scheduling tasks. This algorithm considers both the relative importance of jobs and virtual machines when allocating work. This scheduler is modelled after the firefly algorithm. The burden associated with this method was assessed using both synthetic datasets with different in the context of the Cloudsim simulation environment. We next compared our proposed approach to the ACO, PSO, and GA techniques that served as benchmarks. The simulation findings validated our hypothesis that our proposed solution will have a significant impact over. To do this, we were able to decrease the amount of iterations needed to solve the problem.

Data from Prabhakara et al [15] study's that needs to be analysed to fix the load balancing mechanism in cloud settings To achieve this optimal utilisation of similarly distributed virtual computers, this study develops a strategy-oriented mixed support and load balancing structure. The proposed approach combines heuristic and metaheuristic techniques to get the best makespan and pricing efficiency achievable. To improve job management and cut down on costs and time, the HPOFT-MACO framework combined two methods known as Heuristics Predict Origin

A new hybrid approach, combining the Arithmetic Optimization Algorithm (AOA) with the Swarm Intelligence Search Algorithm (SISA), was proposed by Mohamed and co-workers [16]. (SSA). To kick things off, we present a novel hybrid metaheuristic approach to the issue of selecting and deploying data replicas in fog computing. Both the Arithmetic Optimization Algorithm (AOA) and the Salp Swarm Algorithm (SSA) are utilised in this answer (SSA). As a second step, we use the Floyd technique to plot the cheapest routes for sending data across multiple sites and minimising travel time. The AOASSA method was developed to eliminate the issue of data duplication, and its efficacy is evaluated using a number of datasets of varied sizes. Multiple experiments were performed to prove the efficacy of the AOASSA

method. These results prove the efficacy of the AOASSA approach. The experimental findings show that AOASSA outperforms its competitors on key performance indicators like lowest cost, longest range, and best throughput. Kruekaew et al. [17] proposed a multi-objective work scheduling optimization for cloud computing that is based on the artificial bee colony algorithm method. We call this approach the MOABCQ methodology. The suggested method seeks to balance the load across different virtual machines in terms of makespan, cost, and resource use in order to maximise throughput for all virtual machines. Concurrent concerns place limitations on these goals. CloudSim was used to analyse the suggested method's performance in relation to that of many pre-existing load balancing and scheduling techniques. Some examples of these algorithms are the Max-Min, FCFS, HABC LJF, Q-learning, datasets were used for the study. Experimental results showed that MOABCQ-based algorithms outperformed their counterparts in terms of makespan reduction, cost reduction, degree of imbalance reduction, throughput improvement, and average resource utilisation. The primar aims of the tests were to accomplish these things.

Malathi et al. [18] investigate the advantages of heuristic approaches in order to develop the cloud computing load balancer algorithm. We make two major improvements to previous methods of load balancing in our work. The hybrid method has proven to be the most applicable, and the results have shown exceptional performance in terms of the fastest turnaround time and the most efficient use of virtual machine resources. The lion optimizer was created as a first step toward better load balancing on virtual machines by identifying optimal parameter settings. Two selection probabilities are developed to better the selection process: the scheduling likelihood of tasks and the virtual machine selection probability. The lion optimizer uses fitness criteria that are specific to both the task at hand and the underlying virtual machine. Our second contribution is a genetic algorithm we created by tailoring the global search criteria to the lion optimizer's needs. Results from trials prove that the lion-based genetic hybrid technique is effective.

3. Proposed Methodology

Using virtualization technology, a hypervisor (a software layer) is created on top of a physical hardware platform. A hypervisor is an OS that controls the requests made by VMs and the replies are driven from VMHs, by ensuring the security of VMH resources. Different types of hypervisors are described for different use cases: type-1 hypervisors run directly on the VMH hardware, whereas type-2 hypervisors use the VMH operating system. A VM is a software abstraction that runs on a virtual machine host (VMH) and makes use of its underlying virtual hardware (vCPUs, vRAM, and vHDs). While operating on a virtual machine, a user programme has no access to the underlying hardware. Instead, the hypervisor of the VMH acts as a wrapper around all resources. A VMH is a specialised server that can host and manage several virtual machines. A group of virtual machine hosts (VMH farm), which provides computing resources for a single virtual machine (VM) or a group of VMs. Hypervisors like VMware vSphere, Hyper-V are widely used.A virtual machine (VM) consists of two files: a "configuration file" that specifies the VM's virtual CPU, memory, and hard drive (vHD), and a "disc image file" that stores the user's data (vHD). When a virtual machine is active, it creates a "memory page" in the main memory of the VMH, which is temporary in nature. When a VM is formed, all aforementioned data files are written to the VMH's storage. Consequently, when you delete, copy, or relocate a virtual machine, it indicates the file deletion, copy, or relocation. One of the benefits of virtualization is a single virtual machine (VM) can migrate from one virtual machine host (VMH) to another. In order to run on several VMH platforms, virtual machines (VMs) can migrate between them. If the virtual machine is currently running when the migration begins, it must be stopped. By coping the virtual machine's settings and disc ima

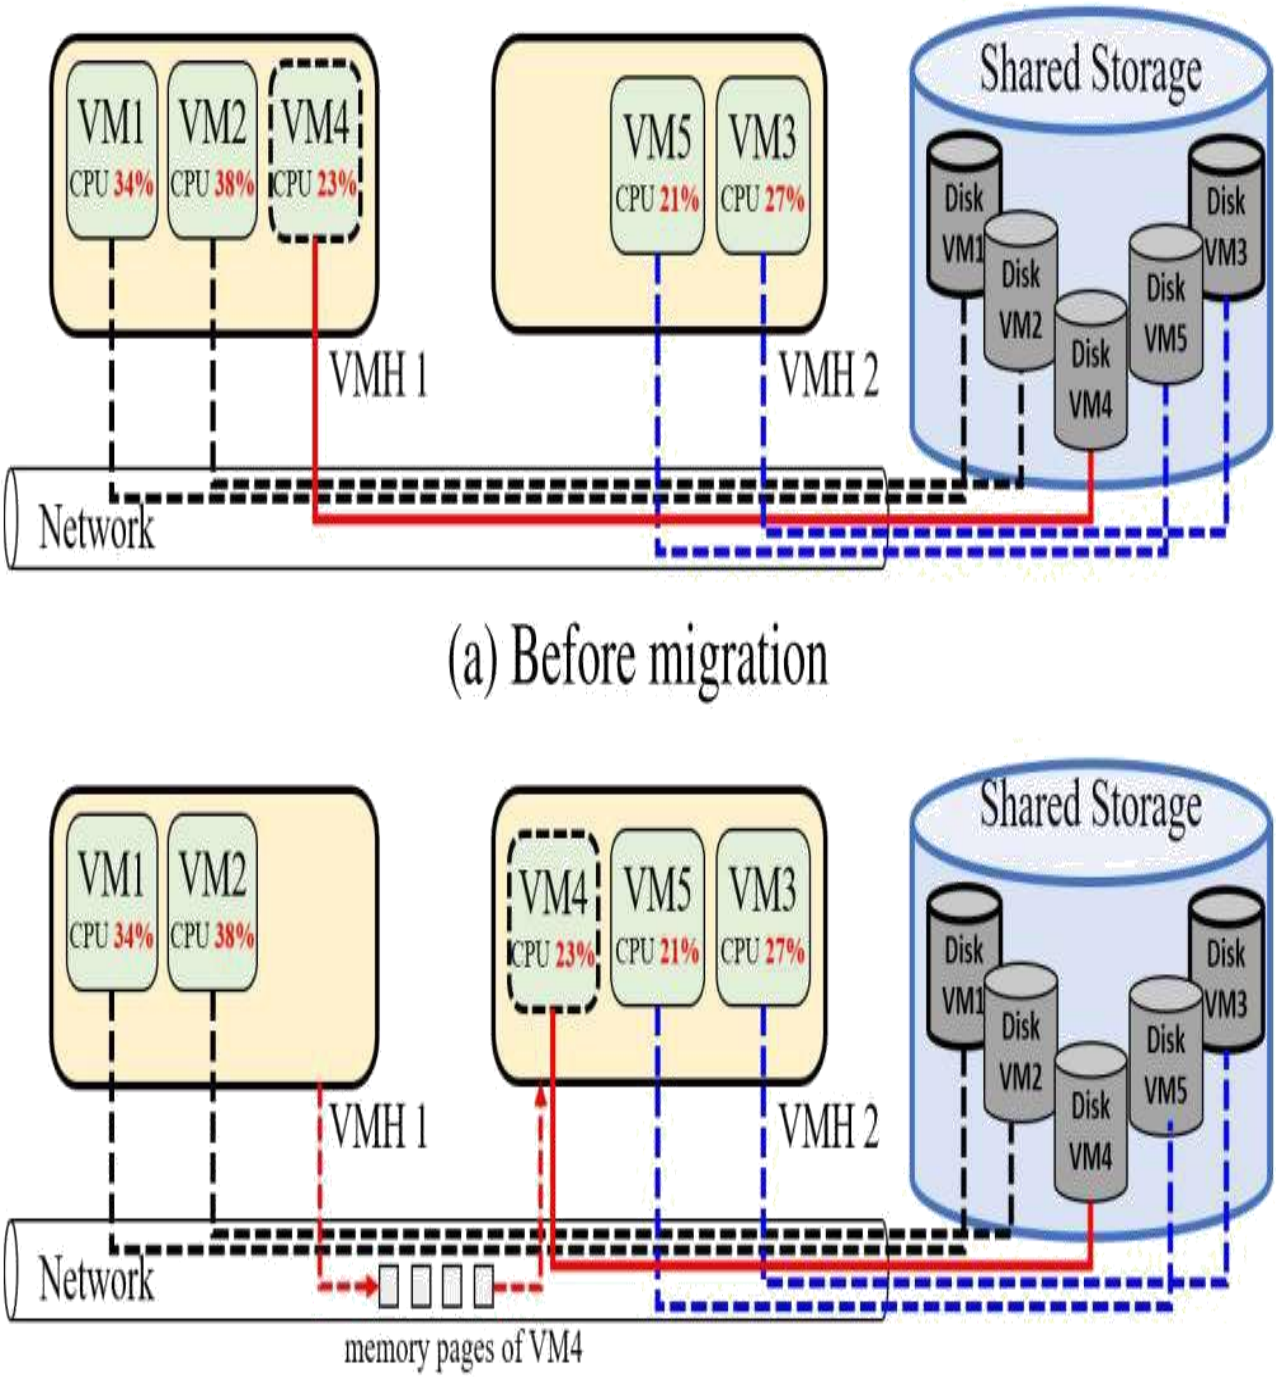

Fig 2. Live relocation with shared storage.

Depending on the size and storage type of vHD and VM can take anywhere changes a few seconds to several minutes. When a virtual machine (VM) is moved, data stored in its vRAM must be sent over the network. The larger the vRAM, the more data must be sent, which places a higher strain on the system. To minimise disruption to virtual machine (VM) users, so-called "live migration" involves a fast re-configuration of vHD and vRAM for migration during which the VMs are powered down for an exceptionally little period of time. Live migration is most frequently used with a shared storage system. Instead of physically moving vHDs, virtual machine migrations can be performed fast and easily by just changing ownerships and disc mapping files (huge sizes). As shown in Fig. 2, this live migration between two VMHs using shared storage is a realistic situation. Let's pretend the admin decides to move VM4. Memory pages are copied from VMH1 to VMH2, and the corresponding disc mapping files for VM4 are moved around in the storage. Load balancing

boosts efficiency and has less effect on running VMs with live migration.

3.1. Problem Formulation

The bulk of a virtual machine's load is determined by the use of its central processing unit (CPU), the quantity of memory that is accessible, the speed of the network, and other variables. Assume that v represents a virtual machine (VM), and the value of ( ) indicates the amount of work being done by that VM. That is shown in the equation (1), the ( ) might be seen as a function.

where (*h*) represents the load on the system and ( ),1– – , represents the load on the virtual machine (VM) v i. In most cases, the SLA will safeguard the load on each VM, and this load should be above a fair threshold in order to keep the service quality high. In addition, the load VM is bounded by quota liability. The upper and lower boundaries of ( ) are both described by Equat

Constants $_*$( ) and *( ) are often established by the superintendent of VMHs in accordance with the terms of the SLA and the necessities of the contract. If ( ) > *( ), the load on the v i is too large, so it results the user's responsibilities are not maintained in a smooth manner. If ( ) is less than *( ), this indicates the load is low, which results in a waste of the resources provided by the VMH.

Let's states there are p virtual machine hosts (VMHs), labelled h 1,...,h p, running in a data centre. The total load carried by each VMH must fall within a tolerable range as well, and this load distribution can be expresswhere $1 \leq \leq$. Also, $_*(h)$ and $^*(h)$ are parameters of control that were established by the administrator. If (h) is more than $^*(h)$, which will not acquire adequate resources until that are operating on h , that will result in a decrease in performance and also decrease in service quality... If (h) $\leq _*(h)$,The computer resources are unused still and being thrown away and in order to maintain the coherence of equation (4) across all VMHs. As a result of the overloading of certain VMHs the event that equation (5) becomes damaged, it is possible that some VMs associated with these VMHs is necessary to be powered down or relocated to other VMHs to achieve LB. After the transfer of VMs, it is anticipated that the load on each and every VMH would be balanced. Suppose h is a VMH that is on the verge of being overloaded, and where h is a VMH that is operating within its safe load, (h) > $^*(h)$, while (h) $\ll ^*(h)$. If migration of q virtual machines, , … , , from h to h is undertaken, the load on and h will alter in the following manner:

Therefore, LB by the migration of virtual machines (VMs) can be viewed as a combinatorial problem. In this scenario, the optimal set of VMs is chosen from the VMHs and then migrated to the appropriate hosts, and equations (4) and (5) are always observed either before or after the VM migration. The following concerns are looked at in detail in this investigation.

After the transfer of VMs, it is anticipated that the load of VMHs would continue to be balanced. In order to avert the target hosts from getting overloaded after the migration, it is required to make a prediction regarding the load of the VMHs. In order to derive the descriptive formulation of ( ) in Equation (2), is the one of the techniques to gather a significant quantity of data and then identify a model that corresponds with the data. Black-box and white-

box are both categories of educational approaches that might be taken. The explainability and was developed which is the primary factor of differentiates the two of them. In system administration point of view, an explainable virtual machine load model can be linked

readability of the regression model and altered with the management system in a more straightforward manner.

A job-assignment optimization problem, which is typically a time-consuming combinatorial explosion problem, it must be solved in order to choose the optimal collection of virtual machines and destination hosts for migration. For load balancing and smooth migration, it is required the selection method that is both efficient and effective. The process of doing research is outlined in Figure 3 below .

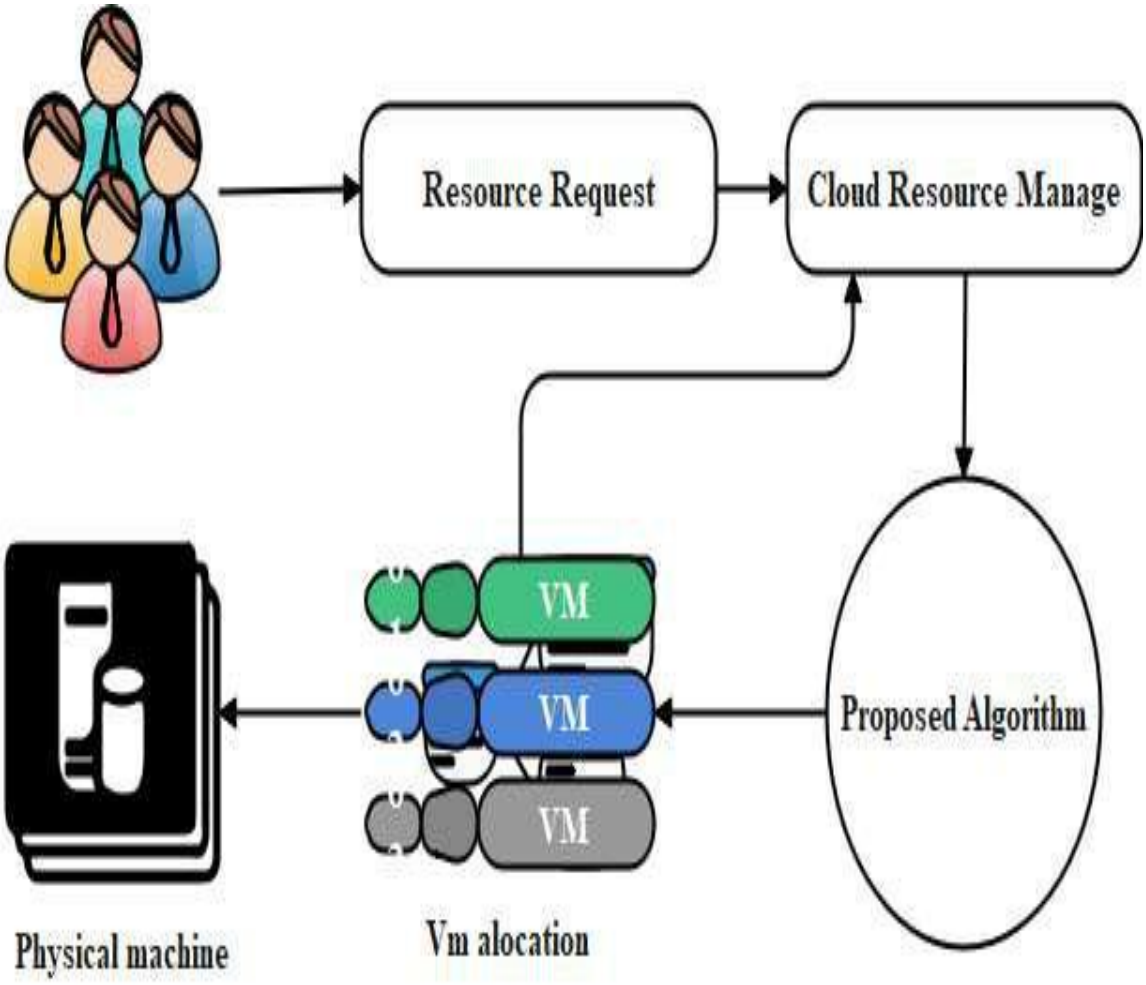

Fig 3: The proposed load-balancing system.

3.2. Proposed AVAO algorithm

This work introduces a novel AVAO method used to optimize the load balancing in VMs. The newly developed AVAO algorithm was developed by changing the AVOA's [19] methods in light of the AO's increased exploration capacity [20]. The population-based AVOA algorithm draws its inspiration from the foraging, navigation, and way of life of African vultures. Selection of the best vulture, estimation of starvation rate, exploration, and exploitation are the four steps of AVOA implementation which include best and second-best solutions to any difficult situations sought after by AVOA. The algorithm has a relatively simple computational structure and highly adaptable. In addition, between resonance and unpredictability strikes a balance are programme successfully. On the other hand, including expanded exploration, narrowed exploration, expanded exploitation, and narrowed exploitation, taking into account the predatory behaviour of Aquila are the four steps applied in AO method. Real-time applications and has a quick convergence rate can be handled by the AO method successfully. Thus, excellent efficiency and quick convergence by merging both the algorithms are achieved by the AVAO algorithm. Following are the steps in the proposed AVAO algorithm.

i) Initialization

Let us assume there are number of vultures. The first step is to initialize the population of vultures in the problem space and can be represented by,

$$= \{ \quad , \qquad\qquad ,\ldots, \quad ,\ldots, \qquad \} \quad (8)$$

where, represents the ith vulture in the population.

ii) Determine the best vulture

Once the population is initialized, the best vulture is determined by considering the fitness of all the vultures. The value of fitness is calculated by using mean square error given by the following equation.

Here, represents the target output, * defines the output of the DMN and n designates the overall sample count.

After the fitness is computed, the best vulture of the first group is selected from the group with the best solution and the one with the second-best value of fitness is considered the second group's best vulture. The best vultures are determined by various iterations.

Here, and are factors have to be calculated ahead of the search operation and has a value in the range [0,1] and the factors to be computed before the search mechanism with the measures between 0 and 1. The term represents the probability of selecting the best vulture and is calculated using the roulette wheel.

iii) Determination of starvation rate of vultures

Usually in search of food the vultures fly to long distances when they are full and this produce high energy. But in case if they are hungry, they feel shortage of energy of exploring long distances and they become aggressive and seek the food near the powerful vulture. Thus, the rate at which the vulture is starving determines the exploration and exploitation phases and it can be mathematically modelled by using the following equations. The satiated vulture is given by,

=		(2 ×	+1)× ×	1 −	+ (11)
= ×		×	+	×	− 1 (12)

where, and denote the present iteration count and the overall count of iterations. , and are arbitrary numbers in the range [0,1], [−1,1] and [−2,2] respectively. Further, is a parameter, whose value is fixed before the searching process, and the probability of exploration enhances with the value of . The vultures hunt for food in varied spaces and the algorithm is in exploration phase, if the value of | | > 1, otherwise the exploitation phase is supported.

iv)Exploration phase

Vultures have good quality of eyesight and retain high capability in identifying weak animals, while hunting for food. But, searching food is highly challenging and the vultures have to perform careful scrutiny of their surroundings for a long period over vast distances. Random areas are examined by the usage of two approaches. An arbitrary parameter , which has a value in the range [0,1] is utilized to select the approaches. Based on the subsequent equations the strategies are selected.

(+ 1) = ( ) − ( ) × if ≥ (13)

(+ 1) = ( ) − + × (−) × +if < (14)

( ) = | × ( ) − ( )| (15)

Here, (+ 1) denotes the vulture position vector, represents the coefficient vector. , and are random variable in the range [0,1]. The terms and denotes the lower as well as the upper limits of the variable.

Relieving equation (13) in equation (15),

(+ 1) = ( ) − | × ( ) − ( )| × (16)

Here, ( ) > ( ) and hence the above equation can be rewritten as,

(+ 1) = ( ) + (× ( ) − ( )) × (17)

(+ 1) = ( )[1 + ×] − ( ) × (18)

In the AO algorithm, Aquila identifies the position of the prey by exploring climbing up and then determining the search area. The expanded exploration ability of the Aquila can be given by,

(+ 1) =( ) × 1 −+ (( ) − ( ) ∗) (19)

Where,

( ) = ∑ ( ) (20)

Assume, = 1

(+1)= ( ) × 1 − − + ( ) (21)

Consider, (+ 1) = (+ 1) (22)

( ) = ( ) (23)

( ) = ( ) (24)

(+ 1) = ( ) × 1 − − + ( ) (25)

( ) = (+ 1) − ( ) × 1 − − (26)

Substituting equation (26) in equation (18),

(+ 1) = ( )[1 + ×] − (+ 1) × + ( ) × 1 − −× (27)

(+ 1) + (+ 1) × = ( ) 1 + × + 1 − − × (28)

(+ 1)[1 +] = ( ) 1 + + 1 − − × (29)

(+ 1) = ( ) [] × (30)

Here, denotes the number of samples and is a arbitrary number.

v) Exploitation: phase 1

Depending on the value of where exploitation is performed in two phases. If the value of |SR| lies between 0.5 and 1, then phase 1 is executed. Rotating flight and siege-fight are the of two techniques comprises by first phase. A parameter is utilised in selecting the strategies, which has to be computed ahead of searching. The parameter is compared to a random variable to select the strategies. If < , then rotating flight approach is implemented, else siege fight approach is performed.

a) Contest for food

The vultures are full and have high energy, if | | ≥ 0.5. Brutal disputes might occur When vultures accumulate on a single food source. The highly powerful vultures wouldn’t share the food with the weak vultures, whereas the weak vultures attempt to

exhaust the strong vultures by assembling around them and snatching the food leading to conflicts.

(+ 1) = ( ) × (+) − ( ) (31)
( ) = ( ) − ( ) (32)

Here, is an arbitrary number in the range [0,1].

b) Rotating flight of Vultures

A rotational flight is made by the vultures for modelling the spiral movement, and a spiral motion is formed among the best two vultures and the other vultures and this can be modelled as,

(+ 1) = ( ) − (+) (33)

= ( ) ×

= ( ) ×

where, and are arbitrary numbers in the range [0,1

× (( )) (34)

× (( )) (35)

vi) Exploitation: phase 2

In the second phase, by using the siege and aggressive strife strategy the food source is determined, where the other vultures aggregate over the food source following the motion of the best vultures. This phase is executed when | | < 0.5. A parameter is utilized in selecting the strategies, which has to be computed ahead of searching. The parameter is compared to a random variable to select the strategies. If < , then the cultures are accumulated over the food source, otherwise aggressive siege-flight strategy is performed.

(a) Accumulation of vultures over food source

Here, all vulture's close examines the motion of the source of food is carried out. When the vultures are hungry, they compete with each other over the food source. This can be represented as,

= ( ) = ( ) −

× (36)

× (37)

Here, ( ) and ( ) denote the best vultures The position of the vulture in the next iteration is given by.

(+ 1) = (38)

(b) Aggressive conflicting for food

The chief vulture becomes too weak to compete with other vultures when it is starved, when | | < 0.5, which turn aggressive and move in multiple directions and leading to the group head in their search for food. This is modelled as,

(+ 1) = ( ) − | ( )| × × ( ) (39) Here, ( ) specifies the distance between a vulture and anyone of the best vultures. vii) Feasibility evaluation

By finding the value of fitness the optimal solution is calculated. If the current solution found has the least fitness, then the existing solution is substituted by the current one.

viii) Termination

The above steps are kept reiterated till a best solution is achieved.

4. Result Analysis

4.1. Simulation Setup

Currently, the CloudSim imitation tool is the most often utilised by academics and developers for

studying cloud-related topics. It has the potential to reduce or even finish with the requirement and associated costs, computational facilities for performance assessment and modelling the research solution. Downloading and integrating this simulation tool's external framework is possible with popular IDEs like Eclipse, NetBeans, Maven, and others. NetBeans IDE 8.2 with Windows 10 run the CloudSim toolkit to mimic the Cloud Computing environment.

To measure the quality of suggested method in a real-world cloud setting, here it is virtualized a number of entities and computing resources to simulate a scheduling and load-balancing situation. Two data centres, six virtual machines, and forty jobs, or cloudlets, were used in the studies, all running on a simulation platform. The number of instructions in the task is created at random up to a maximum of 1,000,000,000,000. (MI). The amount of work that can be assigned to a VM is based on its processing power, memory capacity, and network throughput. Table 1 below summarises the CloudSim configuration settings.

TABLE 1. Hardware necessities.

Component	Specification
Operating Structure	Windows 64-bit OS
Processor	Intel CoreTM CPU @ 1.19 GHz
RAM	16.0 GB

4.2. Performance Metrics

In the context of the cloud, based on the interaction of three parameters the effectiveness of the suggested LB algorithm was evaluated. The following performance matrix is utilised in the process of measuring and analysing the presentation.

1) Makespan (MT): It refers to the amount of time that must elapse before a cloudlet can be planned. To evaluate the effectiveness of scheduling algorithms with regard to the passage of time is the primary purpose of this makespan. It has to be chopped down in order to make room for the efficient execution of other activities and to free up resources for other jobs. In the following equations, CT stands for cloudlet completion time, and n represents the total sum of VM in use. This is how it is measured.

= ( ) (40)

= ∑ ( ) (41)

2) Execution Time (ExT): It is the precise amount of time needed to complete the tasks (cloudlets) have been assigned to a virtual machine. It is recommended that this statistic

be lowered in order to progress the algorithm's overall performance. In the following equations, is measured using AcT, which which stands for the total sum of cloudlets.

= (42)

= ∑ (43)

3) Resource Utilization (RU): This is another measurable statistic, and it is dependent on the metrics discussed above. It is measured to enhance the effectiveness of utilising the resources in a situation where hosted in the cloud. The following equations are used to compute it, where "ExT" stands for "total execution time" and "MT" stands for "total Makespan." The degree to which the suggested algorithm makes effective use of the computer's central processing unit can be evaluated that is based on the average resource usage. This measure has a range of 0 to 1, with a maximum value of 1 representing the best-case scenario, which shows all available resources are utilised, and a minimum value of 0 on behalf of the worst case scenario, which indicates that all available resources are in perfect condition.

= (44)

= × 100 (45)

The objective of performing this experiment is to provide evidence of a dynamic cloud environment

can result in a shorter Makespan and execution time while simultaneously improving the amount of resource consumption. During the process of validating the algorithm, some thought has given to the possibility of preemptively scheduling jobs. This indicates that the task may be stopped in the middle of its execution until workload exceeds the SLA, and it can be transferred to another resource in order to finish its execution. During the process of scheduling, a number of quality of service performance criteria of cloudlets, including as:

Arrival Time: identifies the time at which cloudlets arrive or the moment at which the algorithm gets the user request. Within the CloudSim environment, this point in time is referred to as the cloudlet start time. When using CloudSim, the default setting ensures that all cloudlets reach the broker at the same exact moment. This is known as a random Arrival Time parameter, and it has been changed in order to make adjustments in this experiment so that modifications can be made to postpone the submission of cloudlets. The logic that is implemented in this function will cause the broker to allocate the cloudlets to the VMs in a manner that is completely arbitrary. By making use of this parameter, it is able to construct an algorithm that is capable of operating in a dynamic situation in which the arrival time for each request may be varied...

Task Length: determines the size of tasks in bytes; tasks with a lower size have a greater impact on resource consumption. In CloudSim, every Cloudlet must have a length value which identifies the cloudlet type. This number might indicate whether the cloudlet is a heavy request, a light request, or a medium request. During this experiment, the length of each Cloudlet was measured and given a value determined by chance. It is important for all cloudlets to have random values so that client
each Virtual Machine, the length parameter is a crucial input in the experiment. On the basis of this parameter, it is possible to identify the Time taken to Complete requests present in each VM. On the basis of this, It's able to establish whether or not there is a breach of the SLA...

Deadline: CSPs one of the important tasks by SLA is to establish maximum time taken to complete the task. In the context of this experiment, each Cloudlet has a unique deadline value; thus, each customer will receive a unique SLA contract that is tailored to their specific requirements and the level of service they anticipate by receiving from cloud providers. As a result, it is recommended to utilize the random deadline value rather than a static one. Here, it is determined whether a breach of the (SLA) or not by looking whether the Time taken to Complete the requests before the Deadline.

Table 2 provides an illustration of some of the variables that comprise the workload and are determined by the two factors discussed above (Task Length and Deadline).

TABLE 2. CloudSim simulator requirements.

Type	Parameter	Value
Cloudlet (Task)	Length of task (in bytes)	Random<upper threshold (1000000)
	Total number of task	1-40
Virtual machine (VM)	Count of Virtual Machines	2-6
	(VMs)	9980-15000-MIPS
	CPU frequency and amount of	512-Mb
	RAM in a single VM	1000-Mb
	Cloudlet Scheduler	Time Shared
	The minimum sum of processor elements (PEs) that must be provided	1
	VMM	Xen
Data Center	Sum of Data Centres	2

Here, the effectiveness of the suggested method is measured across three distinct scenarios: There are three options here: (1) two VMs housing 10–40 cloudlets, (2) four VMs housing 10–40 cloudlets, and (3) six VMs housing 10–40 cloudlets. These simulation-based variables can be increased to

better simulate scheduling and workload migration between virtual machines.

As various values are evaluated for work criteria like Deadline, arrival time, and task length, the typical Makespan, Execution time, and resource consumption were recorded. All virtual machines (VMs) in the cloud used for the experiment are identical in terms of their processing power and storage space for each scenario. The allocation of resources is then

modified based on the violation of a VM. Tables 3 to 5 detail the changes in the proposed model's metrics as a result of varying virtual machine types.

TABLE 3. Results were gotten for 2 VMs with 10 To 40 tasks.

Number of cloudlets	Average Execution Time (ms)	Resource Utilization (%)	Average Makespan (ms)
10	195.93672 04	75	261.44009 38

In the course of this investigation, Makespan Time has served as the primary comparative variable of interest. The primary purpose of the Load Balancing algorithm has been presented to improve the use and allocation of cloud resources while simultaneously reducing the amount of time needed to plan a job in order to boost the overall performance of

cloud-based applications. This technique was designed in order to optimise the Makespan and allot cloudlets to Virtual Machines in the most possible effective manner. It makes effective by the use of the resources that are available in the cloud environment. This algorithm was chosen to serve as a point of comparison, that is related closely to the main aim of this research and the framework for its execution. This method included in QoS parameters and priority as part

of the future work that was planned for the Dynamic LB algorithm. The purpose of our algorithm was to highlight how the results might be modified by depending on whether these factors were employed or not. Both of these methods make use of factors like the cloudlet length and the completion time. The LB method has been developed are taken into account various arrival times and deadlines in order to follow up with the SLA document in a manner which is in line with QoS criteria. This result gives improved service for cloud applications. Makespan is used to make comparisons between the outcomes, as illustrated in figure 4, where the y-axis shows the value of Makespan. By conclusion, the results have been achieved for a total of forty different assignments.

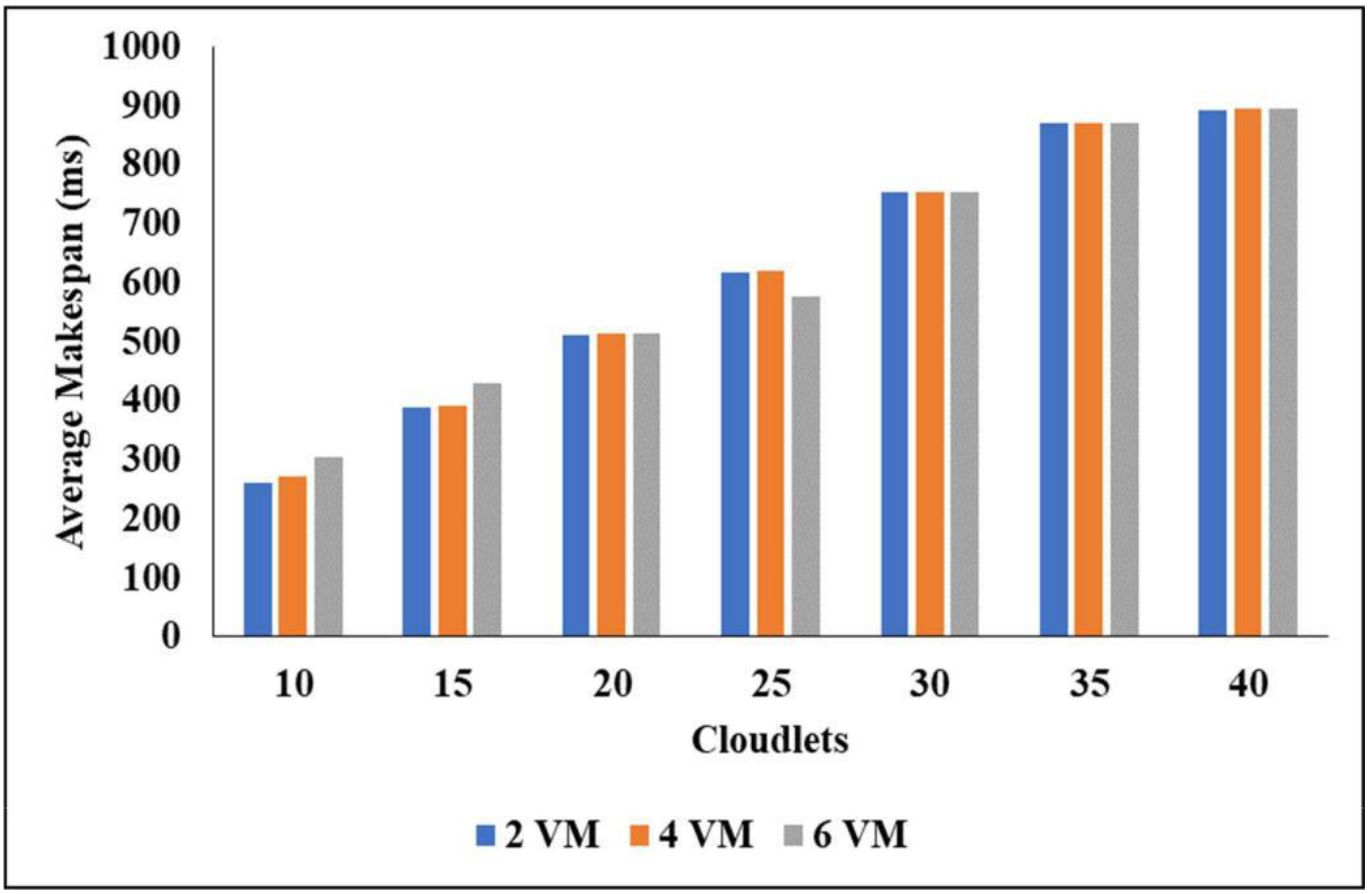

Fig 4: Graphical Representation of proposed model in Makespa

The experiment took into consideration of very broad spectrum of task lengths, which is shown in the graph as a rise in Makespan for the proposed method as the number of tasks grows from 25 to 40. The LB method presented can handle requests for bigger jobs up to 1,000,000 MI in length. Because Makespan is dependent on the load that is placed on the VMs, increasing the task length will also result in an increase in Makespan. Makespan will be indicates the total number of cloudlets (tasks).

reduced for cases involving 25-40 jobs since suggested approach is modified to handle a lesser size.

In addition, comparisons are made between the results based on resource usage, as shown in figure 5, where the y-axis represents the Resource utilisation expressed as a % value and the x-axis

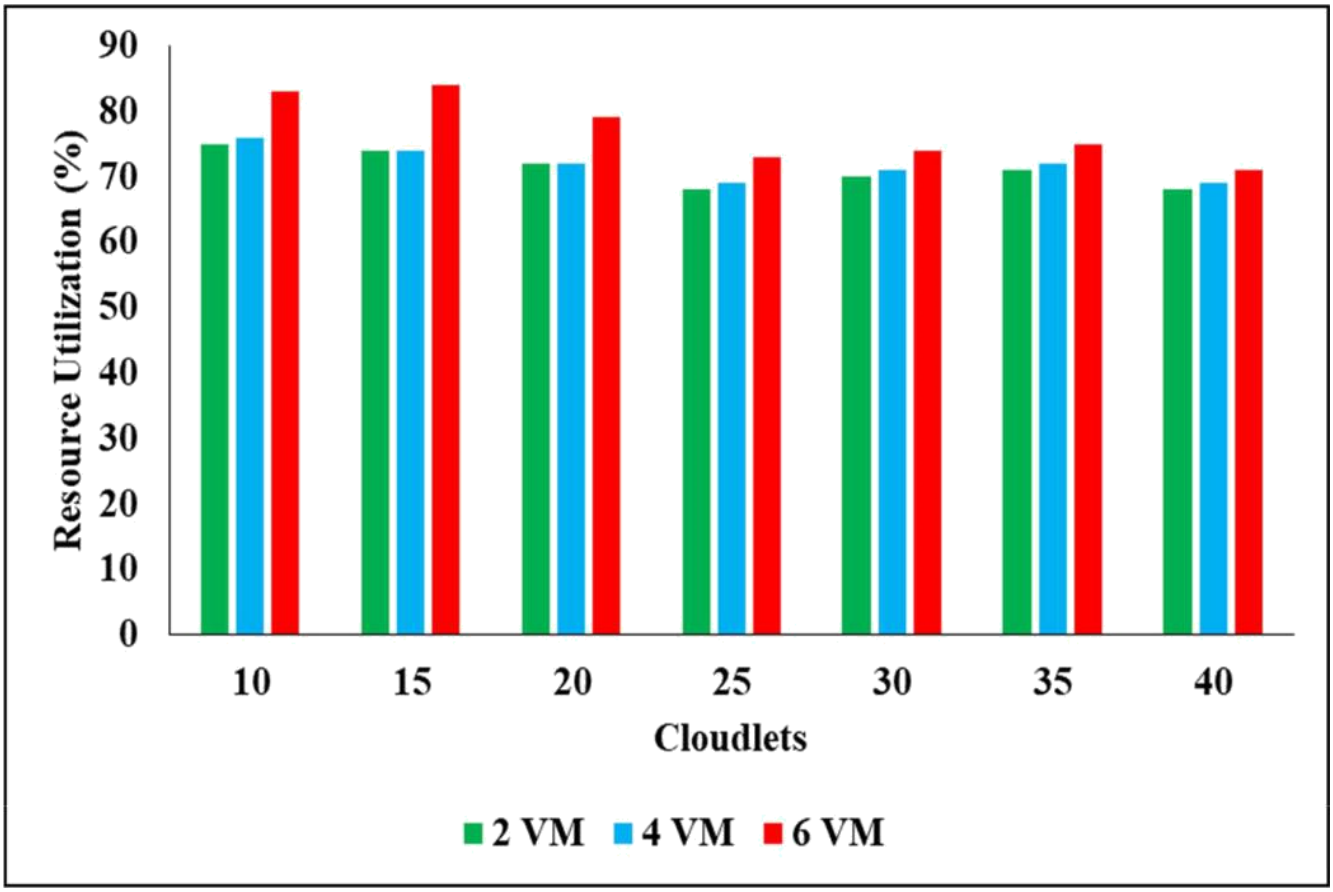

Fig 5: Graphical Representation of proposed model in Resource utilization

The new method achieves a slightly higher level of resource utilisation in 6 virtual machines, by reaching 78% of their total capacity. In the final analysis of the data, it was demonstrated that by considering QoS criteria like the Deadline can be considerably enhance the consumption of resources, hence shortening the Makespan and offering an effective allocation strategy in VMs. In addition, the Workload Balancing Algorithm for Data Centers to Optimize Cloud Computing Applications which are developed might be the assistance to a variety of applications, such as location-, and so on.

5. Summary

This part serves as the paper's conclusion and summarises the findings as well as the outcomes achieved from the suggested LB algorithm. A technique for load balancing that is based on evolutionary computing is presented in this study. When building symbolic regression models of VMs using AVAO, loads on VMs as well as the resource metrics associated with those VMs are monitored and utilised as inputs. The ideal combination of virtual machine and virtual machine host (VM-VMH) assignment is determined by AVAO, which also anticipates VMH loads based on AVAO models and advises the VMs to be transferred for load-balancing purposes. Hence this research gives knowledge about, task scheduling plays a significant role in ensuring that a cloud environment's workload is distributed evenly. The process of load balancing can be improved by utilising task scheduling, which can lead to more effective use of cloud resources. A more efficient algorithm for load balancing was the focus of this particular piece of research. The findings demonstrated that suggested approach shortens the Makespan and maximises the consumption of resources by 78%. It also demonstrates that the suggested algorithm is capable of functioning in a dynamic cloud environment, which is characterised by a large number of variations in the duration of user requests and the arrival of requests from users in an arbitrary sequence. In comparison to the current method, the algorithm is also able to manage requests of a significant scale. By redistributing resources, the programme corrects SLA violations of VMs and the tasks are carried out effectively.

Acne detection using convolutional neural networks and image processing techniques.

Premanand Ghadekar, Aniket Joshi, Atharv Vanjari, Mohammed Raza, Shubhankar Gupta, Anagha Gajaralwar

Abstract - **This paper describes a proposed model for identifying and assessing acne and other facial skin problems using a large number of selfies. The model uses convolutional neural networks and various image processing techniques to extract and analyse specific features of the skin. The model has been evaluated on a sample of 230 test images and has been found to perform better than human assessment in over 50% of cases, with an accuracy of 97% and a F1 score of 98%.**

Keywords— ***skin disorders, acne and pimples, dermal issues, haar cascade , convolutional neural network, object detection***

I. INTRODUCTION

Medical vulgaris which is also known as acne is a type of skin disorder which occurs when the pores of skin get blocked and get filled with dead skin cells and oil. It is most commonly seen in the teen agers and also seen in some aged people also Acne get produced when An oily substance which is also known as sebum that lubricated human skin and hairs and dead skin cells plug hair follicles. Increase of bacteria can multiply the number of pimples and acne on the face and it might also increase the inflammation and infections. Acne results in the inflammation and producing larger and dark red pimples. Medically and technically the check up and the assessment of acne is done by the respective dermatologist and it requires a clinical environment. The given prescriptions of doctor are then followed by the patient over a long period of time to heal the spots and it requires a good capital. The medical field is growing tremendously as this problem is very common in most of the people. From the acne patients who need a day to day treatment or a long-time treatment has to follow the dermatologist and have to visit the clinics frequently just for their basic check-up and doctor's further prescription. According to a survey the average time worldwide for a patient to wait for getting an appointment with dermatologist is 32 days [1]. This leads to big frustration to the acne patients as it affects their day to day life cycle, their food intake, their schedule etc.... To fill this gap model
is been created which will detect the acne by their images. The basic aim of this model is to 1) detect the acne through Images and then also tell, amount of acne through the world-wide data. 2) Accurately assess the acne of face and other dermal issues. 3) Give the predicted and possible image if plastic surgery or medical treatment is to be done in future. 4) To give a possible range of amount required for the treatment. 5) To classify between the acne and non-acne images. 6) To suggest the required medical treatments according to the type of dermal issue.

II. LITERATURE REVIEW

Acne is a common skin condition that occurs when dry hair follicles become blocked under the skin. Acne is an inflammatory blockage of the skin that has sebaceous glands (oil painting) connected to hair follicles containing fine hairs. is. In healthy skin, sebaceous glands produce sebum, which separates hair follicles to reach the surface of the skin[1].

A dermatologist may recommend treatment that mixes one or more of the following: oral antibiotics, topical antibiotics, topical retinoids, peroxide etc: being hooked in to whether the medical substance sometimes used for amusement is general or trade-mark name, amount, and the way many small vessels you get, the worth for antibiotics ranges between $10 and $73. prices are supported means discovered on place in the net and will different by stores for medical substances placing. A time of 5-7 days of antibiotics 1 is suggested in men or women. this is often supported by an ordered paper making clear no important point or amount different in outcomes between 3-7 days of antibiotics made a comparison of to 7 days or longer. benzoyl peroxide: it works as a keeping clean to urge changed to other form the number of germs on the top of your skin. it's usually one of the first ways of doing recommended for warm to middle diseased red marks on face. It comes as a soft paste or face wash having in it 5% benzoyl 3 peroxide 4. Benzac Ac 2.5% Gel 20 gm, 20 at Rs.83 in India topical antibiotics: Triple Antibiotic (bacitracin/neomycin/polymyxin b topical 2) may be a part of a group of the topical antibiotics give substance having effect upon the senses part and is commonly used for bacterial Skin infection[2].opical retinoids: retinoids act to figure back to normal desquamation by making price lower keratinocyte increasing greatly and giving a higher position to making clear as being different . of current interest retinoids also solid mass several important inflammatory footways that are activated in diseased red marks on face. The mean do trade with general public price of tretinoin is $105.60 for 1, 20gm of 0.025% thick a part of milk. you'll may be able to use tretinoin tickets from SingleCare to but for on the money price of tretinoin and money given for work $11.64 for 1, 20gm of 0.025% pipe Of thick a part of milk. Single Care free medical substance sometimes used for amusement tickets are often got back at taking part store for medical substances deep Learning has established itself as a really potent tool over the previous few decades because of its capability for handling huge amounts of information. Hidden layer technology is way a lot of standard than standard ways, significantly for pattern recognition. Convolutional Neural Networks square measure

among the foremost wide used deep neural networks. Now while thinking about a neural community matrix multiplications is been considered however that isn't always the case with ConvNet. It makes use of a unique approach known as Convolution[3].

Before visiting the running of CNN's let's cowl the fundamentals consisting of what's an picture and the way is it represented. An RGB picture is not anything however a matrix of pixel values having 3 planes while a grayscale picture is the equal however it has a unmarried plane. Take a examine this picture to recognize more. Lets take a filter/kernel(3x3 matrix) and use it on the enter photo to get the convolved function. This convolved function is exceeded directly to the subsequent layer[4].

Haar cascade is an set of rules which can stumble on items in images, regardless of their scale in picture and location. This set of rules isn't always so complicated and may run in real-time. Haar-cascade detector is trained to stumble on diverse items like cars, bikes, buildings, fruits, etc.Haar cascade makes use of the cascading window, and it attempts to compute capabilities in each window and classify whether or not it can be an object. Haar cascade works as a classifier. It classifies nice statistics points → which are a part of a model which detects item and bad statistics points → that don't comprise model item. The set of rules may be defined in 4 steps : Haar features calculation followed by integral images creation then implementing adaboost algorithm and then It's importanat to don't forget that this set of rules calls for numerous high quality photographs of facial and bad photographs of non-facial things to train classifier, much like different gadget getting to know models[5].

For a model first goal is to get the hair feature landmarks. The Haar function is actually a calculation performed on a contiguous rectangular region of selected neighbours within the detection. The mathematical operations involves adding of the intensities of pixel from each region and then deviation calculation between the sums. Here are some examples of hair features. Without going too deep into the background calculations (see docs if interested), keyshots significantly speed up the calculation of these hair features. Instead of doing math for each pixel, create sub-rectangles as proxies and create array references to each sub-rectangle. Used to calculate hair properties. Adaboost selects important features by default and trains a classifier to use them. a set of "vulnerable classifiers" is used to create a "strong classifier" that a set of guidelines can use to hit upon elements. A vulnerable newbie is created by means of passing a window over the enter picture and computing the Haar function for each subregion of the photograph. This distinction is as compared to a certain threshold that separates non-articles from articles [6].

From decided on friends in the detection window. The calculation entails summing the pixel intensities of each vicinity and calculating the deviation among the sums. right here are a few examples of hair features.. Because they are "weak classifiers", they require a large set of Haar functions to ensure accuracy in order to form reliable classifiers. A cascade classifier consists of several layers, each of which is a group of weak novices. Weak novices have been trained to use boosting, so implicitly predicting each weak novice produces a very accurate classifier. Based on this prediction, the classifier decides whether it should look for an element (positive) or go directly to the next area (poor). [7].

In this Paper Mr. Tingting Zhao, Hang Zhang And Jacob Spoelstra have dealed with Nestle Skin Health SHIELD. Their main aim was to develop a model using deep learning so that it will help to detect the acne from the selfie images. To deal with the spatial sensitivity of images they used CNN model on the training and the testing images. They had used ResNet 152 pre-trained Model. And they had outperformed a human dermatologist on test images[8].

In the paper Open Face: A general purpose face Recognition library with mobile applications. Mr. Brandon Amos and their team has done the research in the combined field of IOT and deep learning. They have introduced the OpenFace library which fill the gap between the public face recognition system and the private face recognition system. This paper is meant to be for the non-experts in the field of face and pattern recognition. And it helps to get familiar with the various deep learning techniques that that have used[9].

In this paper Mr. Joon Yul Choi and teams worked on the analysis of retinal diseases. They had used the convolutional neural networks and MatConvNet for automated detection of various retinal diseases with fundus photographs. They had built the dataset on 10 different categories, it had been included with normal retian and 9 different diseases regarding retina. Ther outcomes were based on VGG-19 Architecture They got an overall accuracy of 52% and on the multi categorical classifier they got an accuracy of 72.8%. further it can be improved with the help of better algorithms[10].

In this paper Mr. Yi Xiao, Liping Chen and team have given an idea of cost of surgery for removing acne from face. In China market a treatment called as Chemical Peel [CP] is widely accepted as it is used to remove the hyperpigmentation and scarring. The factors which were affecting the willingness to pay were identified using the general linear models and hence an approximate value had been provided with that. They got a response rate of almost 96% among the 476 patients. And as an conclusion they got a result for three time Chemical Peel treatments as 383.4 US dollars[11].

In this paper, they focused and studied to develop a system which detect acne on the face. This system generally detects various types, shapes, or amounts of acne on face. They have used MATLAB program, image processing module. Firstly the system converts RGB colour image to Gray scale image, then absolute maximum value is calculated, then another step is to normalize Gray scale image by reducing of data into it's simplest form, Brightness extraction is done after that image subtraction is done for region of Interest then unwanted features is eliminated, like spots and noise. This system calculates sensitivity, precision and accuracy generally all values are high except for accuracy which they need to be improved[12].

In this paper they gives a brief about acne vulgaris. Acne vulgaris (AV) is that condition of the pilosebaceous unit that results in noninflammatory lesions, such as open and closed comedones, inflammatory lesions, such as papules, pustules,

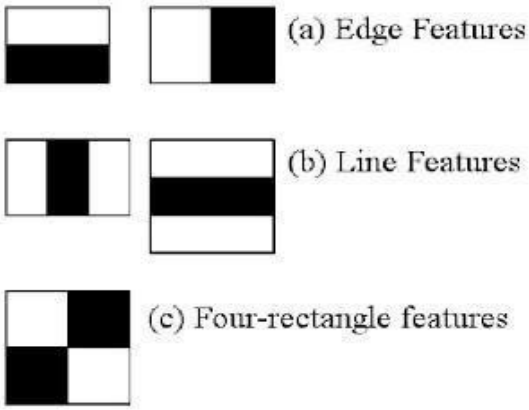
and nodules, as well as scarring of varied degrees. With a lifetime frequency of about 85%, AV is a very prevalent illness that predominantly affects adolescents. AV can linger into adulthood; among women aged 20 to 29, the prevalence of acne was 50.9%, compared to 26.3% among those aged 40 to 49. 2/3rd of all dermatology office visits for acne are from female patients, and one third of these visits are from women older than 25 years[13].

III.APPROACH

Here in this model a practical way of acne detection through images by using CNN- based transfer learning regression model is being discussed. Here the performance of this model is not less than a special trained dermatologist and then it will help to get a better prediction of the total revenue required for the treatment of such acne and also for plastic surgery if done [8]. Here proposed model is a combination method of facial landmark model and OneEye OpenCV model to extract skin regions from different regions of the face for background noise removal. Addressing the limited availability of labeled training data requires image scrolling as an innovative approach to data enhancement. The result is that the transformational regression model with corresponding data augmentation is one of the most effective methods to train a model, regardless of the size of the training set.

HAAR CASCADE

Haar cascade was used in the pre-processing of the image data to crop out faces from the images. It was observed that some of the image failed to detect the faces, hence the model was training with both the faces and background as the noise. It was recommended to use other deep learning model for face detection in the pre-processing stage to improve the quality of model. As for the dataset, there is an imbalance data on the skin tones in the dataset as there is lesser dark skin tone in the dataset [9].



The study from University of California San Francisco suggests that dark skin have a stronger skin barrier, hence this may suggest why there are lesser acne dark skin photo found. This is the limitation of the model. Alternatively, a proposed model is to increase synthetic data for dark skin in order to make up for the imbalance dataset. The model helps the company to identify acne skin consumer. This can be deployed on the website to classify the consumer skin to better recommend a more appropriate skincare product online without the salesperson. Moving forward, the shopping experience can be improved to have live predictions via video instead of images. The electronic device can be placed in stores and can be helpful to the consumers especially when the salesperson was away during the store operations.

Fig. 1. Pre-processing on image

IV.WORKFLOW

Here dataset is filled with total 2156 images, In this the 1010 images are acne while 1150 images are non-acne. The datasets are then divided into 60-20-20 for train, validation and test respectively.

Table 1. Distribution of images in Dataset

Folder	Variable type	No. of images
Train	Non-Acne	690
Train	Acne	610
Validation	Non-Acne	230
Validation	Acne	200
Test	Non-Acne	230

The general flow of the project is:

1. Data Collection and Pre - Processing.
2. Exploratory data analysis (EDA)
3. Modelling and evaluation
4. Conclusion and recommendation
5. Limitation and future development

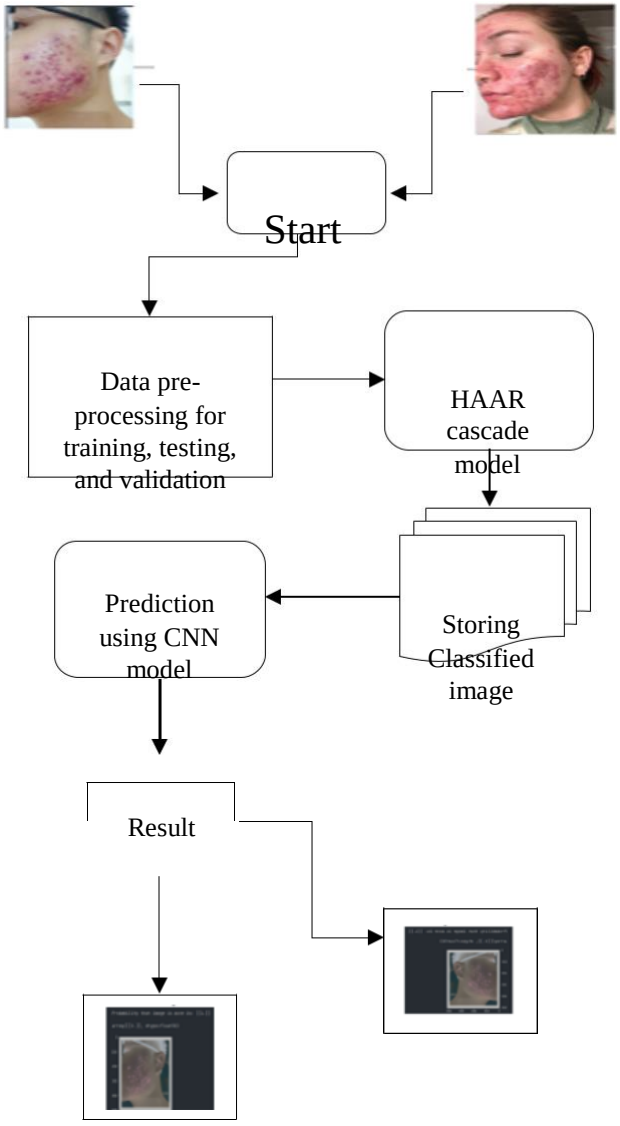


Fig. 2. Proposed flow diagram of acne detection and bill prediction.

As the flowchart shows raw images will be taken as a input which will be pre-processed and after that a series of deep learning algorithms will come into action like CNN and HAAR Cascade through which the unnecessary parts of the images will be removed and the images can directly go for training and testing and the end the final evaluation will be done.

V. Results

In a model the Haar Cascade Classifier is being used. It's an algorithm used in the field of object detection no matter what size and the object has.

Table 2. Accuracy table

	Precision	Recall	f-1 score	Support
Non-Acne	0.97	0.99	0.98	230
Acne	0.99	0.96	0.97	200
Accuracy	-	-	0.98	430
Nacro avg	0.98	0.98	0.98	430
Weighted avg	0.98	0.98	0.98	430

Less complexity of the algorithm makes it more friendly to use in real time. The algorithm can be trained to detect a variety of objects like vehicles, animals, humans, face, cars etc. Here in a model it is used for the removal of unnecessary part of the face that is basically the face cropping is done here.

Fig. 3. Input dataset Images

Fig. 4. Output Results (I)

Fig. 5. Output Results (II)

Basically here once the training and testing of the data set of 2156 images is done model first get the classification of acne and non acne images. and then model pre-process the data and then for removing the unnecessary background, it crop the images by using haar cascade algorithm.

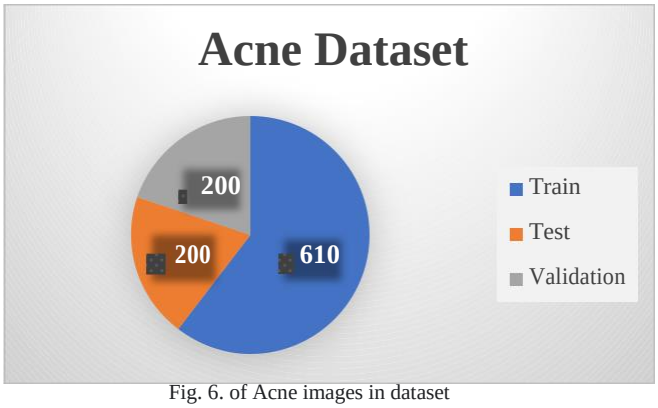

Fig. 6. of Acne images in dataset

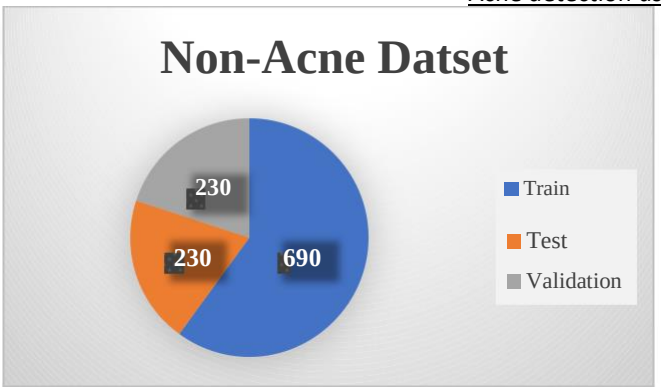

Fig. 7. of Non-Acne images in dataset

VI. Conclusion

The model has an accuracy of 97% on validation data and 98% on test data while the f1 score for validation data and test data are 98%. Compared to the previous models this is the highest precise results acquired. The model has a train score of 99% for both accuracy and f1 score. In order to prevent overfitting, dropout ratio of 50% was introduced in the CNN model.

Table 3. Accuracy per dataset

Dataset	True positive	False positive	True negative	False negative
Train	686	4	606	4
Test	225	5	195	6
Validation	228	2	192	8

In conclusion, the model has high accuracy and f1 score however, it is not able to work well with darker skin tone which can be further improve.

VII. Future Scope

For the further extension of this project we are aiming to develop a bill prediction system which will estimate the total amount to remove the acne by means of plastic surgery. This will require some changes in the previous dataset so that the model will be able to distinguish the difference between natural non acne face and after plastic surgery non acne face.

Block chain Bidding System Using Smart Contract

Shweta Mishra

Computer Engineering Department, Thakur College of Engineering & Technology, Mumbai

shwetamishra5499@gmail.com

Abstract—

The main goal of this project is to develop and implement a secure online bidding system using blockchain technology. For this we will use a smart contract.The purpose of this project is to create a system that allows bidders to connect to a validator network and place an item or product of their choice up for auction. Other customers can view various items for sale, connect to the validator network, and bid on each of those items. For each item, after a specified period of time, the highest bidder wins the item and gets the item at the bid price.Therefore, the system provides an online platform with an easy-to-use user interface for users to buy and sell various commodities. All information about an item is stored on the blockchain, including bids and related information for each item. As a result, this information is securely stored and tamper-proof. Therefore, a detailed record of all bids on an item is maintained and cannot be changed once the sale is confirmed. This ensures that the highest bidder always wins and purchases for the amount specified in the bid.Additionally, information about the item is also stored on the blockchain. The person listing the item cannot mislead bidders about the item, as it must match the description provided when the item was put up for sale. This requires both sellers and bidders to meet their buying goals and ensures that both parties have access to the sale. All information about an item is stored on the blockchain, including bids and related information for each item. As a result, this information is securely stored and tamper-proof. Therefore, a detailed record of all bids on an item is maintained and cannot be changed once the sale is confirmed. This ensures that the highest bidder always wins and purchases for the amount specified in the bid. Additionally, information about the item is also stored on the blockchain. The person listing the item cannot mislead bidders about the item, as it must match the description provided when the item was put up for sale. This requires both sellers and bidders to meet their buying goals and ensures that both parties have access to the sale.

Keywords— Smart contract, blockchain

I. INTRODUCTION

Auctioneers deploy smart contracts that allow users to bid on items within a specified auction time. After the auction time ends, the highest bidder's bid is sent to the auctioneer.

The purpose of this project is to create a system that allows customers to connect to a validator network and offer selected items or products for auction. Other customers can view the various items for sale and connect to her network of validators to bid on each of those items. For each item, after a specified period of time, the highest bidder wins the item and gets the item at the bid price. Therefore, the system provides an online platform with an easy-to-use user interface for users to buy and sell various commodities.

II. PROBLEM STATEMENT

To create and implement a trustworthy bidding system using blockchain technology. Users can list items or bid on existing items, and the results of their bids can be trusted and unmanipulated by anyone. item information is stored on the blockchain along with the description. All valid bids are also stored on the blockchain, so you can always trust the results of your bids.

III. METHODOLOGY AND

TOOLS Hardware Specification

System:

Processor	2.20 GHz
RAM	2GB
Hard Disk	10GB

Software Specification

Operating System	Any OS
Remix IDE	Smart Contract
Language	Solidity
Blockchain Network	Ganache Client
Ethereum wallet	Metamask

IV. RESEARCH WORK

Problem Analysis:
There are various bidding systems available, but this system is unreliable and focuses only on centralized systems, so bidders cannot trust the system and set up a transparent decentralized set of smart contracts on the local Ethereum network. need to do it. A Smart contract code is also available to bidders.

Requirement Analysis:
In this system, the basic requirement is to have an Ethereum wallet so that transactions are automatically possible. After that, you need to connect to the decentralized blockchain network to realize the final goal of the system: a decentralized system.

Technical Research:
The technologies used to develop this system are blockchain and smart contracts, or dapps (decentralized applications).
To study blockchain and solidity programming language I used several websites like –

1. https://www.youtube.com/channel/UCY0xL8V6NzzFcwzHCgB8orQ (YouTube)
2. https://solidity.readthedocs.io/en/v0.5.12/

For understanding the system in well manner I also used different research papers which mentioned in the references.

V. USE CASE

There are two main players in the system, sellers and bidders.
Sellers can log into the system and sell items. When he does this, the item information (description, price, etc.) is written to the blockchain. This information is visible to all other users of the system. Bidders can log into the system and view information
about the various items listed. You can then bid on any item. User information is placed on the blockchain along with the
bid. User must bid higher than the previous bid. When the bidding period ends, the highest bidder wins the item and the item is considered sold. Bidding information is stored on the blockchain, so bidding results are reliable. Therefore, only the highest bidder wins.

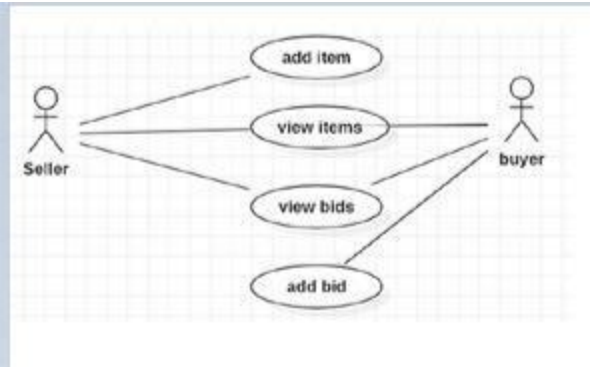

Fig1. Use Case

VI. ROLE OF CLIENT AND TYPES OF TRANSACTIONS

A user can either post an item for sale, or make a bid on existing items. Therefore, there are four defined transactions that the client can perform:

1. Post an Item for Bidding – The client will post an item along with relevant information on the blockchain
2. View items – The list of items that can be bid on

3. Place bid – Making a bid on the listed items
4. View bids – View the existing bids on the items

VII. TABLES STORED IN BLOCKCHAIN

There are two implemented tables:

1. Items table – This table consists of all available items for bidding, and all associated information
2. Bids table – This table contains the list of all bids made.

VIII. FIELDS FOR ITEM

There are five fields for each item:

1. Item ID
2. Item Name
3. Item Description
4. Post time
5. Bidding Expiry Time

IX. FIELDS FOR BID

There are five fields for each bid:

1. Bidder ID
2. Bidder Name
3. Item ID
4. Amount
5. Timestamp

X.SYSTEM ARCHITECTURE

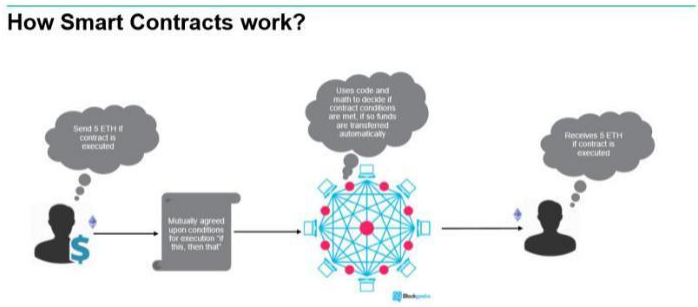

Fig2. Architecture

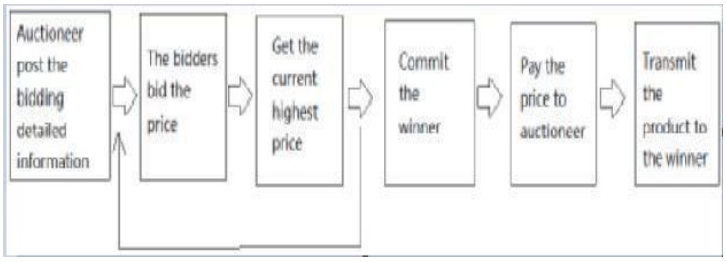

Fig3. The flowchart of E-auction

XI. CONCLUSION:

In this paper we proposed using smart contract for bidding system with the help of bloackchain. Auctioneers deploy smart contracts that allow users to bid on items within a specified auction time. After the auction time ends, the highest bidder's bid is sent to the auctioneer

ACKNOWLEDGMENT

This paper on 'Blockchain Bidding System Using Smart Contract' is a result of the motivation and co-operation by my guide Dr R.R.Sedamkar and teacher Dr. Sheetal Rathi.

Abstract. Many developers were inspired to create the new mobile applications that are utilized as barcode scanners by the widespread use of smartphones with superior capabilities. In essence, QR codes are just a type of 2D barcode that makes it simple to interact with websites, printed materials, and mobile devices by eliminating the need to manually type in contact information or URLs. Most people use QR codes, and some virus writers and cybercriminals also use them. This proposed paper gives detailed information about the design and its uses, and data that may be encoded in QR codes, as well as the clear danger posed by malicious QR codes. The paper will also illustrate a few attack scenarios that make use of QR codes.

Keywords: QR, quick response, scanner, scan, transaction.

INTRODUCTION

Nowadays, everyone has a smartphone, and UPI has just changed the banking system. Every single link is in the form of QR. After 2020, Due to pandemic demand for a standard that could carry large amounts of information without humans touching physical items has been increased. And such a solution is provided by Quick Response(QR code).

Quick Response code includes black and white color modules which are structured in a square shape on a plain color background. The information which can be ciphered should be in one of the 4 standard modes.

By the way, people are committing fraud by using malicious QR codes. And one can't predict the QR code which one is malicious and which one is not by just looking at QR code.

Problem Statement

Quick response code is everywhere now a days whenever customer visit any shop or he needs menu cardin some hotels they directly share QR code with us for payment and information but every QR code [1] that is scanned , customer doesn't know whether it's safe or not doesn't know where it will take us if that website is malicious. So to tackle this problem and aware the normal users for preventing their data from malicious sites and QR.

Literature Survey

In this paper [1], authors have analyzed fishing in this technological world, especially on the internet in which QR codes were used , authors have experimented by visualizing and studying QR codes throughout fourteen million web pages over a 1 year span. The study's findings indicate that attackers frequently employ QR code technology to disseminate malware or point people toward bogus websites. Additionally,

the relatively high number of malicious QR codes discovered during trials indicates that, on a large scale, While exploring the internet, consumers are infrequently exposed to the threats carried by QR codes, and the frequency of these assaults isn't very significant.

In this proposed paper [2] authors have given a solution for determining the JPEG image and QR code which are malicious and benign. They have proposed a system in which they have given a machine learning-based solution in which they have used convolution Neural Network (CNN) by which In order to distinguish between good and bad QR code / JPEG images, they have extracted 10 discriminative characteristics using a machine learning classifier.

In this paper authors [3] have designed new 2 level QR code inorder to increase security of QR codes .They developed two types of QR codes: the public level, which can be read by any QR code reader, and the private level, which employs textured patterns as black modules and is encoded for private message transfer. Also private methods do not affect or interfere in the process of public level thus smooth functioning of this 2-level QR code takes place.

This study [4] demonstrates how to identify perspective distortion in QR codes using edge direction and edge projection analysis.

The authors [5] of this work used a watermark technique for threat detection to develop a blind digital image based on a QR code. The suggested method provides a framework through which modified binary form of data can be embedded into the cover image's DWT domain and used to identify images or QR codes.

This paper [6] shows how QR codes can be used to attack systems . Also authors have discussed different phishing techniques from the point of view of attackers and suggested possible solutions to it .

The authors [7] of this study have suggested a method for reading QR codes based on the correlation of histograms between the reference image for the QR code and the input picture. Paper also proposes new algorithm which provides good accuracy for the trained model

This paper [8] describes the different worm attacks on the QR code and also provides the countermeasures for the same.

This paper [9] discusses the study of different malicious QR codes and also demonstrates how to identify perspective distortion in QR codes using edge direction.

The authors [10] of this study have suggested that specification of the data matrix of the barcode symbol.

This study [11] demonstrates the QR code libraries and provides a case study on their application in the NITK central library.

In this paper [12] authors have designed QR code perspective distortion based on edge

projections and edge directions and their analysis.

In this proposed paper [13] different QR patterns are given and their invariant moments and localisation.

In this proposed paper [14] authors have analyzed the BRISK algorithm (Binary Invariant Scalable Keypoints).

This paper [15] presents Quick QR code detection and recognition in high resolution photos.

4 Structure of QR Code

The QR code contains different areas that contain different patterns. They are as follows:

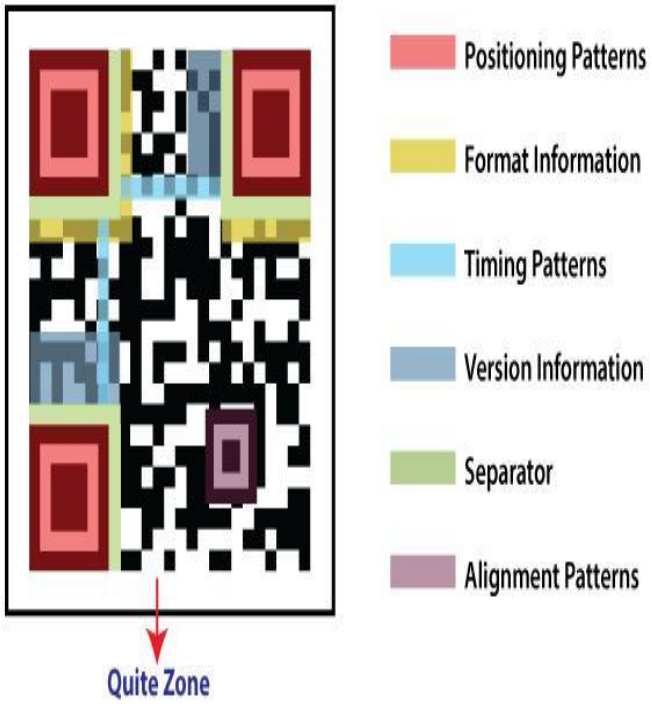

Fig 1 : QR Code Structure

4.1 FINDING PATTERN: This pattern can detect or identify the QR code and it can be read at any angle.

4.2 TIMING PATTERN: This pattern differentiates black and white modules or squares alternatively.

4.3 ALIGNMENT PATTERN: This pattern aligns the data points which are encoded in the data region.

4.4 SEPARATORS: Separators are used to separate the finding patterns.

5 QR Code Attacks

5 . [18]QR COver the past few years, QR codes have become more famous and it is the target

for hackers to spread malwares and steal some information. Hackers can use QR codes for different malicious purposes. Basically there are two main types of QR code attacks or exploits. They are as follows:

5.1 QUISHING

[26]The first type of attack is Quishing and it is somehow similar to phishing attacks. In this

4attack, a phishing page which hackers have designed to steal information like user credentials, personal data or some sensitive information is sent to a victim.[16] This attack can be avoided by making the QR code dynamic because it has more security than static one. Also aging time can be added that means if the user does not use or activate the QR code in specified time then it will become invalid. It can be prevented by encrypting the data as well.[27]

5.2 QRL JACKING

[28]The second type of attack is QRLjacking. In this attack, hackers spread malware to the user's or victim's device. QRLjacking is short for Quick Response Code Login Jacking.[19] Here the user or victim scans the QR code on a fake website which is provided by hackers and then the hackers have all access to the user's account. This attack can be avoided by sending Email/SMS to the users from service providers.[17] Additional authentication methods can be added to user login. For example, sound based authentication.

6 Algorithms Used

6.1 RANDOM FOREST

Random forest and other algorithms for supervised machine learning are frequently used to solve classification and regression issues.[20] It develops decision trees from various data samples, using their average for categorization and majority vote for regression. Random forest perform following procedures[29]:

Step 1: Scan QR code

Step 2: Preprocessing of QR code

Step 3: load the training and testing dataset

Step 4 : Feature Extraction with help of BRISK algorithm

Step 5:In Random Forest, a number of records exist randomly selected derived from dataset

Step 6: An exclusive decision tree is constructed for every sample.

Step 7: An output executes it. produced by each decision tree.

Step 8: For classification and regression, the final result is evaluated using a majority vote or an average as malicious /benign QR code

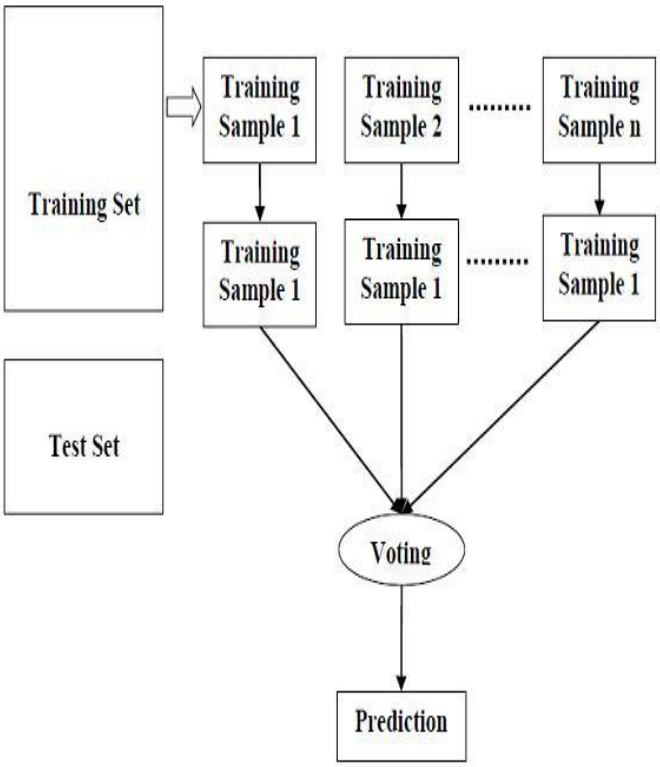

Fig 2 : Random Forest implementation

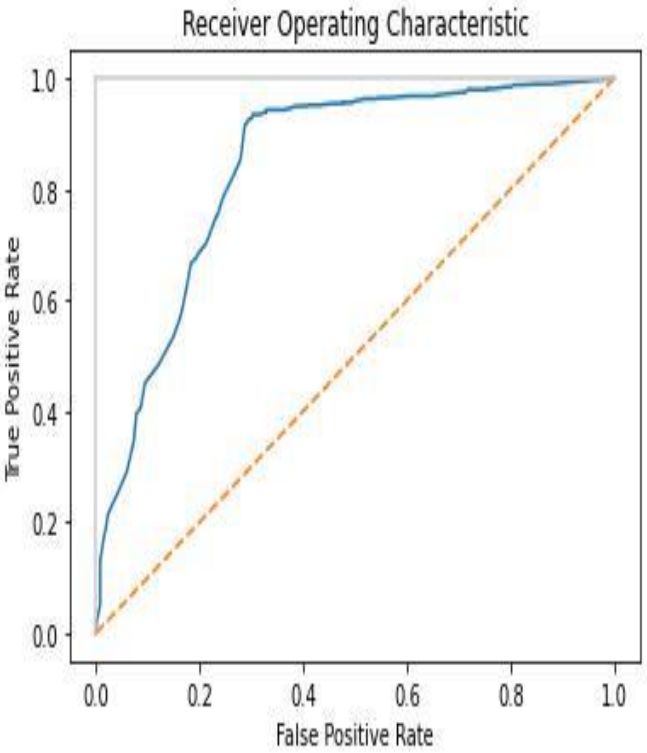

Fig 3: Random forest ROC curve

6.2 DECISION TREE

Decision tree algorithm is used for classification and regression problem analysis based on the nodes of the tree.

Step 1 : Scan QR code

Step 2 : Preprocessing of QR code

Step 3 : load the training and testing dataset

Step 4 : Feature Extraction with help of BRISK algorithm

Step 5 : Applying Decision Tree

Step 6 : Train the model

Step 7 : Detecting type of QR code [malicious/benign]

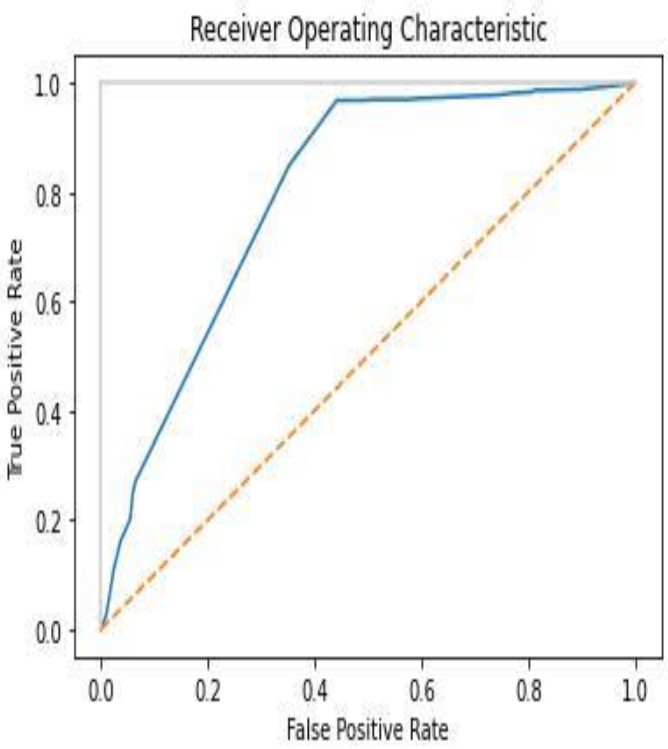

Fig 4 : Decision tree ROC curve

6.3 KNN ALGORITHM:

KNN is a supervised machine learning algorithm in which classification of data points is done on the basis of the closest neighbor class.

Step 1 : Scan QR code

Step 2 : Preprocessing of QR code

Step 3 : load the training and testing dataset

Step 4 : Feature Extraction with help of BRISK algorithm

Step 5 : choose the value of 'K' i.e nearest datapoint

Step 6: based on the value of k and distance of datapoint . KNN will assign it separate classes

Step 7 : Train the model

Step 8 : On the basis of classes it will classify QR code as malicious/benign.

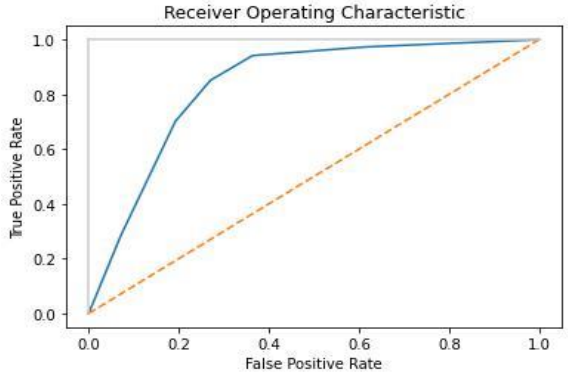

Fig 5 : KNN ROC curve

7 Diagrams

[22]In the proposed system , by using the camera of the system, first of all, scan image QR code. For data preprocessing, the model used various data pre-processing techniques such as scaling, translation etc.

Training-Testing-Model: [21] For training and testing of proposed model, dataset has splitted as 70% training dataset and 30% testing dataset into 2 classes .

After preprocessing QR code images then for training and testing of proposed model extract features from the QR code image .[23] So for extracting features of QR code, selected patterns used in it as features for the purpose of feature extraction. In this there are 3 main features: Finder pattern , Alignment pattern and Timing pattern. And for the purpose of feature extraction here BRISK algorithm is implemented[28] which selects these patterns and find relation between them and select best features from them by using scale invariance and rotational invariance .[30]Once features are selected then creation of separate files of extracted

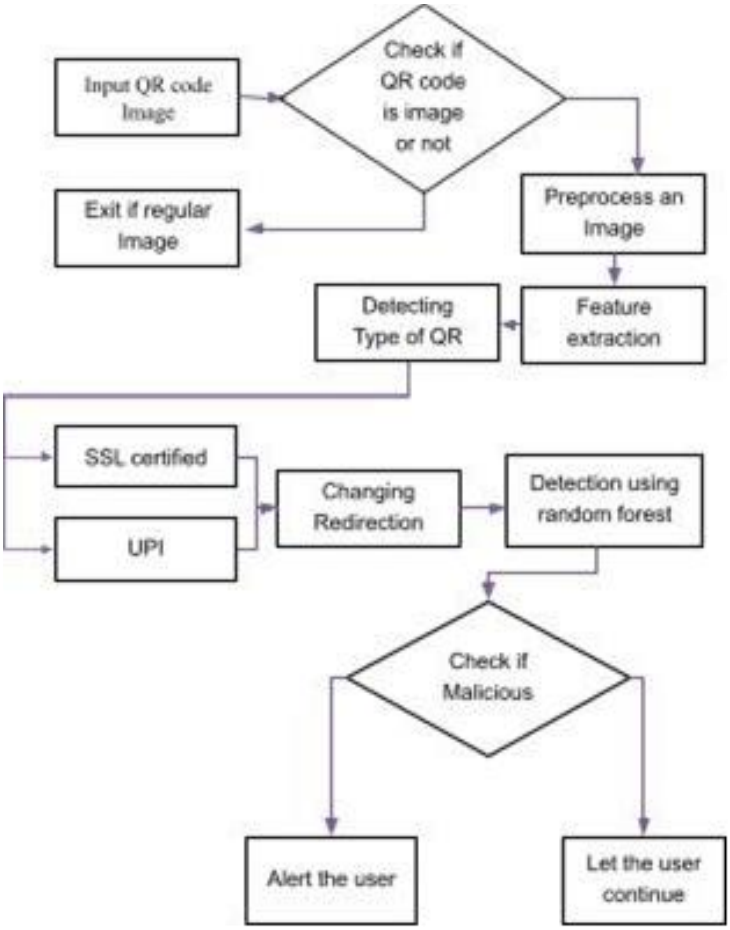

Fig 6 : Flow diagram for proposed System

Once the feature extraction is over , [24] then on the basis of QR code type our system check whether it is SSL (Secure Sockets Layer) or if it is redirecting the user to malicious website or it uses UPI protocol and based on that classification is done in respective types.

After detecting the QR code type, Then by using a random forest algorithm, classify them into two classes: malicious and normal(benign) QR codes which was our main objective. [26] While using the random forest algorithm, features extracted from BRISK algorithm as an input parameter. and with the help of different decision tree [25]classifiers of random forest algorithm based on BRISK features, classify QRs into malicious and normal on the basis of the majority of votes of decision tree classifiers. and hence proposed model have selected random forest as classifying algorithm as its accuracy was the highest. And at the end, print the result as a malicious QR code or normal QR code.

8 Implementation

Our solution is mainly based on two problems: the first is the efficiency of existing Quick response code scanners that is not on that level as of now so the proposed model uses an improved random forest algorithm to increase accuracy and efficiency and the second is to detect the problematic one or malicious QR codes, [6] because QR code fishing is a big issue nowadays so proposed model secures the user perspective for security on QR scanning by showing them proper security warning so user can make better decisions.

9 Comparative Analysis

In the proposed system , the accuracy of the random forest algorithm is 81.46% which is greater than other algorithms like Decision tree classifier (76.76%) and SVM (72%) . so one can interpret that random forest classifier performs better for our proposed system as it uses ensemble learning techniques

11 Future Scope

In the future, there is scope to improve the proposed system model for more accurate detection and classification of malicious QR codes by implementing improved machine learning algorithms.Overall, the emphasis will be on making the scanning and detection process more efficient, as well as providing the user with more detailed and accurate information regarding malicious QR codes.

12 Conclusion

With the help of a model, the detection of malicious QR is easy. A number of suspicious Quick responses will be detected so it will be helpful in the case of authentication, digital information, and especially in payment transactions. It will provide great security and most importantly people will also adapt to it. Every time while scanning QR code they will check it through the model. And the number of frauds in digitalization and transactions will be very low.

Abstract— **Deep neural networks have significantly improved people's daily lives since they were created. Deep learning provides more rational direction than humans can in almost every aspect of daily life. Though it has been likened to alchemy, developing and training neural networks continues to be a challenging and unpredictable process. Automated hy- perparameter tuning has gained popularity in both academic and com- mercial circles to minimize consumer technical barriers. The most im- portant areas of hyperparameter tuning are reviewed in this work. The primary neural network model hyperparameters are introduced in the initial section, along with their significance and methods for defining the value range. The discussion continues with the most popular optimiza- tion approaches and their efficiency. Finally, the second-order optimiza- tion and its usefulness**

Keyword- Hyperparameter tuning Deep neural network Classical searching technique Second-order optimization.

I. INTRODUCTION

Neural network (NN) approaches have expanded and gained influence over the last few years in academic and industrial sectors. NNs have recently shown im- pressive results in the areas of image classification, objective detection, indus- trial control systems, and natural language understanding [1]. The most popular strategy for hyperparameter (HP) tuning is usually based on experience, which implies that to develop a workable set of HPs, researchers must have previous knowledge of NN training. According to the no-free-lunch theorem, all opti- mization problems have a fixed computing cost, and there is no shortcut to solve them [2]. Specialists' prior knowledge, which helps select crucial parameters and narrows the search space, can be used in place of computational resources.

HPs are variables that are fixed throughout the training process of a NN system. Several factors, including the learning rate (LR), loss function, and op- timizer, can influence how well and precisely a model is taught. The activation function and the number of hidden layers are other factors. HP tuning may be

viewed as the first stage of NN training and the final stage of model development [3]. To cut humans out of the machine-learning system's feedback loop, HP tun- ing automatically improves a model's HPs. Before the training process begins, HPs must be properly adjusted with expertise because to their impact on train- ing accuracy and speed [4]. When several HPs are tuned concurrently, adjusting HPs involves a trade-off between computing resources and human effort. HP tuning has become more crucial in recent years due to two new advancements in the development of deep learning models. Upscaling NNs for greater accuracy is the first requirement. Empirical research has shown that more complex NNs with wider and deeper layers often outperform those with simple architecture [5]. The development of a demanding lightweight model with fewer weights and characteristics to provide satisfying accuracy is the second requirement. HP tun- ing is essential in both scenarios: a model with a complicated structure indicates that there are extra HPs to tune, and a well-planned structure entails that each HP must always be set to a certain range in order to repeat the accuracy. The ability to modify manually depends on experience, and researchers may always learn from previous work; thus, adjusting the HPs of a widely used model is con- ceivable. This is equivalent to small models. But, especially for bigger models or freshly published models, the vast array of HP possibilities demands a lot of researchers' painstaking work, as well as a lot of time and computer resources for trial and error. Fig. 1 depicts the block diagram for the HP tuning process.

The major contribution of the study is as follows:

– The discussion of the crucial deep neural network (DNN) model HPs, along with their significance and default settings.

– The major HP tuning strategies are examined in depth to demonstrate their

applicability to the given problem.

- comparison of the second-order optimization technique to first-order

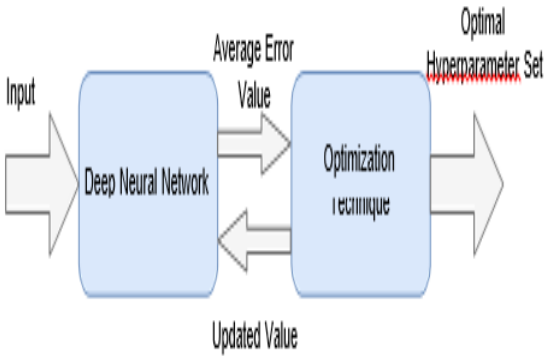

Fig. 1. Block diagram of the HP tuning process.

The rest of the paper is structured as follows. The required HPs and their default values are clearly outlined in section 2. The standard algorithms for HP tuning is discussed in section 3. The second-order optimization applied to NN models is described in section 4. Section 5 summarizes the significant ideas, while section 6 concludes the study.

II. KEY HYPERPARAMETERS AND ITS USEFULNESS

HPs have a significant impact on the effectiveness of NNs. HPs with a higher impact on weights during training are more important for NN training. Hence, it is given preferential attention. There are two types of HPs: those used to build models and those used to train models. NNs may learn more rapidly and perform better when the right HPs are chosen for the model training process.

Performance of the model is more influenced by several HPs such as opti- mizer, LR, loss function, activation function, and network depth. The previously mentioned HPs—aside from batch size and LR—are supplied throughout the model-designing process. When training, the LR, and batch size are considered [5]. This section further explains the HPs that are crucial for model building, training and their impact on models and suggested values.

2.1 Optimizer

Unaware of the optimizer's benefits, many people may be utilizing it to train their NNs. Optimizers, or optimization algorithms, are essential for increasing training efficiency and accuracy. The optimizer's selection, the mini-batch size, and the momentum are all HPs connected to optimizers. Making the right optimization choice is challenging. Optimizers are the algorithms used to modify the weights and LR of the NN to decrease losses and improve network performance. Gradient descent (GD), stochastic gradient descent (SGD), mini-batch gradient descent (MBGD), adaptive moment estimation (Adam), and root mean square propagation (RMS-prop) are some of the popular optimizers [6].

GD is the easiest and most often used optimization technique. It is heavily utilized in classification and linear regression algorithms. Backpropagation technique in NNs also uses the GD technique. A loss function's first-order derivative is necessary for the GD method of first-order optimization. It chooses how to adjust the weights so that the function can attain a minimum. Backpropagation is used to pass the loss from one layer to the next, and the weights of the model are changed to reflect the losses in order to lessen the loss. In GD, weights are adjusted after the gradient on the full dataset has been computed. The weight is updated using Eqn. 1.

$$Wnew = Wold - \alpha * [\partial(Loss)/\partial(Wold)] \quad (1)$$

Where Wnew and Wold are the updated weight and old weight respectively.

SGD is a variation of GD. It seeks to update the model's parameters more often. The model's parameters change when the loss upon every training instance is determined. As a consequence, if the data contains x number of rows, SGD will update the model parameters x times during the dataset cycle as opposed to GD's single update. Since they are updated often, model parameters exhibit large variances and vary in loss functions at different intensities. In order to reduce the significant volatility in SGD and smooth out the convergence, momentum was developed.

The momentum term is often set to 0.9 or, as needed, 0.99 or 0.999. Oscil- lation is minimized by increasing the update's strength in the same direction and reducing its movement in other directions [7]. The impact of momentum on SGD is shown in Fig. 2.

The updated value can be calculated using Eqn. 2.

$$Vnew = \eta * Vold - \alpha * [\partial(Loss)/\partial(Wold)]$$

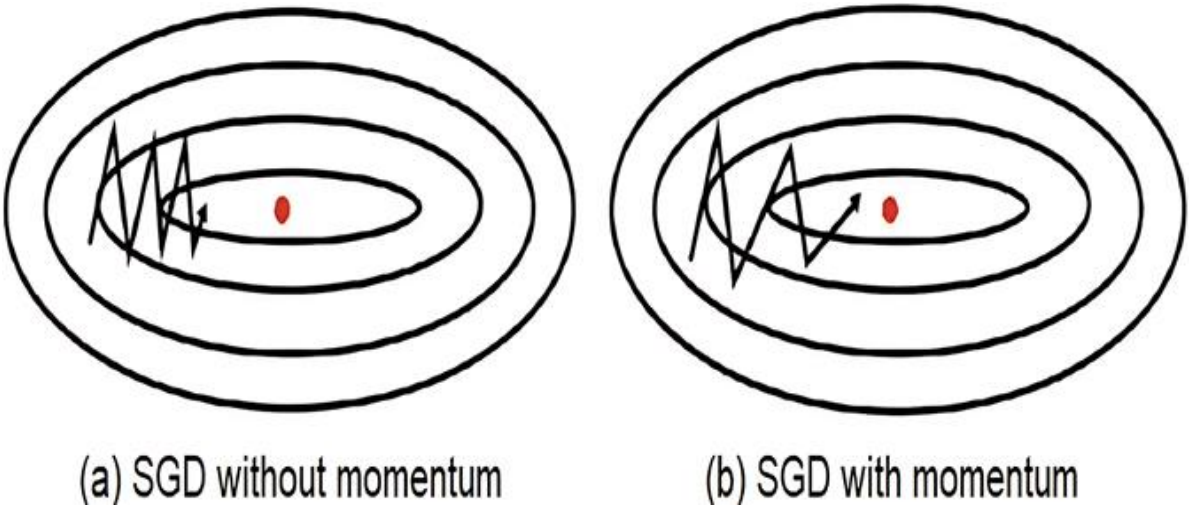

Fig. 2. Effect of momentum over SGD (Source: https://medium.com/mlearning- ai/optimizers-in-deep-learning-7bf81fed78a0).

Where α is a constant and η is the LR.
One of the best GD algorithm variants is called MBGD. In MBGD approach, the dataset is split up into different batches and the parameters are changed in different batches. The HP called mini-batch size has a value that is highly connected with the memory of the processing unit. Because of the GPU/CPU memory access, its value is assumed to be a power of 2. The model will run rapidly if the mini-batch size is a power of two as it accesses GPU/CPU memory with an acceptable default value of 32 [6].
One of the most popular optimizers for DNN training is RMS-prop. The GD is accelerated by RMS-prop, but it performs better as the steps get smaller. The LR is modified in RMSprop by dividing the square root of the gradient. RMSprop speeds the horizontal movement from a considerably greater LR while slowing the vertical oscillation compared to the initial GD [8]. Eqn. 3 is used to

implement RMS-prop. $w = w - lr * (dw/\sqrt{S})$

Adam deals with momentums of the first and second order. The concept be- hind the Adam is that instead of rolling so rapidly just because it can jump over the minimum, it should slow down a little for a deliberate search. Additionally, Adam keeps the average of earlier squared gradients and saves the exponentially decaying average of earlier gradients [8]. The weight and bias is calculated using Eqn. 4 and 5.

$wt = wt{-}1 - [(\eta/\quad Sdwt\ - \varepsilon) * Vdwt\ ]$
$bt = bt{-}1 - [(\eta/\sqrt{S}dbt - \varepsilon) * Vdbt\ ]$

2.2 Learning Rate

The LR is the HP in optimization algorithms that controls how much the model must change each time its weights are changed in response to the projected error. It determines how often model parameters are cross-checked and is one of the most crucial factors while building a NN. Selecting the ideal LR can be challenging because if it is excessively low, the training process may be slowed down. Nevertheless, if the LR is excessively high, the model cannot be well-tuned. Finding an ideal value for LR is difficult yet essential [9]. A small enhancement based on the constant value is setting an initial rate of 0.1 and modifying it to0.01 when the accuracy is saturated and subsequently to 0.001 if required. Fig. 3 illustrates how the LR (from low to high) affects finding minima. Divergent behavior occurs when the LR value becomes too high. When the LR value becomes too small, it takes several updates to achieve a minimal point, the ideal LR value quickly achieves the minimal point, and severe changes occur.

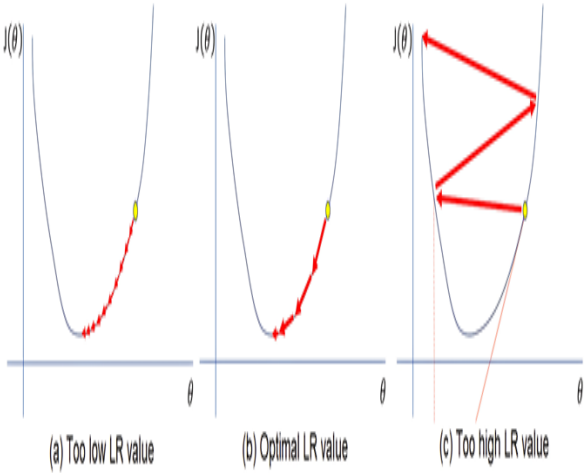

Fig. 3. Effect of LR to find minima (Source: https://www.jeremyjordan.me/nn- learning-rate/).

Different methods are adopted to find out the value of LR. Two common methods are linear decay and exponential decay, which can be implemented using the Eqn. 6 and 7, respectively.

$lr = lr0/(1 + kt)$ (6)

$lr = lr0.exp(-kt)$ (7)

Where lr0 is the previous LR, k is the decay rate, and t is the training time.

2.3 Network Depth

A crucial factor in deciding the entire design of NNs, which directly affects the output, is the number of hidden units. Deep learning networks with even more layers are more likely to produce features with increased complexity and relative accuracy. It's common to practice scaling up the NN by including more layers; however, this raises the model's complexity and can occasionally result in overfitting. Overfitting happens as a result of there being more layers and neurons in each layer. Therefore, it is important to carefully calculate the model's depth [10]. Once more, regularization can be used to handle overfitting. Lasso (L1) and Ridge (L2) regularization, which may be implemented using Eqn. 8 and 9, are the two regularization norms employed to address the overfitting problem. L1 and L2 regression have their benefits and drawbacks.

$$w(L1) = \sum_{i=0}^{N} \left(y_i - \sum_{j=0}^{M} x_{ij} w_j\right)^2 + \lambda \sum_{j=0}^{M} |w_j|$$

$$w(L2) = \sum_{i=0}^{N} \left(y_i - \sum_{j=0}^{M} x_{ij} w_j\right)^2 + \lambda \sum_{j=0}^{M} w_j^2$$

Where the regularization parameter is defined as λ.

2.4 Activation Function

A neuron's activation status is determined by an activation function. According to this, it will perform some straightforward mathematical operations to decide whether the input from the neuron to the network is important or not for the prediction process. The activation function's function is to enable nonlinearity in a NN and produce output from a set of input values provided to a layer. Deep learning relies on activation functions to provide nonlinear characteristics to the output of neurons. A NN without an activation function will just be a linear regression model, unable to reflect intricate characteristics of data. The activa- tion functions must be differentiable for backpropagation and computing weight gradients. The most well-known and often employed activation functions are sigmoid, softmax, hyperbolic tangent (tanh), and rectified linear units (ReLU) [10].

When given a number, sigmoid outputs a number between 0 and 1. It has a fixed output range, monotonicity, continuous differentiation, nonlinearity, and all the other desirable characteristics of activation functions. It is also easy to use. Typically, binary classification issues make use of this. The likelihood that a particular class will exist is provided by this sigmoid function [11]. It can be modeled mathematically using Eqn. 10.

$$f(x) = 1/(1 + e^{-x})$$

The activation function tanh can condense a real-valued number to a range between [-1, 1]. It varies from a sigmoid and generates zero-centered output while being nonlinear. The main advantage of the approach is that negative inputs will be actively mapped to the negative, and zero inputs will be mapped almost perfectly to zero [11]. Eqn. 11 is a mathematical representation of the tanh function.

$$f(x) = (e^{x} - e^{-x})/(e^{x} + e^{-x})$$

ReLU is one of the activation functions that is used in applications the most. The ReLU function's gradient has the highest value of 1, which solves the van- ishing gradient problem. It also solves the problem of saturating neurons because the slope of the ReLU function is never 0. The range of ReLU is 0 to infinity [10]. Eqn. 12 provides a mathematical illustration of the ReLU function.

$$f(x) = x, \text{ if } x > 0, \text{ else } 0$$

Several sigmoids are combined to form the Softmax function. There is a proven relative likelihood. The probability of each class or label is returned by the Softmax function, just as the sigmoid activation function. The last layer of the NN in multi-class classification is most frequently used with the softmax activation function. The softmax function provides the likelihood of the present class to other classes. This indicates that it also takes other classes into account [12]. The softmax function is represented mathematically in Eqn. 13

$$f(x) = \exp(xi)/\Sigma \exp(xj)$$

2.5 Loss Function

A loss function compares the target and anticipated output values to determine how well the NN reflects the training data. During training, we make an effort to minimize this output discrepancy between the expected and the goal. The basic goal of the loss functions is to reduce the average loss by adjusting the weight and bias value. Regression loss function, which includes mean absolute error (MAE), and mean squared error (MSE), and classification loss function, which includes binary cross entropy (bc) and categorical cross entropy (cc), are the two main types of loss functions that are used [13]. The mathematical representations of the loss functions are shown in Eqn. 14–17.

$$MSE = 1/n \sum_{i=1} (y^i - \hat{y}^i)^2$$

$$MAE = 1/n \sum_{i=1} |y^i - \hat{y}^i|$$

$$Loss_{bc} = 1/n \sum_{i=1}^{N} -(y_i \log(p_i)) + (i - y_i).\log(1 - p_i)$$

$$Loss_{cc} = -1/n \sum_{i=1}^{N} \sum_{j=1}^{M} y_{ij} \log(p_{ij})$$

III. SEARCHING TECHNIQUE

In this section, all the classical HP searching techniques are discussed.

3.1 Grid Search Technique

If enough resources are available, grid search is the simplest search algorithm that produces the most accurate predictions, and the user can always identify the ideal combination. Grid search is simple to conduct in parallel since each trial runs independently without regard to time order. Results from one experiment do not affect those from further tests. The distribution of computational resources is incredibly flexible. grid search, however, is cursed by dimensionality since more HPs that need to be tuned consume exponentially more computational resources. When more HPs are utilized in the model, the grid search technique's major downside is the computing time [14].

3.2 Randomized Search Technique

Random search is a fundamentally improved form of grid search [15]. It denotes a randomized search over possible parameter values for HPs from certain distri- butions. The search procedure is carried out indefinitely or until the necessary accuracy is attained, whichever comes first. Grid search is comparable to ran- dom search; however, random search has been shown to produce superior results. When some HPs are not distributed equally, the random search may perform better. In contrast, a longer search period cannot provide better results for a grid search. Another key benefit of random search is its parallelization simplicity and resource allocation adaptability [14]. While random search often outperforms grid search, it still requires a lot of processing.

3.3 Bayesian Search Technique

It is a sequential model-based approach that aims to identify the global optimum with the fewest trials possible. It strikes a balance between exploration and exploitation to avoid becoming trapped in the local optimum. In two ways, Bayesian search is superior to random search and grid search: first, users are not needed to have existing experience of the distribution of HPs; and second, the central concept of Bayesian search, posterior probability, beats both of these methods. The Bayesian search seems to be more computationally effective than random search and grid search, requiring fewer attempts to discover the ideal HP set, especially when highly expensive objective functions are observed [16]. Another outstanding benefit of Bayesian search over grid search and random search is that it may be used whether the goal function is stochastic or discrete, convex or nonconvex.

3.4 Population based Search Technique

Population-based methods, such as evolutionary algorithms [17], swarm-based optimization [18], and covariance matrix adaptation evolutionary strategies, are essentially a series of random search methods based on genetic algorithms [19]. Initialization (random population), Selection (assessment of the existing popu- lation and parent selection), and Reproduction are the three key components of genetic algorithms (creation of the next generation). The population-based approach effectively uses less computing time to identify the ideal HPs.

IV. SECOND-ORDER OPTIMIZATION

Backpropagation is a stage in optimization approaches when an error from the calculated and intended output is monitored. The objective function is mini- mized during optimization in the context of NNs. The GD approach is one of the most widely utilized optimization strategies in NN training. It is a first-order derivatives approach, as seen in Eqn. 18. However, the selection of LR signifi- cantly impacts how well GD performs. An excessively large LR causes significant changes with each iteration and frequently fails to find the minimum point. Bet- ter trajectories through the mountainous error surface that is frequently seen in NNs can be provided by the second-order technique using local curvature information [20].

$$wk+1 = wk - \eta(\partial e/\partial w)$$

With the use of extra Hessian data, the second-order derivatives approach offers a superior training trajectory

over the local curvature of the error surface. By adaptively changing the step size following the various learning phases, the usage of Hessian matrices simplifies the fine-tuning of HPs. The second-order derivative is represented mathematically by Eqn. 19. Inverse Hessian matrices are used in the computation of the next update step.

$$wk+1 = wk - \eta(\partial 2e/\partial w2)-1(\partial e/\partial w)$$

V. DISCUSSIONS

The idea of HP search has been around for a while and is a commonly utilized technique. The DNN has captured the majority of academics' interest in recent years. To adapt the model for various datasets, the HP autotuning approach is absolutely essential. Due to a large number of HPs, many classical methods are becoming impractical. In complicated scenarios, choosing HPs is highly costly. Table 1 briefly compares the main algorithms

Table 1. Comparison of different hyperparameter searching algorithms.

Searching Technique	Advantages	Disadvantages
Grid Search	- Simple and Parallel execution - Almost find the optimal way	- Time consuming - Issue of overfitting
Random Search	- Reduction of overfitting - Faster than grid search	- Potential for variance - Cannot guarantee for optimal
Bayesian search	- Not stock at local minima - Can handle complex problems	- Complex algorithm - Parallelism is difficult
Population based search	- Can achieve parallelism - Not stock at local minima - Almost find the optimal way - Faster than grid search.	- A bit complex to code - Extra parameters to set.

tional neural networks based on the parameter-setting-free harmony search algo- rithm. Optik (Stuttg). 172, 359–367 (2018).

VI. CONCLUSION

DNNs are being used more often in various sectors, which inspired this study. The essential HPs and the approaches for finding them are systematically reviewed in this study, with an emphasis on how to autotune HPs for NNs. Discussing various HPs and their needs served as the study's initial point. Further a brief discussion of HPs with a discussion of various autotuning searching algorithms and their application, and it concludes with a discussion of the second-order optimization methodology. This study is devoted to providing researchers and industry users with a reference summary of information on HP tuning.

Abstract— **Cyber physical deployments include game engines, multimedia systems, internet of things (IoT) systems, etc. Each of these models have certain inputs, several processing layers, and certain outputs. Monitoring & control of such deployments can be automated via their unsupervised analysis, which requires deep learning & pattern analysis methods. A wide variety of such models are proposed by researchers and system designers, but each of them have their own nuances, advantages, limitations, & future research scopes. Moreover, these models have different performance characteristics, that vary in terms of analysis accuracy, precision, recall, fMeasure, delay of analysis, response time, computational complexity, etc. Thus, while deploying such learning models, researchers & system designers are required to perform manual analysis, validation, and testing for automation & control. Due to this cumbersome process, cost & time to market for these unsupervised control models is very high, which limits their scalability, and deployment capabilities. To overcome this issue, a detailed characteristic discussion of these models is done in this text. Based on this discussion, researchers will be able to identify existing unsupervised & semi-supervised learning models, which closely match their deployments. These models are further analyzed in terms of their performance metrics, that includes, accuracy of analysis, response time needed for control, delay needed for analysis, precision of analysis, computational complexity, and cost of deployment. Using these metrics, researchers can evaluate best performing models for their deployments, which will assist them in reducing cost, and time needed for automating their cyber physical systems. This text also discusses certain future prospects that can be explored by researchers in order to further enhance quality of their deployments.**

Keyword- Neural, Network, Cyber, Physical, Unsupervised, Scalability, Empirical, Complexity, Automation, Control.

I. INTRODUCTION

Design of automation controllers for cyber physical systems is a multidomain task, which involves design of methods for input pattern analysis, response analysis, control signal analysis, etc. A typical automation controller [1] for such systems can be observed in figure 1, wherein different inputs are controlled via an input analysis engine, which assists in analysis of different input signals. Signals are generated based on this analysis, and are given to the plant model, which uses design requirements & automatic control engine design tools in order to produce a control design for the model. This design is used to develop a control model, that is capable of automatically controlling the entire plant (or control system) deployment In some models, feedback is also taken from the cyber physical system, which assists in estimating its performance variation due to the deployed control system for different input combinations. Based on this feedback, the model is tuned, and continuous performance enhancement is achieved, which assists in improving underlying model performance under different input & output conditions. Similar models [2, 3, 4], along with their nuances, advantages, limitations, and future research scopes are discussed in the next section of this text. Based on this discussion, readers will be able to identify close similarities with their own deployment models, which will assist them in short listing models that suit their interface requirements. After this discussion, section 3 further analyzes these models in terms of statistical performance metrics that include, accuracy of analysis, response time needed for control, delay needed for analysis, precision of analysis, computational complexity, and cost of deployment under different scenarios. Upon referring to this performance evaluation, researchers will be able to select the best performing model for their deployment, and use it for high-efficiency automation purposes. Finally, this text concludes with some interesting observations about the reviewed models, and recommends methods to further improve their performance.

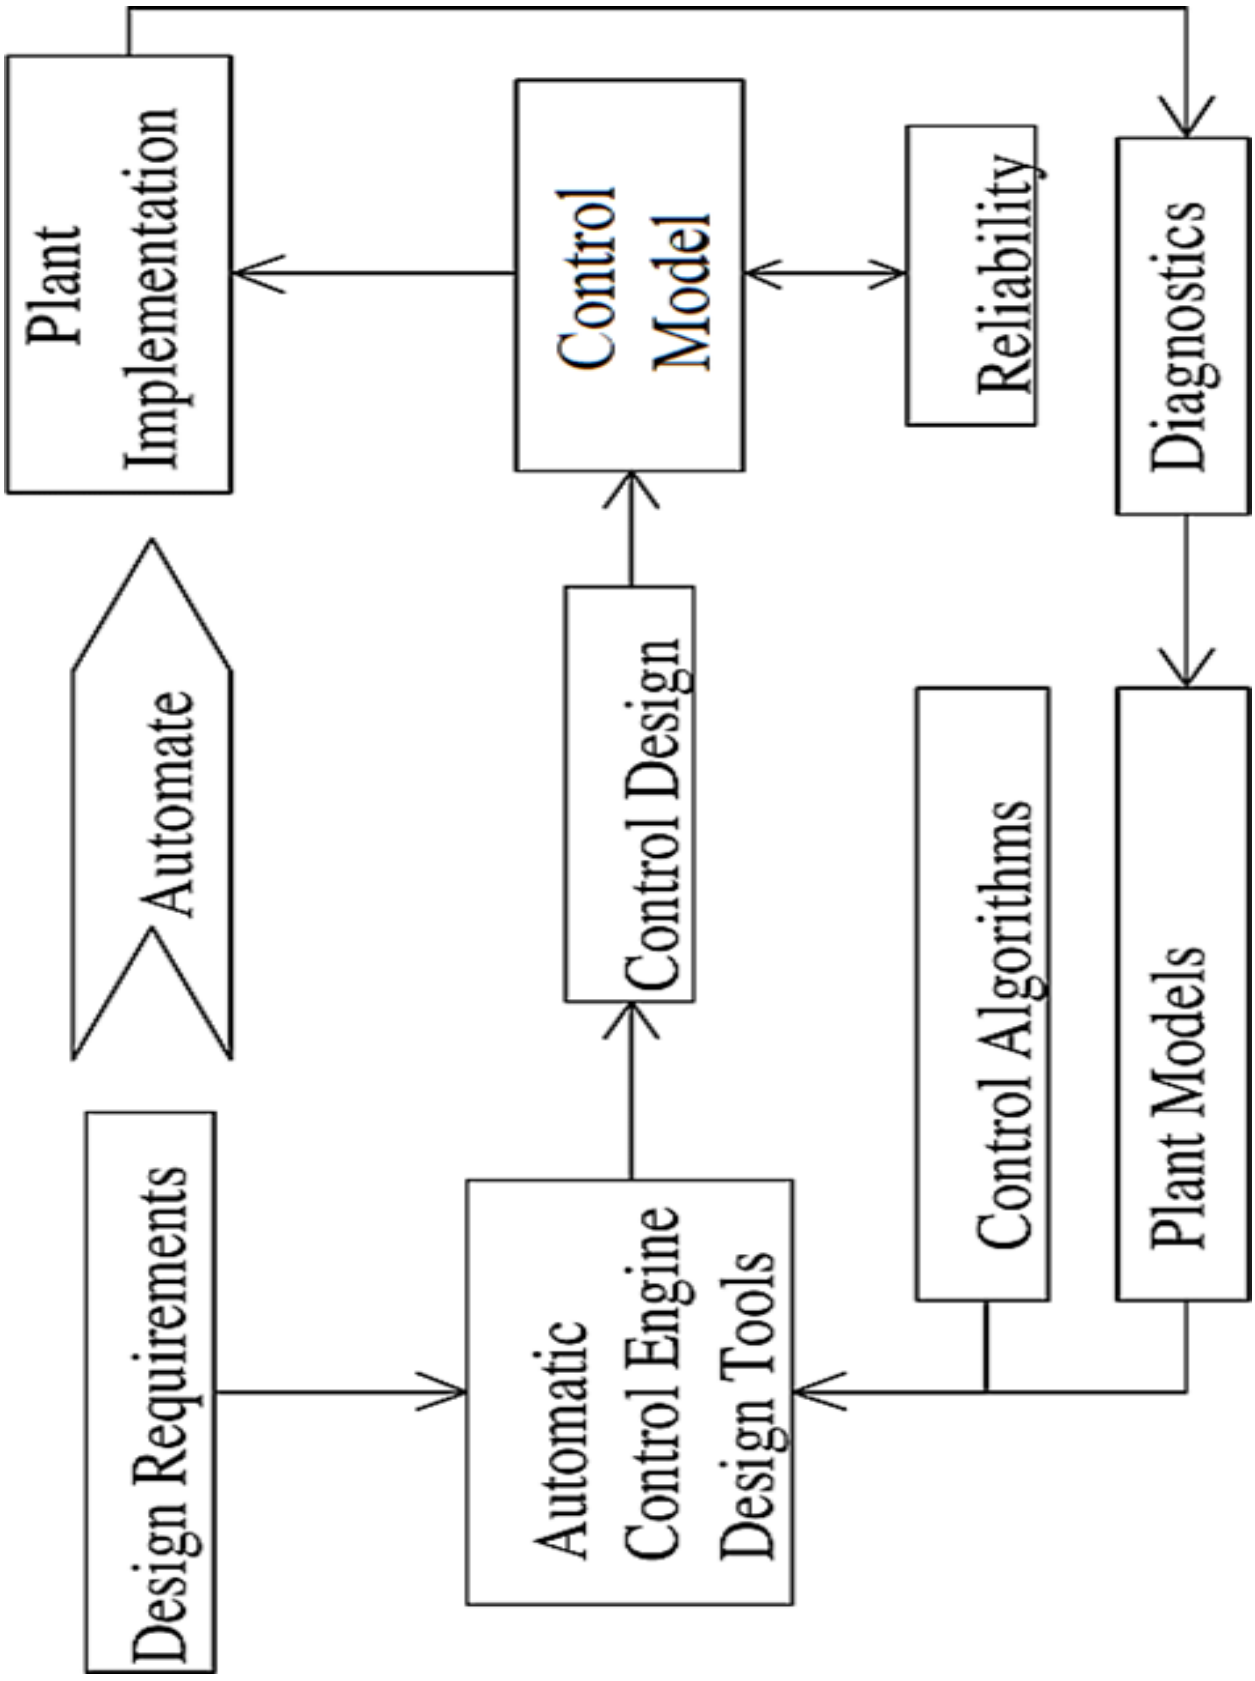

Figure 1. Design of a typical model for automation of control systems

II. PRAGMATIC REVIEW OF UNSUPERVISED LEARNING MODELS

Researchers have proposed a wide variety of unsupervised learning methods, which can be used for solving multidomain tasks including classification, clustering, prediction, etc. Each of these models have their own characteristics, and are deployed for context-specific applications. For instance, work in [1] proposes use of Incremental & Unsupervised Domain-Adversarial Neural Networks (IUDANN), which are highly flexible and can be used for prediction of output combinations via pattern analysis of different input types. The model uses a combination of feature extraction layer with label classifier to obtain classification outputs. These outputs are further tuned via use of domain classifiers which assists in estimation of error functions. IUDANN Models use gradient reversal layer (GRL) to tune their internal training constants to reduce these error functions Working of this model is depicted in figure 2, wherein inputs, their intermediate processing layers, and output classes are visualized, and can be applied to multiple scenarios.

This model is applied for Optical Character Recognition (OCR), Number Plate Recognition, and other applications that involve 2D input datasets. But it can be extended for other applications via internal parameter tuning and cross validations. The model showcases an accuracy of 96.95% for multiple applications, which is higher than Convolutional Neural Network (CNN) (57.53%), DANN (68.23%),

improved CNN (iCNN) (72.62%), and iDANN(85.91%), thus recommending use of IUDANN for large-scale deployments. But efficiency of this model is limited when applied to 1D or 3D datasets, which makes it useful for image processing applications. To overcome this limitation, work in [2] proposes use of two-stage unsupervised multiple kernel extreme learning machine (TUMK-ELM) which assists in data extraction from multiple sources to perform closed-loop learning under heterogeneous datasets. To perform this task, multiple types of kernels are deployed, such that each kernel is capable of solving single task with high efficiency, which improves overall performance via k Space data construction, and kernel combination coefficients (kCCs). These values are processed via use of an ELM based engine as depicted in figure 3, which assists in continuous tuning of kCCs via an incremental learning process.

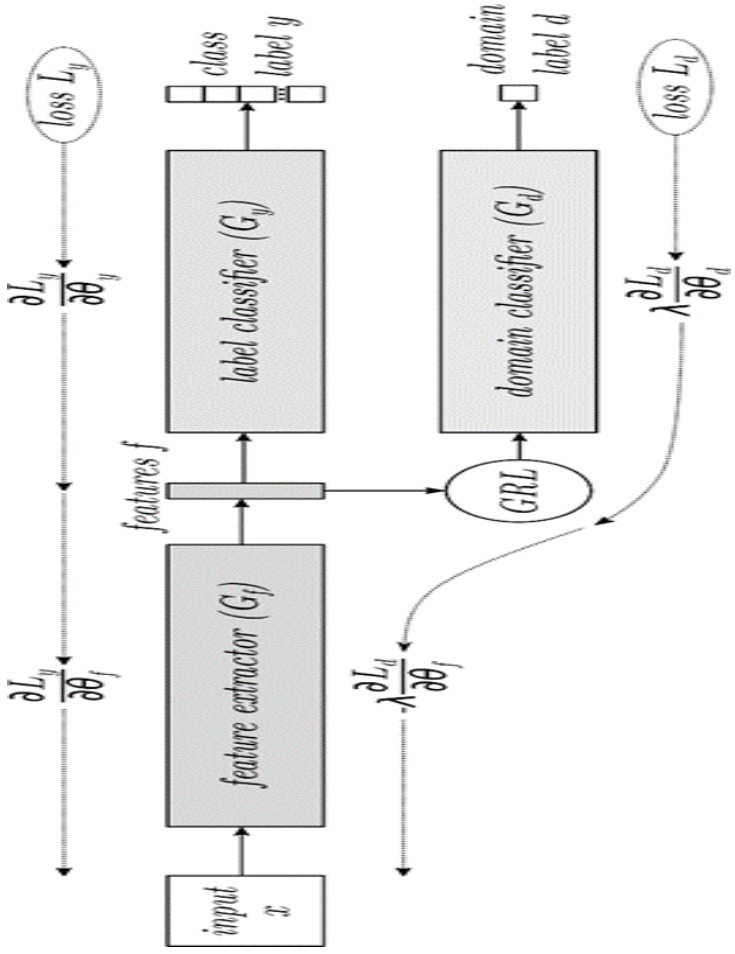

Figure 2. Design of IUDANN for continuous performance optimizations [1]

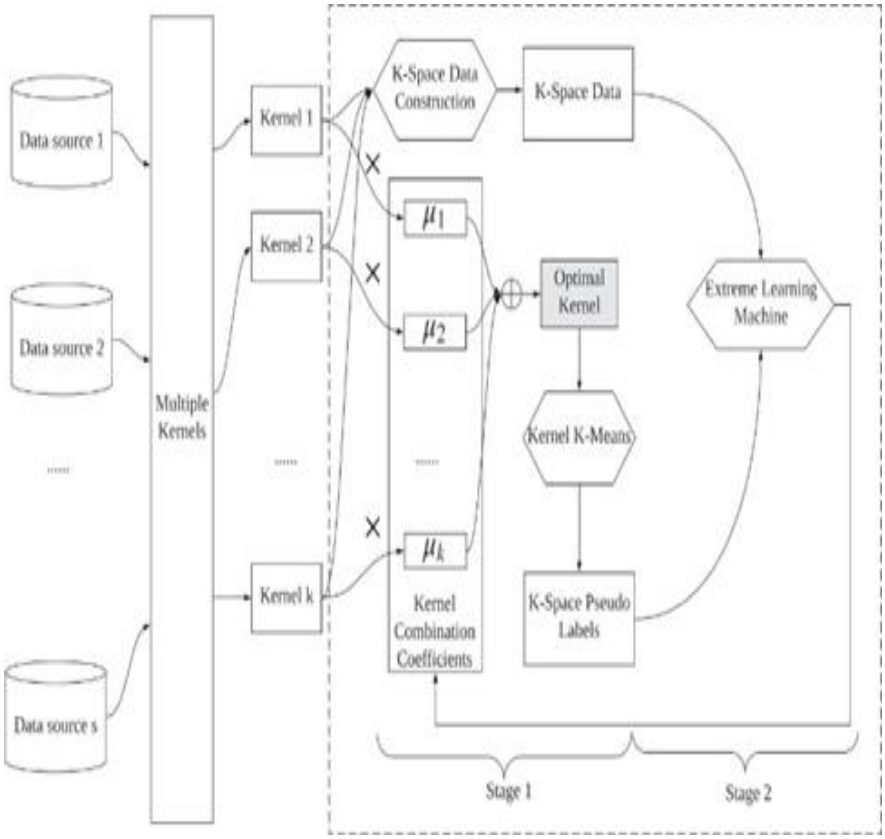

Figure 3. Design of TUMK-ELM for heterogeneous data processing [2]

Due to continuous learning, the proposed model is capable showcases an accuracy of 93.5%, which is higher than Robust Multiple Kernel K Means (RMKKM) (85.5%), and Linear MKKM (LMKKM) (86.4%) models, which makes the underlying model useful for large-scale deployments. But the model requires implementation of multiple kernel types, which increases its computational complexity. To reduce this complexity, work in [3] proposes useof Unsupervised Cross View Metric Learning (UCVML), which can be used for 2D & 3D datasets. The model uses shared mapping for exploration of shared features via estimation of Nonparametric Maximum Mean Discrepancy (NMMD) metrics, that is used for domain adaptation & transfer learning operations. The model showcases an accuracy of 96.2% on different datasets, which is higher than Cros View Quadratic Discriminant Analysis (XQDA) (75.4%), Cross View Discriminant Component Analysis (CVDCA) (83.5%), and Clustering- based Asymmetric Metric Learning (CAMEL) (85.5%) under different datasets. This model requires larger training data, thus is only applicable for big data applications, thus it needs to integrate data augmentation to improve its scalability performance. Augmentation models are capable of deployment for small scale to large scale applications, which increases their deployment capabilities. Such models are discussed in [4], wherein researchers have proposed use of Artificial Neural Network (ANN), Hierarchical Cluttering, Bayesian Clustering, Partitional Clustering, Mixture Distribution, Blind Signal Separation, Hidden Markov Model (HMM), Probabilistic Graph Models (PGMs), Generative Topographic Model (GTM), Nonlinear Clustering with Multidimensional Data (NCDM), Auto Encoders (AE), Self-Organizing Kohonen Maps (SOKM) and Stochastic Neighbour Estimation (SNE). These models are applied to network applications, but can be extended for other classification & post-processing tasks. It was observed that ANN achieved an accuracy of 83.5%, HMM showcased an accuracy of 79.8%, PGMs had an accuracy of 75.4%, NCDM achieved an accuracy of 64.5%, SOKM showcased an accuracy of 85.5%, while SNE had an accuracy of 74.9% on different datasets. These models must be validated on multiple datasets, and their performance can be improved via application of sparse coding & other deep learning techniques. Such a technique is discussed in [5], which proposes use of Unsupervised Transfer Learning using Multiple Scaled Convolutional Sparse Coding (UTL MSCSC) for medical applications. The model uses different filter sets to extract features, which assist in continuously improving its training & validation performance. Flow of the model is depicted in figure 4, wherein Colour Decomposition (CoD), Multiple Scale Convolution, Absolute Value Rectification at element level (Abs), Local contrast normalization (LCN) and Max Pooling (MP) operations are used to design a UTL Network, that is capable of classifying multiple data types.

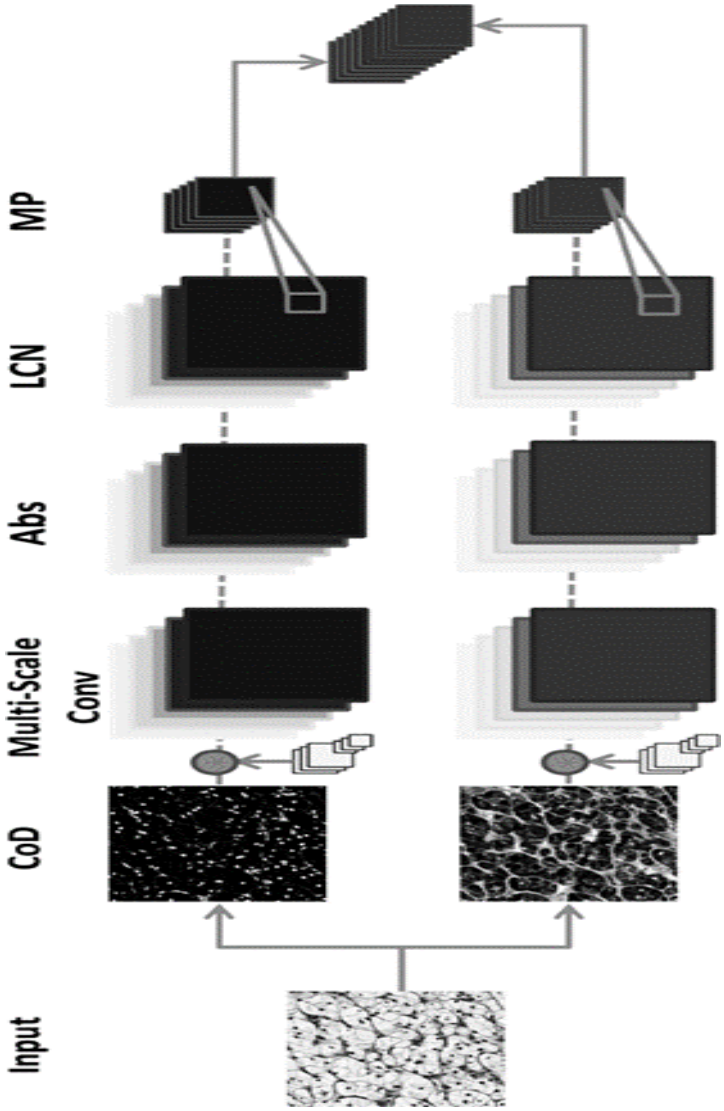

Figure 4. Design of the UTL MSCSC Model for efficient feature representations [5]

Due to use of these filters, the model showcases an accuracy of 93.42%, which is higher than Pseudo Multiple Scaled CSCSPM (PMS CSCSPM) (92.86%), Power Spectral Density with Stacked Predictive Sparse Coding (PSD2SPM) (91.85%), Sparse Morphometric Linear Spatial Pyramid Matching (SMLSPM) (92.35%), Sparse Coding (ScSPM) (79.58%),
and Kernel SPM (KSPM) (85%) for the same dataset applications. But the model is highly complex, cannot detect irregularities in input datasets and requires large training & validation delays. To overcome these limitations, work in
[6] proposes use of Implicit Irregularity Detection (IIRD) via use of unsupervised learning on temporal data patterns. The model uses a combination of Regression Analysis, Gaussian Distribution, Fuzzy Rule-base, and Probabilistic Modelling to estimate feature sets that can add periodicity to data samples. It initially constructs a Basic Regular Group (BRG) and performs its expansion via augmentation models. This augmentation is applied till periodicity is not achieved in the datasets, due to which the model is capable of achieving a linearly increasing accuracy 98.5%, that is higher than Density-Based Spatial Clustering of Applications with Noise (DBSCAN) (94.1%), k Means (75.5%), and Hierarchical Clustering (HC) (78.9%) across multiple datasets. This model's performance can be further extended via use of Uncorrelated and Discriminative Feature Selection which is implemented via Constrained Spectral Analysis for efficient feature selection (DUCSAFS) as discussed in [7], which can be deployed

initially explores low-redundant discriminative features, and avoids trivial solutions, which simplifies the optimisation process. Due to these characteristics, the model is applicable for multidimensional datasets with different classes and has minimum overheads. It is capable of achieving an accuracy of 89.5% under different applications, which is higher than

Least Squares (LS) (64.5%), Nonnegative Discriminative Feature Selection (NDFS) (71.9%), Joint Embedding Learning and Sparse Regression (JELSR) (74.8%), Simultaneous Orthogonal basis Clustering Feature Selection (SOCFS) (83.5%), and Structure Optimal Graph Feature Selection (SOGFS) (89.1%) when evaluated under the same datasets. This model showcases superior performance, but doesn't incorporate explainable characteristics, which can be used to further improve it usability. To perform this task, work in [8] proposes use of SOM-based Explainable Clustering Methodology (SOM ECM), for generation of synthetic explanations. It calculates Unified Distance Matrix (U Matrix) for different component planes in order to solve segmentation, clustering, and classification tasks. The model is able to achieve an average accuracy of 79.5% under different applications.

Models that use Unsupervised & Nonlinear Adaptive Manifold Learning (UNAML) [9], Data Normalization for Neural Networks (DNNN) [10], Heterogeneous Coupling with Unsupervised Learning to represent Categorical datasets (HCUL) [11], and use of g Support Vector Machine (SVM) under unary and binary modes [12] are also discussed by researchers. The UNAML Model is capable of handling unsupervised datasets, while DNNN can be used to handle data from heterogenous sources with high efficiency and good classification performance. These models must be combined in order to design an integrated high-performance model that can cater to large-scale datasets. While HCUL showcases higher efficiency for representing data used in classification applications, under multiple heterogeneous datasets. The model

which can be extended via use of SVM for achieving better accuracy, precision, recall and Area Under the Curve (AUC) levels. The UNAML model achieved an accuracy of 85.4%, while ANN showcased an accuracy of 73.9% under different applications. Upon similarevaluation, HCUL that uses multiple kernels was able to classify data with 91.5%, while SVM showcased an accuracy of 83.5% for MicroRNAs based classification applications. But these models do not use clustering techniques, which limits their data representation capabilities. To overcome this limitation, work in

[13] proposes use of Hybrid Unsupervised Clustering (HUC) via integration of Sub-Space Clustering (SSC) & One Class Support Vector Machine (OCSVM) which assists in improving classification performance for multidimensional datasets. The HUC SSC OCSVM Model achieves an accuracy of 89.9%, which is higher than SSC with EA (86.2%), DBSCAN (85.9%), and k Means (83.4%) when averaged for different applications. This efficiency can be improved via integration of model enhancements in existing Neural Networks. Work in [14] proposes such a model, which uses Unsupervised Learning perceptron adopting phase change memory (PCM) synapses with Spike Timing Dependent Plasticity (STDP) & Neural Redundancy (NR) methods. These methods assist in integration of long-term memory availability, which improves classification performance when applied for multidimensional data applications. The PCM STDP NR model showcases an accuracy of 91.5%, which makes it useful for real-time deployments. This model must be validated on larger datasets, and can be further extended via use of Confidential Correspondence Consistency (CCC) as discussed in [15], which assists in high- efficiency augmentation of image sets to improve classification performance for data limited applications. The CCC model is depicted in figure 5, wherein Siamese CNN along with initial disparity, correspondence consistency, and positive sample propagation are used to achieve an accuracy of 91.2% under different datasets. This accuracy is higher than Content CNN (84.5%), and Global Context CNN (GCCNN) (89.5%) which makes it useful for a wide variety of real-time applications

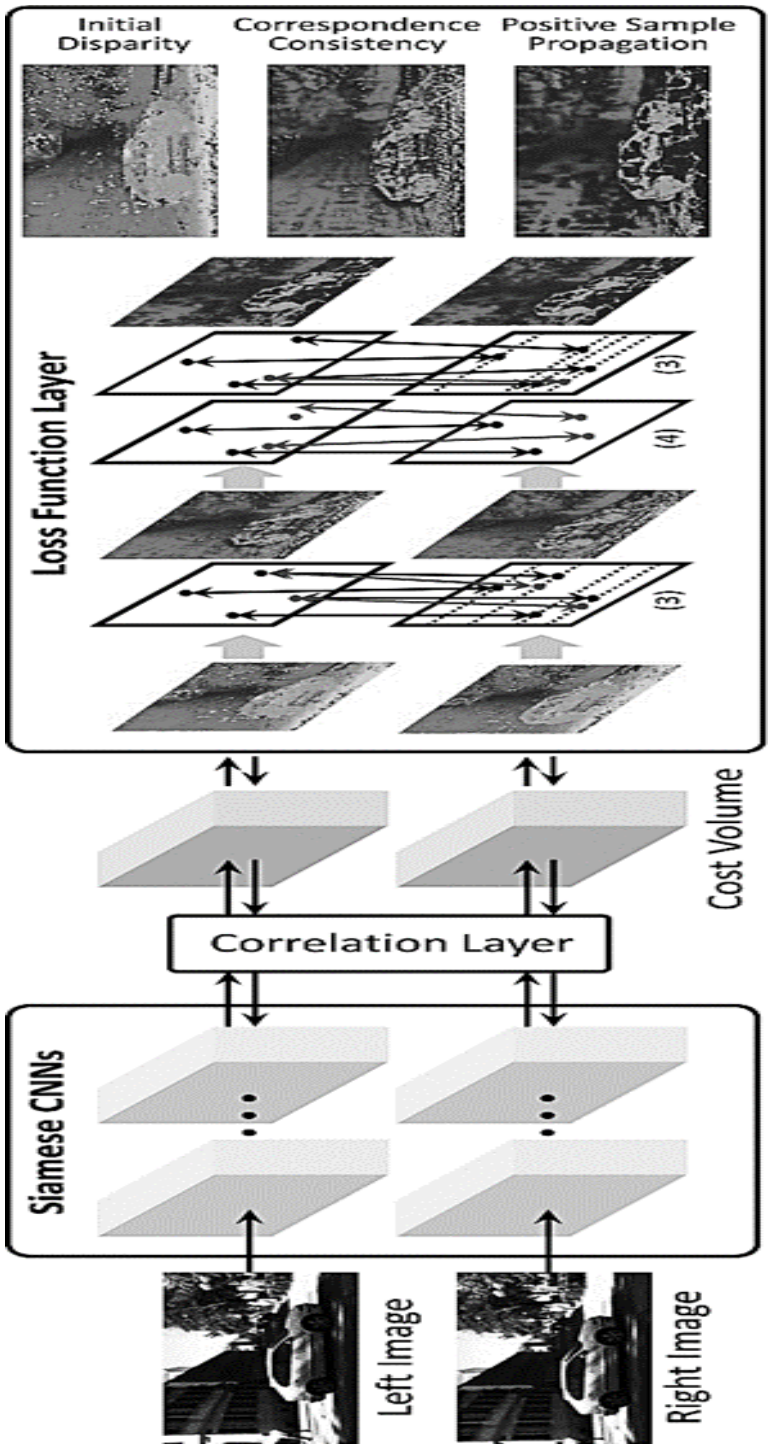

Figure 5. Design of CCC based CNN Model for low error & limited data capabilities-based classification applications [15]

The model must be tested on different datasets, and can be extended via use of low-cost & high- efficiency Q-Learning methods for incremental performance optimizations. Such models are discussed in [16, 17], which propose use of Multistage Method for Leveraging Order- Independent Transparency (MMLOIT), and combination of Event Shift with Histogram Shape (ESHS) which assists in continuously improving model performance via high-density feature extraction & selection techniques. The MMLOIT model is mainly used for data visualization, and can be deployed for a wide variety of applications, while the ESHS model is used for event analysis in terms of event chronology, periodic similarity and aperiodic similarity levels. A combination of both these models should be done to improve classification & representation performance. The MMLOIT model showcases an accuracy of 64.5%, while the ESHS model showcases an accuracy of 91.3% across different datasets. Extensions to these models are discussed in [18, 19] which propose use of Neural Network-Based Blind Equalization (NNBBE), and design of a new distance metric (NDM) which is based on dynamic attribute-level weights that are evaluated via use of frequency probabilities. These models assist in improving classification & pattern analysis performance for multiple applications. The NNBBE model is useful for training existing Neural Networks by integration of blind equalization which improves their accuracy performance. It showcases an accuracy of 96.5%, while NDM is able to achieve clustering accuracy of 91.4%, due to which, both models are useful for high-performance application deployments. These models must be validated on heterogeneous applications, which will assist in estimating its real-time performance. Such applications are discussed in [20, 21], which propose use of pattern analysis for text classification, and perceptual category learning based use cases. Text classification applications can use Variational Autoencoder Neural Networks (VANN) with Graph Regularization (GR), which assists in achieving an accuracy of 85.9% across different datasets.

This model showcases better performance than Autoencoder (AE) (82.8%), Sparse AE (SAE) (78.5%), Stacked AE (STAE) (79.1%),
Denoising AE (DAE) (85.9%), Restricted Boltzmann Machine (RBM) (72.3%), and Deep Belief Networks (DBNs) (73.5%) for the same datasets. While the perceptual category learning model initially converts all datasets into Gaussian distributions, and then mixes these distributions to design Online Mixture Estimation (OME), which assists in achieving an accuracy of 90.5% across different 1D datasets. To performance can be further improved via use of Extreme Learning Machines (ELMs) [22], Unsupervised Linear Discriminant Analysis (ULDA) [23], Support Vector Machine with Measure of Textual Lexical Diversity (SVM MTLD) [24], and CNN fused with Differentiable Feature Clustering (CNN DFC) [25], each of which assist in improving pattern analysis performance via feature augmentation process. ELMs are observed to be highly complex, and thus can be used under high-performance computing scenarios, while ULDA is capable of processing multidimensional data with high efficiency with low complexity, thus it is recommended that ULDA must be used for initial feature representations, while ELMs must be applied for feature learning process. SVMs also showcase good classification performance, and thus can be used to replace ELMs, but they cannot be used for applications with higher number of classes. The CNN DFC model is able to achieve both these characteristics due to use of Differentiable Feature Clustering, which assists in pre-processing the data before actual classification. Due to which, the CNN DFC model is highly useful for large-scale classification applications. The ELM model showcases an accuracy of 96.63%, which is higher than Laplacian Eigenmaps (LE) (91.5%), Spectral Clustering (SC) (89.2%), Deep Autoencoder (DA) (90.2%), and k Means (89.5%) for different datasets. While, the accuracy of ULDA is 86.5%, which is higher than LDA (85.2%), and Real Time LDA (RTLDA) (85.3%) across different multidimensional datasets. SVM showcases an accuracy of 83.1%, but has lower complexity than other models. The CNN DFC model is depicted in figure 6, and outperforms all these models by achieving an accuracy of 95.4%, due to integration of Normalized Response Maps (NRMs), and filtering models for achieving better data processing capabilities.

These models are useful when applied to 2D or 3D datasets, but 1D datasets are used in a wide variety of practical applications. Work in [26, 27, 28] proposes use of SP theory based Neural Networks (SPNNs), customized 1D Reconfigurable Intelligent Surface Beamforming Neural Network (1D RISBNN), and Heterogeneous Unsupervised Domain Adaptation with Grassmann's Linear Monotonic Maps with Geodesic Flow Kernel (GLMM GFK), which assist in extraction of multidomain feature sets for highly efficient data representation purposes. These models utilize Fully Connected Neural Networks (FCNNs) for classifying & processing the extracted data into different application-specific categories. The SPNN Model is highly complex, but showcases an accuracy of 97.5%, which is better than 1D RISBNN that showcases an accuracy of 96.1 %, but can be used for multidimensional datasets. The GLMM GFK uses incremental feature updates, due to which it is capable of achieving accuracy between 86.1% to 96.4% for different applications. These models must be deployed for different applications, which will assist in estimating their real-time performance across multiple scenarios. Work in [29, 30] discusses such applications, wherein Kalman Filter with Pose CNN (KFP CNN), and Unsupervised Two- Path Neural Network (UTPNN) are applied to

video processing, and high-density cell-based image processing applications. The KFP CNN model showcases an accuracy of 98.7%, while UTPNN achieves an accuracy of 85.6% under different datasets. The UTPNN model also proposes a custom Convolution Long-Short- Term Memory (Conv LSTM), which assist in extraction of multiple levels of features for improving data representation efficiency across different scenarios.

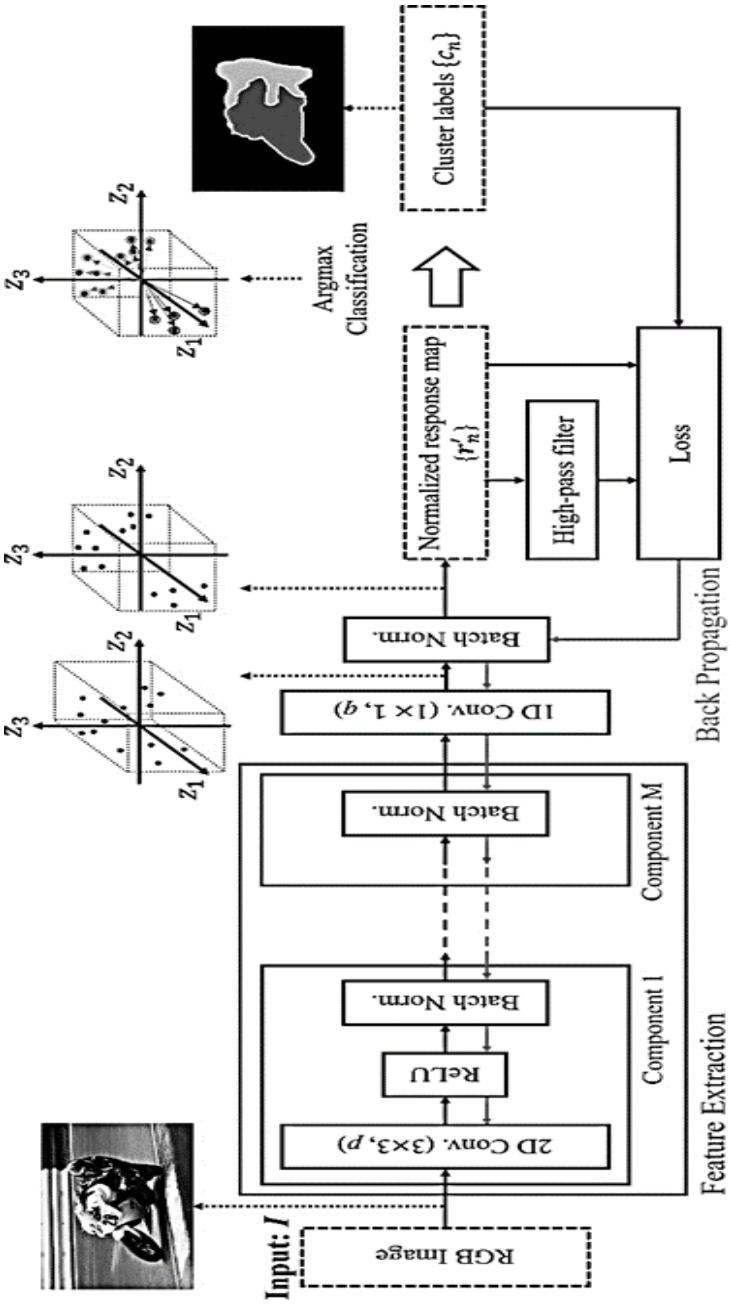

Figure 6. Integration of CNN with DFC for better signal processing performance

Pattern analysis models are also useful for solving issues that require remote & real-time monitoring for multiple inputs. Such applications, and their ML based solutions are proposed in [31, 32, 33], which discuss use of Prediction-based Proactive Drone Management (P2DM) with SVM, Variational Auto-Encoder (VAE) for Unsupervised Deep Spectrum Sensing, and Coupled CNN with Adaptive Response Function Learning (CCNN ARFL) for Unsupervised Hyperspectral Super Resolution applications. The P2DM Model is highly context sensitive, with low energy consumption and lower complexity, but achieves an accuracy of 73.5% under for drone sites. While the VAE Model showcases an accuracy of 93.5%, which makes it useful for spectrum sensing, but can be extended for other use cases. Similarly, the CCNN ARFL uses a combination of Low Resolution & High Resolution Hyper Spectral Imaging with Autoencoder (Lr & Hr HIS AE) as depicted in figure 7, which assists in achieving an accuracy of 91.5% under different dataset configurations. But these models are highly complex, and require large datasets for efficiency operations. To overcome this limitation, work in [34, 35, 36] proposes use of Two Stage CNN (TSNN), Unsupervised Deep Feature Learning (UDFL), and Instance-Based Learning with Q-Learning (IBQL) for data augmentation that can be used with low density datasets. These models integrate different information processing layers, which increases data representation efficiency for cross dataset applications. They also use incremental learning, which assists in continuous training set updates via correlation matching based feedbacks. Due to which the TSNN model showcases an accuracy of 89.1%, while UDFL achieves an accuracy of 94.8%, and while IBQL showcases an accuracy of 96.5% under different dimensional & different categorical datasets.

Extended deep learning models that use Masked Generative Adversarial Networks (M GAN) [37], Spiking Neural Network with Cross Modal Processing (SNN CMP) [38], and Selective Unsupervised Learning via Autoencoder with GAN (SUL AE GAN) [39], are discussed and deployed for large-scale applications. These models utilize application-specific feature processing in order to represent data with minimum overheads. The represented features are processed via augmented learning models which assists in improving their cross-dataset efficiency for different applications.

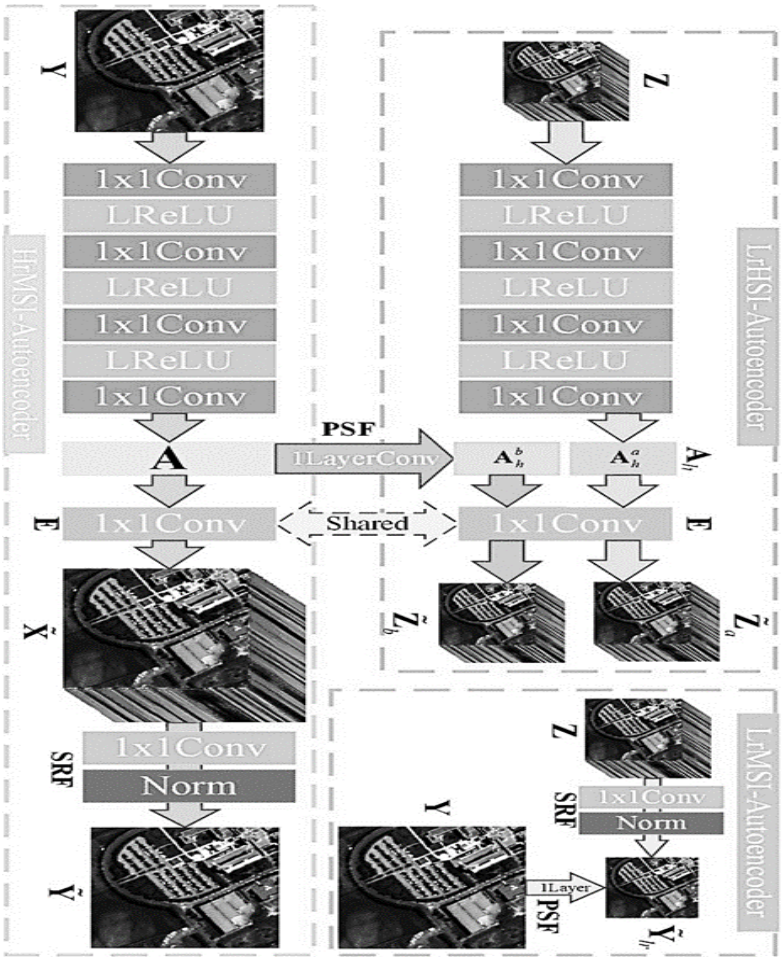

Figure 7. Design of CCNN ARFL Model for deploying high efficiency classification process

The M GAN Model showcases an accuracy of 97.6%, while SNN CMP achieves can accuracy of 95.5%, while SUL AE GAN showcases an accuracy of 92.7% for multidimensional data applications. Extensions to these models are discussed in [40, 41, 42], which proposes use of different metrics like Response Time for Aberrant Response (RTA), kernel density maximum entropy (KDME), and discussion of different fusion & deep learning models which assist in improving processing performance for multiple application types. The RTA model showcases an accuracy of 83.4%, while KDME showcases an accuracy of 93.4% which makes them useful for real-time data processing applications. This performance can be improved via use of bioinspired models like Genetic Algorithm (GA) [43], Genetic Neural Network (GNN), [44] and Particle Swarm Optimization (PSO) based SVM [45] which assists in stochastically modelling different use cases for better learning performance. The GA Model assists in achieving an accuracy of 85.5%, while GNN showcases an accuracy of 91.4%, and PSO with SVM showcases an accuracy of 97.5% under different applications. These models have different use cases, but can be deployed for large-scale scenarios. To further analyze scalability of these models, they are compared in terms of accuracy, precision, recall, computational complexity, and scalability performance in the next section of this text. Based on this discussion, researchers will be able to identify best performing models, for their application-specific use cases.

III. EMPIRICAL EVALUATION AND COMPARISON OF REVIEWED MODELS

From the literature survey it can be observed that existing learning models used for unsupervised analysis of existing cyber physical deployments have wide variety of applications. These models have performance variations based on context, deployment type, data type, and applicability. To facilitate model selection, this section compares the reviewed models in terms of their accuracy (A), precision (P), recall (R), computational complexity (C), and scalability (S) measures. These values are accumulated via pragmatic evaluation of these reference models. Out of these metrics, computational complexity & scalability do not have absolute values, thus, values of these metrics are evaluated in terms of fuzzy ranges of Low (L=1), Medium (M=2), High (H=3), and Very High (VH=4), which will assist readers to identify context-specific models for their deployments. These values can be observed from table 1 as follows,

Model	**A (%)**	**P (%)**	**R (%)**	**C**	**S**
IUD ANN [1]	96.95	74.24	75.60	H	M

Table 1. Statistical evaluation of different unsupervised learning models

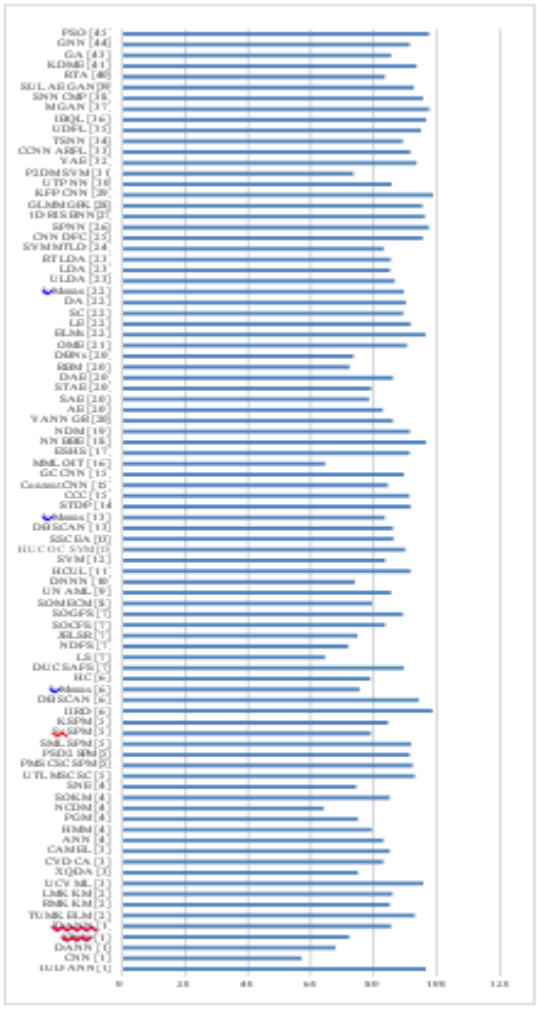

Figure 8. Accuracy of different models

Based on this evaluation and figure 8 it can be observed that KFP CNN [29], IIRD [6], M GAN [37], SPNN [26], PSO [45], IUD ANN [1], NN BBE [18], IBQL [36], ELMs [22], UCV ML [3], Based on this evaluation and figure 8 it can be observed that KFP CNN [29], IIRD [6], M GAN [37], SPNN [26], PSO [45], IUD ANN [1], NN BBE [18], IBQL [36], ELMs [22], UCV ML [3],

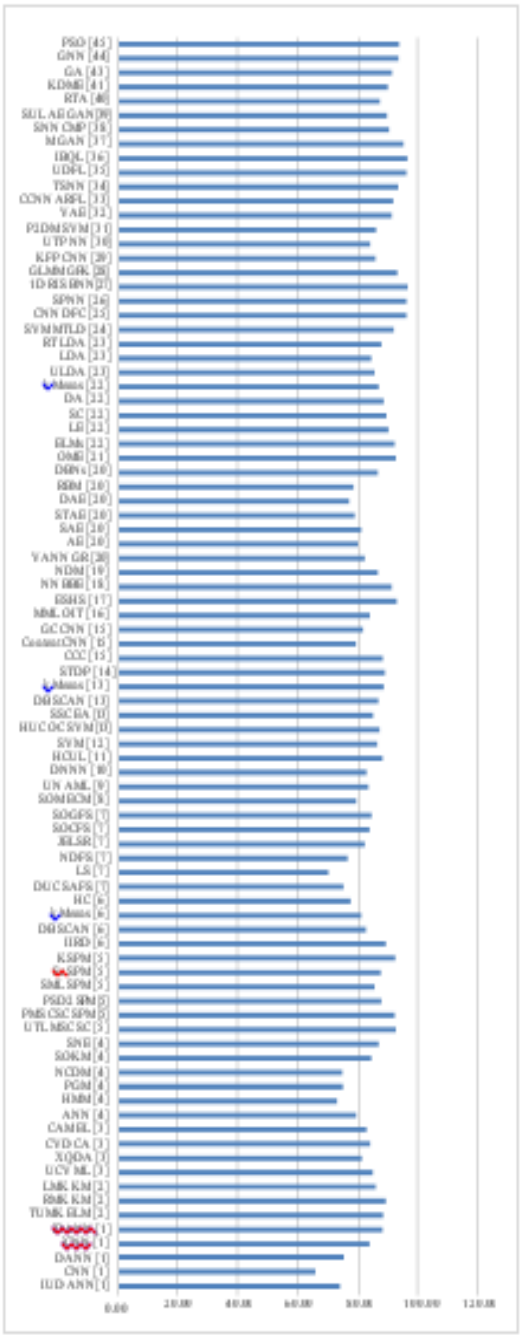

Figure 9. Precision of different models

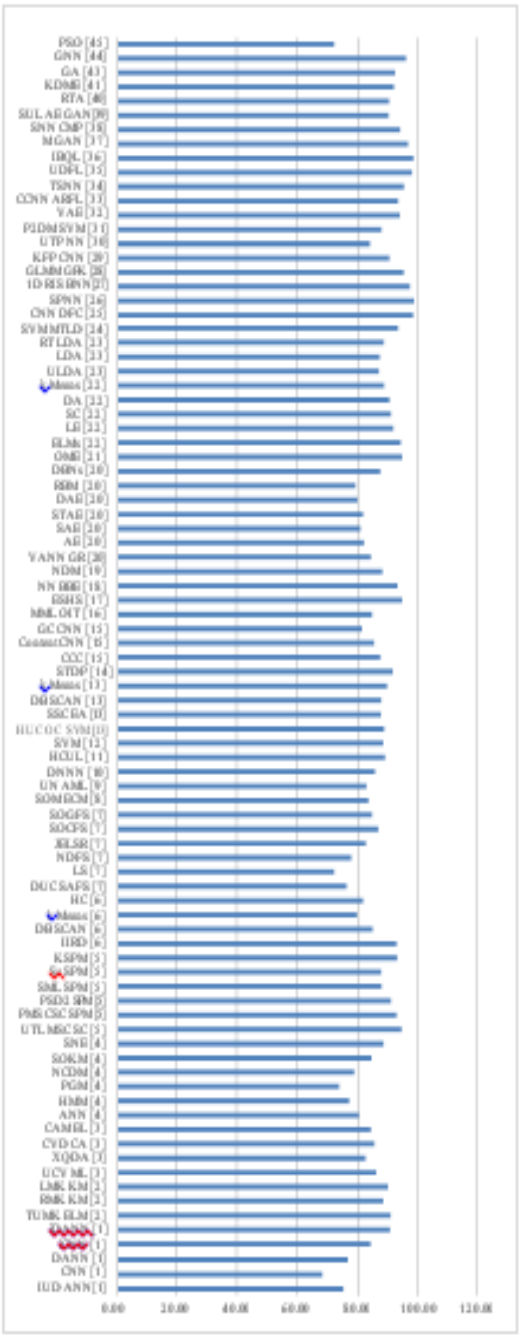

Figure 10. Recall of different models

Similarly, from table 1 and figure 9, it can be observed that 1D RIS BNN [27], IBQL [36], CNN DFC [25], SPNN [26], UDFL [35], M GAN [37], PSO [45], GNN [44], and TSNN [34] have better precision, which makes them useful for applications that require consistent performance across different evaluations.

Similarly, from table 1 and figure 10, it can be observed that SPNN [26], IBQL [36], CNN DFC [25], UDFL [35], 1D RIS BNN [27], M GAN [37], GNN [44], TSNN [34], and GLMM GFK [28] have better recall, which makes them useful for applications that require low error performance across different evaluations.

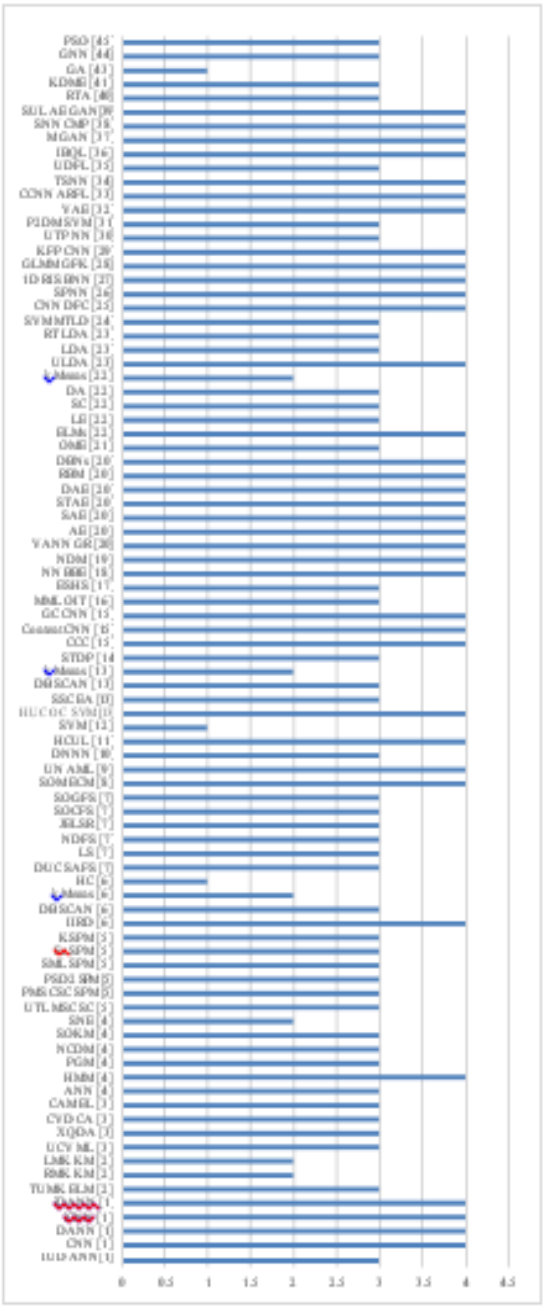

Figure 11. Computational Complexity of different models

Similarly, from table 1 and figure 11, it can be observed that HC [6], SVM [12], GA [43], RMK KM [2], LMK KM [2], SNE [4], and k Means [6] have lower complexity, which makes them useful for high-speed applications across different evaluations.

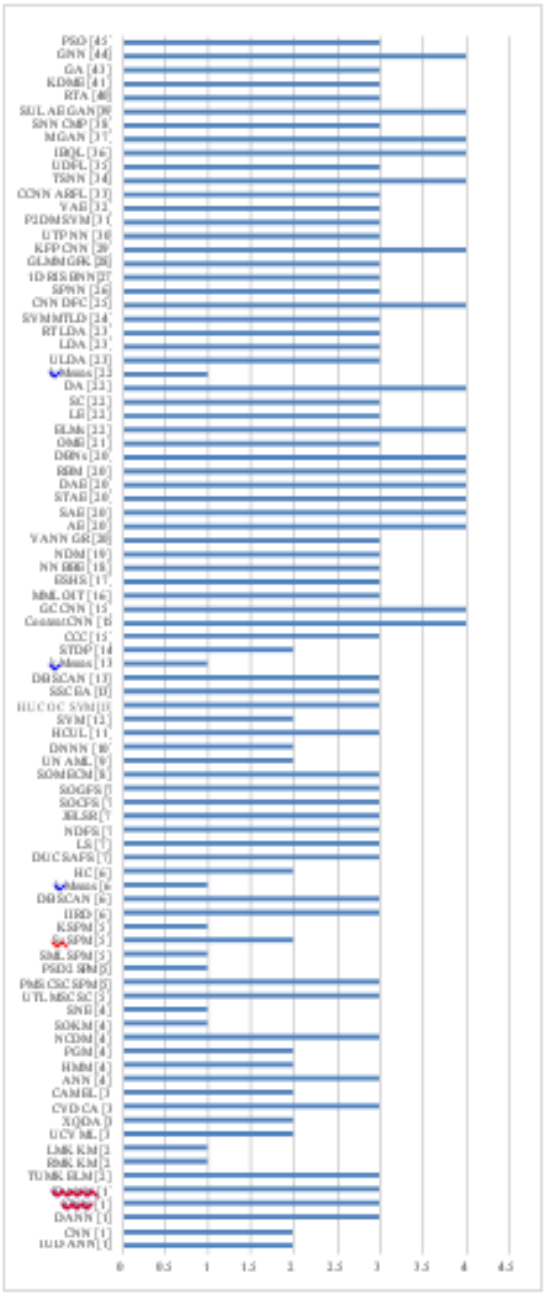

Figure 12. Scalability of different models

Similarly, from table 1 and figure 12, it can be observed that Content CNN [15], GC CNN [15], AE [20], SAE [20], STAE [20], DAE [20], RBM [20] , DBNs [20], and ELMs [22] have higher scalability, which makes them useful for large- scale applications.

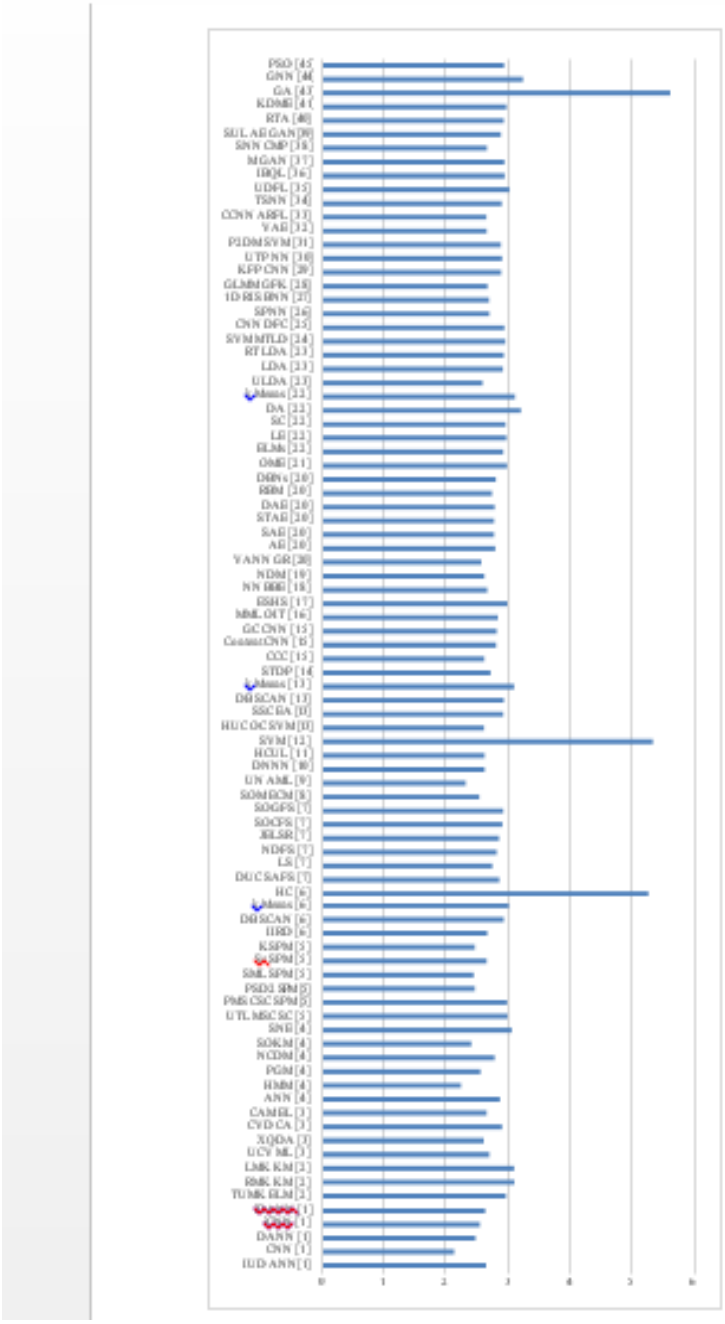

Figure 13. NRM of different models

To further assist in improving model selection

process, a Novel Rank Metric (NRM) is evaluated via equation 1, which assists in combining accuracy, precision, recall, complexity and scalability metrics.

$$NRM = \frac{P + R + A}{300} + \frac{4}{C} + \frac{S}{4} \dots (1)$$

Based on this evaluation and figure 13 it was observed that GA [43], SVM [12], HC [6], GNN [44], DA [22], k Means [22], RMK KM [2], LMK KM [2], SNE [4], UDFL [35], UTL MSC SC [5], ESHS [17], PMS CSC SPM [5], OME [21] , and KDME [41] have better overall performance, which makes them useful for high accuracy, high precision, high recall, low complexity and highly scalable application deployments. Thus, these models must be used when designing unsupervised learning applications for optimum performance under different use cases.

IV. CONCLUSION

This text extensively compares different unsupervised learning models in terms of their context-specific nuances, application-based advantages, functional limitations, and recommends various future enhancements, which will assist in improving its real-time performance. From this evaluation it was observed that existing models use ML methods along with bioinspired techniques for continuous performance optimizations, which assists in improving their real-time performance under different applications. It was also observed that effective feature representation along with optimized distance metrics have better performance when compared with their counterparts. This evaluation concludes that KFP CNN, IIRD, M GAN, SPNN, PSO, IUD ANN, NN BBE, IBQL, ELMs, UCV ML, and D RIS BNN have highest accuracy, D RIS BNN, IBQL, CNN DFC, SPNN, UDFL, M GAN, PSO, GNN, and TSNN have better precision, while, SPNN, IBQL, CNN DFC, UDFL, D RIS BNN, M GAN, GNN, TSNN, and GLMM GFK have better recall, which makes them useful for high accuracy applications that require low error performance across different evaluations. It was also observed that HC, SVM, GA, RMK KM, LMK KM, SNE, and k Means have lower complexity, while Content CNN, GC CNN, AE, SAE, STAE, DAE, RBM, DBNs, and ELMs have higher scalability, which makes them useful for high-speed & large-scale applications. These metrics were combined and a Novel Rank Metric was evaluated, which recommends that GA, SVM, HC, GNN, DA, k Means, RMK KM, LMK KM, SNE, UDFL, UTL MSC SC, ESHS, PMS CSC SPM, OME, and KDME have better overall performance, which makes them useful for high accuracy, high precision, high recall, low complexity and highly scalable application deployments. Thus, these models must be used when designing unsupervised learning applications for optimum performance under different use cases. In future, it is recommended that researchers must use a combination of these models which will assist them in improving their real time performance under different use cases. Furthermore, validation of these models must be done for large-scale applications, which will assist them in recognizing their scalability performance for multiple application scenarios.

Utilizing Machine Learning for Detecting and Mitigating Distributed Denial-of-Service (DDoS) Attacks

Varsha Dange, Swapnil Aphale, Anuj Harad, Mayur Babar, Ananya Kulkarni.

Vishwakarma Institute of Technology, Pune-411037, Maharashtra, India

Abstract — **An attack known as a DDoS (distributed denial-of-service) occurs when the victim is subjected to an excessive volume of requests from the attacker. In order to accomplish this, an attack is launched simultaneously from a huge number of comprised devices, including laptops and Internet of Things (IoT) devices. The primary objective of this attack is to prevent the targeted servers from responding to valid requests, ultimately rendering them unreachable to users.**

The bandwidth and buffer size reduction on the targeted servers is one of the most significant effects of a DDoS attack. This is due to the fact that the servers are overloaded with requests, making it impossible for them to manage all incoming traffic. The outcome is that the targeted servers are overloaded and unable to handle any legitimate requests.

Recently, there has been an increasing trend of DDoS attacks, with attackers frequently using this method to target servers and networks. In response to this, researchers have proposed the utilization of various machine learning techniques, such as logistic regression, random forest classifier, and k-nearest neighbors classifier, for detection and classification different types of DDoS attacks. These machine learning techniques are useful when to analyze network traffic and identify patterns that are indicative of a DDoS attack. By utilizing such techniques, DDoS attacks are detectable in real-time, and protective steps can be taken to safeguard the targeted networks and servers.

Keywords — DDoS, Machine learning, DoS, Security, cyber security, IoT devices.

1.INTRODUCTION

Nowadays, everything from ecommerce to the medical sector has become dependent on the internet [1]. With this rising trend, the malicious activities on the internet have risen too. These activities range from stealing valuable information, stealing access to straight away restricting the services of the target [2]. These restrictions on services attacks in cyber security are called Denial-of-service attacks. Such attacks involve the attacker sending an excessive number of requests to the target website, server, or application. [3]

These attacks aim to restrict access to a particular website, server, or application by overwhelming it with a flood of traffic or requests [4]. The goal of a DoS attack is to make the targeted system unavailable to legitimate users, typically, by overwhelming the system's resources or disrupting its normal functioning [5].

These attacks can be launched using a variety of techniques, such as sending a lot of requests (more than the victim could ever handle) to a server, flooding a network with traffic, or exploiting a vulnerability in a system's software or hardware [6]. Some attackers use botnets, which are networks of compromised computers that can be controlled remotely, to launch DoS attacks [7].

DoS attacks can have a wide range of impacts, from causing temporary disruption of services to causing long-term damage to a system or organization [8]. They can also be used as a smokescreen for other types of cyber attacks, such as data breaches or ransomware attacks [9].

It is important for organizations and individuals to take steps to protect themselves from DoS attacks [10]. This can include implementing firewalls and intrusion detection systems, as well as monitoring network traffic for unusual activity. Additionally, organizations should have incident response plans in place to quickly identify and mitigate the effects of a DoS attack [11].

A DDoS (Distributed-denial-of-service) assault is when this attack is carried out from numerous other machines that are known as botnets or zombies and are directed at a single victim [12]. These requests are far too numerous for the target to process effectively, which forces the target to shut down and renders it unreachable to its actual users, doing a lot of harm [13].

This extremely potent electronic assault has been used to target network equipment and services all over the internet [14]. The detection of DoS and DDoS types of assaults has become an urgent issue as the total number of devices grows day by day as a result of IoT technology.

Machine learning is another field that is becoming more and more popular. A subset of artificial intelligence known as "machine learning" can learn and mimic human learning processes to provide predictions that are more accurate. With the amount of data available during training and testing, machine learning algorithms' performance gradually improves [15].This makes it an excellent choice for predicting such dangerous DDoS attacks. This paper provides following contributions to this topic:

1) Researching several DDoS detection technologies that have recently been created.
2) Analyze and apply multiple feature selection methods prior training the model.
3) To increase the effectiveness of DDoS detection systems and differentiate between various intrusions and DDoS attacks, the proposed system applies various ML models to real-world datasets.

2. LITERATURE REVIEW

This section thoroughly discusses the work done by authors of different research papers that we have studied while researching this topic. Authors of [16] have written about how industries are entering the fourth phase or otherwise known as Industry 4.0 in which the production systems have the man, machine and the product all interconnected. This digitalization has brought a whole new set of disadvantages with it. It has created new opportunities for cyber assaults, including Distributed denial of service (DDoS) attacks, which were not conceivable under the prior system due to its analogue makeup. These cyber attacks are intended to threaten whole production lines or even human lives. In the paper, they used machine learning to build several DDoS attack detection techniques for Industry 4.0 and employ a machine learning strategy to identify cyberattacks. They were getting network traffic data from an actual semiconductor manufacturing facility. They extracted 45 bidirectional network flow features and created several labeled datasets for ML model training and testing. They examined 11 different supervised, unsupervised, and semi-supervised algorithms and evaluated their performance through large-scale simulations. The results show that the supervised algorithm outperforms both unsupervised and semi-supervised algorithms in terms of detection performance. In particular, the decision tree model has an accuracy of 0.999 while limiting the false positive rate to 0.001. They have collected this data from production facilities of a Semiconductor company called Infineon.

To analyze DDoS attack detection performance using the latest CICDoS2019 dataset, work in [17] applied WEKA (an open-source software that provides tools for data preprocessing) with various machine learning (ML) algorithms were used. The model that produced the greatest outcomes was found to be CICDDoS2019. There are six different kinds of machine learning: K Nearest Neighbors (K-NN), Super Vector Machine (SVM), Naive Bayes (NB), Decision Tree (DT), Random Forest (RF), and Logistic Regression (LR) (ML). The methodology applied in this investigation. In the evaluation that was provided, the Decision Tree (DT) and Random Forest (RF) algorithms produced the best accuracy results, with 98% and 98%, respectively. However, the DT is superior to RF since its computing time is lower (4.53 s vs. 84.2 s, respectively). The following is followed by the presentation of concerns for potential future research

On the other side, the authors of [18] suggested a DDoSNet intrusion detection system for SDN settings. . This referred system combines auto encoders and recurrent neural networks and was developed using the Deep Learning (DL) technique (RNN). The CICDDoS2019 dataset has been used to assess the created system. When compared to the current methodologies, authors found that assault detection has significantly improved. In order to secure SDN environments, the suggested solution delivers considerable assurance

A study in [19] used the CICDDoS2019 dataset, to examine the effects of data balancing practices on network traffic categorization issues for various types of DDoS attacks. It provides a wide range of knowledge about reflection- and exploit-based attacks. The gathered data showed the effectiveness of data balancing methods to detect network attacks, including synthetic minority sampling, naïve random sampling, and adaptive synthetic sampling.

The authors of [20] suggested a system that could identify various DDoS attack types using the CICDoS 2019 dataset and a variety of classification techniques. Additionally, they extracted packets from the SDK environment, processed the dataset using a preprocessing function, and then used a classification method to find DDoS assaults. According to the authors, the decision tree outperforms SVM and Naive Bayes machine learning techniques.

A study described in [21] uses various machine learning techniques to analyze the success rate of intrusion detection systems. Using CICDDoS2019, there have been studies on a number of machines learning algorithms, including ANN, Support Vector Machines (SVM), Gaussian Naive Bayes, Multinomial Naive Bayes, Bernoulli ave Bayes, Logistic Regression, K-Nearest Neighbors (KNN), Decision Trees, and Random Forest techniques.

The study illustrates that the most accurate predictive models are K-Nearest Neighbors, Logistic Regression, and Naive Bayes models.

The authors of [22] employed the Deep Neural Network (DNN) to detect DDoS attacks in a sample of packets taken from network traffic using a deep learning technique. Since the DNN model includes feature extraction and classification methods, it can perform quickly and with a high level of detection accuracy even with little samples. The CICDDoS2019 dataset, which consist of a range of DDoS attack variations created in 2019, served as the basis for the researchers' testing. The referred system uses a deep learning model to attain an accuracy rate of 94.57%.

3. PROPOSED SYSTEM

Attacks that use distributed denial of service (DDoS) target IoT devices' vulnerabilities caused by out-of-date firmware or improper configuration. This has to be also considered when designing the models for DDoS detection systems.

The programming language chosen for this research was python. The following libraries were included which are necessary for the project:

1) *Logistic regression* - This is a type of supervised learning model which is often found to be used in classification and predictive analysis. It is also known as the logit model. It models the probability of an event taking place by having a linear combination of one or more independent variables [15,16,17,18].
The logistic function is given by

$$p(x) = \frac{1}{1 + e^{-(x-\mu)/s}}$$

2) *Random forest* - Is a learning technique that is frequently used for classification, regression, and other tasks. It works by building decision trees while the model is being trained [19,20,21,22,23,24]. When decisions or binary outcomes are provided at each phase of a machine learning job, decision trees are a common technique [25,26,27].

3) *K - nearest neighbors* - The k - nearest neighbor or k–nn is a non-parametric learning classifier based on supervised learning. It utilizes proximity of data points when making classification or predictions about the grouping of that data point. Few of the several distance measures that is used to detect these distances are Euclidean distance

$$d(\mathbf{p}, \mathbf{q}) = \sqrt{\sum_{i=1}^{n} (q_i - p_i)^2}$$

, Manhattan distance

$$D_{manhattan} = |x_2 - x_1| + |y_2 - y_1|$$

, etc [28,29,30].

The dataset that has been used for the machine learning model is NSL-KDD dataset. It is an improved dataset over the previous version of this dataset - KDD '99 data set, which was said to have some inherent problems.

4. METHODOLOGY/EXPERIMENTAL

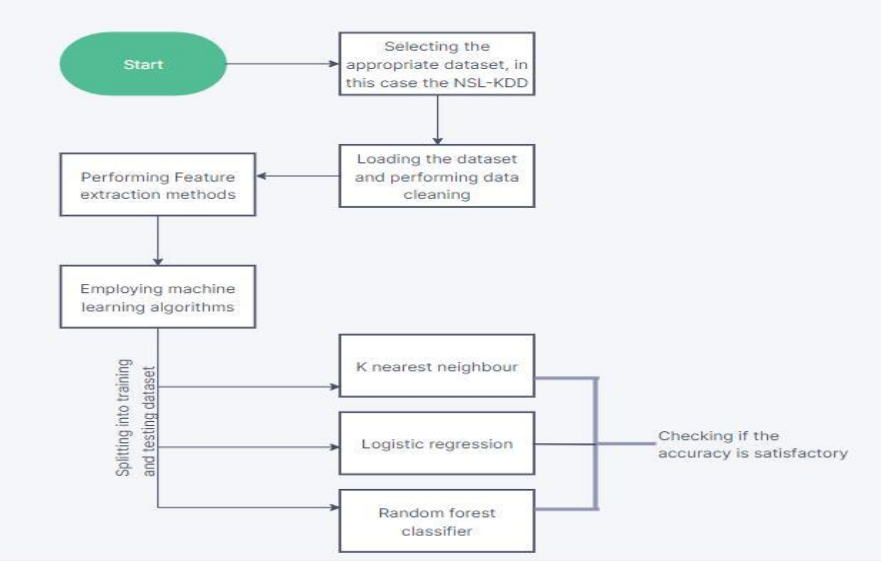

Figure 1. Flowchart for the procedural steps to attain the final result.

Here in the above flowchart (Figure 1), the procedural steps used by the system are shown. This system has included several libraries and modules in its work (Shown in figure 2), including numpy for working with arrays and performing mathematical operations, pandas for data analysis and manipulation, seaborn and matplotlib for data visualization and plotting, and various libraries from sklearn for machine learning and accuracy evaluation.

```
import itertools

import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import seaborn as sns
# model imports
from sklearn.ensemble import RandomForestClassifier
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import accuracy_score
from sklearn.metrics import confusion_matrix
from sklearn.model_selection import cross_val_score
# processing imports
from sklearn.model_selection import train_test_split
from sklearn.neighbors import KNeighborsClassifier
```

Figure 2. Libraries used.

The dataset used in this study is the NSL-KDD dataset.The NSL-KDD dataset (NSL stands for "Network Security Laboratory") is a data set of network intrusion detection system (NIDS) created by researchers at the Department of Defense (DoD) Cyber Crime Center (DC3) and the Air Force Research Laboratory (AFRL). The NSL-KDD dataset contains a total of around 25,000 instances, with around 10% of them being attack instances and the rest being normal instances. This covers a broad range of attacks, including as Denial of Service (DoS) attacks, unauthorised access from a remote computer (R2L), and illegitimate access to local superuser (root) rights (U2R). This dataset is in .csv format and does not include column names. The system required the addition of column names and required flagging of all attacks as 1 and normal as 0.

The dataset is then divided into the lists of dos attacks, probe attacks, sybil attacks, and U2R. This proposed system uses a function to map the dataset according to their attack types and plotted pie charts for better visualization of the data. It also plots the pie chart of attack vs normal and normalMCS vs attack pie chart.

After visualizing the dataset, the system splitted the dataset into training and testing parts, using a ratio of 80:20. The proposed system has used the random forest classifier, k nearest neighbor, and logistic regression algorithms for prediction and evaluated the results. The findings demonstrated that, in contrast to logistic regression, which did not perform well and was very inconsistent, both the KNN and Random Forest classifiers performed well and consistently produced high-quality results. While both the KNN and the random forest were producing fast results, the random forest was slightly slower than the KNN.

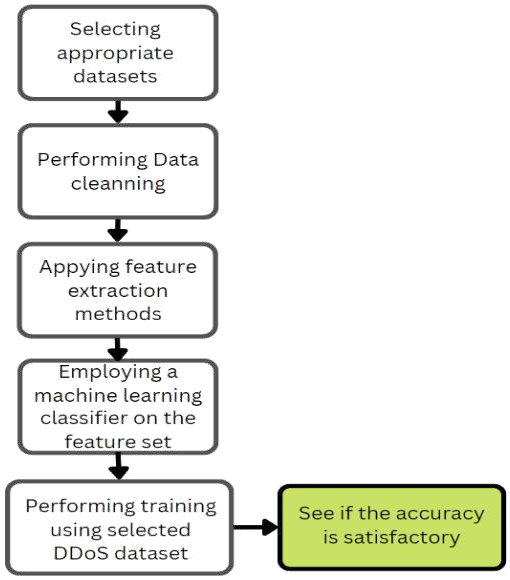

Figure 3: Block diagram for the entire process.

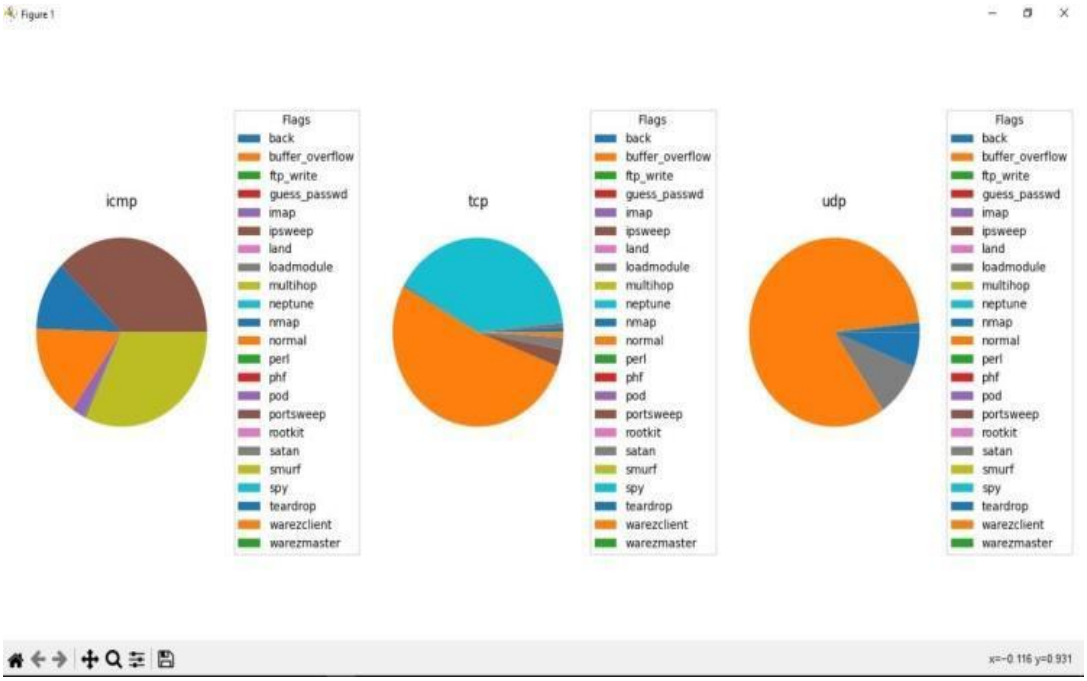
A more general view of the process can be taken from the above block diagram (Figure 3)

The accuracy for both the KNN and Random forest classifier was over 99% while accuracy for logistic regression was barely over 40% and was very inconsistent. Finally, the proposed system plotted the confusion matrix as a performance metric for analyzing their model. This matrix showed DDoS attacks differentiated from the normal and the other intrusion attacks. The terms predicted attack, predicted normal, actual attack, actual normal, predicted attack refers to the attack predicted by the algorithm, and predicted normal refers to the normal predicted by the dataset, whereas the terms actual predicted and actual normal refer to the actual that are actually the attacks and normal, respectively.

5. RESULTS AND DISCUSSIONS



Therefore, these are the attacks on various network protocols, as indicated in figure 4. UDP, TCP, and ICMP. Here, several flags signify various network attacks.

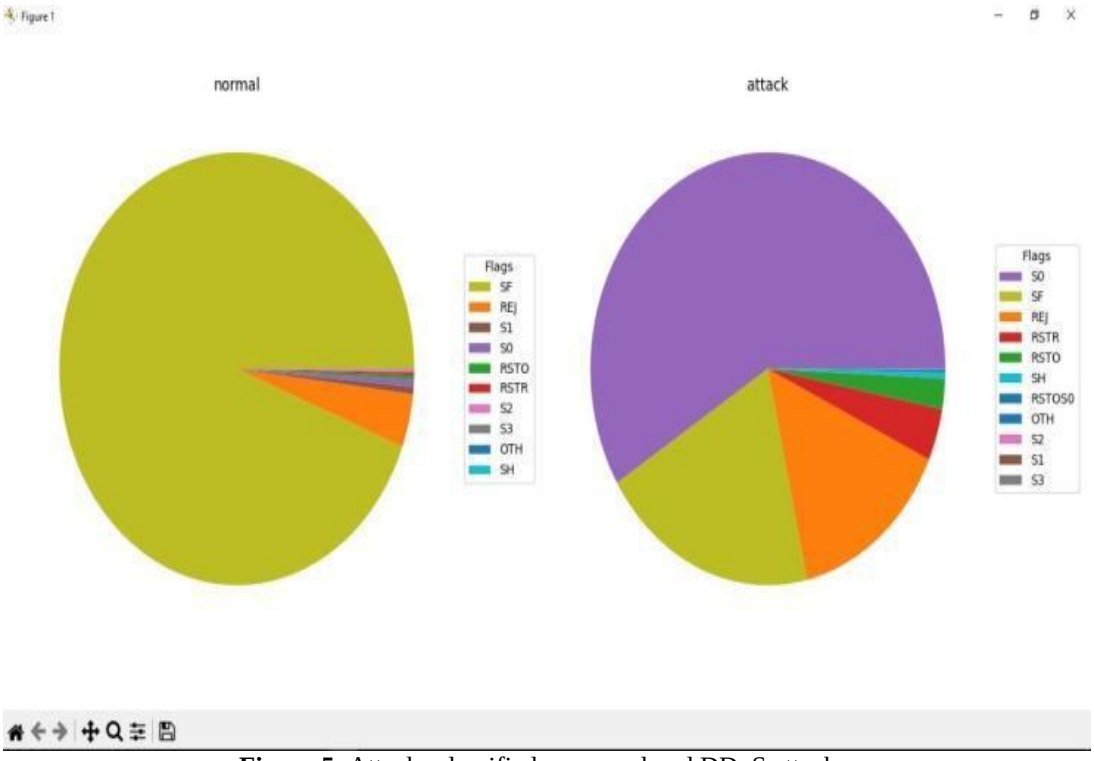


Figure 5: Attacks classified as normal and DDoS attacks.

After this in Figure 5, the attacks are classified into two types of attacks ‘normal’ and ‘attack’- which is DDoS attacks.

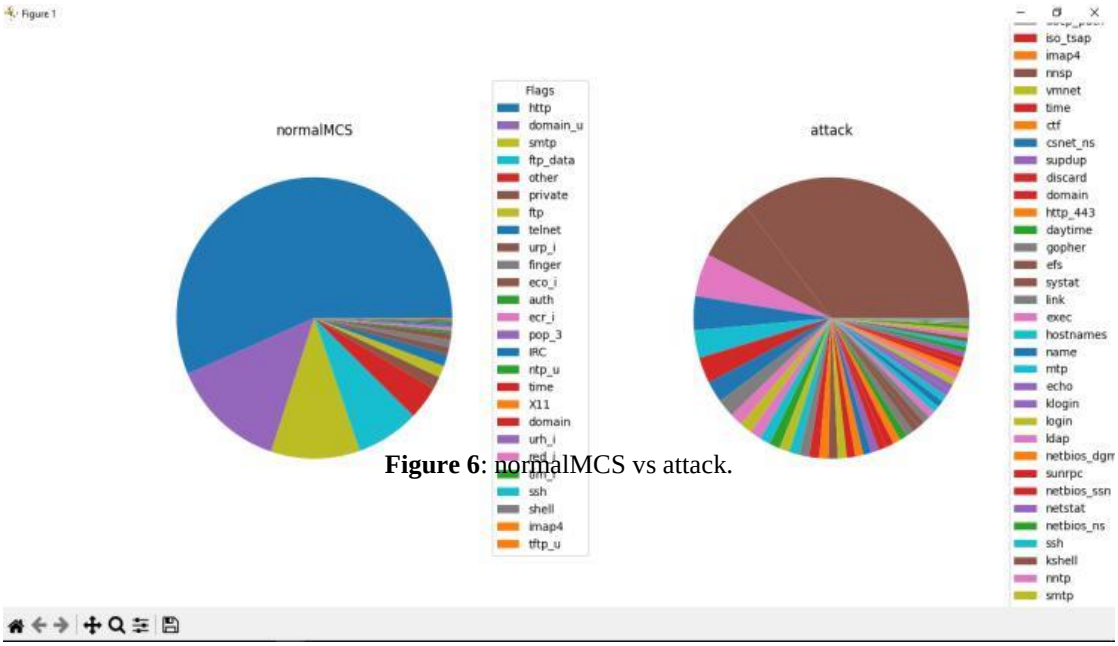

Figure 6: normalMCS vs attack.

Figure 6 illustrates the trends of several flags for attacks and normalMCS. In this context, MCS stands for modulation coding scheme, a industry measure that contains details on numerous factors relating to the relationship between a client and a wireless access point.

After visualizing the dataset, they were predicted using three different models, random forest, k nearest neighbor and logistic regression. The following two observations were made:

1)Both the KNN and Random forest classifiers performed well and were very consistently providing good results while logistic regression did not perform well and was very inconsistent.

2)While the KNN and random forest were providing good results, random forest was taking slightly more time as compared to KNN.

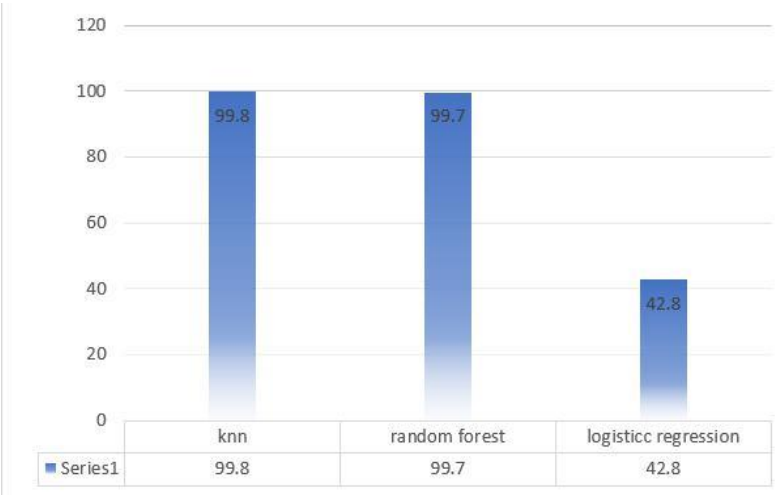

Figure 7: Comparison of accuracies for KNN, Random forest and logistic regression models

As shown in Figure 7, accuracy for both the KNN and Random forest classifier was over 99%, while accuracy for logistic regression was just 40% and was quite inconsistent.

TABLE 1. Comparison between all reviewed papers.

Research work	**Algorithm**	**Detection accuracy**
[16]	Decision Tree	0.95
[17]	Random Forest	0.98
[18]	Recurrent Neural Network with autoencoders	0.9254
[19]	SMOTE	0.9351
[20]	Decision Tree	0.9215
[21]	Artificial Neural Network, Support Vector Machine, Guassian Naïve Bayes, Random Forest Algorithm & K-Nearest Neighbor	Naïve Bayes offers the best detection accuracy
[22]	Deep Neural Network	0.9457
This paper	K- NN, Random Forest and logistic regression	0.99

Finally, the confusion matrix was then plotted as a performance metric for proposed model. DDoS attacks can be distinguished from common intrusion attempts and other attacks in the Figure 8.

There are four categories in the confusion matrix: predicted attack, predicted normal, actual attack, and actual normal. The predicted attack refers to the attack predicted by proposed algorithm, and the predicted normal refers to the normal predicted by proposed system dataset. The actual predicted and actual normal, on the other hand, are the actual, which are, respectively, the attacks and the normal.

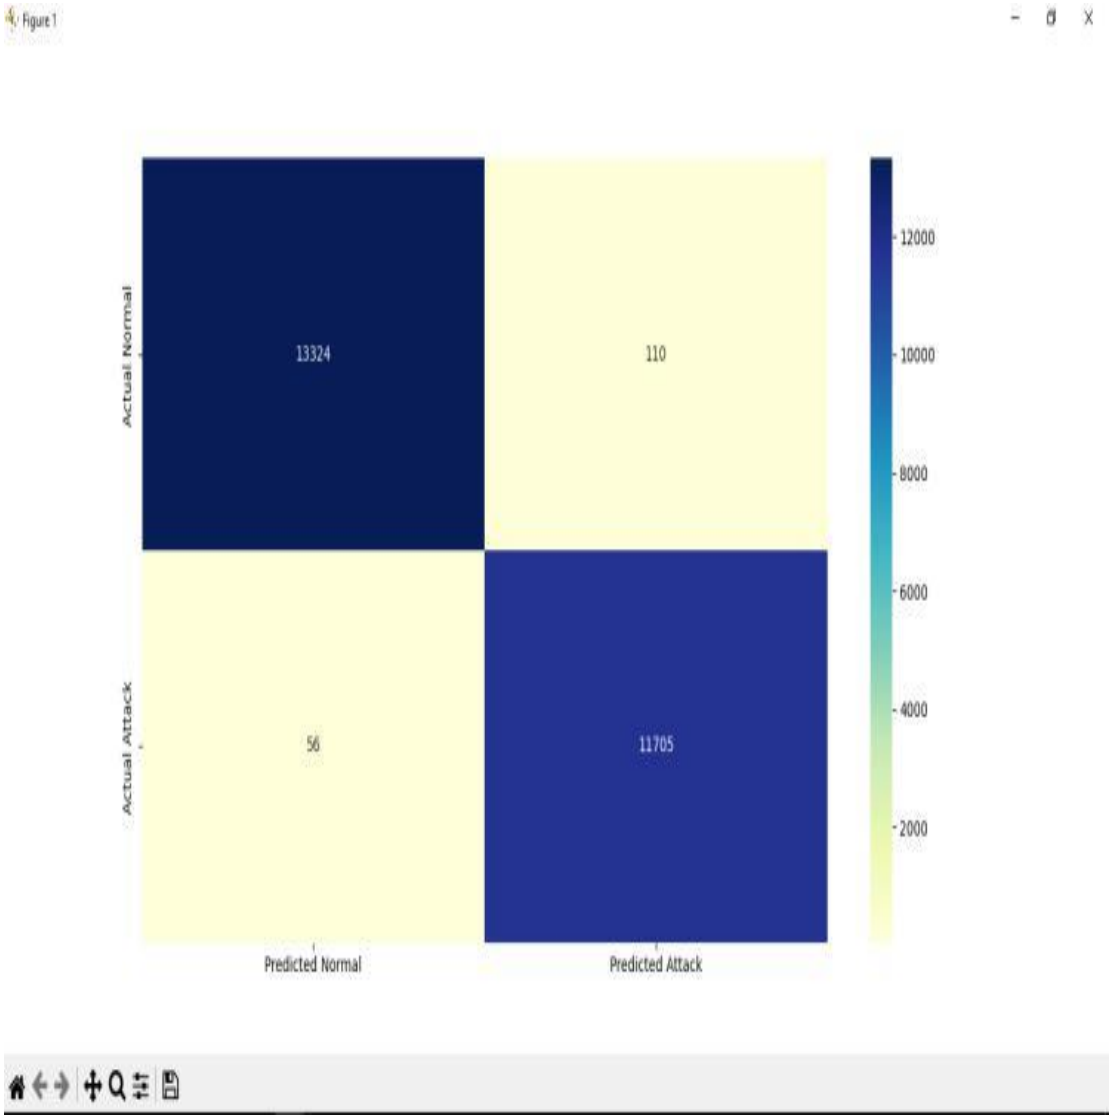

Figure 8: Confusion matrix of the result achieved.

traffic, making it difficult for legitimate users to access the targeted system.

Machine learning (ML) has proven to be a valuable tool in detecting and mitigating DDoS attacks. Network traffic analysis using ML algorithms can be used to detect patterns in behaviour that refer to a DDoS attack. For instance, ML models can be trained to identify particular traffic kinds or pattern types that are frequently used in DDoS attacks.

The source of an attack can be detected using ML-based DDoS detection systems, which is crucial for tracing the attackers and taking appropriate action. In addition, ML can be used to create mitigation strategies like rate limiting or traffic shaping that can lessen the effects of an attack.

6 CONCLUSION

DDoS attacks, a subset of DoS attacks, target a single system or network by using a number of compromised systems. These attacks are launched by a distributed network of attackers, often using botnets, which makes them more difficult to detect and mitigate. DDoS attacks can generate a massive amount of

Although ML has demonstrated potential in the defense against DDoS attacks, considerable work remains. DDoS attacks are always changing, and attackers are constantly coming up with new techniques for preventing attacks. Additionally, locating DDoS attacks might be challenging. because to the complexity and volume of network data. However, researchers and practitioners are constantly enhancing ML-based DDoS detection and mitigation strategies due to the ongoing growth of ML technology.

Abstract. **Currently, the most dangerous cyber-attack is the distributed denial of service attacks also known as the ddos attack. This is primarily accomplished through network traffic bombardment, in which attackers attempt to generate a large number of fake IP address requests, which can affect the server's ability to provide resources to legitimate customers, and which can affect server resources, such as bandwidth speed, buffer size, fiber optic cable transmission rate which are slowed down. This work proposes a machine learning approach for distributed denial-of-service assaults. To detect assaults and typical circumstances, machine learning methods such as K-Nearest Neighbor, Decision Tree, Logistic Regression, Naive Bayes, and Quadratic Discriminant Analysis are utilized. The Mininet's auto generated dataset is used for experimental purposes. In this study, the Google colab platform was employed for implementation, and the findings were analyzed and compared. Other machine learning techniques employed in denial-of-service attacks are compared to previous work.**

Keywords: DDoS Detection, Mininet decision tree, naive bayes, quadratic discriminant analysis, k-nearest neighbor and logistic regression.

1 Introduction

In today's world the internet has become one of the fastest advancing technologies. Everything is available at the user's fingertips. However, with technological advancements, security threats have also become very common. In more specific terms, network attacks are the common threat among various organizations. One such attack is called a Denial of Service (DoS) attack. In such an attack the server of service provider, also called as target machine, is flooded with heavy traffic in the form of multiple bogus requests which eventually make the server inaccessible to the genuine requests. This is because of the reason that a server can accept and respond to only a specific number of requests at a particular time. Hence this practice ultimately shuts the system or network down. Hence DoS attack affects the intended workflow of the organization. DoS attacks are however easier to detect since the IP address of the sender will be the same of every request and hence the attacker can be easily traced or the attack can be mitigated. The advanced version of DoS attack is called DDoS attack. It stands for Distributed Denial of Service (DDoS) attack. In these types of attacks, the requests are sent to the target machine from multiple source machines with different IP addresses. The network of these source machines is known as botnets and all the devices in this botnet are controlled by the attacker.To recognize and avoid this kind of attack, the target machine will have to distinguish between the attacking requests and the genuine ones and hence need to block all the attacking requests In this work, various machine learning models have been proposed which will carry out the task of detecting malicious requests. These machine learning algorithms can very accurately differentiate legitimate requests from the malicious one. The models are trained on a dataset which is generated by using Mininet emulator and it is a SDN specific dataset. It is mostly employed by various deep learning and machine learning algorithms for the classification of requests. Thus, the attack can be prevented by blocking all those detected malicious requests.

2 Literature Review

In the field of Cyber security, DDoS attacks have more risk. In most DDoS attacks, the victim's device and the attacker's device are connected to each other in the network at the application and network layers. This attack can lead to huge loss of data, security and private information and can also lead to huge financial losses if some business has been targeted by the attacker. In order to avoid this, it is important to be able to classify between the legitimate and illegitimate requests i.e., one must be able to detect the illegitimate requests to avoid huge traffic of requests and thus prevent DDoS attack. So, to solve this issue, machine learning models like Naive Bayes which is a probabilistic model or a Random Forest classification model can also be used to detect DDoS attacks by training these models on the past datasets containing the records of legitimate and illegitimate requests [1].

Cloud Computing has been like a boon in this Information Technology domain. It provides resources to the users quickly and requires less maintenance. But cloud computing also has some vulnerabilities which leads to a scope for DDoS attacks. These assaults rank among the most severe ones that negatively impact cloud performance. A DDoS assault targets vulnerable machines that have been compromised. C.4.5 is an algorithm which has been designed to detect DDoS attacks. This algorithm uses digital signatures to validate the legitimate requests by generating a decision tree [2].

DDoS attacks are often placed from the cloud by the attacker instead of using the attacker's own device. Attackers use this approach to place DDoS attacks because it provides higher network bandwidth and also helps the attacker to achieve anonymity. As per past records it is very difficult to trace back the attacker if the attacker uses this approach. Different machine learning models can therefore be employed to detect such attacks in order to overcome this problem. A model can be trained based on the past records and statistical analysis of the cloud's server. This type of model was built by some researchers and they had obtained a very high accuracy of 99.7% in successfully detecting such attacks [4].

Distributed Denial of Service (DDoS) attacks occur at various OSI layers like the transport , application and network layers. The research paper is composed of the CIC IDS 2017 dataset. The dataset has been generated on various application layer protocols using twenty-five users. The protocols used are HTTP, SSH, FTP and HTTPS. The machine Learning models used in this research were Random Forest and MLP. [6]

Various mitigation techniques like blacklisting IP addresses, white-listing IP addresses, rate limiting etc. are used to place DDoS attacks. DDoS attacks lead to loss of money as well as prestige of an organization. CIC IDS 2017 dataset consists of weekly reports related to all requests made. The DoS attacks details are present in Wednesday's reports. The authors have deployed different kinds of models like AdaBoost, Neural Networks, XGBoost and Random Forest. In this research all the incoming requests are sent for signature extraction after which the above-mentioned machine learning algorithms are applied to them. If the request is benign, then the request is processed otherwise an alert is issued for possible DDoS attack.[7]

In the article, lower-level functionality is abstracted, and enables network administrators to set up, manage, alter, and automate network behavior management. This article gives the ideas of how to implement SDN controller security. What DDoS looks like Identifying attacks requires categorizing incoming requests for which machine learning techniques have been utilized for separating the connections into valid and unauthorized connections. The two models utilized were the neural network (NN) and the support vector machine (SVM).[9]

The authors of this study have suggested a Network the NIDS (Intrusion Detection System) can DDoS assaults can be of both the old and new kind. The ability of this NIDS's ensemble models to combine a variety of classifiers with the idea that each classifier may concentrate on a particular area is one of its key features, as it allows for a more thorough understanding of the various features and types of incursions system for defense against additional incursions. The success rate for this system was found to be 99.1%.[10]

They suggested a DDoS detection and protection strategy in this work by using machine-learning-based Software Defined Network (SDN) technologies Deep neural network (DNN) and machine learning (ML) models. The DNN and ML classifiers combined with SDN variables which are centralized can effectively alleviate the negative impact of DDoS attack on the network system. Furthermore, they have undertaken two sorts of different assault scenarios, one from within and one from beyond relating to the network system. Experiment results show that the more sophisticated DDoS detect mechanism may not yield more accurate findings, than the straightforward one.[11]

DDoS attacks have become fatal for internet networking. Early detection of these attacks is the key to mitigate them. Automatic identification of such attacks through the use of machine learning techniques is the major mechanism at play in this area. However, performance of attack detection is dependent on the accuracy of these machine learning models. Consequently, DeepDefence, a deep learning-based strategy, is recommended. Deep learning is capable of detecting such attacks with better accuracies as deep learning approaches are capable of extracting high level features from the dataset utilizing the low-level ones.[13] The networking design known as Software Defined Network (SDN) enables the creation of virtual hardware components. This adds a feature to dynamically change the connections which was restricted in the earlier architectures. SDN is however prone to DDoS attacks. To handle or detect these DDoS attacks, machine learning approaches are good to use which can automatically detect the attacks. Decision Tree or Support Vector Machine (SVM) are two examples of the many machine learning models that can be utilized. Based on several researches, Decision Tree and SVM are the models which outperformed various other machine learning models especially when SDN specific datasets were used.[14] Deep Face Forward (DFF), a deep learning technique along with SVM(Support Vector Machine) has been used to detect Distributed Denial of Service(DDoS) attacks. Preprocessing is conducted on the dataset to speed up the classification process. The DARPA Intrusion Detection Evaluation Dataset has been used to evaluate the various models. The DFF technique has been known to classify data with a higher accuracy. [18]

3 Methodology

3.1 Dataset Description

The quantity of valid records and attributes must be taken into consideration when selecting or importing datasets, as well as the sort of methods that should be employed, which might be supervised, unsupervised, or semi-supervised approaches. Supervised techniques have been used in this research paper. The dataset used is a SDN (Software Designed Network) specific dataset[1] which is created by using the Mininet emulator. It is used to classify network

traffic using machine learning models. A Mininet emulator is a tool which works in a virtual environment for visualizing switches in SDNs. While creating the dataset, ten

topologies were created in the Mininet emulator. A Ryu controller was connected to all the switches. The data from one switch (the victim) was considered and all the other nine switches were placing benign or malignant attacks on the victim switch. The type of requests sent to the victim switch were:

1. Benign UDP (User Datagram Protocol) and malignant UDP flood attack
2. Benign TCP (Transmission Control Protocol) and malignant TCP Syn attack
3. Benign ICMP (Internet Control Message Protocol) and malignant ICMP attack

The dataset comprises 23 features out of which the last feature is the target variable. It has 2 values - benign traffic is labeled as 0 and malignant traffic is labeled as 1.

The dataset contains 20 numeric and 3 categorical features.

The dataset consists of excised features. Some more features are derived from the excised features.

The Mininet simulation was kept running for a total of 250 minutes. In the total run time about 1,04,345 instances of records were collected. The dataset is saved in CSV format and its dataset's qualities are logical and competent, allowing for a precise and efficient forecast of an engineering graduate's salary. The dataset schema is depicted in Table 1.

label	int	0,1

Table 1. Dataset Schema

3.2 Dataset Preprocessing

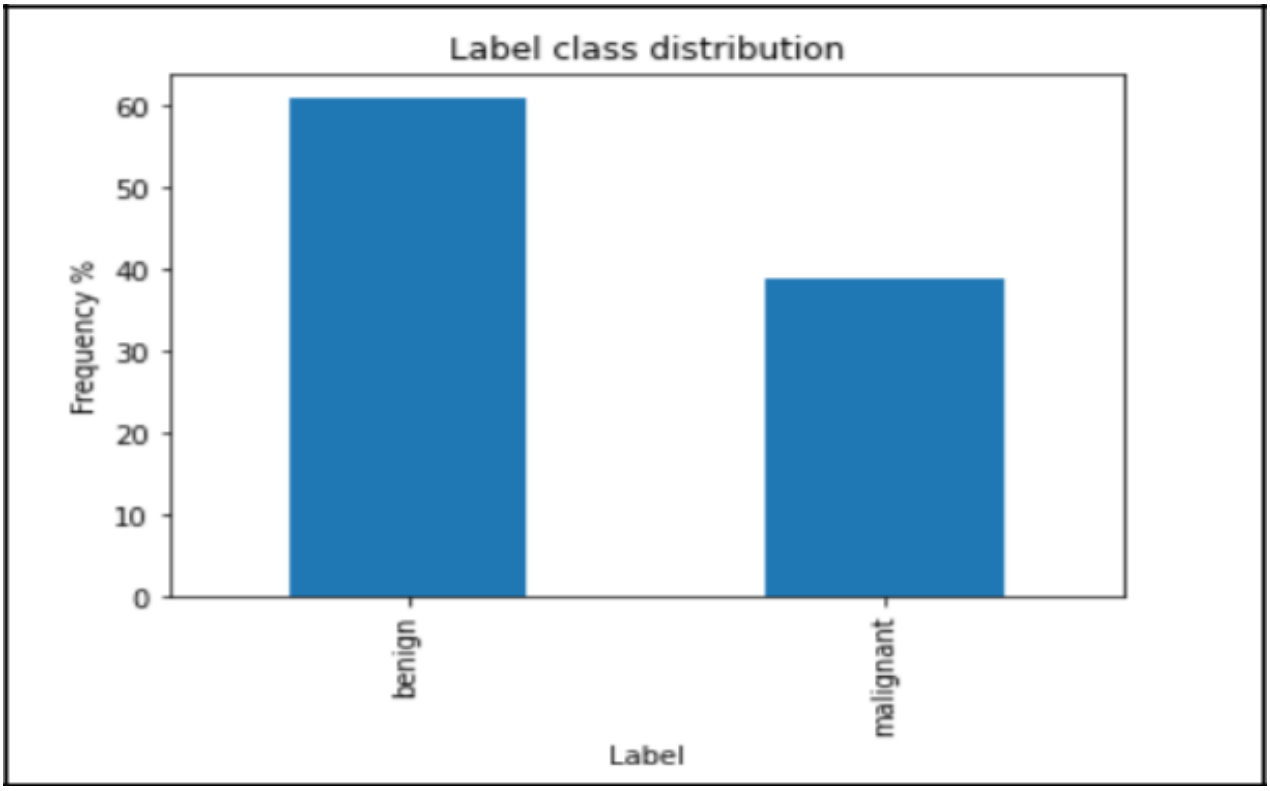
Data Cleaning

The data cleaning method entails finding the data, extracting it, cleaning it, and integrating it into a dataset that can be analyzed as per requirements. It was observed that two features, tot_kbps and rx_kbps contained null values. All the null values were set to 1 and then imputed with their mean to get better results and remove any abnormalities.

On visualizing the data it was found that 60.9934% of requests in the data were benign and 39.0065% were malignant. (Fig 1.)

Fig 1. Distribution of Benign and Malignant Labels

The distribution of all the protocols for the malignant attacks were calculated and depicted in Fig 2. UDP Flood attack was the most commonly used attack with a value of 42.5%, TCP Syn attack was the second with 34.2% and ICMP attack had value 23.3%.



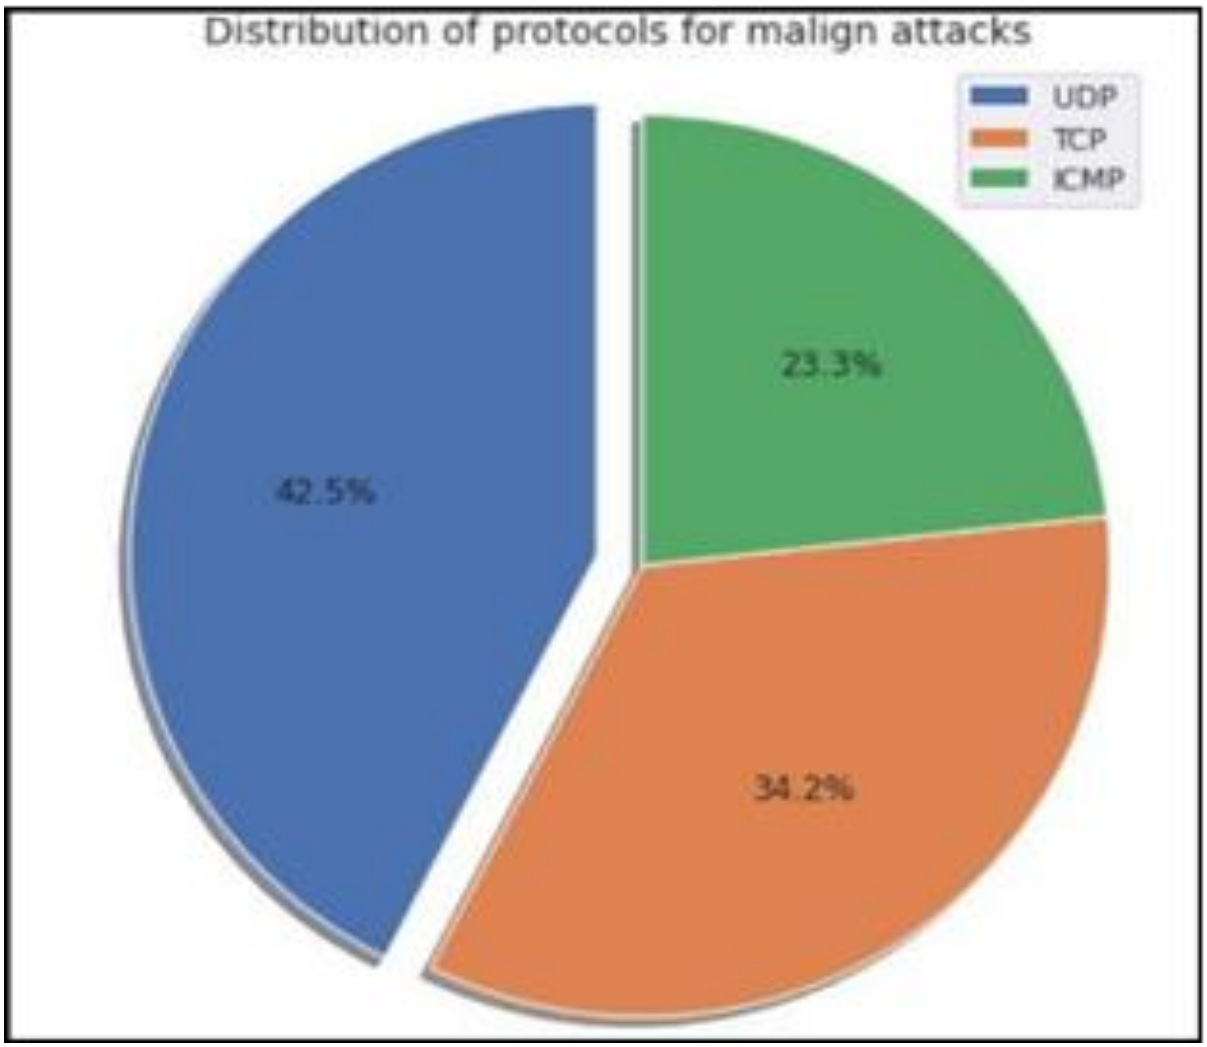


Fig 2. Distribution of Protocol for Malignant attacks

All duplicate records were removed to prevent bias in the performance of machine learning models. Continuous and discrete features were identified. While analyzing the categorial features, i.e. src (the source address) in Fig 3, dst(the destination address) in Fig 4 and the Protocol In Fig 5 were observed.

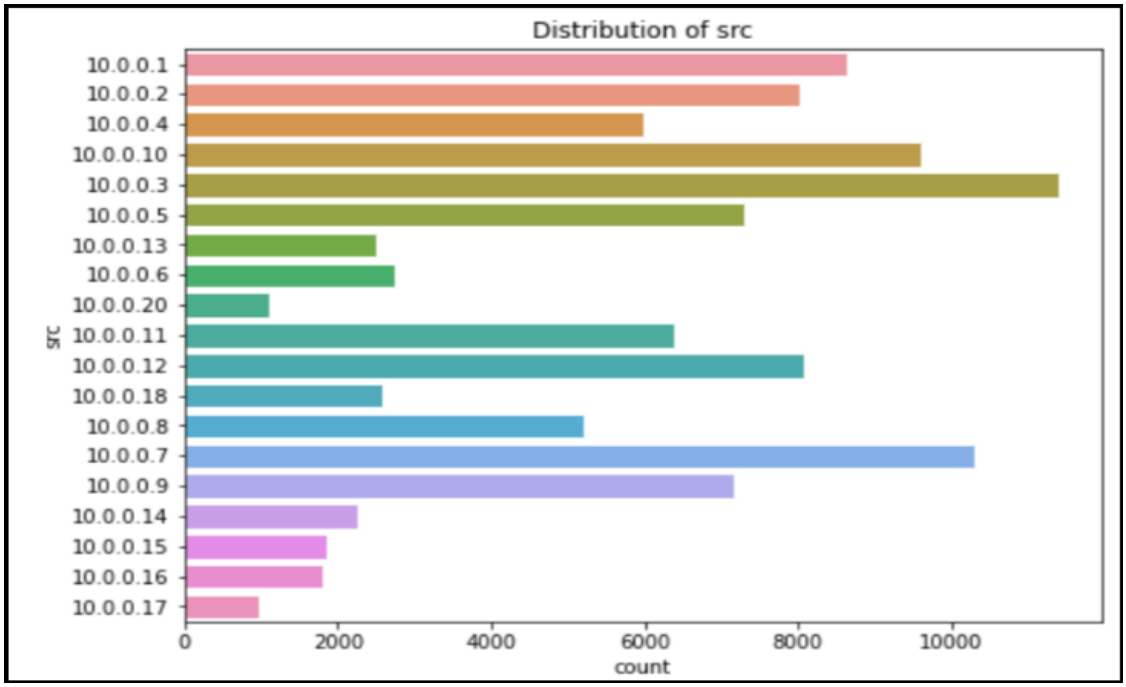

Fig 3. Distribution of src (Source IP Address)

Fi

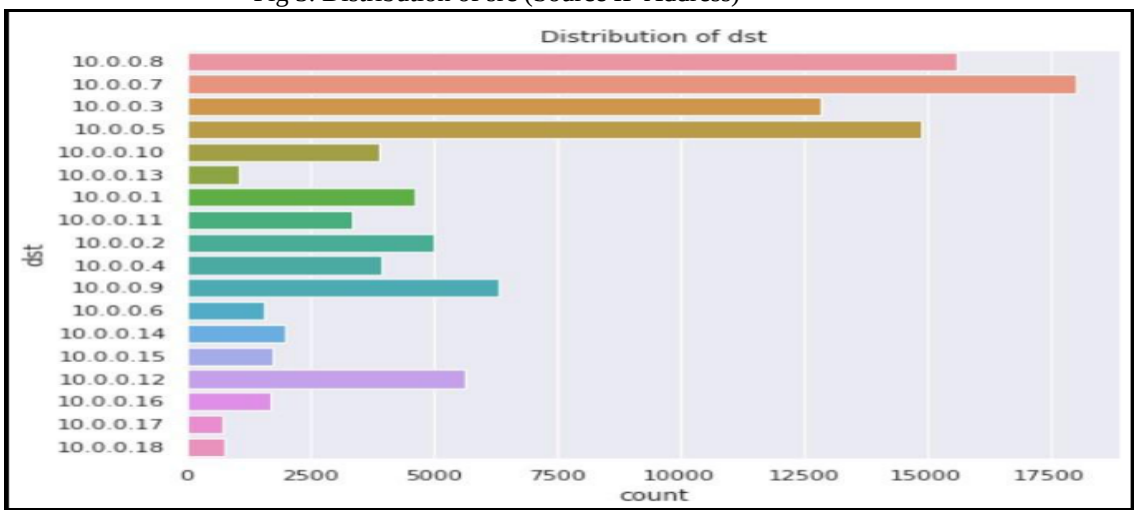

Fig 4. Distribution of dst (Destination IP Address)

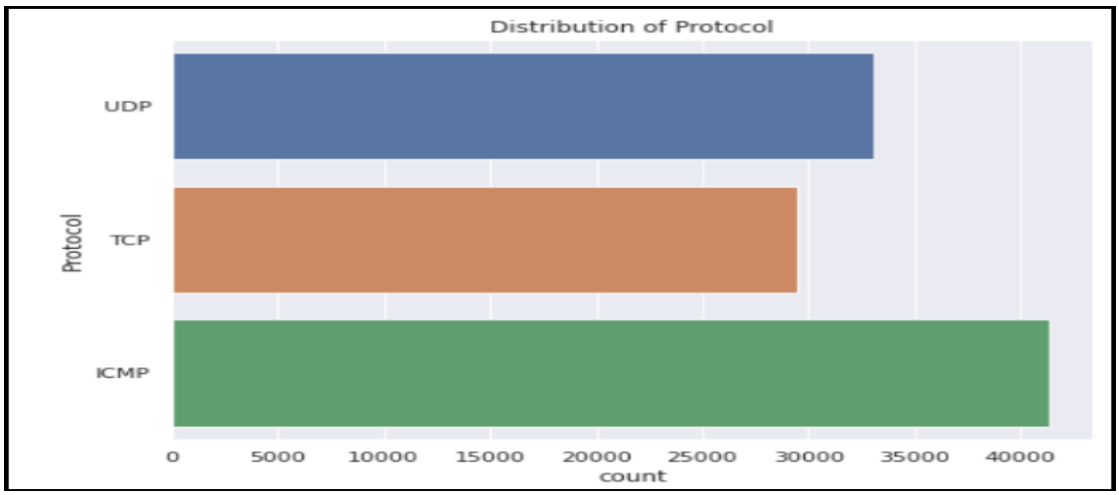

Fig 5. Distribution of Protocol

On visualizing the data, outliers were discovered for pktcount for different Protocols which had to be eliminated since they decrease the correlation by scattering the data and causing r to approach zero. As a result, the pktcount column outliers were removed using their index positions to enhance the r2 value. The categorical features - src,dst and Protocol were encoded. After encoding the dataset had 103839 rows and 57 columns. Fig 6. illustrates the system workflow.

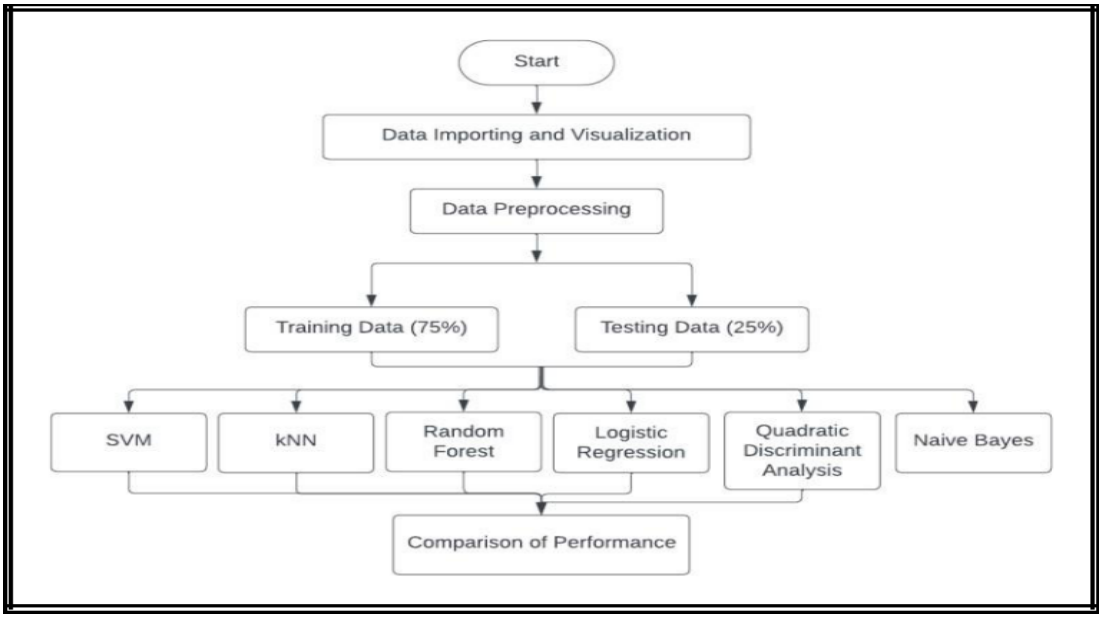

Fig 6. Workflow

10

To classify the attacks 5 supervised machine learning models were used - K-Nearest Neighbors, Logistic Regression, Quadratic Discriminant Analysis, Decision Trees and Naive Bayes Algorithms. The dataset was divided into 75% training data and 25% testing data.

Regression Modeling

a) Manhattan Distance -

$$(,)=\sum| - |$$
$$=0$$

b) Euclidean Distance –

$$(,) \quad =\sqrt{\sum(-)^2}$$
$$=0$$

c) Minkowski Distance –

$$(,) \quad =(\sum| - |)^{1/}$$
$$=0$$

K-Nearest Neighbor

K-Nearest Neighbor also known as kNN is a supervised learning classification model which classifies the data according to similarity or by grouping individual data points. In kNN, the distance of one data point from its neighbors is calculated. The common methods of calculating the distances are:

The accuracy of this classifier was found to be 96.47%.

Decision Tree Regression

A regression model is built in the shape of a tree structure in the decision tree technique. It gradually splits the dataset into small chunks and builds a decision tree to go with it. The ultimate result is a tree with leaf nodes and decision nodes. A decision node can contain multiple branches, each representing a value for the characteristic under consideration. The test attribute's information gain is calculated first, and the formula is provided below.

The entropy for each characteristic is then determined, which is nothing more than the information gain minus the likelihood of that attribute. Finally, the gain for each property is computed, and the attribute with the highest gain is designated as the root node. Similarly, a numerical goal selection is represented as a leaf node. The root node represents the uppermost decision node in a tree that shows the best predictor. The accuracy for this classifier was found to be 96.51%.

$$( )=-\sum ( ) \quad 2 ( )$$

Naive Bayes Classifier

The Bayes theorem and strong (naive) independence assumptions form the foundation of the fundamental probabilistic classifier known as a naive bayes classifier. The classifier is mostly based on the concept of conditional probability principle. In the project scenario, it will evaluate the likelihood of both situations where it will treat the hypothesis as true first for that the detected ddos attack is real and then calculate the probability and finally for that the detected ddos attack is false and calculate the probability. The hypothesis with the highest probability will be accepted. The accuracy of this classifier was found to be 71.59%.

$$(|)= \quad (|)\cdot()$$

Quadratic Discriminant Analysis

Each class in QDA, or quadratic discriminant analysis, is believed to have a Gaussian distribution. It resembles linear discriminant analysis a lot. The only difference is that in QDA every class has the same average and co-variance. The percentage of data-points that belong to a class are called class-specific priors. The average of the input variables that are included in a class gives the mean vector. The covariance of the class-specific vectors results in a covariance matrix which is class specific. The accuracy of this classifier when applied on the DDoS attack detection dataset was found to be 50.33%.

Logistic Regression

Using a predetermined set of independent factors, logistic regression is used to predict the categorical dependent variable. In classification problems, the output is predicted via logistic regression. As a result, the output must be a discrete or categorical value. But it provides the probabilistic values that fall between 0 and 1. Logistic regression is quite similar to linear regression. The main difference is that machine learning models based on linear regression are generally used to address regression problems in which the output variables are continuous while classification problems in which the output variables are discrete classes, are solved by making use of machine learning models based on logistic regression. The logistic function's curve shows the possibility of several things, including whether or not the cells are

malignant, whether or not a mouse is obese depending on its value, etc. While classifying observations using various sources of data, logistic regression can be used to quickly identify the factors that will work well. The projected values are converted to probabilities using a mathematical tool called the sigmoid function. The logistic regression's result must fall within the range of 0 and 1, and because it cannot go beyond this value, it has the shape of an "S" curve. We apply the threshold value idea in logistic regression, which establishes the likelihood of either 0 or 1. Examples include values that incline to 1 over the threshold value and to 0 below it. The accuracy of this classifier was found to be 83.90%.

$$( ) = 0+ 11+ 22+\cdots+$$

Results

After applying all the data preprocessing and refining methods on the dataset, different machine learning classification models were applied on it. The results obtained after application of various machine learning algorithms on the columns are as presented in Table 2 and Fig 7.

Classification Models	Accuracy
Decision Tree	96.513867
KNN	96.472137
Logistic Regression	83.901515
Naive Bayes	71.590909
Quadratic	50.327427

Table 2. Accuracy Comparison

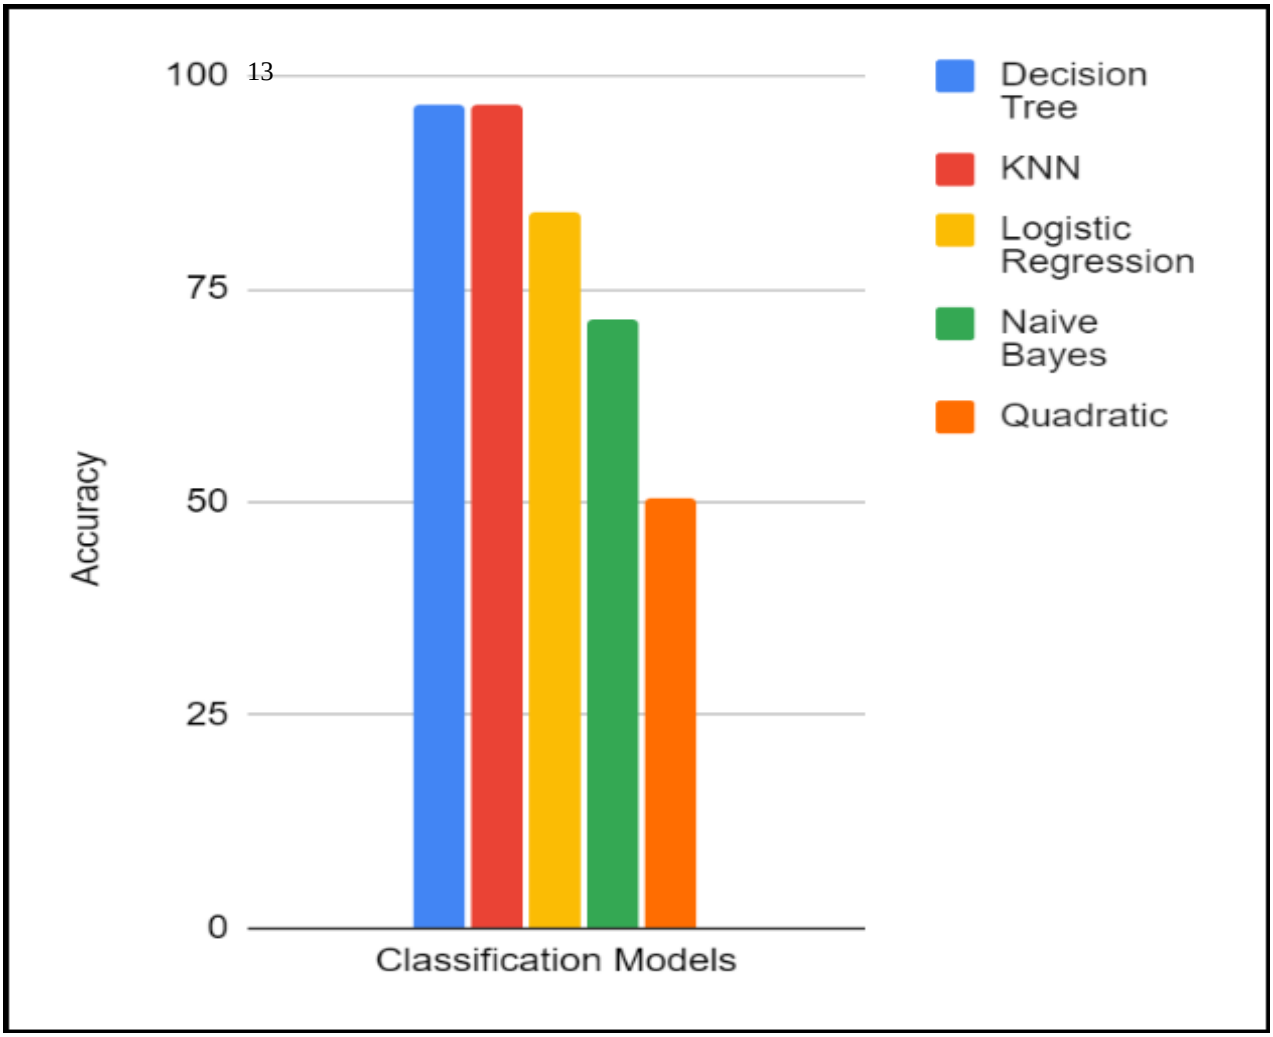

Fig 7. Bar chart depicting accuracy of different classification models

After comparing the results of all the models, the best accuracy of 96.513867% was obtained by applying the Decision Tree Classification model. KNN model also resulted in a good accuracy of 96.472137%.

Fig 8. represents the confusion matrix for the Decision Tree classification model. In Fig. 8, True positive (TP) denotes the number of positive predictions (1) which were correct. False positive (FP) denotes the number of positive predictions (1) which were incorrectly classified. False negative (FN) shows the number of negative predictions (0) which were incorrectly classified. True negative (TN) highlights the number of negative predictions (0) which were correctly classified. Thus, by using confusion matrix, various performance parameters of machine learning models including accuracy, precision and recall are formulated as

(+)∗100
(%)= + + +

( )∗100
(%)= +

(%) = ( )∗100
+

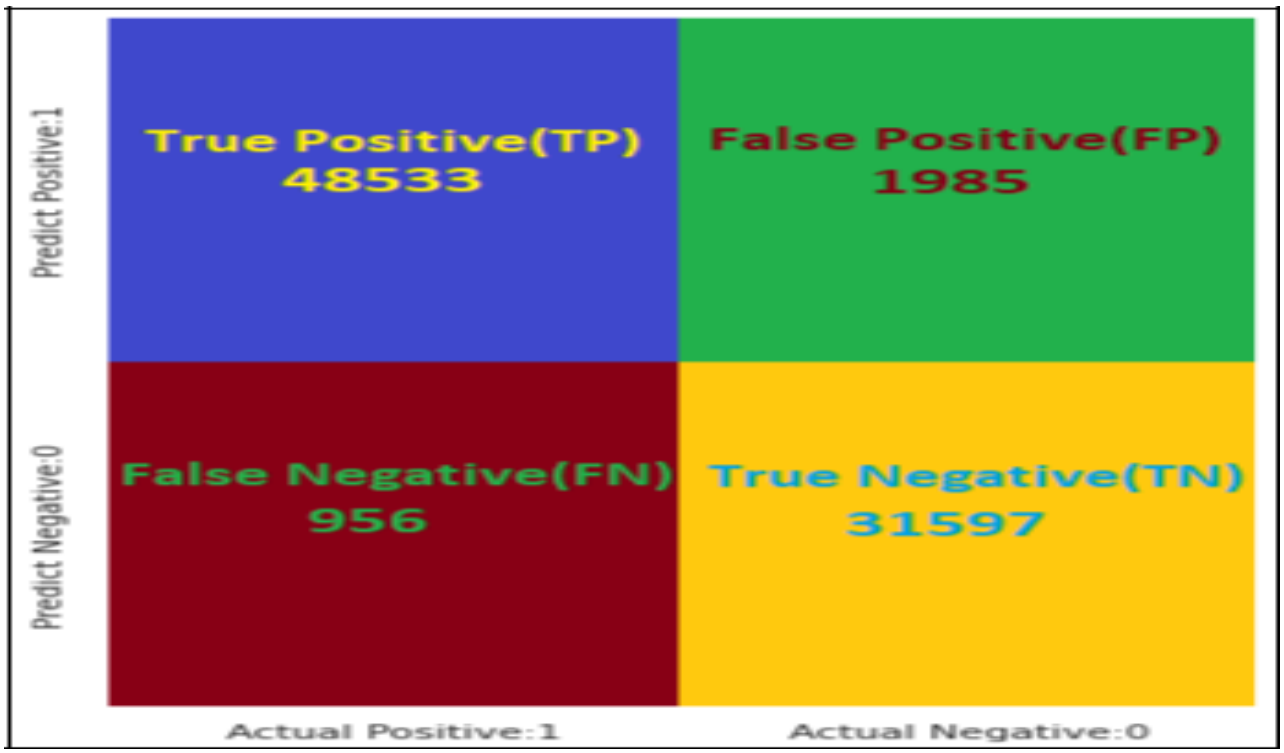

Fig 8. Confusion Matrix for the Decision Tree classification model

Hence accuracy of 96.513867% was obtained after applying the Decision Tree model. Also, other performance parameters such as recall and precision were calculated as 97.0696% and 94.4098% respectively.

5 Conclusion

DDoS attack detection is possible using machine learning methods. This simply means that the genuine requests and attacking requests can be distinguished using a machine learning approach.
In this work, DDoS attack analysis has been done using a dataset which is based on SDN. The dataset contained a total of 23 features originally.

The last column of the dataset is the output feature. The output feature is a class label that categorizes the traffic type into two classes i.e., benign and malignant. The malignant traffic requests are labeled with 1 whereas the benign traffic requests are labeled with 0. Dataset has total 104345 entries. The data pre-processing steps were performed. This includes data cleaning, followed by One Hot encoding and finally normalization. After the preprocessing of data, the data-frame entries were reduced to 103839 with 57 features which were later fed into the model.

After performing the tests, the machine learning model of Decision Tree which provided the most accurate results was used as the prominent model. The accuracy of the Decision Tree model was better than that of the other machine learning models which were used in the study. The accuracy of the Decision Tree was found to be 96.51% and is approximately equal to the accuracy of KNN model (96.47%).

Handwritten modi character and digit recognition using a deep learning algorithm.

Shubham Bakal, Dr. Uttara Gogate
M Tech. Student at School of Engineering and Applied Sciences
Shivajirao S. Jondhale college of Engineering, Dombivli

Abstract: - 'MODI' is an ancient writing script compared to other Indian languages. In ancient human society, the dominant information is stored and communicated through the medium of documents. Hence document image analysis is an important research area in image processing and pattern recognition.

In the offline recognition system, neural networks have emerged as fast and reliable tools for classification towards achieving high recognition accuracy. .An artificial Neural Network (ANN) is used as the backend for classification and recognition tasks. This paper aims to discuss implementation of the Convolutional Neural Network (CNN) algorithm for handwritten character recognition. With the help of this algorithm, the approach will be generalized and accurate.

Keywords: - Artificial Intelligence, Handwritten Character Recognition (HCR), Convolutional Neural Network, Deep Learning Algorithm.

I. Introduction: - MODI is a very

popular and most used ancient script which was used for writing purposes only, a cursive type of writing in 'Marathi' (the primary language of Maharashtra state in western India). There are several theories about the origin of this script. One of them claims that in the 12th Century, MODI was developed by 'Hemadpant' or 'Hemadri. In this paper, the topic of discussion is the Handwritten Character Recognition (HCR) technique. HCR has been in quite a few research works in the last decade and is getting much more attention daily. It is essential because we can make the computer learn and recognize the regional languages pretty well. If we do that, it opens a new world of endless possibilities. Most of the works about HCR pertain to the recognition of handwritten characters, which can directly serve as the input for the computer. Research has been done on common languages such as English, French, and Hindi and other foreign languages such as Chinese, Japanese, etc.

For an offline character recognition system, the input image is acquired from the scanner. As we obtained the scanned digital image, the second step is preprocessing [1]. It essentially enhances the image rendering it suitable for segmentation. Erosion, dilation, opening, closing, and smoothing operations are used for preprocessing. The binarization process converts a grayscale image into a binary image using a global thresholding technique. Detection of edges in the binarized image using the Sobel technique, dilating the image and filling the holes present are the operations performed in the last two stages to produce the preprocessed image suitable for segmentation.

The segmentation process divides the input image into distinct characters, and each character is subsequently enlarged into m x n pixels in the direction of the training network. The features will be extracted from Boundary tracing and their Fourier Descriptors. The character will be identified by analyzing its shape and

comparing the features that distinguish each character.

The Selection of the appropriate feature extraction method is probably the most critical factor in achieving high recognition performance. Several methods of feature extraction for character recognition are available. The widely used feature extraction methods are Template matching, Deformable templates, Unitary Image transforms, Graph description, Projection Histograms, Contour profiles, Zoning, Geometric moment invariants, Zernike Moments, Spline curve approximation, Fourier descriptors, Gradient features, Gabor features [2].

II. Literature Survey: - Kulkarni et al. [3] introduced a chain coding and image centroid-based recognition model for vowels in MODI script. The median filter was used to reduce noise, the global threshold for binarization, flood fill to prevent boundary breaks, and size normalisation in this study. Two layers of feed-forward Neural networks and SVM were used to classify the data. and received a recognition rating of 65.3 % to 73.5 %.

Recognition of MODI Scripts Besekar D.N. & Ramteke R.J. [4] conducted the theoretical analysis, and Devanagari, MODI, and Roman scripts were compared. This experiment revealed that structural pieces for the MODI script were difficult to extract. Internal and external segmentations were examined and advocated in this paper. MODI script internal segmentation. Both structural and topological aspects were proposed in this study.

According to this study, HOCR for MODI script was a difficult procedure comparing to other handwritten scripts because to the cursive nature, variances in character, handwriting habits, and comparable structure of characters. Solley Joseph and his colleagues [5] For text detection in the MODI script, a CNN autoencoder implemented as a feature representation is recommended. The CNN au- to encoder was used to decrease the feature set size from 3600 to 300. SVM was used to classify the acquired characteristics. The accuracy of MODI script text detection is 99.3%, which is higher than any other MODI script letter accuracy rate. The attainment of great accuracy in MODI text detection is the study's key contribution.

Tamhankar et al [6] addresses each character from archaic MODI Script manuscripts are segmented in this study. Only when consecutive letters are split by a zero-pixel column could the vertical Projection Profile (VPP) approach properly distinguish characters from a line. Based on the authors' earlier research, the study proposes a unique technique for extracting each character from a line that use a dual thresholding criterion to reduce segmentation error. In terms of execution time, the tactics used in this study are basic and relatively successful.

Savitri Chandure and Vandana Inamdar's [7] work includes establishing an image dataset for MODI handwritten characters as well as constructing a supervised Transfer Learning (TL)-based classification system. To retrain the network and transfer weights, it employs Deep CNN Alexnet as a pre-trained network. As a feature extractor, this network pulls features from many network levels. To create classifier models, SVM is trained on activation properties. These models are being examined further in terms of accuracy and feature analysis. To choose in-depth discriminant features, both subjective and objective evaluations are applied. Handwritten MODI character identification was 92.32% accurate, whereas handwritten Devnagari character recognition was 97.25% accurate.

Manisha Deshmukh and her colleagues [8] offer a technique for recognising off-line handwritten Modi Numerals. A non-overlapping blocking method is employed to extract the characteristics of the handwritten Modi numeral chain code feature extraction technique. For Modi numeral recognition, a correlation coefficient is employed. Different numerical image non-overlapping divisions and other data set sizes are used to assess the experimental outcomes. On a database of 30000 images, the maximum identification rate of 85.21% was attained through testing. The recognition findings reveal that 5X5 grid divisions work better.

Snehal R. Rathi et al. [9] described the many procedures involved in converting Modi characters to English using image processing techniques. Several important papers written in the 'Modi' language have remained dormant. These publications include vital information and data. If correctly deciphered, they can be quite useful. The challenge of Modi OCR and handwriting recognition is a difficult one, and professionals are working hard to analyze the difficulties and come up with alternative solutions. Many issues remain unsolved, and active research in this field is required to bring this potential problem to favorable levels when items including the answer become available to the general public.

Sanjay S. Gharde et al [10] presents the ability to recognize and identify handwritten MODI characters is displayed. To construct a database of handwritten samples, the ANESP programmed is utilized. The MODI script manuscript has been obtained and pre-processed. Invariant Affine and Moment Two methods for extracting features from handwritten separated samples are Moment Invariant and Moment Invariant. For identification and recognition, machine learning technology is applied. A support vector machine is one of the machine learning algorithms that is used as a classifier. This support-vector machine uses a linear kernel function to do classification. For handwritten MODI script samples, this system has a good recognition rate. Researchers will be able to learn more about a previously unknown time of history because to this finding.

Table 1: Summary of Literature Review.

Title	methodology used	Results	Remark
Recognition of handwritten modi numerals using hu and zernike features (2014)	feed-forward Neural networks and SVM	65.3 % to 73.5 %.	The accuracy is less
Handwritten character recognition of MODI script using convolutional neural network-based feature extraction method and support vector machine classifier (2020)	CNN	99.3%,	There is need of increase the dataset also need to use transfer learning algorithm
A novel approach for character segmentation of offline handwritten marathi documents written in modi script (2020)	dual thresholding segmentation and CNN	96.25%	The system is accurate, this can be extend to multilingual systems
Handwritten modi character recognition using transfer learning with discriminant feature analysis (2021)	Deep CNN Alexnet	97.25%	Limited dataset is used
Off-line handwritten modi numerals recognition using chain code (2015)		85.21%	The accuracy is low
Recognition of characters in Indian MODI script (2016)	SVM	78%	The accuracy is low

III. PROBLEM STATEMENT:-

This project aims to pre-process, segment, and recognition of MODI characters. The

segmentation and recognition of the MODI character from a handwritten script incorporate considerable problems. Hence, this system takes the handwritten MODI characters as input and effectively trains the CNN algorithm to recognize the pattern.

IV. OBJECTIVES: -

To create a dataset for MODI characters and digits
To pre-process and segment the data
Prepare the dataset as training and Testing
To develop an algorithm for MODI character detection and recognition
To test the system on unknown samples
To evaluate the performance of the system

V. METHODOLOGY

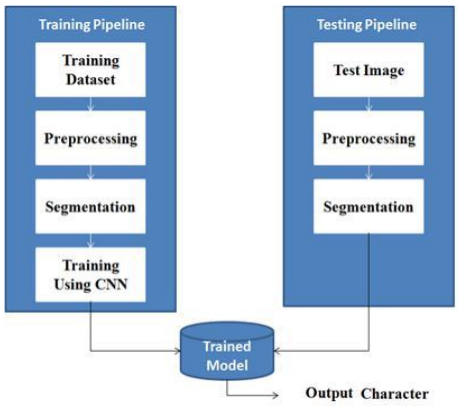

Fig.1. Block diagram of MODI character recognition system.

Block Diagram Description: -

A. MODI Character Dataset

The proposed system uses handwritten MODI characters dataset from IEEE Dataport. Different writers of different writing styles create the handwritten MODI character dataset. The variation in the writing style and capture of images in the different light conditions makes the system more accurate. Hence the dataset is created with different styles and in different light conditions.

All 46 characters with its label are shown in Fig. 2. For each character folder is created separately with its folder name as its label. So, there are total 46 folders as shown in Fig. 3. Each folder has 90 samples of respective characters.

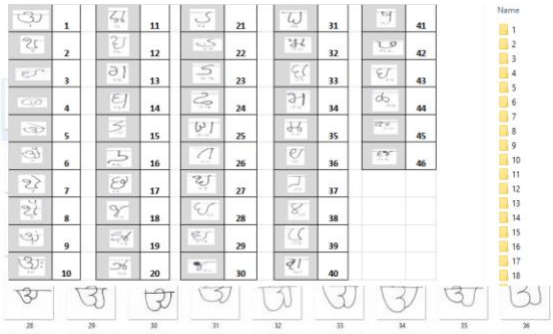

Fig.2 Basic MODI characters with its labels.

Fig.3 Characters image samples of class label 1

B. Preprocessing

The captured images may be of different sizes. Hence to get uniformity in the dataset images, each image needs to resize to the exact size. In this system, the images are resized into 256x256. The images are also affected by different noises like salt & pepper and Gaussian noise. The median filter is used to remove the salt & pepper noise, and the Gaussian filter is used to remove the respective noise.

C. Segmentation

The background of the captured image and character segmentation is performed using thresholding. The thresholding technique converts the image into binary. The region

of interest, i.e., the character, is cropped and saved for further processing.

D. Training and Testing using CNN

This system trains the training data with the convolutional neural network. The detailed blocks of the CNN are shown in Fig.2.

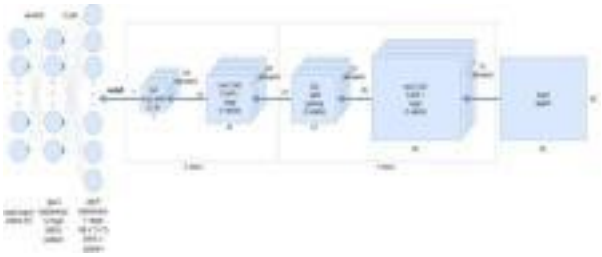

Fig.4 Block Diagram of CNN algorithm.

Convolutional Layer

The Convolutional layer performs the core building block of a Convolutional Network that does most of the computational heavy lifting. The primary purpose of the Convolution layer is to extract features from the input data, an image. Through the use of tiny squares from the input image to learn image attributes, convolution preserves the spatial relationship between pixels. By using a group of teachable neurons, the input image is distorted. This produces a feature map or activation map in the output image, and after that, the feature maps are fed as input data to the next Convolutional layer.

Pooling Layer

The pooling layer reduces the dimensionality of each activation map but continues to have the essential information. The input images are divided into a set of non-overlapping rectangles. Each region is down-sampled by a non-linear operation such as average or maximum. This layer achieves better generalization and faster convergence, is robust to translation and distortion, and is usually placed between Convolutional layers.

ReLU Layer

ReLU is a non-linear operation that includes rectifier-using units. It is an element-wise operation, which means it is applied per pixel and reconstitutes all negative values in the feature map by zero. To understand how the ReLU operates, we assume that there is a neuron input given as x, and the rectifier is defined as $f(x)= \max(0,x)$ in the literature for neural networks image. The FCL aims to employ these features for classifying the input image into various classes based on the training dataset. FCL is the final pooling layer feeding the features to a classifier that uses the Softmax activation function. The

Fully Connected Layer's output probabilities are added up, and the result is

1. By utilising Softmax as the activation function, this is secured. A vector of arbitrary real-valued scores is compressed by the Softmax function into a vector of values between zero and one that adds up to one.

Flattening Layer

High resolution data is efficiently resolved into representations of objects using a convolutional neural network. Therefore, it is possible to see the fully connected layer as adding a conventional classifier to the network's information-rich output in order to "understand" the findings and ultimately provide a classification result. Linking this fully connected layer to the network requires flattening the convolutional neural network's dimensions output.

Fully Connected Layer

The FCL aims to employ these features for classifying the input image into various classes based on the training dataset. FCL is the final pooling layer, given the features of a classifier that uses the Softmax activation function. The sum of all the output probabilities from the FC is 1. The Softmax function is used as the activation function. The Softmax function reduces a vector of arbitrary real-valued scores to a vector of

values that range from zero to one and add to one.

Training and Testing using Vgg16

The ImageNet Large Scale Visual Recognition Challenge is an annual computer vision contest (ILSVRC). Each year, teams participate in two challenges. Object localization, the initial stage, is locating objects in an image that fall within 200 classifications. The second method includes classifying each image into one of a thousand different groups. Karen Simonyan and Andrew Zisserman introduced VGG 16 in 2014.

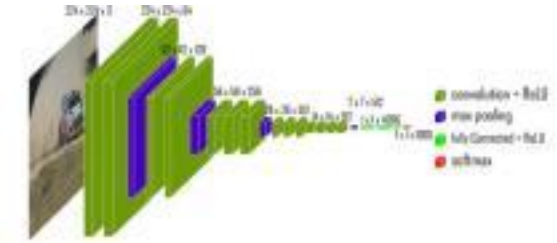

Fig.5 VGG-16 model architecture [11]

On the ImageNet dataset, which has 14 million photos divided into 1000 classes, this model achieves top-5 test accuracy of 92.7%. A dimensional image is sent to the network as input (224, 224, 3). 64 channels and a 3*3 filter size are present in the first two layers along with the same padding. Two layers with 256-layer convolutions, a filter size layer, and a max pool layer of stride (2, 2) are added next (3, 3). A stride (2, 2) max pooling layer that was exactly like the one before it came next. The next two convolution layers contain 256 filters each, with a 3 and 3 filter size. Next, there are two sets of three convolution layers, and then a max pool layer comes after that. Each has 512-filter size and the same padding (3, 3). This image is then sent to the stack of two convolution layers.We use 3*3 filters in these convolution and max pooling layers instead of 7*7, ZF-11*11, and AlexNet filters. Additionally, some of the layers use 1*1 pixels to change the number of input channels. After each convolution layer, 1-pixel padding is provided to prevent the spatial characteristic of the image. After adding a convolution and max-pooling layer to the stack, we got a (7, 7,512) feature map. To construct a feature vector with the value 1, 25088, this result is flattened.

There are then three completely linked layers that come next: the first produces a vector of size (1, 4096) using the most recent feature vector as input, the second produces a vector of size (1, 4096), and the third produces a vector of size (1, 1000) using the ILSVRC challenge's 1000 classes. The output of the third fully connected layer is then passed to the SoftMax layer, which normalizes the classification vector. the top five categories for assessment after the output of the classification vector. ReLU is used by every hidden layer as its activation function. ReLU is more effective in terms of computing since it yields.

A research effort called ImageNet aims to create a sizable library of photographs with annotations, such as labels for the pictures. InceptionV1, InceptionV2, VGG-16, and VGG-19 are just a few of the pre-trained models that have been trained using ImageNet's diverse set of image classifications. These models were built from scratch and trained on millions of photographs from a vast variety of various image categories utilizing powerful GPUs. As a result of the model's extensive training data, it has developed a solid understanding of low-level features like shapes, edges, rotations, and lighting. Based on the principles of transfer learning, the pretrained model should be able to extract pertinent characteristics from these incoming photos even if they belong to entirely different categories than the original dataset.

SOFTWARE & HARDWARE:

A. Hardware

1) Hard Disk: 200 GB

2) RAM: 8 GB

3) Processor: Intel Pentium i5 and above

B. Software Resources Required

1) Technology Used: Python

2) IDE: Python IDE

3) Operating System: Windows XP or above

ADVANTAGES & APPLICATIONS

Easy to recognize ancient characters and numerals.

The system will be more accurate. Training required more time.

In the history department, to understand the ancient character.

In the history department, to understand the ancient character in literature.

CONCLUSION:

In this approach, the MODI character recognition using a convolutional neural network algorithm has been presented. Different writers of different writing styles create the handwritten MODI character and the numeral dataset. The dataset is split into training (80%) and Testing (20%). CNN algorithm is used to train and test the MODI character, and numerals and performance are evaluated using precision, recall, and F-measure parameters.

Abstract – **Today's world is experiencing a water shortage, making it urgent to implement clever irrigationtechniques. The project explains how IOT may be used to manage irrigation intelligently. The goal of this project is to save time and steer clear of issues like ongoing vigilance. By intelligently allocating water to the plants/fields according to their water needs, it also promotes water conservation. Thus, tailoring the amount of water to the specific needs of different plants/fields. Additionally useful in agriculture, parks, and lawns, this system. This system basically measures the moisture level of the soil and if it is found to be low, it automatically pumps waterto the soil till the soil moisture reaches a threshold value. On a user's mobile phone, access to and monitoring of this data is simple.**

Keywords: Soil moisture sensors, IoT, Arduino IDE, Android,Node MCU..

I. INTRODUCTION

The development model of smart agriculture can become a real-time observation system of properties which includes temperature, moisture, soil moisture, and pH. By sacrificing the concept of modern irrigation systems, farmers can save up to 51% of water. This idea relies on two of his irrigation strategies: B. Overhead sprinkler, flood supply system. Through IoT, you can manage multiple operations of the sector from anywhere at any time. To overcome these shortcomings, new techniques are used in irrigation techniques that apply only small amounts of water to the basal zone component of the plant.

Soil wetting stress in plants is prohibited as fields are automatically irrigated by following their watering schedule. Usual techniques such as mechanical equipment and surface irrigation require almost half as much water. Fields can also be supplied with appropriate amounts of water. Dry rows between fields can result in continuous bandages throughout the watering method. Fertilizers can also be applied in this manner and are lessexpensive.

The new technology significantly reduces soil and wind erosion compared to overhead mechanical jig systems. Soil properties can outline the shape of dripping properties within the root zone of plants that receive moisture. It offers an artistic approach to living, allowing you to manage your electronics with your smartphone while saving energy. It has impacted all areas of business, not just smart farming, smart parking, smart building, environmental monitoring, and careful transportation.

II. LITERATURE REVIEW

A literature review of smart irrigation systems using NodeMCU microcontroller boards can be divided into three main areas: the use of NodeMCU in irrigation systems, the benefits of using smart irrigation systems, and the challenges and future directions for the development of these systems. NodeMCU has been included into a number of smart irrigation systems to regulate and track a number of irrigation-related variables, including soil moisture content, water flow, and environmental conditions. NodeMCU has been used in various smart irrigation systems to control and monitor various aspects of the irrigation process, such as soil moisture levels, water flow, and weather conditions.

The underneath steps are taken into consideration during the initial investigation: understanding the current methodologies, comprehending the demands, and creating a system abstract. In this study, sensors were placed in the root zone of the plant to measure temperature, humidity, and soil moisture. The sensors sent data to an Android application. To control the amount of water, a microcontroller was programmed with the threshold value of a soil moisture sensor. The android app displays information on temperature, humidity, and soil moisture. The goal of this project, "Irrigation with IOT Sensors," is to create an automated irrigation system that turns on and off the pumping motor based on how much moisture is present in the soil. Along with measurements for soil moisture, the planned project also provided temperature and humidity values. For a remote agricultural plantation that needs water, this research article suggests a NodeMCU-based remote irrigation system. When the soil's humidity drops below the predetermined level, provisions must be made for water. However, we were unaware of the soil moisture level at the time, therefore to address this shortcoming, a system that incorporated additional features for temperature and soil moisture values that were shown on farmer mobile applications was proposed. The system made use of a NodeMCU esp-8266 board, which comes with a Wi-Fi module already installed. Improved crop yields, lower labour costs, and higher water efficiency are all advantages of employing smart irrigation systems. These devices can also aid in resource conservation and the reduction of water waste. To further optimise irrigation, smart irrigation systems can be used with other technologies like weather forecasting and precision farming.

Smart irrigation systems are designed to improve the efficiency and productivity of agricultural irrigation, but their implementation is not without challenges. Some of these challenges include scalability, reliability, and security. Scalability refers to the ability of the system to function effectively in different sized areas and environments. Reliability is crucial, as the system must be dependable and consistently provide the desired results. Security is also a concern, as these systems often rely on

remote monitoring and control and may be vulnerable to hacking or other forms of cyber-attack.

To overcome these challenges, research is needed to develop more accurate and cost-effective sensors, and to improve the integration of these systems with other technologies. The use of IoT sensors, for example, can improve the precision and automation of irrigation systems, and can also provide valuable data on factors such as temperature and humidity. Additionally, the integration of IoT technology in agriculture can help address issues of food security, supply, and distribution.

However, most studies on smart irrigation systems have been conducted in controlled environments, and further testing is needed to address real-world challenges. Additionally, the use of NodeMCU microcontroller boards has demonstrated potential for improving irrigation efficiency and crop yields, but further research and development is necessary to fully realize this potential.

Overall, smart irrigation systems have the potential to significantly improve agricultural irrigation, but further research and development is needed to overcome challenges and fully realize this potential. As technology continues to advance, it is likely that smart irrigation systems will become increasingly popular among farmers.

III. METHODOLOGY

Write the NodeMCU code in the Arduino IDE and then upload it in the NodeMCU using a USB cable. Then enable the device hotspot and then check the 'Online' status in the Blynk App. Then insert the probes of soil moisture sensor inside the soil. For obtaining values for temperature and humidity of the surrounding area, we make use of DHT 11 sensor.

The app displays records of moisture level detected by the soil moisture sensor, as well as temperature and humidity readings taken by the DHT11 sensor. Fig 1 shows the system flowchart for better understanding of our project.

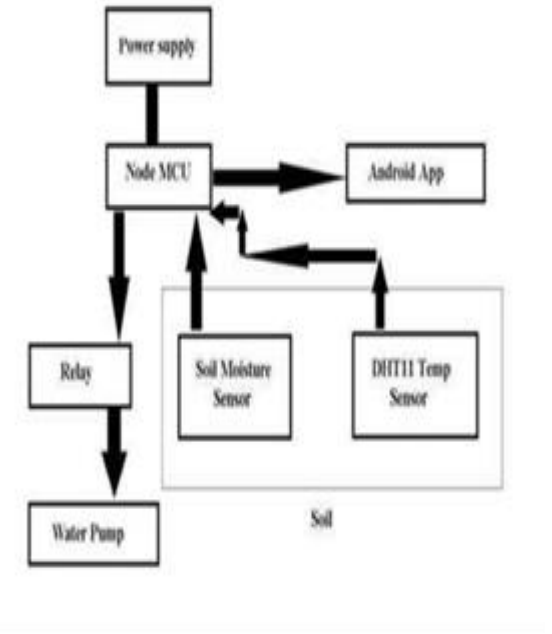

Fig 1. System Flowchart

It can be said from the flowchart that first power supply is given to Node MCU. The DHT11 Temperature Sensor and Soil Moisture Sensor then sense the temperature and the level of soil moisture, respectively, and send those results to the NodeMCU. If the moisture value is less than 500, then the motor starts, and the soil is watered. Else when the value is greater than 500, the motor remains in off position. As a result, the values are shown on the "Blynk" Android app.

The given figure Fig 2 shows the app interface of our project. We can see the readings of moisture, temperature and humidity (in percentage). We can also turn on the water pump manually by tapping on the "ON" button.

Fig2. Blynk App Interface

The given figure Fig 3 portrays the hardware setup of our project.

Fig 3. Hardware Setup

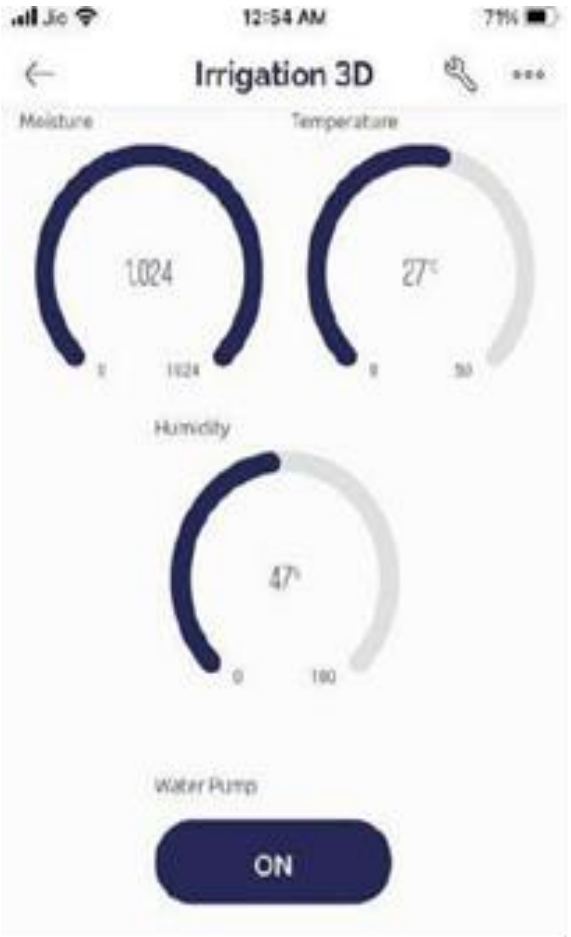
IV. SYSTEM ARCHITECTURE A. Hardware

The hardware components of our system include thefollowing components: -

- ESP8266 Node MCU Wi-Fi Module: A

sophisticated Application Programming Interface for hardware input/output devices is NodeMCU [6]. It uses Lua, an interactive script, as opposed to Arduino-style code. It is an open source Internet of Things platform. Espressif Systems firmware is used to put it into practise. There are 16 input/output pins on NodeMCU. They

have 16 input/output pins. Consequently, a single node can link to 16 nodes. The ESP8266 Wi-Fi SoC is integrated with the Tensilica Xtensa LX106 core, which is often utilised in IoT applications. Instead of the development kits, "NodeMCU" often refers to the firmware. ESP8266, a NodeMCU with a built-in WiFi



module, as shown in Fig 4

Fig 4. ESP8266 Node MCU Wi-Fi Module

• Soil Moisture sensor: A kind of soil moisture sensor is depicted in Fig 5. It includes two tests that involve injecting current into the soil. After that, it examines the soil's blockage to determine the soil's amount of moisture. We know that when water is close by, dirt is more likely to conduct power easily, meaning that such soil has less resistance (R), however, dry soil has low conductivity, and thus, offers higher resistance than wet soil. This intensity feature is the foundation of the sensor. The resistance must be converted to voltage at some point; this is accomplished using a circuit that is visible inside the sensor and that does the conversion

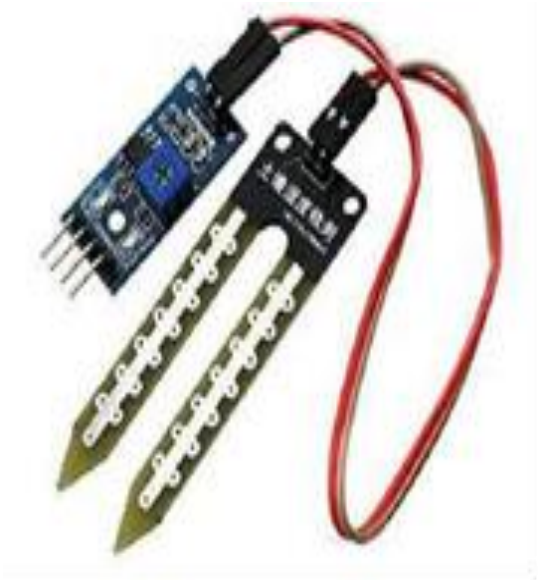


Fig 5. Soil Moisture Sensor

• DHT11 sensor: Temperature and humidity measurements are accurate to +0.5 degrees. On the rear of the sensor, the DTH-11 sensor has an IC, a temperature sensor, and a moisture sensing sensor. It includes both 4 and 3 pins. Fig 6 shows an explanation of connection using the DTH-11 sensor.

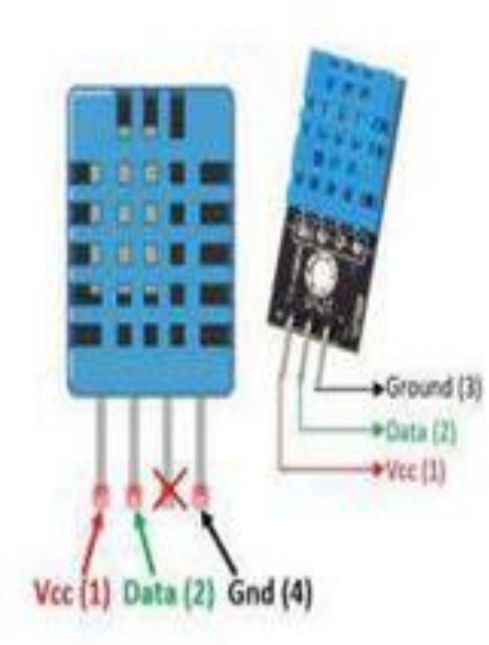

Fig 6. DHT-11 Sensor

• Pump motor - Draw water from a water source

```
}
//virtual button
BLYNK_WRITE(V0) {
  motor = param.asInt();
}

void pumpmotor () {
  if (sensor > 500) {
    digitalWrite (D5, LOW);
  }
  else if (sensor < 500) {
    digitalWrite (D5, HIGH);
  }
}
void stoper () {
  digitalWrite(D5, HIGH);
}
void loop()
{
  digitalWrite (D6, LOW);
  digitalWrite (D5, HIGH);
  Blynk.run();
  timer.run();
  sendTemps();
  if (motor == 1) {
    pumpmotor();
  }
  else if (motor == 0) {
```

Fig 7. Arduino IDE Code Snippet

Jumper wires - Connecting components of the system with the NodeMCU.

B. Software Used

Arduino IDE and BLYNK App were used as

software in our system.

- Arduino IDE - Used for writing the hardware code.
- BLYNK App - Application for automating our system.

In the Arduino IDE setup part, we first have to install the required libraries. Then from the Blynk Web we have to obtain our Authorization token of our account. This verifies the user's account. Then we have to set our mobile phone's hotspot name and password as ssid and pass respectively.

We then take two variables for storing humidity and temperature values as float values. Then allocate those values to virtual pins of Blynk App. Similarly, we store values of temperature.

For motor we take motor variable to read status of motor. Then we write pump motor function. In this we check the reading of soil moisture sensor. If the value is If the value is greater than 500 then the digital pin of NodeMCU is made Low. Else it turns High. Then we write a stoper function for maintaining the motor in off condition.

In Loop part we run the Blynk function. Here we check the motor status using if-else. If it is on then pump motor function is executed else stopper function is executed. Fig 7 portrays the code snippet

C. Hardware Connections

The DHT11 sensor consists of three pins +, OUT and

-. + connected to the 3V3 of NodeMCU, OUT with the D4 and - to the GND.

Soil moisture sensor module has four pins AO, DO, Vcc, GND. AO connected to the controller's AO, GND to the

GND and Vcc to the 3V3 power supply pin of NodeMCU. positive and negative terminal of the module is connected with the sensor.

Sr No.	Time	Temperature	Humidity (percentage)	Soil Moisture readings	Pump status
1.	9:00 am	21 °C	38%	480	ON
2.	10:00 am	24 °C	87%	940	OFF
3.	12:00 pm	28°C	68%	674	OFF
4.	3:00 pm	31°C	52%	557	OFF
5.	4:00 pm	30°C	33%	440	ON
6.	6:00 pm	27°C	89%	976	OFF

Relay module has IN, GND and Vcc. IN pin connected to the D6 pin, GND to GND and Vcc to the 3.3 V power supply of NodeMCU. The output of the relay is then joined with the motor and the external battery source. The given figure Fig 8. explains the pin diagram of the setup.

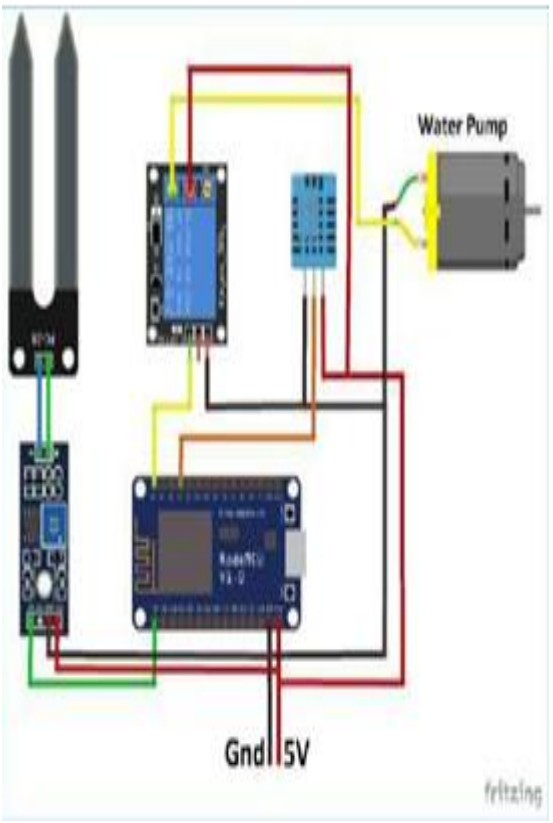

Fig 8. Pin Diagram

V. RESULT AND DISCUSSION

We obtained result of the experimental setup for one day. In that we checked the values of temperature, humidity and soil moisture for various time slots. We analysed the watering levels for the soil for a particular day.

In Table 1. it is seen that the soil moisture level goes down in the afternoon time slot from 12pm to 4pm.

Table 1. Result of Experimental Setup

We can conclude that auto watering level of soil can be setup once in morning slot at 9:00 am and again in afternoon slot at 4:00pm.

VI. FUTURE SCOPE

Water use efficiency can be improved by better predicting irrigation needs, adjusting times and amounts to meet crop water needs, and adaptively compensating for water losses. This reduces irrigation water consumption and increases yields. As systems become more sophisticated and intelligent, better trained models will be deployed to make betterirrigation decisions. Therefore, much of the stress andburden associated with irrigation is alleviated for farmers and users.

VII. CONCLUSION

The primary purpose of this irrigation project is aimed at farmers and consumers who can effectively manage their watering schedules to irrigate their plants and crops. This project will be of great benefit to farmers facing water shortages. Intelligent farming has been successfully implemented to improve consumers by checking the real-time values of temperature and humidity on the app. This also saves parameters in a very convenient way. This project allows consumers to check the status of various parameters on-site at any time. You can better control or maintain the parameters of the field.

Finally, it can be concluded that automatic irrigation systems are more efficient than scheduled irrigation.

ACKNOWLEDGMENT

We are grateful to those who have helped guide and provide feedback throughout the project, as well as for providing the necessary resources to make the project a success. I would also like to extend my gratitude to My team members for helping me in the formatting of this paper. I am also immensely thankful to all my other colleagues who gave a thoughtfulinsight into this paper. Finally, I wish to thank my parents for their support throughout the study

Satellite IOT: Internet from Space

Ajay Talele, Smita Mande, Milind Rane, Mustansir Bohari, Asif Mursal, Omkar Mundlik, Mohit Chawla
Vishwakarma Institute of Technology,
Pune 411037, India

Abstract - **Today, the majority of people on the planet need access to high-speed internet. In this age of online labour and commerce, everyone—including offices and businesses, their employees, teachers, and students— an Internet service with a high speed is necessary for their jobs to function effectively. Satellite internet of things can be used to solve this issue. By optimizing satellite orbits in certain regions, satellite constellation design enables greater communication demands to be met with fewer satellites. LEO satellite constellations offer better global coverage, low propagation loss, and minimal propagation latency compared to conventional geostationary earth orbit (GEO) systems. LEO broadband will be a crucial component of the connectivity toolset. Starlink would produce an aerial numerical degree of concentration of approximately 0.01 objects per square degree, a constellation of 12,000 satellites that would dominate LEO below 600 kilometres. To ground-based observatories, such massive spacecraft at low altitude look visually bright. An overview of possible effects on ground-based astronomy was provided by the anticipated number of bright satellites as a function of the season, the length of the night, and latitude**.

Keywords – ***Satellite, IOT, Constellation, Internet, LEO, Starlink, Edge computing.***

I. INTRODUCTION

IOT is a world in itself of smart technology where devices are connected in a network. This network of computers need fully functional Internet connection. Current infrastructure of Internet depends highly on optic fiber cables laid underground, since cellular coverage only reaches approximately 15% of earth with limited connectivity and for places with harsh terrains like North-Eastern India these cable connections are non-economic and non-feasible. This results in decline in growth of those regions. To overcome these challenges Satellite IOT comes into picture. The term "satellite IoT" describes the use of satellite networks and services to connect servers with terrestrial Internet of Things endpoints and sensors.

Satellite internet works by transmitting a fibre internet signal from the system server to a satellite in orbit. The satellite dish is then used to catch the internet signal. All of the devices are linked to the internet using a modem that is connected to the dish. FTTH technology is presently being used by mobile network operators in India, including Reliance JIO, Bharti Airtel, BSNL, and many more. At a time when internet speed is a key concern, high- speed internet services based on satellites, like Starlink, may change the game.

How does the Internet work?

The majority of Internet services need a complex network of optic fibre lines to send data. Your phone may initially be connected to this network of optical fibre via cellular data or any WiFi hotspot. Data from data centres is transmitted across optical fibre lines as light pulses upon request.

How does Satellite Television work ?

All satellites used for satellite TV purposes are parked in GEO orbit of around 42,000 km earth. A channel has a video production facility which beams its signal to a rented transponder in GEO. Any DTH(Direct-to-home broadcasting service) provider can access the signal once they have made a business agreement with program source. Then they transmit signals to end user via other satellites which are angled to dish antennas. These signals have to travel a huge distance via two satellites. Even though the signals travel at speed of light such a large distance would cause a delay of 0.5 seconds (latency). Due to this latency GEO satellites can not be used to provide internet services throughout the globe.

II. LEO SATELLITE CONSTELLATION

A comparison between LEO constellation IOT systems and conventional geostationary orbit systems is made in reference [7]. The benefits are described, including low propagation delay, minimal propagation loss, and global coverage. The authors provide an explanation of why modernizing the IoT protocol is essential to enhancing the compatibility of LEO satellite constellations with terrestrial IoT systems.

It suggests structure of LEO constellations, spectrum allocation, suitability for heterogeneous networks, and access and routing protocols. Paper describes the drawbacks of terrestrial based LPWAN and other traditional systems like WiFi and NFC. It also highlights advantages of LEO satellite constellation technology like, time efficiency in terms of propagation delay, shorter signal loss and unconstrained from extreme topographies.

Authors have discussed limitations of geostationary satellite systems like weather influence indirect results and system cost. Paper emphasizes on how LEO constellation without inter satellite links are more suitable for data tolerant applications due to their low cost and complexity.

Due to severe propagation limitations, the current satellite operating frequencies, the Ku and Ka band, have considerable power consumption. Since there is no universal method for frequency distribution, authors explain how using permitted frequency ranges requires local suppliers to engage with local radio authority. The conclusion is that using the same frequency channels as domestic Iot applications for LEO constellations is now a practical alternative.

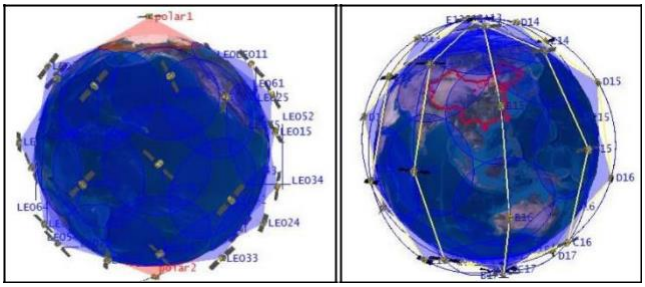

Figure 1. LEO Constellation A. Without ISL & B. With ISL
Source: Adapted from [7]

Reference[8] mainly talks about how we can use satellites for environmental studies of remote areas. It explains how the researchers built a satellite-enabled Internet of remote objects to transmit collected data from remote locations of the Tibetan plateau.

The proposed system will transmit and retrieve data using the Xingyun satellite constellation. The key environmental variables that the system tracks include air temperatures, relative humidity, precipitation, snow depth, temperature of the ground, rate of stream flow and species that can synthesise sunlight. The authors have showed how the satellite Internet of remote objects architecture can send data monitored to a data centre through satellites.

According to authors, ground IOT terminal, the constellation of IOT satellites, and a centralized data centre to store data are the three primary components of the architecture of the Internet of Remote Things network facilitated by satellites.

On the Tibetan Plateau, authors have set five IOT terminals on the ground. Three terminals are located in isolated sections of the Qilian highlands and are used to monitor snow depth and tree growth in that region. The first terminal is used to gather weather data at the end of Mugagangqiong Glacier.. The second terminal is on the slope opposite Jialabailei Glacier.

Using the Xingyun project constellation, authors have created a system to monitor data in the most isolated regions of the Tibetan plateau. The relative humidity, temperature of the ground, depth of snow, radiation that has been triggered by photosynthesis, tree stemflow rate and diameters of tree stemare all monitored by this IORT network. The findings in the paper's conclusion show that the IORT network performed better consistently when sending cached data of packets which are smaller than 200 Bytes in size.

Reference [9] notes different satellite IOT constellations and evaluates their quality of experience (QOE). It proposes a architecture for satellite constellation based on satellite IOT changeable network topology. QOE factors defined in the paper are optimized using a multi-layer tabu search algorithm (MLTS). Satellite constellations built using MLTS algorithm are tested and proved to be superior to traditional constellations.

Steps for constructing satellite constellation:

1. SIOT network model is build.
    a. Using a space time graph(STG), the dynamic network topology of SIOT is analysed
    b. The problem is intended to maximise the user's quality of experience
2. QOE evaluation is done by 4 factors
    a. Coverage performance - It directly affects QOE so is treated as a prerequisite
    b. Communication fluency - It is promoted using classical tabu search (CTS) algorithm
    c. Regional demand capacity - It is expanded using tabu greedy search (TGS) algorithm
    d. Profitability - It is improved using tabu search genetic algorithm (TSGA)
3. QOE value is calculated using weighting formula
4. Satellite's orbit determines its constellation

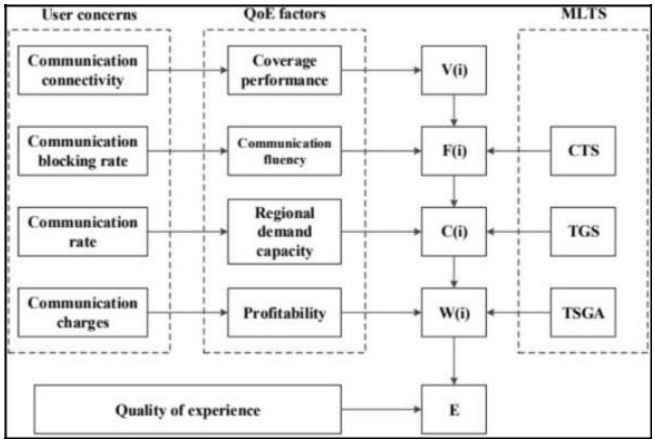

Figure 2. A. QOE Aware Evaluation Framework
Source: Adapted from [9]

$$\text{Max } E = \frac{\sum_{i \in N_i} V(i)[\frac{F(i)}{F_{average}} \cdot \rho_f + \frac{C(i)}{C_{sat}} \cdot \rho_c + \frac{W(i)}{W_{max}} \cdot \rho_w]}{N(i)}, \quad (1)$$

subject to:

$$\rho_f + \rho_c + \rho_w = 1, \quad (1a)$$

$$V(i) = \begin{cases} 0, if\ \theta_{UA} \geq \theta \\ 1, if\ \theta_{UA} < \theta, \end{cases} \quad (1b)$$

$$S_r(i) \cdot f[i] < S_{sum}, \quad (1c)$$

$$B(i) \cdot f[i] < B_{th}, \quad (1d)$$

$$C(i) \cdot f[i] < C_{total}. \quad (1e)$$

Figure 2. B. Objective Function To Maximize QOE
Source: Adapted from [9]

Reference [11] proposes a framework for simulation of network behavior of big satellite constellations like Starlink, Kuiper and OneWeb who have planned to launch thousands of satellite in LEO to provide global broadband internet.

Authors mention that use of satellite for internet connectivity is not a new idea. These constellations, which have fewer satellites, have been utilised in the past for satellite telephony, shipping, and limited connection for remote locations. Paper has discussed the drawbacks of GEO satellites and how we can use LEO satellites to improve it.

Paper has taken into consideration some of networking challenges of LEO networks and thus proposed Hypatia and analysis framework which provides packet level LEO simulation and network visualization. Using the regulatory data that businesses have submitted to regulating agencies like the Federal Communications Commission, It investigates end-to-end relationships between LEO constellation networks in terms of path topology and shifting latencies. Additionally, it shows how constellation networks' hotspots for traffic evolve when more satellites are added.

Along with explaining the architecture of Hypatia, the paper also outlines how to build up a LEO simulation network. The outputs are GS-satellite and ISL connection as well as time-varying forward state. It accepts inputs such as satellite trajectory, TLE, and ground station locations.

The research finishes by outlining how Hypatia not only gives quantitative support for recent works, but also

highlights the difficulties associated with LEO networking and fills in the infrastructure gaps necessary for advancement. Many intersatellite link (ISL) relays can transmit Internet of Things (IoT) messages that have been captured by satellites to a ground gateway, where they can then connect to a ground network.

Mega-constellations with enormous satellites require more ISL relays than ordinary constellations do, and the quantity and position of terrestrial gateways have a big impact on this requirement. In this article, we concentrate on the ISL usage for connecting satellites and gateways and offer a creative, practical method for computing the ISL utilization statistic. We then use model transformation to build a mixed-integer optimization model with a focus on reducing overall ISL utilization for the gateway site optimization (GSO) problem.

One ISL relay is also referred to as one hop. The requirement for ground gates is significantly reduced by the usage of ISLs, and expanding the number of gateways can reduce the number of ISL hops required to reach gateways.

We want to lower the overall ISL usage in MCN by making the greatest use of the gateway locations while the gateway number is fixed. In order to decrease the overall ISL usage, this study formulates a gateway site optimization (GSO) problem to determine the best sites from the provided candidate set. Here, the relationship between ISL and Ground gateway stations is inverse.

Following is the summary of major contributions:

A fresh approach to measuring ISL utilisation is suggested: ISL consumption is measured as a traffic-weighted hopcount. the needed ISL hop-count was calculated using an analytical hop-count model, which is less computationally expensive than standard route calculating methods.

In order to, reduce this ISL generally speaking utilization, we are making an optimization model for mixed integers for addressing the site improvement for gateways (GSO) problem. Decoupling of the gateway allocation is followed by a reduction of the GSO problem for a problem in algebraic nonlinear programming. An IBD-PSO method with three distinct schemes is proposed to resolve the GSO problem.
Modeling demonstrates that the suggested ISL utilization assessment approach saves over 80% more computing time than the conventional way and validate the method.

The proposed IBD-PSO method is also supported by the results. We then examine implications of gateway count and requirement for traffic patterns using Starlink. The difference in hop-count between satellites that are rising and descending is discovered and examined. Due to the uneven distribution of traffic demand, gateway locations in heavy need locations were desirable (not in outer sea).

Reference [13] aims to provide internet access to the places which are non-feasible, non-economic in terrestrial way. LEO is the solution to the aforementioned problem. We are unable to use GEO due to the key advantages of LEO, including its small loss, small delay and high coverage and high orders of magnitude.

Due to its rapid rotation, traffic analysis is crucial. It is difficult to examine the LEO satellite-based IoT's business model because terminals are distributed around the globe and LEO satellites move swiftly, in addition to the fact that there are many different businesses. In order to develop a LEO space - based Internet of Things' design, it's important that we examine both the rule and the traffic features. Beam coverage and traffic sources are continually shifting because of the rapid movement of many satellites.

Additionally, business distribution is made more complex and unstable by the unequal distribution of terminals worldwide.

Reference [14] takes into consideration how satellite IOT can revolutionize every day IOT devices and their networks in our surrounding. It proposes a miniaturized multi-band circularly polarized antenna design for addressing satellite-terrestrial communication. The microstrip antenna operates on super high frequency (i.e. microwaves) and are intended to be used by existing satellite in geostationary orbits.

Authors have designed complete structure of antenna along with its design equation. This antenna's patch size is determined using the following formula:

$$W_p = \frac{c}{2f_r\sqrt{\frac{\epsilon_r + 1}{2}}}$$

Where
f_r : frequency of resonating.
c : is speed of light in air which is given by $3x10^8$ m\sec.
ϵ_r : permitivity of dielectric substrate is 4.4.

Figure 3. Patch Width Formula
Source: Adapted from [14]

Simulation results show obtained loss values of 5.8 GHz, 6.76 GHz, and 8.4 GHz, respectively, at -36.67 dB, -27.22 dB, and -40.83 dB which are way better than the desired loss of less than -10dB from conventional antenna design.

Because of its small size, cheap price, construction simplicity, poor profile, and easily portable, this antenna also finds use in Along with satellite IOT, there are army, aerospace, naval transport, oil, and gas uses.

III. CLOUD EDGE COMPUTING

Networking devices is one of the main prospects for the development of the Internet in the future. Even though More IoT gadgets are being created, a few isolated regions lack internet connectivity.

Thanks to the vast satellite television channels' reach, the problems covering of the ground and communication disruption caused by natural disasters may both be handled. Commercial satellite providers like OneWeb [19], and SpaceX Starlink[20] have put forth proposals for satellite constellations, boosting spending and research on satellite-related technologies and enhancing the capability and intelligence of satellites.

In traditional satellite communication, there is no network and most satellites are single stars or single chains for observation, relay, and communication.

The available processors aboard the satellites are underpowered and unable to keep up with the rising demand for space computing jobs because of the energy consumption restrictions. However, neither the pace of satellite communication between satellites nor that between satellites and the earth has generally increased [15].

Improvement in communication of satellite to ground or satellite to satellite.

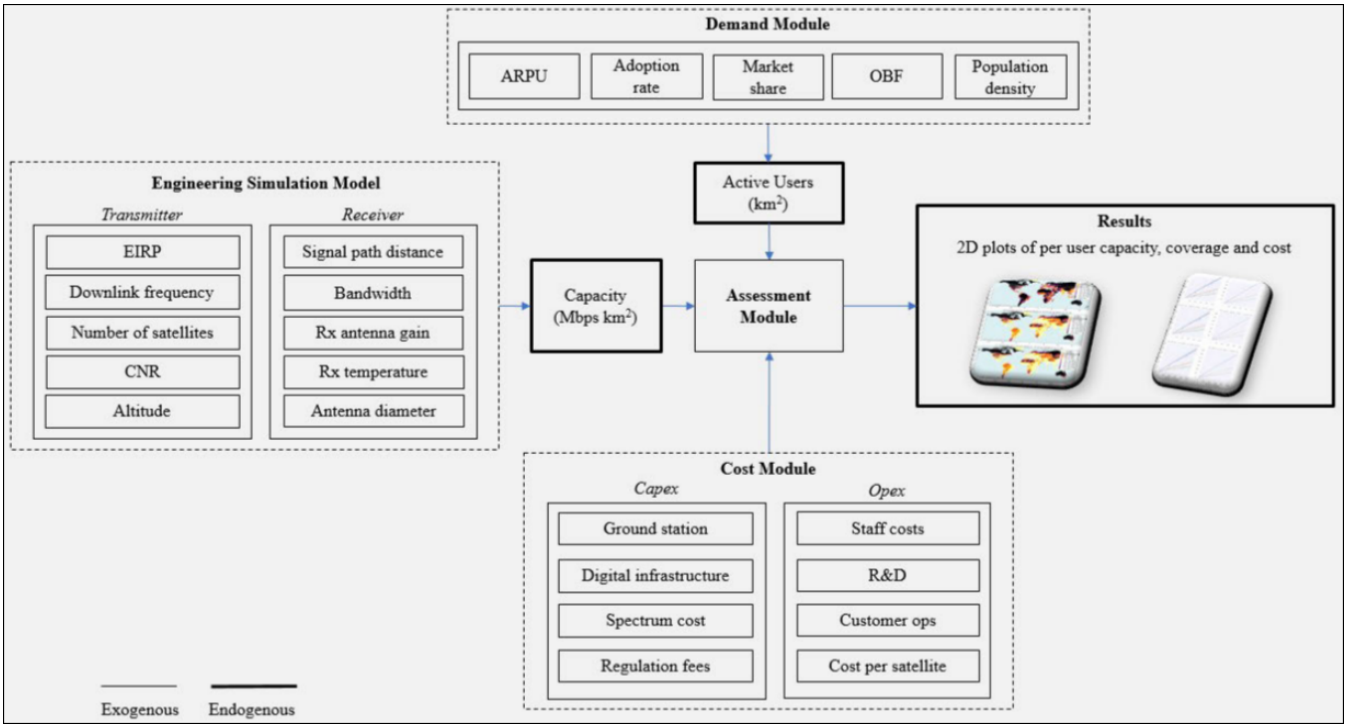

Figure 4. Framework For LEO Satellite Network
Source: Adapted from [19]

Generally, Due to onboard data generation and continuous computation leads to delay in transmission. Let us, take an example of this – Image data processing.

- Large image data is transferred from cloud computing center of satellite ground station
- Then with reasoning through deep learning model, the processed result is distributed to user
- But image generated is of Gigabytes size, so transmission have delay, as it occupy large satellite bandwidth, and as simultaneously large data computation is also happening there

Consequently, paper proposes the idea of "Edge Intelligent Computation"

1. Cloud (Cloud Node = connection nodes)
2. Fog (Edge Node = gateway nodes)
3. Mist (Ground Node= ground nodes)

In paper [19] authors gave each satellite some computation power to satellite too which utilize each satellite as an edge device, allowing processing to be done while the satellite is in orbit and reducing transmission time.

On one hand edge device can ask help to other two or also help them by combining other edge devices to form a fast service cluster.

If we want High computation power and real time retrieval of data then cloud node will be the best option but If we want High Computation and low real time retrieval the ground node will be the best option. Because if data is requested by a client then first it makes a request to its nearest ground station and then it goes to the satellite connected to it and then it get transfers to satellite near to the database and finally from database it retrieve data and transfer it to the client.

Most powerful computation is of ground station which is followed by cloud node and least computation power is given to edge node which is mostly used as support node.

So, cloud-edge computation can reduce data processing and communication latency, conserve bandwidth, and enhance bandwidth interconnection and reduce pressure on ground stations. Paper explain the architecture of A storage system, an IoT satellite constellation, and a terrestrial IoT endpoint make up the three primary components of a space - based Internet of isolated objects system.

In order to give space missions (nanosatellite terminals) high-speed continuous broadband access from the burgeoning Internet service suppliers in space, We offer a technique for creating an orbital multi-layer information network (SIN). The rapid development of nanosatellite constellations in lower orbits for satellite downstream analysis, such as earth observation, satellite imagery, and Internet of Things (IoT) data collecting, as well as satellite technology such as satellite downsizing and recyclable rocket launch., have all served as inspiration for this idea. In particular, broadband communication directly to/from the nanosatellites can be used with satellite- enabled internet suppliers like OneWeb, SES O3b, and Starlink, allowing to higher levels of interconnection among structures of space networks.

Additionally, such a kind of setup achieves real-time and dependable space communications while having more profitability and obviating the requirement for too many ground stations. To achieve this goal, Effective scaled space backhauling must be created by use of inter-satellite links (ISLs) along with inter-orbit connectivity (IOLs). The key factors that made this new idea possible are specifically using software-defined networking (SDN)-based design and service-oriented radio access methods that apply the best routing strategies over a large number of ISLs and IOLs. Therefore, establishing this mutual connection between adaptable satellite nodes in various orbits will bring about a development in the planning and management of satellite networks and upcoming space missions.

We offer advice on how to create an data network in space with multiple layers and orbits (SIN) so that the expanding space-based Internet suppliers may supply high-speed, uninterrupted broadband access to space missions. Real-time and trustworthy communications in space are made possible by this configuration, which is also more inexpensive This gets rid of the requirement for too many ground stations. The key enablers for this novel strategy are software-defined networking (SDN)-based system and service-oriented radio access techniques [16].

Additionally discussed are the most current NGSO satellite-based broadband technologies, satellite network improvements, and nanosat satellite projects. More interconnections for space network topologies is made possible by the recommended connectivity design, which may also enable nanosats to reach their full potential.

The report outlines a novel strategy for resolving the connection problems that several satellites in lower orbits are experiencing. The proposed connectivity design enables increased connectivity for space network topologies. A lot of technical obstacles need to be removed in order to build such a network structure. This essay's key objectives are the development of effective SDN-based satellite networking and routing mechanisms and appropriate radio access strategies.

The suggested architecture in this article has the potential to change the development and deployment of upcoming satellite missions while also opening up new options for satellite operators. The report opens the door for a seamless connection between nanosat missions and space-based Internet infrastructure, which will encourage more study in this area.

IV. STARLINK AND OTHER SPACE TECH GIANTS

Project Starlink is a satellite Internet constellation being managed by Elon Musk's SpaceX, that provides satellite-based Internet access around the world. The Starlink constellation consists of interconnected satellites in its LEO (Low Earth Orbit) communicating with dedicated ground transceivers. Starlink may only provide services in countries that SpaceX has authorized to provide services in those territories. Starlink is not yet fully mobile. Starlink claims that it will initially need about 30,000 satellites in the sky for the Starlink constellation to be complete and "fully mobile". Currently, the US Federal Communications Commission (FCC) allows the company to launch about 12,000 satellites into the sky [1].

Paper [18] begins by describing how the proposed 12,000-satellite mega constellation Starlink would dominate space below 600 kilometers, resulting in an aerial number density of about 0.01 units per sq degree. To ground- based observatories, such enormous and low-altitude satellites look visually dazzling. The projected number of lighted satellites has been predicted by the author as a function of latitude, time of day, and season [18]. The author has also outlined potential ramifications for ground-based astronomy.

Authors of [18] has used the U.S. catalogue of space Starlink to launch Darksat, whose nadir surface had an unique covering, is also discussed in the paper. Initial observations indicated that this covering had essentially no impact on the brightness of the satellites [18].

The effects of bright satellites passing through observatories' fields of vision, including ghost pictures, electronic crosstalk, and effects on flat fluids, are shown in Paper [18]. When passing near some telescopes, bright satellites may scatter light into the field and reduce the limiting magnitude. Additionally, these satellites are probably strong thermal infrared generators. The last section of Paper [18] focuses on the rapidly changing population of large satellite mega constellations in orbits under 600 kilometres, which affect ground-based observations of space, particularly by serving as sources of reflected sunlight, twilight observations and long- exposure observations with large fields of view can be made. According to the authors of [19], there is still no open-source approach for gaining access to the technological economics of satellite broadband communication. The paper provides a generalizable technoeconomic model to access the economics of satellite constellation engineering. It also provides an evaluation of the Kuiper, OneWeb, and Starlink LEO constellations' potential capacity and price per user. The importance of LEO broadband as a component of the connectivity toolset is discussed by the authors.

Motivated by the reality that a huge portion of the global population still lacks access to a reliable broadband service Theoretical model presented in the paper enables approximate estimation of constellation capacity based on parameters submitted to the Federal Communications Commission. The code base for model is completely open source. Modern results revealed that mean aggregate capacity of around 11 Gbps, 4 Gbps and 8 Gbps could be accomplished by Starlink, Kuiper and One Web respectively. It also highlights that success of these models depend on subscriber densities required to be lower than 1 user per 10 km2.

The article describes a few topics, including what could be the maximum capacity per user for four different kinds of constellations, how much capacity different LEO broadband constellations might supply, what might be the potential cost per user, and which geographical areas are the most lucrative for Leo constellations?

Comparing LEO systems to other MNO systems' scalability is discussed in the paper. A variety of models make up the technological economic framework for satellite networks: System model, cost model, system and economic model integration, demand model, and engineering simulation model are the first five. Free space path loss, received power, carrier-to-noise ratio, spectral efficiency, channel capacity, and aggregate channel capacity are studied in relation to the Starlink, OneWeb, and Kuiper constellations [19].

V. FUTURE OF SATELLITE IOT AND RESEARCH

Future research can concentrate on the issue of non-linearity in the multiple access to satellite resources in order to improve on the current simplifications. The framework can also be changed to accommodate other anticipated

objects as a source of obtaining data for research. Author has
generalizable for satellite constellations. The results of the
proposed a model for observing impacts of mega satellite
investigations being done now may create a market for the
sale
in LEO with the help of observing group
of extra C-, Ku-, and Ka-band facilities for
geostationary
SeeSat. This model demonstrates that most satellites are
easily
satellites. This example demonstrates
situations where
visible to the naked eye from dark places. The attempt by
business locations are situated in remote
regions and

reciprocal connection can only be accomplished through satellite communications.

Institutional services that are provided between these institutions also need for ICN-based solutions because they need specific security measures. Another crucial necessity in this regard is the multicast capability, which is required in some systems that only distribute data to specific user groups. Since remote entities are the main recipients of data sharing, a hierarchical name method seems more viable because it may also be used to satisfy multicast needs. Application of identity-based signatures (IBS) combined with encryption in the latter situation, where source (identity)validation is first carried out before content decryption, is particularly effective.

VI. Conclusion

Interest in the possible use of satellite constellations for Internet of Things applications is developing. LEO constellation based IoT is worthy of attention and study given the booming IoT environment and its potential as a strong companion to terrestrial systems. Further studies on the system security, transmission technology and low power consumption design are required to turn this topic into a reliable cost-benefit solution.

Starlink encircles the entire planet, from Antarctica to the middle of the ocean, it can offer internet access wherever. Due of the price differential between Starlink and Indian Internet Service Providers, the Indian market may cause challenges for Starlink.

Abstract—**Machine Learning has become the need of today's world. Any intelligent system is incomplete without Machine Learning. People use ML models in various applications. Every ML-based project has to go through some of the steps during the development process. This process consists of certain common steps which every ML project needs to follow. The process of building ML models is tedious and time consuming. There are some common problems which people face while developing ML-based projects. That includes lack of resources and infrastructure, lack of uniformity in codebase and writing repetitive code for every project. These problems are very serious as building ML models needs a lot of effort and time. This paper aims to describe some of the problems that people face during the development of ML-based projects. It also provides a solution to reduce many problems and save efforts in the development process. The system proposed in this paper can save a lot of time and effort in building ML models. It will help to build projects faster and increase efficiency.**

Keywords—Machine Learning, ML pipeline, ML models, Web based Portal.

I. INTRODUCTION

Currently, to make any project involving machine learning or data science[4] one thing that comes at the forefront of the project is the data preprocessing[5] part. Without the proper data preprocessing, no project can be made that can give the desired results. Whenever, a database is picked up to work on, in its raw form it has many flaws, irregularities and redundant data as well. All these irregularities need to be overcome and the data must be made feasible to serve machine learning models or to make any future assumptions from this data. This process of removing the irregularities is nothing but the preprocessing.

Presently, the preprocessing part is carried out by using various coding techniques and making use of various data science libraries. Examples of such libraries are Pandas, Numpy, Matplotlib, etc. Below image shows the typical coding snap of any data preprocessing part.

Figure 1: Typical Preprocessing Process

Any data cleaning or data preprocessing part involves few standard steps:

a. Exploratory Data analysis
b. Data Preprocessing
c. Feature Engineering

Presently, these steps are implemented by coding using the libraries as discussed earlier.

However, since these steps of data preprocessing are something very standard and need to be done every time you start with a fresh dataset. When one has to do it every time with every new project, then it feels the requirement of some easier process to do so. At the same time, for the people who do not want to code, or don't know how to code, for them this becomes a big hurdle to get the data done to start any fresh project.

Here, this portal is proposed, which can conduct all these steps of data preprocessing without using a single line code. A user of the portal has to just upload the data set and get his job done by just a few clicks.

Figure 2: Upload the Database

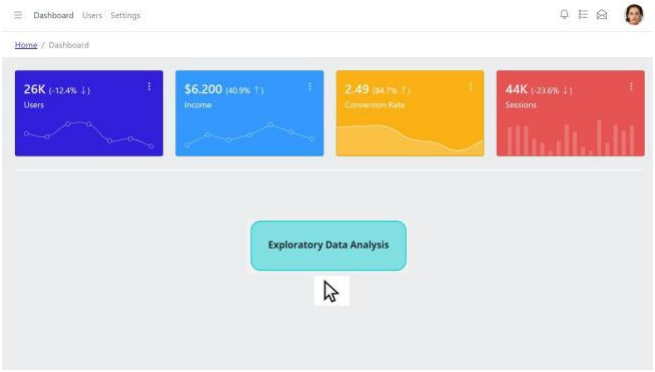

Figure 3: Select the Functionality

Such a portal will prove to be handy for the frequent coders who don't want to code every single time the same steps and also it's going to save a lot of time in the development of bigger projects.

II. LITERATURE SURVEY

Machine learning is one of the popular domains on which people write articles, technical papers and books. In this literature people write about various architectures, different techniques to implement models, various machine learning algorithms and problems that people face during its implementation.

There are certain challenges that people face during practical implementation of machine learning models. In the research paper "Challenges In The Deployment And Operation Of Machine Learning In Practice" by Bair, Jöhren and Seebacher[1] , many such problems are discussed in detail. This paper contains a complete analysis of various challenges that ML practitioners face. That includes pre deployment issues like encryption of data, data format,etc and deployment issues like scalability and resource availability issues to train on big data. It also talks about some non technical challenges such as interpretability and transparency of complex machine learning models. It also suggests some solutions to solve some of the problems that are described in this paper.According to this paper, there are many problems which are unknown to ml theretitians. In order to get complete data they conducted interviews and surveys of industry experts who are working in this field for many years. It is focused on studying the cause of these problems in order to solve them.

According to Ashmore [2], for developing any ML-based project there are four stages:

- **Data management**, means collecting and transforming data into correct format
- **Model learning**, means learning features used in prediction
- **Model verification**, means testing accuracy of results from model
- **Model deployment**, means using a trained model in a production environment.[6]

There are many small steps under each of four stages. In the paper "Challenges in Deploying Machine Learning: a Survey of Case Studies" by Andrei Paleyes, Raoul-Gabriel Urma and Neil D. Lawrence [3], detailed description about various problems in each of these steps is mentioned. It also describes main causes for these problems.

There are more such papers and articles describing problems related to ml pipeline, workflow and deployment of models. It shows that developing and managing ML models is a difficult task and a lot of resources are used to do this task. There is a need for some generalized pipeline to reduce some of the problems and fasten up the process of developing and deploying ML models.

III. PROBLEM DESCRIPTION

Every ML project goes through some common steps in the development phase. Some of the common steps are:

1. Gathering Data
2. Generating Hypothesis
3. Exploratory Data Analysis (EDA)
4. Data Preprocessing
5. Feature Engineering
6. Model Selection
7. Model Training and Evaluation
8. Hyperparameter Tuning
9. Model Deployment

Traditional way of writing code for these steps is very tedious. There is no uniformity in the code. People write repetitive code for various steps in the ML pipeline in every project. It is time consuming and requires a lot of resources to build. There is a need to automate some of the steps of this pipeline. This can save a lot of time and resources. People can build their project in less time and effort. It can boost efficiency and improve the quality of the project.

3

IV. Proposed System

The proposed system for the problems and hurdles discussed so far in the field of data engineering, would be this "Web Based Portal For Complete Data Engineering". The overview of features of this system can be seen pictorially as;

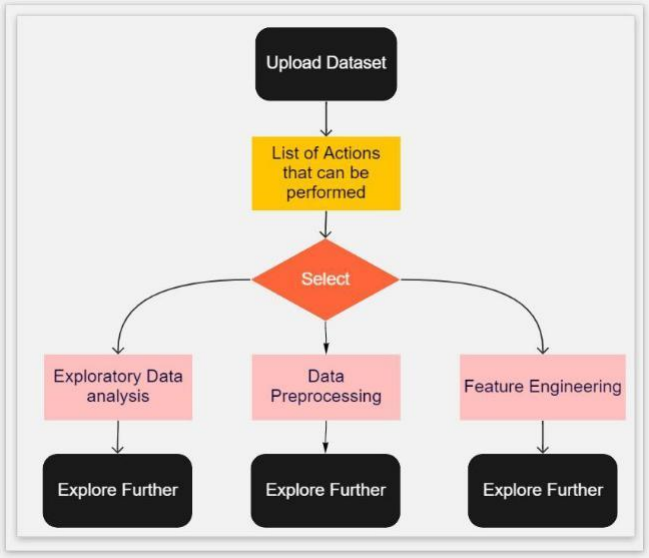

Figure 4: Features Overview

The detailed features of this system are as follows:

1. Users must login to the account.
2. Users should be able to load a dataset from source(File, Database, Cloud Storage).
3. Users should be able to choose a component from the below 3 categories.
    a. Exploratory Data analysis
    b. Data Preprocessing
    c. Feature Engineering
4. User should select any options like If user select Exploratory Data Analysis, the user will get
    a. All column details like missing values in specific columns, mode, median, mean, memory size, etc.
    b. Correlations between dependent and independent features.
    c. Missing values Plotting as well as % of missing values in each column.
    d. Sample of First rows and last rows
5. In EDA we have a lot of Graphs (count plot, scatter plot, box plot, etc) and we have to provide the ability to plot graphs based on the dataset. Eg: If a user wants to perform some specific task like outliers detection then here user will get an option to plot a scatter plot or box plot.
6. If the user select Data Preprocessing, the user will get 4 options:
    a. Data Cleaning
    b. Data Integration
    c. Data Reduction
    d. Data Transformation

    Example: If user select data cleaning
    - User will get a percentage (%) of missing values in each column
    - If in our columns we have 95% of missing values user should drop this column
    - If in our columns we have 40% of missing values and our columns are categorical columns, users can apply mode here and so on.
7. If the user select Feature engineering, the user will get 4 options
    a. Handling Imbalanced data
    b. Handling categorical data
    c. Based on categorical data, users should do the operations like One-Hot Encoding, Label encoding, Target encoding, etc.
    d. Users should also add a manual process to handling categorical data.

V. CONCLUSION

Machine Learning is being used in almost all the projects. There are some problems that people face while building, deploying and maintaining ML models.These problems are very common and serious. The portal described in this paper can help to reduce some of the problems that people face.The portal will be helpful to perform some important steps of the ML pipeline such as Exploratory Data Analysis, Data Preprocessing, Feature Engineering, etc with less effort and in less time. It will improve the speed of development and will reduce repetitive work.

Abstract— **Video Game is a part of entertainment that grows fleetly. To enhance the development of content, games must be suitable to produce anon-boring game atmosphere similar to Replay- capability. The Roguelike game relies on Procedural Content Generation as a vessel for games and perm death systems. The existing system have minor loopholes and some glitches containing in them. The A* Pathfinding algorithm is used to create space and content from a game grounded on the direction the algorithm is going. And methodology like ray casting for shooting and line of site are used in our game. Game design further using unity assets. Future works for our project is to make it 3D and adding many more features by using assets for 2D version.**

Keywords— ray casting, pathfinder, unity.

1. INTRODUCTION

A top-down shooter is a type of video game in which the player views the action from a top-down perspective, typically with the player character at the bottom of the screen and the enemies or targets at the top. In Unity, a 2D top-down shooter can be created using the UnityEngine.Tilemap package, which allows for the creation of tile-based levels, and the UnityEngine.InputSystem package, which allows for player input and movement. To create a basic top-down shooter in Unity, you would need to do the following: Create a new Unity project and set it up for 2D developmentCreate a player character, which can be controlled using the Unity Engine [2]. Input System package to handle player input Create enemies or targets for the player to shoot, which can be randomly generated or placed in the scene using the Unity Engine. Tile map package Implement a shooting system, which can be accomplished using Unity's built-in physics engine or by creating custom script to handle bullet spawning and collision detection Add a user interface, including a health bar, score, and other elements that will provide feedback to the player Add sound effects and background music to the game.It's important to note that this is a high level overview and you would need to have knowledge in programming, game design and Unity to implement it.

2. LITERATURE SURVEY

The Make Code environment is an open source online web environment that allows programming in blocks of code, using the scripting language JavaScript and Python. The simulator can be controlled with a keyboard, or with a gamepad connected to the computer (e.g. Xbox gamepad). It is also possible to test the created games on a special game console (approx. 35 €), and on mobile devices [1].

Construct 2 enables anyone to create a computer game in easy and straightforward fashion. Drawings on old-school 2D games, objects (main character, platforms, gems, signatures) have been created. The environment is accessible and easy to use, with an interface susceptible to third party plug-ins [2]. Over 30 Games were chosen to form a representative set, mixing older titles and new ones. Patterns were chosen taking into account their relevancy (if it is often mentioned in the community or works) and recurrence (if they were observed in a substantial amount of the games that were played) [3].

Literature in the field offers a number of papers devoted to the development of indie games. The process of making an indie survival game was explained by David Michael and how to choose the right tools for your needs [4].

An action game is a game that requires hand-eye coordination and fast response from players. In 2D avatar based actionplatform games, a player has to navigate an avatar through 2D environment. Both the avatar and its enemies have limited number of hits that they can take before they are considered defeated. Previous work described an experimental game that could read and execute ADL. In this paper, we used ADL to create a dataset of enemies from existing action-platform games. These enemies were then used to evaluate our AI through battle performance comparison [5].

The proposed method uses machine-learning methods available at Unity's ML-Agents library. The most important design aspect to be considered in the presented method is the relative configuration of the dungeon strategic rooms. In this paper, the chosen event rooms were the boss and shop. Event rooms are present in many dungeon crawler games, such as The Legend of Zelda and The Biding of Isaac. It is important to design the map positioning of these rooms so designers can have more control over the order they appear [6].

The input device which is primarily used to manipulate video games is called a game controller. Some of the most common game controllers are gamepads, mice, keyboards, and joysticks. Playing games by using keyboard will not give a realistic feeling. If we play the games using our hand gestures it will be more realistic [7].

New technologies enable the realization of game ideas that previously only could be implemented through significant effort. This paper presents the design, implementation and

verification of a generic version of the A* pathfinding algorithm, with the capability to navigate in multidimensional space, thereby given a 5D sparse matrix, enabling the creation of 3D worlds in computer games that could be used to facilitate time-travel and travel between parallel universes in a straightforward fashion [8].

A proposed framework that captures data while the user plays a game in order to generate a graph that can be shown at the end of the session. It also informs to the game designer characteristics and behaviors of the gameplay as well as the player's behavior during the game [9].

We examine the field of psychology and what works have been done to gain insights into differences among peoples' characteristics and motivations. In particular, we dive into player-centric video game research. Goals and rewards are linked concepts that underlie both human society and neurology. They remain a powerful driving force in influencing human behavior [10].

The summary from the literature survey is that The proposed method uses machine-learning methods to design dungeon strategic rooms, such as the boss and shop. The input device used to manipulate video games is called a game controller, and new technologies enable the realization of game ideas. This paper presents a generic version of the A* pathfinding algorithm, with the capability to navigate in multidimensional space, and a proposed framework that captures data while the user plays a game to generate a graph. It also examines the field of psychology and what works have been done to gain insights into differences among peoples' characteristics and motivations.

3. PROBLEM DEFINATION

Performance optimization: The game may experience lag or reduced frame rates, affecting the overall user experience.
Balancing: The game may be too difficult or too easy, causing players to become frustrated or bored.
User interface: The user interface may be confusing or poorly designed, affecting player engagement.
Collision detection: The player's bullets and other game objects may not be colliding correctly with each other, causing unexpected behavior.
Level design: The levels may be poorly designed or too repetitive, affecting player interest.
Sound effects: The sound effects may not be synchronized with the game play, causing distractions for the player.
Performance optimization: To resolve performance issues, consider using object pooling, reducing the number of active objects on the screen, and using optimized sprite renderers.
Balancing:To resolve balancing issues, consider implementing adjustable difficulty levels, providing more opportunities for player progression, and adjusting the strength and frequency of enemies and power-ups.
User interface: To improve the user interface, consider using clear and concise text, intuitive button placement, and providing visual cues for important actions.
Collision detection: To resolve collision detection issues, consider using Box Colliders and Polygon Colliders, and ensuring that the colliders are correctly positioned and sized for each object.
Level design: To improve level design, consider adding variety to the environment, providing clear objectives and paths, and adding interesting obstacles and power-ups.
Sound effects: To resolve sound effect issues, consider using sound effects that are synchronized with the game play, and adjusting the volume levels to provide an immersive experience.

4. EXISTING SYSTEM

The game's parcels include parameters that control the scene rendering or physical behaviors, such as camera, audio, drugs, and new variables added by the game developer. The actors are responsible for representing any game element and executing the game sense, and can acquire new parcels to meet the game needs. Each scene is composed of a set of actors and a list of rules[6].

5. PROPOSED SYSTEM

Game Concept: Fast-paced, top-down shooters where the player must navigate through levels filled with enemy forces and defeat the final boss to win. The player will use ray casting to shoot enemies, and the AI will use line of sight and pathfinding to navigate the environment and attack the player.
Game Mechanics: The player will have a range of weapons at their disposal, including a primary weapon and secondary weapons. The player will use ray casting to shoot enemies,

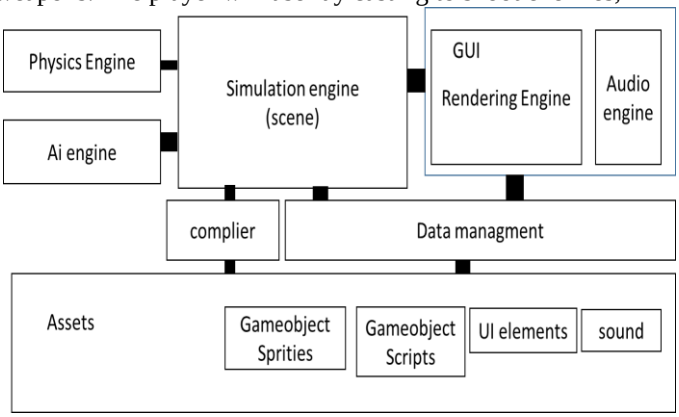

Figure 1

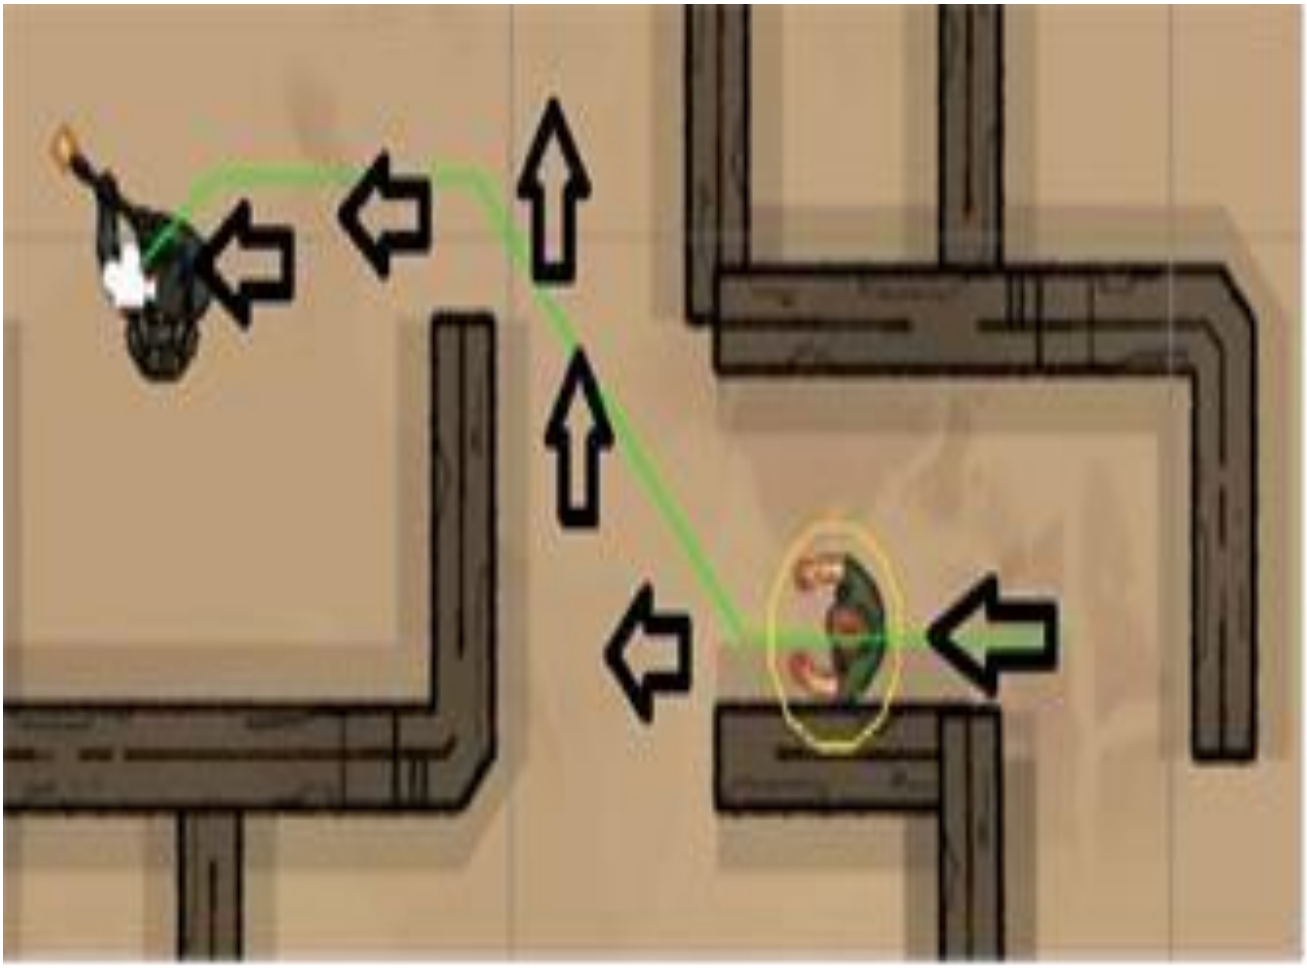
and the AI will use line of sight and pathfinding to navigate the environment and attack the player. The player will also be able to collect power-ups and upgrades throughout the game to enhance their abilities.
Levels: The game will feature a variety of levels set in different environments, including urban, industrial, and extraterrestrial locations. Each level will present different challenges and obstacles for the player to overcome. Art Style: The game will have a stylized look and feel, using shaders to enhance the visual effects.
Target Audience: The game is aimed at players who enjoy fast-paced action and challenging gameplay. It will appeal to fans of classic top-down shooters, as well as those who enjoy stylized

and visually impressive games. Monetization: The game will be sold for a one-time fee, with no in-app purchases or advertisements. Ray casting Shooting: Use ray casting to detect if the player's shots hit enemies. You can use the Physics2D.Raycast method to shoot rays from the player's weapon and check for collisions with enemies. Shade: Create shades to add visual effects to the game. For example, you could create a simple sprite shader to change the sprite's colour or add a flash effect when the player or enemy is hit. UI System for Health: Implement a UI system to display the player's health. You can use Unity's built-in UI system to create health bars and other UI elements.

5.1 GAME DESIGN

Creating a score UI in Unity 2D can involve several key steps:
Creating the UI element: This can be done using Unity's built-in UI system, such as creating a Text or Image element, or creating a custom UI using Unity's canvas system. Displaying the score: The UI element should display the player's current score, which can be stored in a variable and updated as the player collects items or defeats enemies.
Positioning the UI element: The UI element should be positioned on the screen in a location that is easy for the player to see, such as the top-centre or top-right of the screen. Updating the score: The score should be updated in real-time as the player collects items or defeats enemies, this can be done by using a script that updates the score variable and displays it in the UI element.
Adding a script: To handle the score updating, you will need to add a script to the UI element, the script should check for events such as collecting items or defeating enemies, and then increase the score. High score: You can add a high score system, where the player's high score will be saved and displayed, this will make the game more challenging and re-playable. Customizable: You can make the UI elements customizable by adding options in the main menu to change the font size, colour, position, etc.
Testing: After implementing the score UI, it is important to test it in game to make sure that everything is working as expected, and to make any necessary adjustments. By following these steps, you can create a functional and visually appealing score UI in your Unity 2D game
Creating a health system for the player in Unity 2D can involve several key steps:

- Creating the UI element: This can be done using Unity's built-in UI system, such as creating a Text or Image element, or creating a custom UI using Unity's canvas system.
- Displaying the health: The UI element should display the player's current health, which can be stored in a variable and updated as the player takes damage or uses health items.
- Positioning the UI element: The UI element should be positioned on the screen in a location that is easy for the player to see, such as the top-centre or top-right of the screen.
- Updating the health: The health should be updated in realtime as the player takes damage or uses health items, this can be done by using a script that updates the health variable and displays it in the UI element.
- Adding a script: To handle the health system, you will need to add a script to the player character, the script should check for events such as taking damage or using health items, and then update the health variable accordingly.
- Death: When the health reaches 0, the player dies, you can implement death mechanics such as game over screen, or respawn the player at the last checkpoint.
- Testing: After implementing the health system, it is important to test it in game to make sure that everything is working as expected, and to make any necessary adjustments.
- 5.2 PATHFINDING ALGORITHM
- A* (A-Star) pathfinding is a popular algorithm used for finding the shortest path between two points in a game. In a top-down shooter game, A* pathfinding can be used to create intelligent enemy AI that can navigate around obstacles and chase the player character. To implement A* pathfinding in a Unity top-down shooter game, the first step would be to create a navigation grid or map of the game world. This grid would divide the game world into small cells or nodes, each of which can be marked as walkable or not walkable. Next, the A* algorithm would be implemented to find the shortest path between the enemy character's current position and the player character's position. The algorithm would use the navigation grid and a set of heuristic rules to determine the most efficient path. Once the path has been found, the enemy character can then move along the path using character controller systems. A* Pathfinding can also be used to implement other features such as cover system, where the enemies can hide behind cover, and flanking, where the enemies can try to move to a player's side or rear to gain an advantage. It is important to note that A* Pathfinding can be computationally expensive and may have a performance impact on the game, especially in large and complex game worlds. To mitigate this, various optimization techniques such as caching, multithreading or using a different pathfinding algorithm should be considered.



- Figure 2
- Overall, A* pathfinding can greatly enhance the gameplay of a top-down shooter game by providing intelligent enemy AI that can navigate the game world and pursue the player character. With the right implementation and optimization, it
-
- can be a powerful tool for creating engaging and challenging Figure 5 show the failure at the level and menu button direct gameplay [8]. us to play that level again to unlock the next level.
-

6. RESULT AND DISCUSSION

Based on the implementation that was done, the game had been created, and the following screenshots were directly Taken from the game.

Figure 3: Menu Display

Figure 3 show that the main menu of this game that shows how controls is there game. Here, the player can access how to play, controls of the game.

Figure 4 : Mission Complete Display

Figure 4 show the completion of the level and menu button direct us to the next level.

Figure 5 : Mission Failed Display

Figure 6 : Mission/Level Display

Figure 6 show levels in the game there are 5 -6 mission. After completion of 1 st then only next mission will be unlock otherwise play it again till mission is completed.

Figure 7 : Game play Initial Display

Figure 7 show th e goal for successfully completing the mission and unlocking the next mission. The health icon on top left corner shows the health of the player. And on top right corner show how much kill is done.

Figure 8 : Playing Zone Display

Figure 8 shows the play er hiding behind the tree from the enemy.

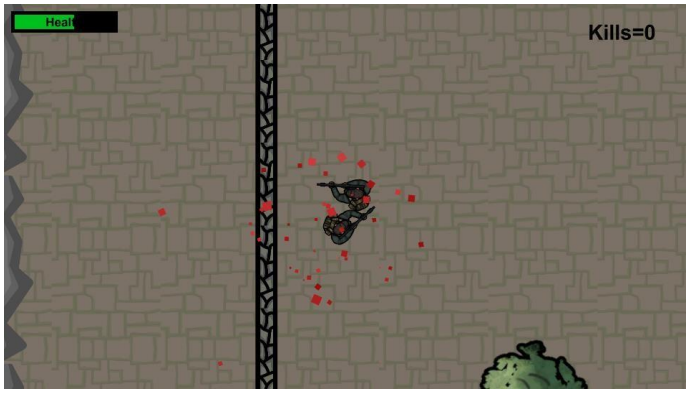


Figure 9 : Fighting Display

Figure 9 shows the fight between the players and red marks indicates blood. And in top left you can see reducing health due to fight.

6. APPLICATION

1. Entertainment
2. Easier to pick up 2D than 3D games.
3. A 2D game can be easily processed and runs on any PC with lower RAM (Random Access Memory)

7. CONCLUSION AND FUTURE WORK

A 2D top-down shooting roguelike game with A* algorithm has been designed and developed. This game was built with Unity Engine 2019 and only has one type of game mode with a different game atmosphere. For future work, we will develop in 3D Platform. And in 2D format will be adding multi-player facilities and Enhanced enemies.

ACKNOWLEDGMENT

Estimate elastic constant of Mild steel plate using welch's periodogram method

Vijaykumar Bhanuse, Sanika S Patankar, Jayant V Kulkarni
Department of Instrumentation Engineering, Vishwakarma Institute of Technology, Pune, India.
vijaykumar.bhanuse@vit.edu, sanikapatankar@gmail.com, vitjvk@yahoo.com

Abstract – **Mild steel(MS) plate used different type of construction design. To find the vibration analysis of plate is important work to find the fundamental frequency. In this paper ball is impact on metal plate with different height and different plate area to find the fundamental frequency. Apply welch periodogram method to vibrating signal and find the fundamental frequency. Fundamental frequency by welch periodogram method compare with ANSYS software by finite element method. It observed that fundamental frequency accuracy is very good by Welch method. Further elastic constant also estimate by method .Estimate result it show that elastic constant from Welch method is very accurate.**

Compare fundamental frequency estimated by impact testing with ANSYS software .Observed that MS plate fundamental frequency by proposed method is accuracy 3.92%.Young modules estimate for MS plate by proposed method is accuracy is 7.2%.

Keywords: — Metallic plate; harmonic analysis.

I. INTRODUCTION

Elastic constant estimate for metal plates is through fundamental frequency is very important role. Accuracy of elastic constant calculates by finite element analyses.

There are different algorithm is design different author for for elastic constant. Some are listed in this paper. Their utmost potential can be obtained. Vibration analysis is widely applied in area of failure analysis . In the area where safety, reliability and quality control are highly considered, the development of harmonic analysis technique becomes inevitable.

Vibration has been extensively studied. Chladni [1] Mechanical vibration analysis done by Rao S S.[2] Navier and Lavy obtained analytical solutions for special boundary conditions[4]. The metal plates analysis several approximations have been proposed by Rayleigh [7] and Iguchi [6] Gorman Methods available for harmonic response analysis are full, reduced and mode superposition. Full method uses full system matrix to calculate harmonic response. [3]

The harmonic analysis of plate is under different impact height. Various techniques have been developed for harmonic vibration analysis of plate and for finding out natural frequency of plate.

II. METHOD AND MATERIALS

A. Metal plates

Two metal plates prepared of low carbon steel are used for the vibration test. The chemical composition of the plate is 0.055% C, 0.25% Mn, 0.02% Cr, 0.01% Ni, 0.02% Mo, 0.021% Si, 0.004% S, 0.015% P. The chemical

analysis is finished and the material is the same as HR sheet (D) as a type material. The plate thickness is 1.6mm. The plate areas are 30 cm x 30 cm and 22.5 cm x 22. The weight of ball is 0.225 kg.

B. IMPACT TESTING SET UP

Figure 1: Impact testing setup

Figure 2: 30cm X 30cm MS plate

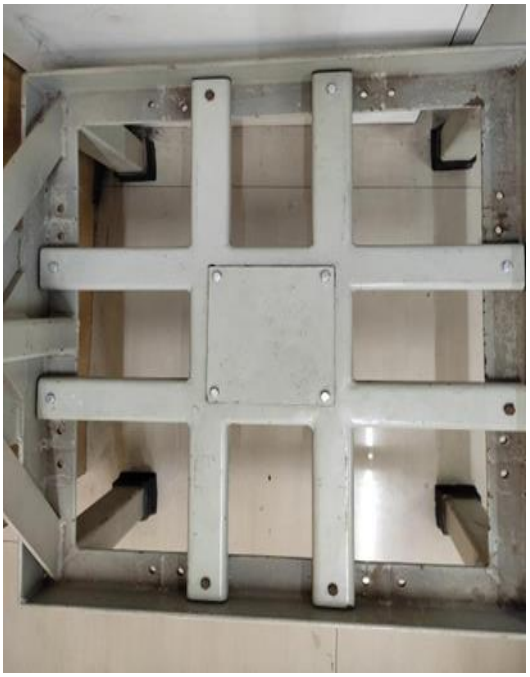

Figure 3: 15cm X 15cm MS plate

Figure 4: 22cm X 22cm MS plate

The experimental set-up used to obtain the vibration signal is shown in figure 1. The experimental set up consists of a frame on which plate is mounted, steel ball ,hook arrangement for release of ball from height, a piezoelectric sensor, scale for measuring ball height

Metallic plate is fixed on a frame which is kept on a stand. A piezoelectric sensor that is accelerometer is positioned on plate from where we are capturing impact vibrations. The ball is freely falls on centre of plate. The stand on one side there is scale from height 10 cm to 150 cm from where ball is impacted on plate.

The piezoelectric sensor used is MIL-521 which measures vibration signal. The vibration signal is collected at different height of ball impact on plate.

Vibration signals are accumulated from the corners of the plate using accelerometers with NI data acquisition devices. Accelerometers consist of piezoelectric materials as the sensor material. The collected vibration data are processed with the software package MATLAB. Various operating parameters are selected in the software for ball impact testing.. NI Data acquisition card is sampling rate of 51.2kS/s.

The vibration data is collected after each impact from different heights. Height is varied from 10 cm to 100 cm. For 10 different height we get vibration data and this data is analysed through spectral analysis using matlab. After analysis natural frequency of material is estimated.

C. Proposed method.

The ball is impact on metal plate in different height an vibration signal is generated . Vibration signal is captured by accerometer. Capture vibration signal pass to different signal processing technique as shown in block diagram figure

5. Final result is of fundamental frequency is compare with ANYSIS software by FEA and accuracy is calculi

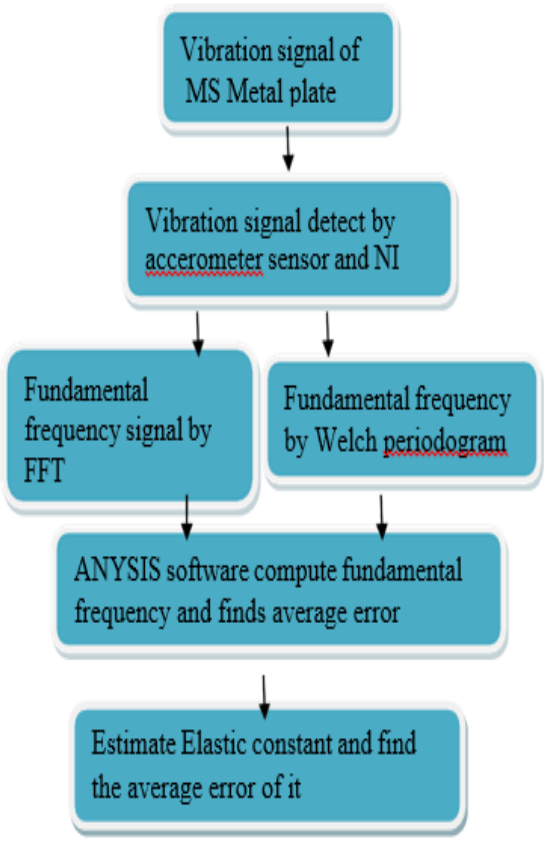

Figure .5: Block diagram for proposed method

D. FAST FOURIER TRANSFORM

The Fast Fourier Transform is a special case of the Discrete Fourier Transform. FFTs are used in vibration analysis because they provide information about the frequency content of vibration signals in the time domain. FT is calculated using,

. H(f)= dt (1)

Fast Fourier transforms is,

x (k)= (2)

(2) Fast Fourier transforms are used to analyze complex random signals such as vibration signals. Therefore, after impact, the vibration signal is detected and the sampling frequency is adjusted for spectral analysis.

E. Welch Periodogram.

The Welch periodogram estimate of the spectral density of a signal. In Welch's method original signal data is split up into several data segments with overlapping form. A time domain window is applied to the individual data segments after the data is split up into overlapping segments. Welch periodogram is define as,

$$\overset{i}{P}_{xx}(\Omega) = \frac{1}{MU}\left|\sum_{n=0}^{M-1} x(n)\, w(n)\, e^{-j\Omega n}\right|^2, \quad i = 0, 1, 2, \ldots, L-1$$

W (n) –window function,

X(n) –original signal ,

U- Normalities Factor

III. EXPERIMENTATION AND RESULTS

a) FFT fundamental frequency

Impacts are done with various kinetic energy. Steel ball is first dropped from height 10 cm and vibration signal is acquired through accelerometer and DAQ system. After this, ball is dropped at successively increasing height of 10 cm incremental from 10cm to 100cm. At each height vibration signal is collected and data is stored to excel sheets. Here at each height the kinetic energy associated with ball is changes. The graphs obtained from vibration analysis are given below.

The piezoelectric sensor used is MIL-521 which measures vibration signal. The vibration signal is collected at different

height of ball impact on plate. The 80cm, 100cm height

ball impact on MS plate shown fundamental frequency in figure 6

and figure 7. This time domain signal given to Matlab software where time signal estimate fundamental frequency through

Fast Fourier Transform (FFT) for that sampling frequency 5k Hz and 16000 total data length use for FFT calculation

b) Welch Periodogram.

The data length of vibrating signal is 16000. Divide data length in segment by 16000/2= 8000. Total length of segment is 8000.L- length of segment and R is overlap window. Given algorithm if overlapping window 1000 than SNR ratio is very high. Maintain overlapping in 1000. The fundamental frequency by Welch algorithm is 197.2 as shown in figure 8.

C) Finite Element Analysis (FEA) : FEA for MS plate with an chemical composition of the plate is 0.055% C, 0.25% Mn, 0.02% Cr, 0.01% Ni, 0.02% Mo, 0.021% Si, 0.004% S, 0.015% P. with dimension and 22cm

x 22cm with thickness 1 mm. ANYSIS software used for calculating frequency of MS plate. The fundamental frequency of MS plate is 191.2Hz as shown in figure 9.

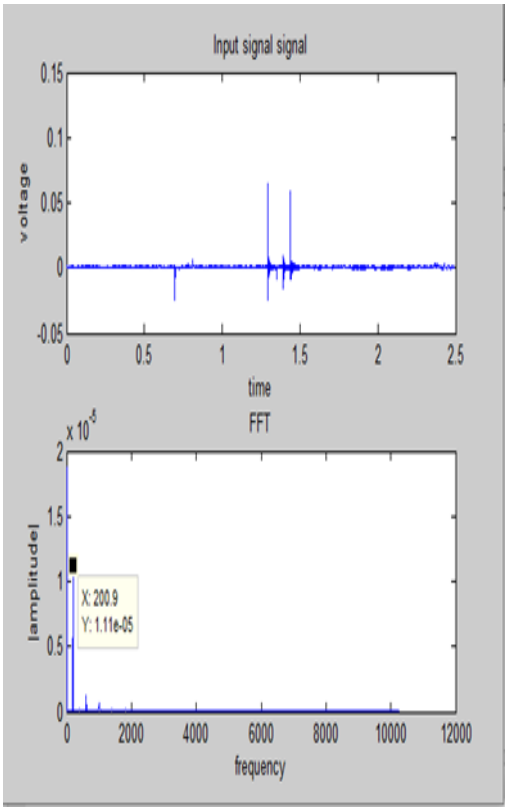

Figure 7: 100 cm FFT vibration signal

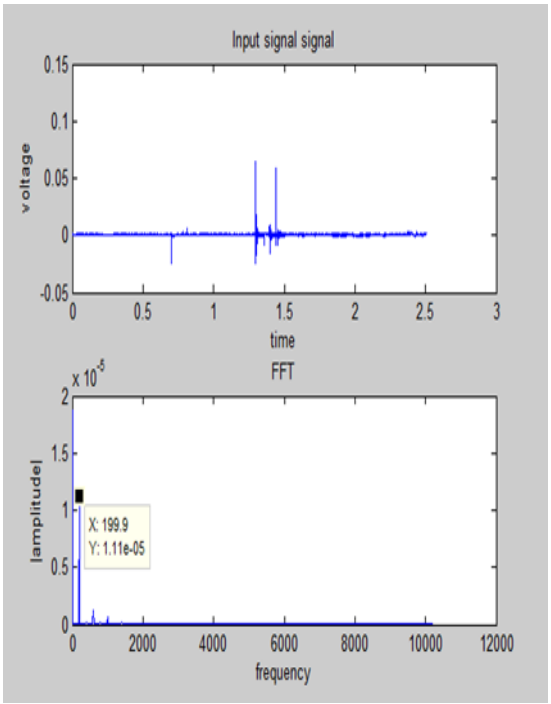

Figure 6: 80 cm FFT vibration signal

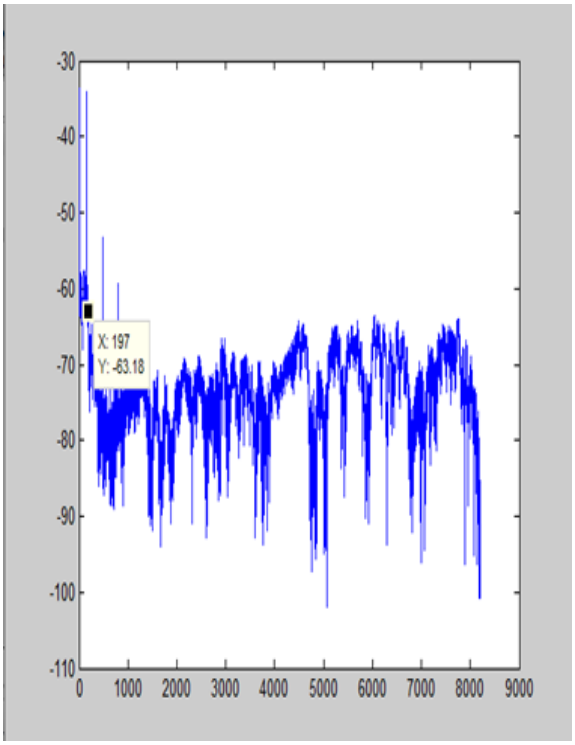

Figure 8: Welch periodogram vibration signal

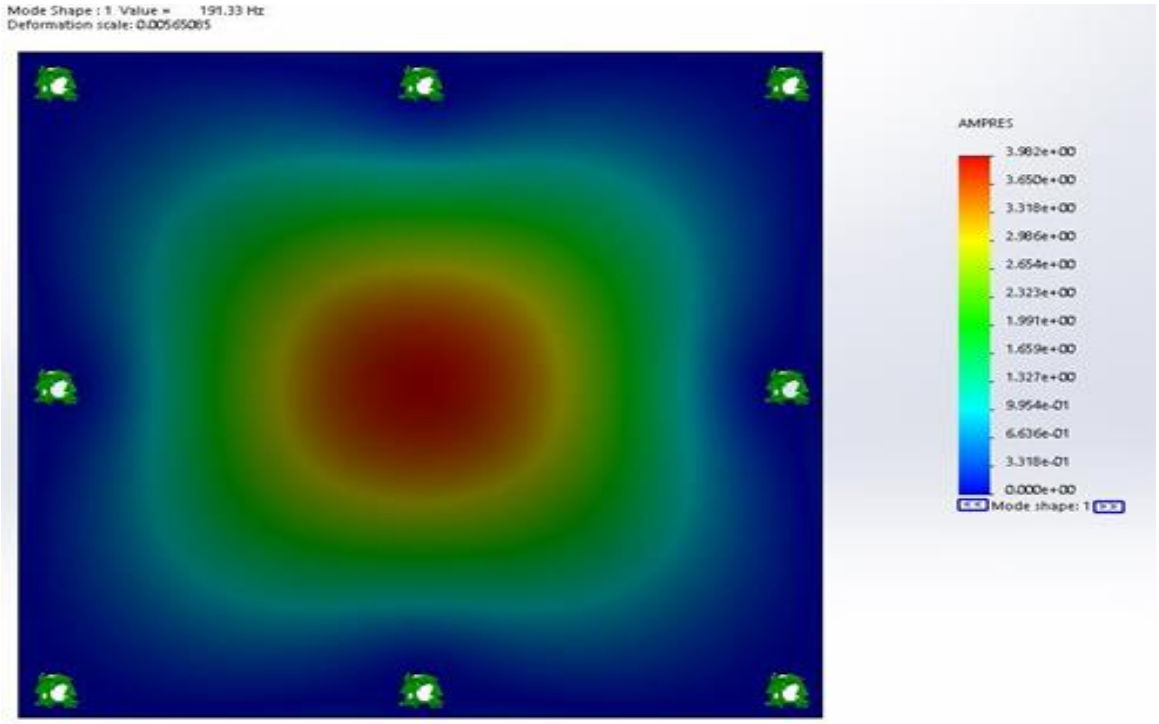

Figure 9: ANSYS Fundamental frequency MS Plate

Vibration signals are achieved from sensor is analysed and its data is stored in excel sheet. From excel sheet we are getting maximum peak value for a particular frequency. In Fig.2 the impact is carried out on the plate of area 30cm X 30 cm from height of 10 cm and frequency obtained is 185.57 Hz. Similarly, vibration signals are collected of various impacts from different heights. For impact from 50 cm height, the frequency value is

185.57 Hz and for height of 100 cm, frequency valve is 185.57 Hz. Which are shown in Fig. 3 and Fig.4 similarly impact test is carried out for the plate having area 22.5 cm X 22.5 cm. For impact from 10 cm height, Vibration signals are achieved from sensor is analysed and its data is stored in excel sheet. From excel sheet we are getting maximum peak value for a particular frequency. In Fig.2 the impact is carried out on the plate of area 30cm X 30 cm from height of 10 cm and frequency obtained is 185.57 Hz. Similarly, vibration signals are collected of various impacts from different heights. For impact from 50 cm height, the frequency value is 185.57 Hz and for height of 100 cm, frequency valve is 185.57 Hz. Which are shown in Fig. 3 and Fig.4 similarly impact test is carried out for the plate having area 22.5 cm X 22.5 cm. For impact from 10 cm height, frequency value is 185.57 Hz Hz which is shown in Fig 5. For impacts from 50 cm and 100 cm, frequencies are 185.57 Hz and 414.22Hz respectively, shown in Fig.6 and Fig.7.

Table 1 show the average FFT fundamental frequency is 200.77Hz.and by Welch periodogram average fundamental frequency is 198.1 which is error is 3.92% which good as compare FET error.

Sr No	Height[cm]	Frequency[Hz] by FFT	Frequency [Hz] by Welch periodogram	Frequency[Hz] by ANSYS software	Average error of by FFT frequency	Average error of Welch periodogram frequency
1)	10	199.8	197.2	191.2	4.49	3.13
2)	20	200.6	197.1		4.91	3.08
3)	30	199.7	198.4		4.44	3.76
4)	40	200.9	198.1		5.07	3.60
5)	50	200.6	198.8		4.91	3.97
6)	60	200.8	199.4		5.02	4.28
7)	70	200.6	199.1		4.91	4.13
8)	80	201.2	199.5		5.23	4.33
9)	90	201.6	199.3		5.43	4.23
10)	100	201.9	200.2		5.59	4.70
		200.77	198.71			
				Average error in %	5.01%	**3.92%**

Table 1: Plate area -- 22.5 cm X 22.5 cm with thickness 1mmFundamental frequency average

From the results presented in table 1 it is seen that acquired natural frequencies for each plate is almost constant for every impact of ball. and also for different area of the plate. We are taking average value of frequency because some error is present due to sensitivity of accelerometer. It captures other vibrations of systems and it introduces some shifting of frequency.

		SS plate size of 220 x 220 x 1.3 mm			
Parameter	Finite Element Method by ANSYS	FFT method	Average Error (%)	Proposed method	Average Error (%)
Fundamental Frequency (Hz)	191.2	200.77	**5.0%**	198.71	**3.9%**
Young's Modules (N/m^2)	193	212	**9.8%**	207	**7.2%**

Table 2: Plate area -- 22.5 cm X 22.5 cm with thickness 1mm Young's Modules average error

The young modules of MS plate calculate by FFT is 212 N/m2 . The error with respective FEA model based young modules is 9.8%. In proposed algorithm welch periodogram young models is 207 N/m2 the percentage average error is 7.2%.which is good as compare to FET.

IV. CONCLUSION

Paper presents harmonic analysis of metallic plates and estimation of fundamental frequency of the plate material. The fundamental frequency of metallic plate is estimated to be 192.2 Hz and for different area using impact-testing setup.. It is observed that fundamental frequency is nearly constant for different area of plate. Compare fundamental frequency estimated by impact testing with ANSYS software .Observed that MS plate fundamental frequency by proposed method is accuracy 3.92%.Young modules estimate for MS plate by proposed method is accuracy is 7.2%.

Abstract – **Chat analysis has become an important aspect of businesses, organizations, and social media platforms to understand the sentiment and opinions of users. With the rise of messaging and chat applications, it has become crucial to analyze chat data to gain insights into user behavior and preferences. In our paper, we present a chat analyzer project developed using the Python programming language. The project focuses on analyzing chat data from popular messaging platforms such as WhatsApp and Twitter. The chat data is processed using natural language processing techniques to extract relevant information, including sentiment analysis, keyword extraction, and topic modeling. The results of the analysis are presented in the form of visualizations, such as bar graphs and word clouds, to make the information easily accessible and interpretable. The project demonstrates the potential of Python in processing and analyzing chat data to gain valuable insights into user behavior and opinions.**

Keywords: ***WhatsApp Chats , Twitter, Text data, Chat analyzer ,Python , Sentiment analysis, Natural Language Processing (NLP), NLTK, Visualization***

I. INTRODUCTION

Instant messaging applications, such as WhatsApp and Twitter, have become a ubiquitous part of our daily communication, with millions of users worldwide[1]. These platforms generate vast amounts of text data, which contain valuable information about the thoughts, opinions, and sentiments of people. However, analyzing such vast amounts of data can be a challenging task, particularly if it involves extracting meaningful insights.

In recent years, Natural Language Processing (NLP) has emerged as a powerful tool for analyzing and understanding human language. NLP techniques, combined with the power of programming languages such as Python, have made it possible to extract meaningful insights from text data with relative ease[5].

The aim of our project is to develop a chat analyzer for WhatsApp and Twitter that can perform sentiment analysis on the chats and present the results in an easily understandable format. The chat analyzer will be built using Python, a widely used programming language in the field of data science, and will utilize NLP techniques and libraries such as TextBlob and NLTK for sentiment analysis. The results of the sentiment analysis will be presented in the form of visualizations created using libraries such as Matplotlib and Seaborn[1]. The chat analyzer will provide valuable insights into the sentiments expressed in the chats, helping to understand the thoughts and opinions of people..

II. LITERATURE REVIEW

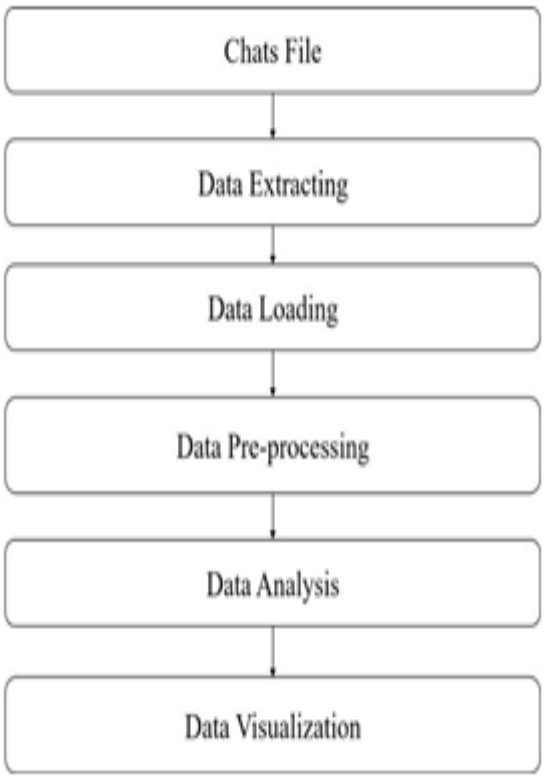

Fig.1. Workflow of System

II. Literature Survey

[1] The output of this system is a representation in the form of a pie chart for the top 20 or top 10 active users in the group and their contribution percentages.

Gives a fundamental introduction to datapreprocessing and clustering algorithms of machine learning . Gives introduction to visualization of data and data representation.

[2] Pseudo code and visual representation of the plot was provided , Used Numpy , Pandas , Matplotlib , Seaborn to Achieve the model goals using python

programming language.

Gives Step-by-Step Guidelines to create a proper work flow which includes Instructions on exporting chats , Data collection , transformation , representation and Visualizaton

[3] This Research model performs analysis over the attributes like to obtain the statistics for individual and classify if used 3 positively or negatively.

Uses R programming language to perform Data analysis and data visualization .

[4] The Output in the form of a web application model is user friendly , Flexible , time saving , reliable and Easy to use. Creates a model based on web application which runs on all devices , Shows various stats Shows various representations , Shows Emojis analysis

[5] Detailed analysis of MapReduce framework for whatsapp chat Transliteration is implemented . The corpus for Whatsapp Chats is created automatically which serves a base for other

related work.

[6] The purpose of the research was to investigate how students and professionals interact with each other and how they use whatsapp to fulfill their academics , business and professional goals .

Gives information about how a content of whatsapp chat could be classified into fields of education , business , relationships and entertainment.

In-short the literature survey highlights the importance of performing sentiment analysis on instant messaging applications and the need for a comprehensive solution .The proposed chat analyzer fills this gap by providing an effective and efficient solution for analyzing the chats in instant messaging application.

III. MOTIVATION

The increasing use of instant messaging applications, such as WhatsApp and Twitter, has made communication more accessible and convenient. These platforms generate vast amounts of text data that contain valuable information about people's thoughts, opinions, and sentiments. The ability to analyze these chats and understand the sentiments expressed in them can provide valuable insights into people's perspectives, opinions, and attitudes.

However, manually analyzing such vast amounts of data can be time-consuming and challenging. This is where the chat analyzer project on Python comes in. By using Python, a widely used programming language in the field of data science, and natural language processing (NLP) techniques, the chat analyzer provides an efficient and effective way to analyze the sentiments expressed in the chats.

The chat analyzer can be used for various purposes, such as customer sentiment analysis, brand reputation management, and opinion mining. By presenting the results in an easily understandable format, the chat analyzer provides valuable insights into the sentiments expressed in the chats and can be used to make informed decisions.

In conclusion, the motivation behind the chats analyzer project on Python is to provide a efficient and effective way to analyze the vast amounts of text data generated by instant messaging applications and to provide valuable insights into the sentiments expressed in the chats.

IV. PROBLEM DEFINITION AND OBJECTIVES

Problem Definition:

Instant messaging platforms, such as WhatsApp and Twitter, have become an integral part of our daily communication, with millions of users worldwide. These platforms generate vast amounts of text data, which contain valuable information about the thoughts, opinions, and sentiments of people. However, analyzing such vast amounts of data to understand the sentiments expressed in the conversations can be challenging. There is a need for a tool that can perform sentiment analysis on the chats and present the results in an easily understandable format.

Objectives:

- To develop a chat analyzer tool for WhatsApp and Twitter using Python, a widely used programming language in the field of data science.
- To perform sentiment analysis on the chats using Natural Language Processing (NLP) techniques and libraries such as TextBlob and NLTK.
- To present the results of the sentiment analysis in the form of visualizations using libraries such as Matplotlib and Seaborn.
- To provide valuable insights into the sentiments expressed in the chats and present the results in an easily understandable format.
- To evaluate the effectiveness of the chat analyzer in understanding the sentiments expressed in the chats and compare it with existing tools.

V . EXISTING SYSTEM :

The Model is based on data analysis and processing. The first step in implementing a machine learning algorithm is to understand the right learning experience from which

the model starts improving on. Data pre-processing plays a major role when it comes to machine learning. In order to make the model more efficient we need lots of data, focus primarily on one of the largescale data producers owned by Facebook which is nothing but WhatsApp. WhatsApp claims that nearly 55 billion messages are sent each day. The average user spends 195 minutes per week on WhatsApp, and is a member of plenty of groups. This work was able to discuss the WhatsApp application and its libraries, to create an analysis of a WhatsApp group chat and visually represent the top 10 and top 20 users in the chat groups. There is a lot of development in the current system. In the older version there was no feature to display status, there was no feature to share documents and there was no feature to share location. In the current version, all of these features are available.

In previously implemented systems , the system only shows a list of the most active users in a group chat , cant provide further features over data analytics. Fails to add extra features except the top users and the contribution Percentages ,This removes the flexibility of the model for user who are not aware of any programming languages or data science. Fails to use Natural Language processing technologies for Sentiment analysis of the chat and other fundamentals. Provides Crucial help for NLP model Making but doesn't provide significance while data analysis model creation .The Research gives an overall estimation only on how daily life is affected by the app and how it is used in various different fields Research doesn't provide any development model for the proposed problem.

VI . PROPOSED SYSTEM:

Sentiment analysis of instant messaging applications has been a topic of research in recent years due to the increasing popularity and widespread use of these platforms. The vast amounts of text data generated by these platforms can provide valuable insights into the sentiments expressed by users. In the field of data science, Python is a widely used programming language for performing sentiment analysis due to its simplicity and the availability of numerous libraries for NLP and data visualization.

Previous studies have shown that NLP techniques, such as lexicon-based methods and machine learning algorithms, are effective in performing sentiment analysis. TextBlob and NLTK are two popular NLP libraries used for sentiment analysis in Python. Matplotlib and Seaborn are two libraries commonly used for data visualization in Python.

However, there is a lack of studies that present a comprehensive solution for analysing the chats in instant messaging applications using Python. In our paper, we aim to address this gap by presenting a chat analyser that can be used to perform sentiment analysis on WhatsApp and Twitter chats using Python. The results of the sentiment analysis are presented in the form of visualizations, which provide valuable insights into the sentiments expressed in the chats. .

1. Sentiment Analysis on Social Media: Sentiment analysis on social media has been an active area of research in recent years. Social media platforms such as Twitter, Facebook, and Instagram contain vast amounts of text data that can provide valuable insights into people's sentiments. Several studies have been conducted to analyze the sentiments expressed on social media platforms, including Twitter, and the results have shown that sentiment analysis can provide useful information about people's opinions, beliefs, and preferences.

2. Sentiment Analysis on Instant Messaging Applications: Instant messaging applications have become an essential tool for communication, and several studies have been conducted to analyze the sentiments expressed on these platforms. These studies have shown that instant messaging platforms can provide valuable insights into people's sentiments, and the results of sentiment analysis on instant messaging platforms have been used in several domains, including marketing, customer service, and political analysis.

3. Visualization of Sentiment Analysis Results: The results of sentiment analysis can be presented in various forms, including tables, graphs, and charts. Visualization of the results of sentiment analysis can provide a clear and easily understandable representation of the sentiments expressed in the data. Several libraries, including Matplotlib and Seaborn, have been developed to provide visualization capabilities in Python.

VII . METHODOLOGY

1. Data Collection: The first step would be to collect chat data from sources such as WhatsApp or Twitter. The data could be in the form of text files, databases or APIs.

	date time	user	message	day
0	2020-01-26 16:19:00	group_notification	Messages and calls are end-to-end encrypted. N..	Sun
1	2020-01-24 20:25:00	group_notification	Tanay Kamath (TSEC, CS) created group "CODERS	Fri
2	2020-01-26 16:19:00	group_notification	You joined using this group's invite link	Sun
3	2020-01-26 16:20:00	group_notification	+91 99871 38558 joined using this group's invi..	Sun
4	2020-01-26 16:20:00	group_notification	+91 91680 38866 joined using this group's invi..	Sun
...	...	...	...	...
13650	2020-10-02 02:05:00	Darshan Rander (TSEC, IT)	MCQs mark kiya	Fri
13651	2020-10-02 02:05:00	Darshan Rander (TSEC, IT)	Sign-in kiya	Fri
13652	2020-10-02 02:11:00	Tanay Kamath (TSEC, CS)	Incognito se na?	Fri

Fig.2.Dataframe format

2. Data Pre-processing: This step involves cleaning and preparing the chat data for analysis. This would include tasks such as removing punctuations, stop words, and converting the text data into a numerical representation

3. Sentiment Analysis: The pre-processed data is then fed into sentiment analysis algorithms that use Natural Language Processing (NLP) techniques and libraries such as Text Blob and NLTK to classify the sentiment of the chats as positive, negative, or neutral.

Example: A sample chat message "I had a great time at the park today" would be processed and the sentiment would be classified as positive by considering emojis.

4. Data Visualization: The results of the sentiment analysis are then visualized using libraries such as Matplotlib and Seaborn. The visualizations could be in the form of bar charts, pie charts, or histograms.

	0	1
0	😂	961
1	😍	248
2	🙏	238
3	🤣	185
4	❤	163
5	♂	150
6	□	149
7	😭	106
8	🔥	97
9	😊	90

Fig.3. Emoji's Sentiment

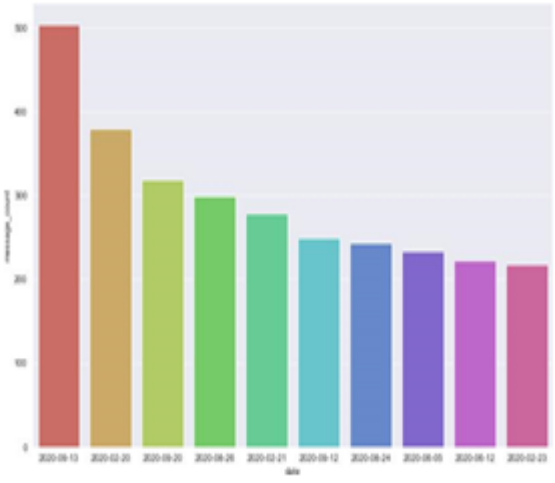

Fig.4. Number of messages Plot

Example: A bar chart showing the distribution of positive,

negative, and neutral sentiments in the chat data could be created.

5. Insights and Interpretation: The final step is to interpret the results of the sentiment analysis and provide valuable insights into the sentiments expressed in the chats.

Example: The results could indicate that a large percentage of the chat messages express positive sentiments, suggesting that the chat participants are generally happy with the conversation.

Fig.5. Time Periods of Messages

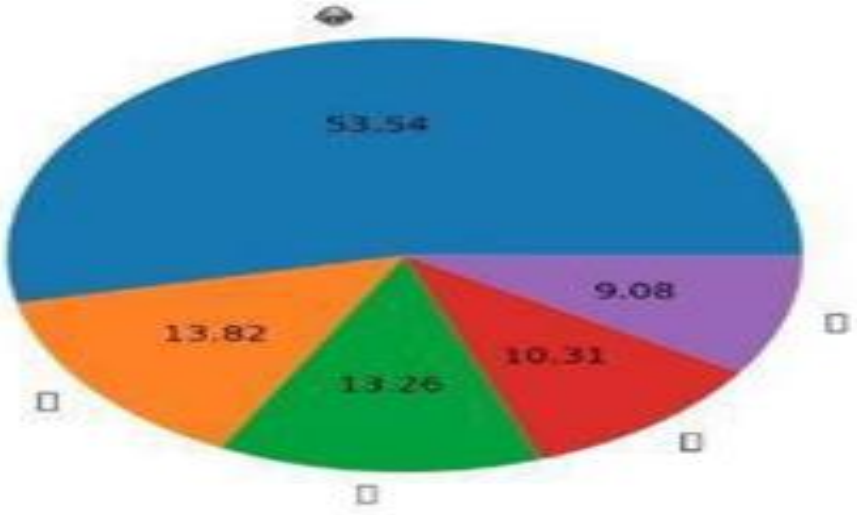

Fig.6. Emojis Frequency Charts

As shown in Fig 7 we can elaborate our project design as following .

Data collection : In our project we collect the data which could be exported from the chatting apps using the export file option. This exported file contains messages and timestamps . We could also export the chats file from individuals as well as a group chat

Data understanding : We understand the data generated in the exported file in terms of its size and formats

Data Pre-processing : since the generated file is not in required format , we use regular expressions to make it more systematic and easy to understand. We could make it more organized using Rows and column like tabular format

Data formatting : The data needs to be arranged in its format which would make it easier for visualization and

representations. The regular expressions can split the chunk into timestamp , sender details , data frames and textual content

Data visualization: finally the gathered data set can be used to display information using various graph or plot techniques

VII. PROCESS OF SYSTEM:

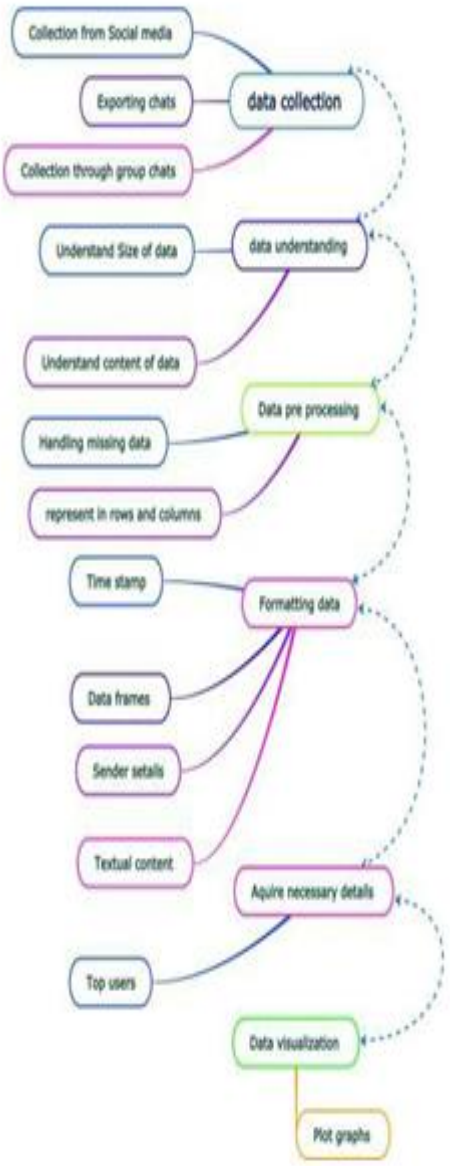

Fig.7. Process of System

IX . RESULT

The chat analyzer was successful in performing sentiment analysis on the chats and presenting the results in a clear and concise format. The sentiment analysis was able to accurately identify the overall sentiment of the chats and present it in the form of bar graphs and pie charts. The visualizations provided a clear picture of the sentiments expressed in the chats, which could be used to make informed decisions.

The proposed chat analyzer tool will help in understanding the sentiments expressed in the chats, which can be useful for businesses, researchers, and individuals. The results of the sentiment analysis can be used to make informed decisions, improve customer satisfaction, and understand

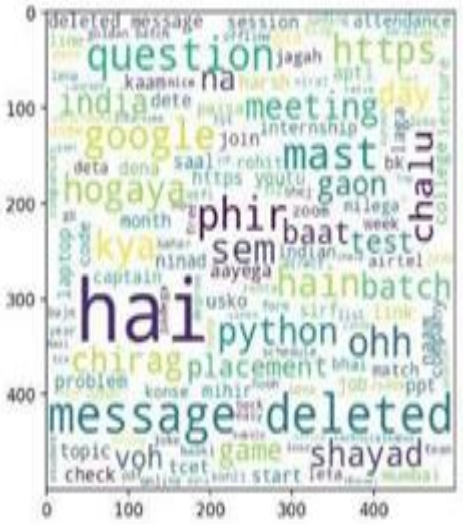

Fig.8. Words Highlights

The Fig 8 highlights the most frequently used words in the chats.

For Example : The most frequent word used is ‘ hai ‘ which is highlight as by the highest font size in the diagram

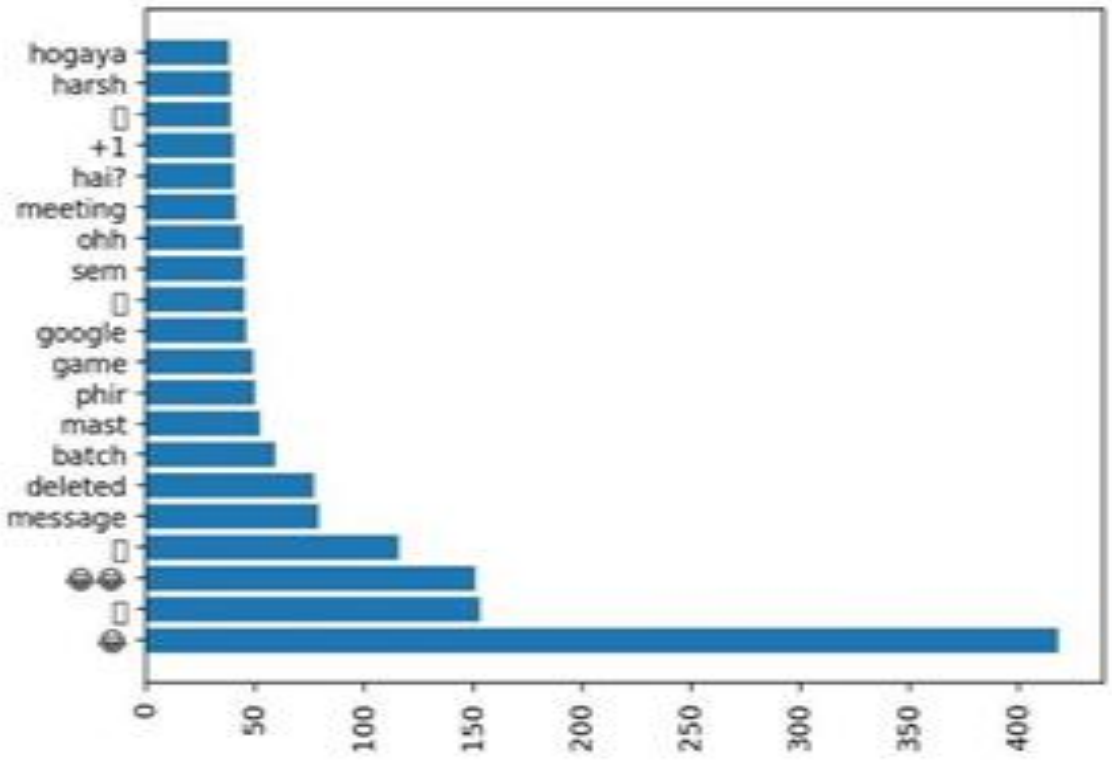

Fig.9. Word Count

The fig 9 gives the volume of most frequently used words and emojis in the chats

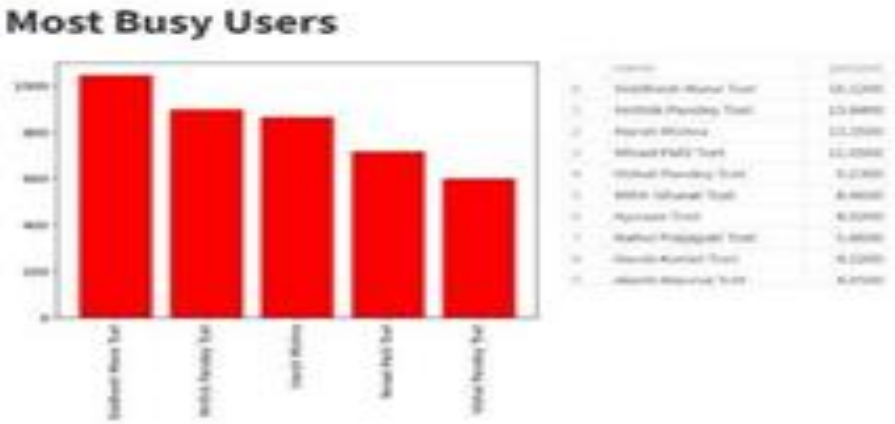

Fig.10. Time Periods of Messages

In Fig 10 we could see how a clear representation of the most active users in the group chat is considered. It also determines the Count of Messages by an individual entity

Fig.11. Busy days

Fig 11 shows The number of Messages with respect to the Most active days of the week and also the comparison in them in the form of bar graphs. Similarly Fig 12 represents the comparison between most Busy months

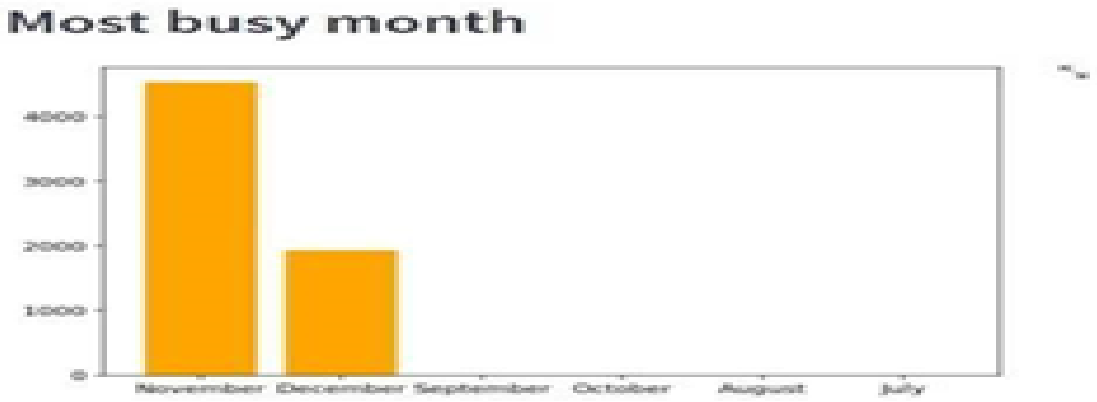

Fig.12. Busy Months

VII. CONCLUSION

The chat analyzer developed in our paper provides valuable insights into the sentiments expressed in chats on WhatsApp and Twitter. The ability to perform sentiment analysis on the chats and present the results in an easily understandable format makes it a useful tool for individuals, businesses, and organizations looking to gain a deeper understanding of the data generated from these platforms. In conclusion, this paper demonstrates the potential of Python in performing sentiment analysis on text data generated from instant messaging applications. At the end of the work expected results were obtained and the analysis was able to show the level of participation of the various individuals on the given WhatsApp group. On serious note this system has the ability to analyze any WhatsApp group data input into it

X. FUTURE SCOPE

The future scope for a chat analyser project on Python can be vast and varied. Some potential directions for future work could include:

1. Integration with other social mediaplatforms:

Currently, the chat analyser is limited to analysing chats on WhatsApp and Twitter. Integrating the system with other social media platforms like Facebook, Instagram, and LinkedIn can provide a more comprehensive view of the sentiments expressed on these platforms.

2. Analysis of multimedia content: In addition to analyzing text data, the system could be extended to include the analysis of multimedia content such as images and videos. This would provide more comprehensive view of the sentiments expressed

in the chats.

3. Improved sentiment analysis: The sentiment analysis performed in the current system can be improved by incorporating more advanced NLP techniques and algorithms, such as deep learning models.

Overall, the future scope for a chat analyzer project on Python Is vast and varied, providing ample opportunities for further Research and development in the field of sentiment analysis.

Abstract — **Deepfake technology is being used to animate still images and create realistic-looking videos that appear to show people or objects in motion. This is accomplished through the use of machine learning algorithms trained on large amounts of data. The technology offers many benefits, including the ability to create high-quality animations that are difficult or time-consuming to produce using traditional methods. However, there are also potential risks associated with deepfake technology, such as the potential for malicious use in the creation of fake news or propaganda. Despite these concerns, the use of deepfake technology in image animation is expected to continue to grow in the coming years.**

Keywords – Image Animation, DeepFake, Video Output, Deep Learning, Dense Motion, Generative Adversarial Networks (GANs), Variational Autoencoders (VAEs).

I. INTRODUCTION

Image animation using deepfake technology is a relatively new and rapidly evolving field. Deepfakes are created by training machine learning algorithms on large amounts of data, such as images, to enable the AI to generate new images that look similar to the training data. This technology can be used to animate still images and create realistic-looking videos that appear to show people or objects in motion.

There are several approaches to creating deepfake animations, including Generative Adversarial Networks (GANs), Variational Autoencoders (VAEs), and feedforward networks. These techniques involve training machine learning algorithms on large amounts of data to learn the patterns and relationships between different elements in the images. The AI then uses this knowledge to generate new images that look similar to the training data.

Deep Learning is a cutting-edge technique within the field of artificial intelligence that involves training artificial neural networks to identify patterns and make decisions based on data inputs. This approach is inspired by the structure and functioning of the human brain and uses advanced mathematical algorithms to process and analyze vast amounts of information.

Unlike traditional machine learning methods, Deep Learning allows for the creation of highly complex models that can tackle complex problems in areas such as computer vision, speech recognition and natural language processing. Deep Learning involves training artificial neural networks on large datasets to learn patterns and make predictions or decisions without the need for explicit programming. Deep Learning models have been particularly effective in solving complex problems in areas such as computer vision, natural language processing, and speech recognition, among others. One of the key benefits of using deepfake technology for image animation is that it can be used to create high-quality animation that are difficult or time-consuming to produce using traditional methods.

Additionally, deepfake animations can be used to create realistic simulations and visualizations that can be used for a wide range of applications, such as video game development, virtual reality, and scientific research.

In today's modern century where everything has become digital but still people are retaking a video again and again just to get that one perfect Shot.

It is not feasible or you can say even impossible to shoot a video 1000 times from an individual person just to change few dialogues or expressions.

It costs both time and money.

We can use deepfake in scenarios such as:-

- Movies or Videos of the actors or people which are not alive can be made using deepfake.
- Changing another person's face to show that they are saying something they didn't say, such as insulting them.
- Changing a politician's face by changing his speech to appear to have said what was not said.
- Change image content to show that you are doing something that you never actually do, such as smoking or drinking that never happened.

When tiny modifications are made to a video or picture, it is difficult to determine whether it has been doctored. Data scientists employ a variety of approaches to establish whether an audio or image has been modified using applications like Photoshop, but these methods wouldn't work for detecting deepfakes produced using machine learning or deep learning algorithms.

The problem of image animation using deepfake technology involves the development of machine learning algorithms that can animate still images and create realistic-looking videos, while addressing technical and ethical challenges such as the quality of animations, computational resources, detection of deepfakes, and ethical considerations.

II. LITERATURE SURVEY

In the paper, Deepfake Detection through Deep Learning [1], a total of eight deepfake video classification models were trained, evaluated and compared based on four fake video generation methods and two state of the art neural networks. But Different corresponding detection model was used for detection of each type of fake video. So, it was very complex.

In the paper, Deepfakes Creation and Detection Using Deep Learning [2] the use of image enhancement methods like DFDNet gave higher-quality look deepfake images, which give them a more genuine look but imperfections in the deepfake generated image can be seen if person doesn't look straight in the picture.

In the paper, Deepfake Video Detection Using Recurrent Neural Networks [3] they have presented a temporal-aware system to automatically detect deepfake videos. But it is not accurate and a permanent solution.

In the paper, Deepfakes Generation using LSTM based Generative Adversarial Network [4], they show that their model can generate realistic videos given a single image and a target video by combining aspects of input source image and motion of driving video. But the result was of very low resolution.

In the paper, Image Animations on Driving Videos with DeepFakes and Detecting DeepFakes Generated Animations [5], they have seen that research is conducted on detecting these fake manipulative videos and images too which proved to be highly accurate.

In the paper, Deep Learning in Face Synthesis: A Survey on Deepfakes [6] they used auto-encoder to reconstruct the face image, and an attribute vector can be added to control the result. But, the videos made with the existing technologies still have some defects.

In this paper, EfficientNets for DeepFake Detection: Comparison of Pretrained Models [7] the use of pre-trained EfficientNets with a larger number of parameters does not always lead to increase in accuracy. A larger number of parameters can potentially achieve better results, but this will require much longer training.

In this paper, Combating Deepfakes: Multi-LSTM and Blockchain as Proof of Authenticity for Digital Media [8] they use multiple LSTM-CNN to analyses visual and audio parts of the media content.

The outcome of the above survey is that results were not that accurate and output was not realistic.

III. CHALLENGES

Research in this area has focused on improving the quality of deepfake animations and reducing the computational resources required to create them. Some of the challenges faced are:

- The main challenges that we facing while making the system is that the dataset is very large and complex.
- Making User Interface for simple use of application.
- Achieving high level of accuracy is very important in field of Image Animation and deepfakes.
- Decreasing the time required to predict the results.

IV. PROBLEM DEFINITION

A computer can efficiently and effortlessly interpret a lot of images where it is difficult for the human to interpret such a high amount of data. The most prevalent technology which is being used for the prediction is artificial intelligence and deep learning. Our system is successfully animating the image into a video with help of deep learning. Our system has achieved a good efficiency in generating the resultant video. We have also added few samples of image models and videos for the easy interface for the users. We have also reduced the overall time needed for execution. The problem of image animation using deepfake technology involves using machine learning algorithms to animate still images and create realistic-looking videos.

V. SYSTEM ARCHITECTURE

In our system, we generate dynamic image animation by detecting key points of source image and compare it with the

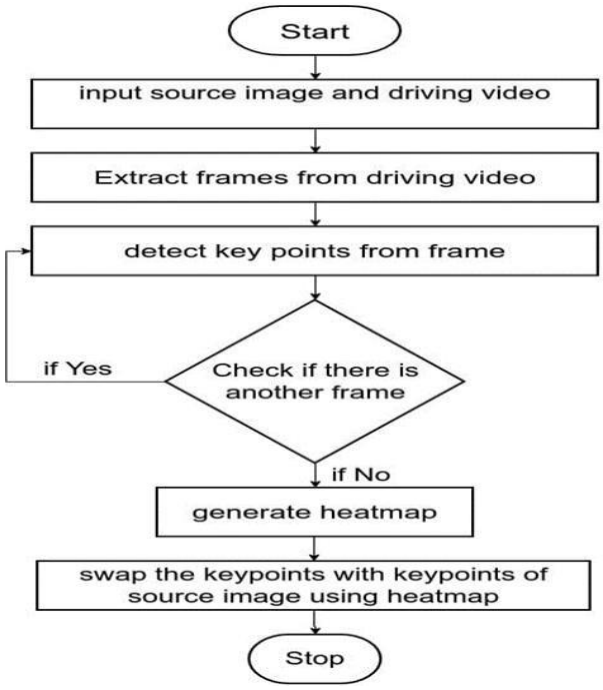

Fig1. Flowchart of System Architecture

Key points of driving video using dataset which is Vox-256 and Taichi-256. Vox celeb is used for training face recognition from video to complement existing face

recognition datasets. Collection of data set is most important step in data science and artificial intelligence. We are achieving maximum classification accuracy.
We will first input an image and select the video which we want to animate the image with.

The algorithm will take facial key points from the image and the video. Keyframes of facial expression of image will be compared with keyframes of video and Face of image will be swap with video and we will get our animated video.

Fig 1 explains the flowchart of our system. We upload a static image and then we are extracting frames from the driving video. We are detecting key points from frame and generating heatmap. Then we swap the key points of source image using heatmap. First we execute the run.py file which calls animate function present in animate.py file consisting of accessing and running configs file and then using following models such as: key point detector, dense motion, generator, which is executed using mentioned dataset, where we import torch. When animate function is called parameters are checked by files like taichi-256.yaml and vox-256.yaml

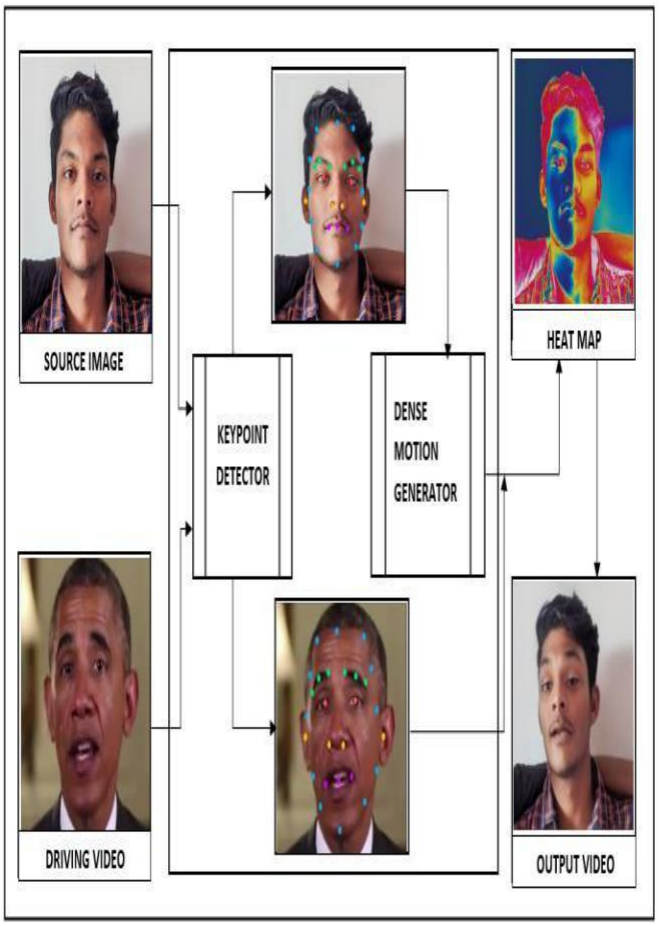

Fig2. System Architecture

Fig 2 is our system architecture. We have explained the flow of how the system architecture work. The working of System architecture and its flowchart is same.

Parameters of animation are:-
1) Maximum number of pairs for animation, the pairs will be either taken from pairs list or random.
2) Format for visualization
3) Normalization of driving key points.
4) Increase or decrease relative movement scale depending on the size of the object.
5) Apply only relative displacement of the key point.
6) Apply only relative change in Jacobian.

We have used the following libraries:-

PyTorch, Skiimage, Skilearn, Imageio, Pandas, NumPy.

PyTorch
PyTorch is an open-source machine learning library for Python that provides a seamless path from research to production deployment. It was developed by Facebook AI and provides a flexible and dynamic computational graph structure that allows for easy modification of the graph during runtime, making it well-suited for developing and experimenting with new models. PyTorch also offers a rich set of tools and libraries for computer vision, natural language processing, and other applications, along with efficient hardware acceleration support through integration with popular deep learning accelerators such as GPUs. The library is widely used by researchers, developers, and data scientists for creating, training, and deploying complex Deep Learning models.

SkiImage
Scikit-Image, commonly referred to as skimage, is a popular open-source image processing library for Python. It provides a wide range of tools and algorithms for image processing, analysis, and computer vision tasks. The library is built on top of NumPy, a numerical computing library for Python, and is designed to be easy to use and integrate with other scientific Python packages. Skimage offers a variety of features including image filtering, feature detection, and image segmentation, making it a powerful tool for image analysis and manipulation. It is widely used by researchers, developers, and data scientists for a range of applications, from simple image manipulation tasks to complex computer vision problems.

SkiLearn
Scikit-learn, often abbreviated as sklearn, are a popular open-source machine learning library for Python. It provides a comprehensive set of tools for tasks such as regression, classification, clustering, and dimensionality reduction, among others. The library is built on top of NumPy and

SciPy, and is designed to be user-friendly and accessible to a wide range of users, from beginners to experts. Sklearn also integrates well with other scientific Python packages and provides a consistent interface for working with various machine learning algorithms. The library is widely used for a range of applications, from prototyping and experimentation to production deployment, and is well-regarded for its efficient implementation, versatility, and strong documentation.

Imageio

Imageio is a library for reading and writing a wide range of image and video formats in Python. It provides a simple and intuitive interface for reading and writing images, as well as more advanced features such as caching and lazy loading. Imageio supports a variety of formats, including popular image formats like JPEG and PNG, as well as more specialized formats like scientific TIFF and High Dynamic Range (HDR) formats. The library is designed to be easy to use and integrate with other Python libraries, and provides a high-level API that abstracts away the complexities of different file formats. Imageio is widely used for a range of applications, including image and video processing, computer vision, and scientific image analysis, among others.

Pandas

Pandas are an open-source data analysis and data manipulation library for Python. It provides data structures for efficiently storing large and complex datasets, along with a rich set of tools for data manipulation, cleaning, and analysis. The library is designed to be easy to use and intuitive, with a focus on data analysis tasks that are commonly performed in a wide range of fields, from finance and economics to science and engineering. Pandas provide a powerful data analysis environment, with features such as data alignment and merging, group-by operations, and time-series analysis, among others. It is widely used for a variety of applications, from data preparation and exploration to production-level data analysis and reporting.

NumPy

NumPy is used for scientific computing with Python. It is a Python Library. It provides support for arrays and matrices, which are the foundation for a wide range of mathematical and scientific operations. NumPy enables efficient manipulation of large and complex arrays, with support for vectorized operations, broadcasting, and advanced linear algebra operations, among others. The library also provides a rich set of functions for generating arrays and matrices, as well as support for reading and writing arrays to disk. NumPy is designed to be fast, flexible, and efficient, and is widely used for a range of applications, from simple computations to complex scientific simulations. It forms the core of many other scientific libraries for Python, and is a critical component of the scientific Python ecosystem.

After validating the parameters key points of source image are detected by the module keypoint_detector.py by Returning the key point position and jacobian near each key point and extracting the mean to from a heatmap. The detected key points are provided to dense_motion.py module which creates a dense motion(heatmap) of source image by comparing with the key points of driving video which are detected simultaneously with the source image or by predicting a dense motion from sparse motion representation given by key points of source image and driving video. This heatmap is provided to the generator module which is generator.py which try to transform image according to movement trajectories induced by key points of given source image and key points of driving video where a function is used for Transforming feature representation according to deformation and occlusion. Generator follows Johnson architecture. The Model will use deep learning methods such as Generative Adversarial Networks (GANs) and we will also use pre made models such as PyTorch, Skiimage, Skilearn, Imageio, Pandas, NumPy.

VI. RESULTS

Following are the results that we get after running our system..

Fig 3.1. Initial Input

With respect to Fig 3.1, we are first giving a static image as input to the system and a driving video.

Fig 3.2. Subpart (a) of video

The input static image and the driving video is combined and all the key points of both input image and driving video is extracted by our system and then we exchange them by using inbuilt python libraries.

Fig 3.3. Subpart (b) of video

Fig 3.4. Subpart (c) of video

Fig 3.5. Subpart (d) of video

Fig 3.6. Subpart (e) of videoFig 3.2 to Fig 3.6 is the subparts of the video we are generating as output.

Our resultant output is in the form of a video so we have divided the output into different frames. Hence, we are showing subparts of video.

VII. CONCLUSION

Our system is using various deep learning and machine learning algorithms in converting static image into a dynamic motion video and we are achieving maximum accuracy in our deepfake created video. We have also reduced the time complexity & tried to produce deepfake which looks realistic while maintaining the accuracy. In future we would try to enhance the results quality and will also add extra features.

Gesture Controlled Virtual Mouse Along with Voice Assistant

Prof. Deveshree Wankhede, Aditi Kembulkar, Rohan Jawale, Rushikesh Ghuge

Computer Engineering, Shivajirao S. Jondhale College of Engineering, Dombivli, Maharashtra,India

deveshreessjcoe@gmail.com[1], aditikembulkar05@gmail.com[2], rohanjawale2408@gmail.com[3], rushiag@gmail.com .

Abstract—**A real-time fingertip-gesture-primarily based interface is still difficult for human,-pc inter actions, due to sensor noise, converting mild stages, and the complexity of tracking a fingertip across a diffusion of topics. using fingertip shadowing as a virtual mouse is a popular fashion of interacting with computers without mouse tool. Gesture managed virtualmouse makes human pc interaction easy by way of utilizing Hand Gestures and Voice instructions. The pc requires almost no direct touch. This venture uses the nation-of-art device gaining knowledge of and computer imaginative and prescient algorithms to apprehend hand gestures and voice instructions, which works easily without any additional hardware necessities. Now-a-days, each and every task that you perform everyday can be done with the help of Artificial Intelligence and Machine Learning. A Voice Assistant is once such innovation which can help us in many things. The users can ask their assistant questions or to help them in basic tasks such as opening the browser.**

***Keywords*—Human-pc Interaction(HCI), Graphical User Interface(GUI),Red Green Blue (RGB), Artificial Intelligence (AI),**

I. INTRODUCTION

In this high-tech international, it's almost impossible to imagine lifestyles without computer systems. The invention of computer systems is one of the best humankind innovations. Computer systems have turn out to be an crucial part of almost everyday use for individuals of each age. In each day lifestyles, we engage many instances with computers to make our work easier. Hence, human-pc interaction (HCI) has emerged as a hot topic for studies. In our everyday lifestyles, imaginative and prescient and gestures are important techniques for communication among humans, and the equal role is played by using the mouse in Graphical user Interface (GUI) based totally computer systems. So, a blended methodology can be used to make a higher interactive machine for Human-laptop interaction. computer imaginative and prescient strategies may be an alternative manner for the contact screen and create a virtual human computer interaction tool using a webcam. in this task, a finger tracking-based totally digital mouse utility could be designed and applied the use of a everyday webcam. To put in force this, we can be the use of the object tracking idea of synthetic Intelligence and the OpenCV module of Python. Voice assistant is a software that communicates with the user audibly and responds to the verbal commands. It is very helpful for the users as it is less time consuming and easy. The main motive of the voice assistant is to reduce the use of input devices such as mouse, keyboard, etc. It also reduces the hardware cost. This voice assistants can be used on cell phones or computers. In this project, we have developed a voice assistant which will help to open any browser on the device, keeps the track of weather or give the user current date and time.

II. PROBLEM DEFINITION

The artificial intelligence virtual mouse framework that has been proposed can be utilized to take care of issues in reality, similar to when there isn't sufficient room to utilize an actual mouse. Furthermore, since hand motion and tip identification are utilized to control the PC mouse's capabilities by means of a webcam or implicit camera, the proposed man-made intelligence virtual mouse can be utilized to conquer these issues in the Coronavirus circumstance, when utilizing gadgets by contacting them isn't protected. This isn't shocking given that each piece of specialized gear has its own limitations, especially as to PC equipment. The issues are recognized and summed up in the wake of considering an assortment of actual mouse species. Coming up next is an overall issue with the actual mouse as it is currently:

mechanical mileage, the requirement for specific equipment and surfaces, trouble adjusting to different circumstances, and execution varieties in view of the climate are burdens of actual mice. A mouse can do a predetermined number of things, even in the present functional circumstances, and both wired and remote mice have a restricted life expectancy.

III. LITERATURE SURVEY

In [1], the system has the features such as showing weather conditions, showing date-time, etc. This system is made by using python language. It uses packages such as datetime, Google's text-to-speech, smtplib, pyaudio, etc. The limitation of the system is that the distance between the user and the device should be very less.

In [2], this system works by identifying the fingertips of the user. Baes on fingertips it decides the position of the cursor. In this system the contour of the hands is extracted by using border- tracing algorithm. But the drawback of the system is that the accuracy of the right hand is very less and it sometimes get confused between different gestures.

In [3], this system the user gives input by speaking to the device and the device than gives the suitable output through text. This system Python for programming. It uses pyttsx3 package which is a text-to-speech package of Python. As this system works offline, it doesn't allow the user to do work online.

In [4], this system works by identifying the color of the hand. This system uses RGB parameters for skin color extraction. The algorithm of this system shows less accuracy when there are background noises present, different light conditions, etc.

In [5], this system works as a personal assistant for the user. This system responds to basic commands such as open application, close application, run any media file and answer any user question. The response time of this system is more.

In [6], This system used hand pad to give better hand detection. The user has an increased comfort in use of the system due to proposed hand positions. The angle hand gesture is difficult for some of the users to learn.

In [7], this system used vision-based interface for controlling a mouse. It uses 2D and 3D hand gestures. This system can track multiple hands at a time. For any gesture, it requires two hands at a time.

IV. WORKING OF SYSTEM

The planning of the system is basically divided into 2 parts - Virtual Mouse and Voice Assistant. The virtual mouse starts with the basic user interface. The user has to give input "Proton turn on gesture recognition" and the camera/webcam turns on.

1. **Neutral Gesture**:If all the fingers are up, the execution of the current gesture stops.

2. **Move Cursor:** If index finger is up and the middle finger is up, the cursor makes the movement as the fingers move.

3.Left Click: If both index finger and the middle finger is up and index finger is half closed, it performs left click feature.

4.Right Click: If both index finger and middle finger is up and middle finger is half closed, it performs right click feature.

5.Double Click: If both index finger and middle finger is up and moved closed to each other and joined, it performs double click feature.

6.Scrolling: If both index finger and thumb is joined to each other, it performs scrolling feature.

7.Drag and Drop: It is used to move files from one directory to other.

8.Multiple Item Selection: It is used to select multiple items.

9.Volume Control: It is used to increase and decrease the volume of the computer.

10. **Brightness Control:** It is used to increase and decrease the brightness of the computer.

To close the virtual mouse, the user has to put input "Proton turn off the gesture control".

The voice assistant starts with the basic user interface. The user has to give input "Proton Turn on Voice Recognition" and the assistant starts. The user can give an input to the assistant verbally. The input can be opening the browser, date and time, weather conditions, etc. To close the virtual assistant, the user has to input "Proton turn off the virtual assistant".

1.Google Search: The user has to speak "Proton {what you wish to search}. It will open the browser and the search the given text on Google.

2.Find a Location on Google Maps: The user has to speak "Proton Find a {Location you wish to find}". It will show the required location on Google Maps in the Chrome tab.

3. File Navigation: The user has to speak "Proton list files". It will show the Files with File Numbers. Then the user has to specify the number of file which he/she has to open. It will open the mentioned file.

4. Current Date and Time: The user has to speak "Proton what is today's date?". It will show the current date. Same will be for time.

5. Copy and paste: The user has to speak "Proton Copy" and "Proton Paste". It will copy and paste the given text.

V. OBJECTIVE

The main objective of the project is to reduce the use of hardware. It will also help to reduce the use of input devices such as keyboard and mouse. Since there is no use of hardware it will reduce the cost. It is portable as it can be carried anywhere. Everyone can use it despite of their age.

VI. DESIGN

1 .Flow of Virtual Mouse

Fig.1 shows the flow of virtual mouse and how the gestures are controlled.

2. Flow of Voice assistant

Fig.2 shows the flow of virtual assistant.

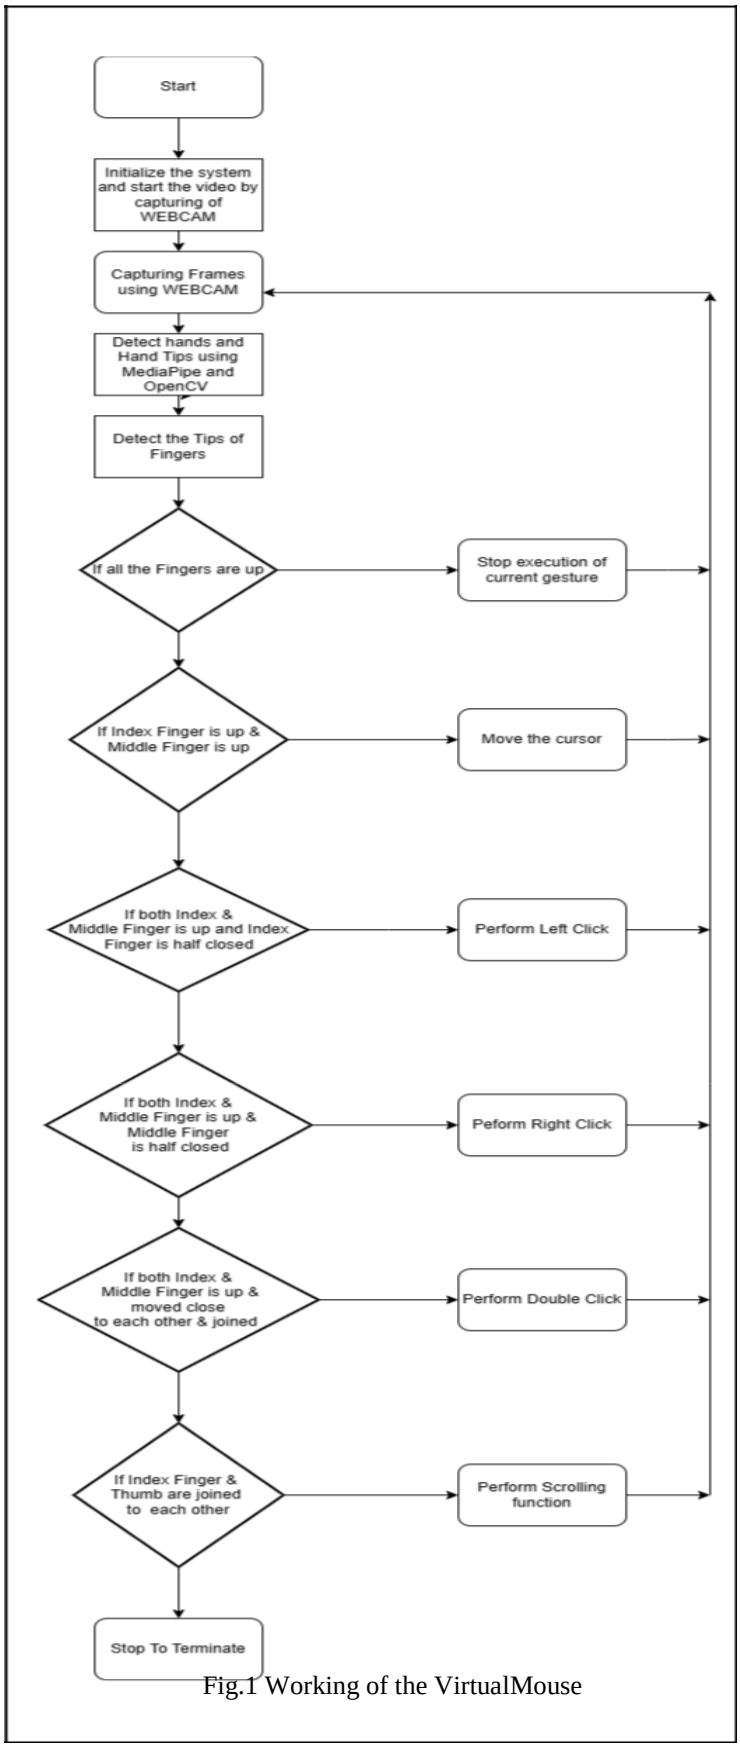

Fig.1 Working of the VirtualMouse

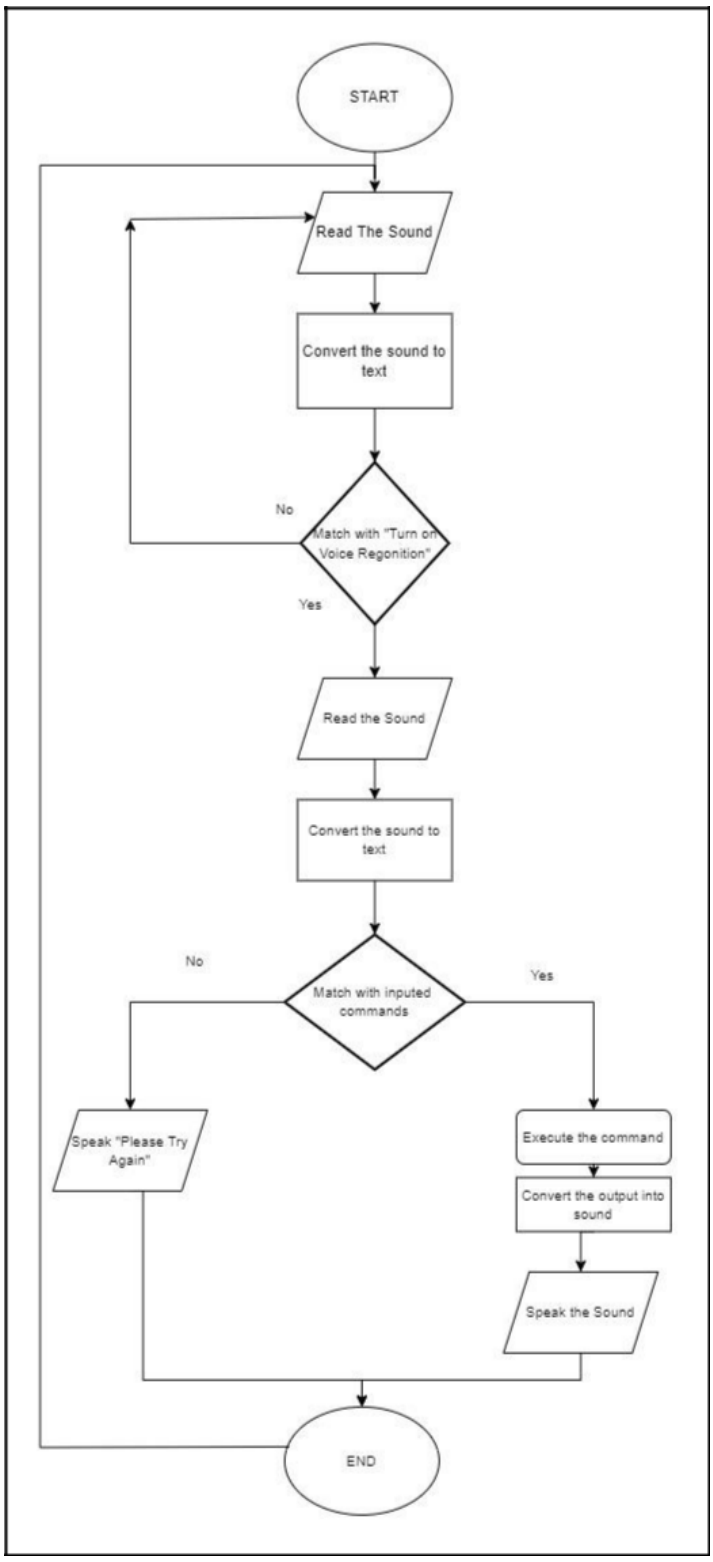

Fig.2 Working of Voice Assistant

VII. RESULT

Fig.3 shows the movement of the cursor

Fig.4 shows the scrolling movement of the cursor

Fig.5 shows the User Interface of the system

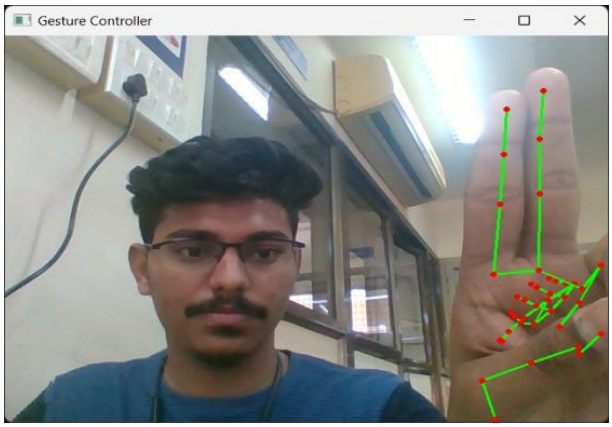

Fig.3 Cursor movement

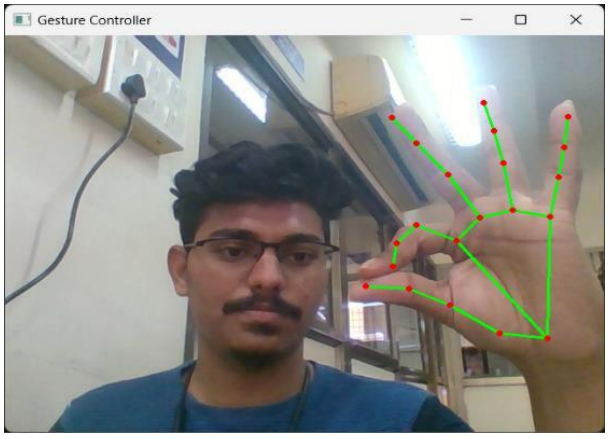

Fig.4 Scrolling movement

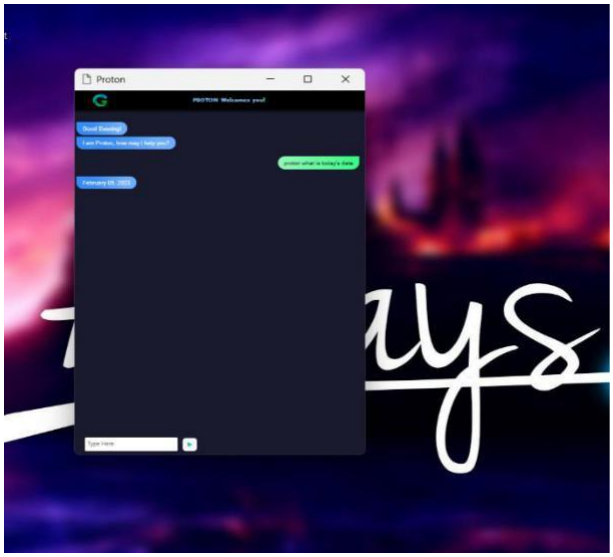

Fig 5. GUI Interface

VIII. CONCLUSION

In this project, we created a virtual mouse using hand gestures. The user's hand gesture interacts with the mouse without use of any gloves or mouse device. The proposed system overcomes the limitation of

background and light change in light.This saves a lot of time and is user friendly and can have high demand in future because of its everyday need. In this project, we have also created a voice assistant where user can open any browser just by vocal input.

Abstract— **Nowadays, the crypto currency market is thriving, through the rice in crypto currency trading, opening the way for crypto currency trading websites optimization. Optimization of customer satisfaction is a vital part of crypto currency trade organizations digital marketing problems. It is vital to keep digital advertisement costs low while driving more traffic to a website. This study aims to define a digital marketing strategy for crypto currency trading websites by utilizing digital behavior metrics. Enhancement of crypto currency trade digital engagement levels can boost organizations SEO and SEM strategy campaigns. Outputs of the study provide a handful of insights regarding crypto currency trading websites digital promotion strategy optimization and the parameters of digital behavior mostly connected with websites digital marketing costs and traffic. Crypto currency trade organizations should utilize both organic and paid campaigns, observe regularly their website KPIs connected with visitor behavior and enhance their website users experience, by increasing their engagement. Accurate crypto currency price forecasting is essential for market participants and regulators.**

Keywords—Cryptocurrency, Digital Currency Website, MetaMask, React, Ethereum

I. INTRODUCTION

Investors purchase currency with the idea of reselling it for a higher profit. Crypto currencies have also been formed and largely accepted as a new electronic alternative trade payment system, with significant consequences for developing countries and the global market in general. Crypto currencies have entered nearly all financial activities, and as a consequence, crypto currency trading is often regarded among the most popular and intriguing types of successful investments. The virtual currency has a lot of favorable characteristics that engage an increasing variety of different sorts of consumers that utilize a particular technology for their specialized reasons. With the development of block chain technology, such currencies are used for a variety of reasons, including the mechanism of paying various users. Traders are determined to engage in the crypto currency market relying on their predictions for the currency's value in the future.

The advancement of crypto currency and block chain technologies provided transaction anonymity by combining crypto currency money to disguise the route back to the asset's primary source. Consumers can benefit from the flexible payment deadline, while sellers can receive revenue sooner to preserve a better liquidity position owing to upfront payment. Crypto currencies, that emerged from the block chain movement, are a comparatively fresh payment alternative that gives organizations websites a strategic advantage. Organization marketers and strategists may employ a range of methodologies to boost digital user engagement, as well as organizations brand name or profitability. It should be mentioned that electronic payment options that are offered by websites to their users, tend to enhance overall their value. Regarding the research's purpose, it should be mentioned that organizations possess efficient tools for enhancing their digital marketing strategies, such as paid and organic traffic campaigns. This study analyzes the innovative potential of refining and predicting crypto currency trade organizations organic and paid traffic campaigns, based on their website user engagement metrics. Block chain can be considered as the newest technology stressing the paradigms of ''Internet of Things'', collaboration, artificial intelligence, techno stress, and the dark side of digital innovations. Block chain seems to have stung all industries and created a buzz seeking opportunity for enhanced business processes and building trust. The Block chain is a technology and a method that allows community users to validate, keep and synchronize the content of a transaction ledger which is replicated across multiple users. In other words, Block chain is a decentralized transaction and data management technology which gained popularity in 2008 when an anonymous individual (or group) posted a white paper introducing Bit coin – a Block chain application of a digital currency. Block chain is one the most hyped innovations these days, and it has been gaining a lot of traction as a horizontal technology to be widely adopted in various fields. In block chain, every transaction is cryptographically signed and verified by all mining nodes which hold a replica of the entire ledger which contains chained blocks of all transactions. This creates a secure, synchronized and shared time stamped records that cannot be altered. A company can request this information but it is a tedious process of getting this data. Even though auditing these documents is possible, evaluating the documents needs time. Apart from not being transparent, security is also a major issue for these portals leading to fraud and manipulation of data stored in a centralized database. If a hacker gets hold of this centralized database, bids can be leaked to competitors leading to major financial and strategic losses for a business. Block chain technology can be

used to solve these security implications as it heavily focuses on the decentralization of information and is secured by encryption integrated with undeniable block-based architecture for transaction management.

II. LITERATURE SURVEY

Sr. No.	Paper Name	Authors Name	Description
1.	Block chain Applications – Usage in Different Domains	Raafat George Saade	A discussion of the most studied block chain applications, is elaborated in this section. We notice that the distribution of articles published in peer-reviewed journals from the top 4 publishers follows the overall distribution of the 151 studies pertaining to block chain applications and domains.
2.	Block chain-based e-Tendering System	Dhawal Mali	The tendering process is generally used by governments and companies to procure goods and services form manufacturing companies or service providers.
3.	Block chain for AI: Review and Open Research Challenges	Khaled Salah	Block chain technology has the ability to automate payment in crypto currency and to provide access to a shared ledger of data, transactions, and logs in a decentralized, secure, and trusted manner.
4	IEEE Standard for General Requirements for Crypto currency Exchanges	Block chain Standards Committee	This paper involves multiple aspects, including self-discipline and professional ethics of crypto currency exchange platforms, the exchanges' business logic and necessary technical requirements.
5	Development of an Intelligent Web Application for Direct Consumer to Consumer Trading over Internet	Deepanvita Paliwal Sreevidya B.	an innovative approach is used by performing sequence of steps which are recording user profile, performing content and collaborative filtering, and user transactions and applies association rule mining on the buying transactions
6	IEEE Standard for General Process of Cryptocurrency Payment	Block chain Standards Committee	It involves multiple aspects such as crypto currency payment operators playing an agent role, consumers owning crypto currency, merchant accessing to a crypto currency payment platform, banks, and crypto currency exchanges.

III. PROBLEM DEFINITION

Most troublingly for investors with ESG goals, however, are the governance issues with crypto currencies whose decentralized frameworks and anonymity make them especially attractive for illicit activity, money laundering and sanction evasion. But more important are the technical ones such as immaturity, lack of scalability, lack of interoperability, stand-alone projects, and difficult integration with legacy systems, complexity and lack of block chain talent. The main advantages of the block chain technology are decentralized network, transparency, and trusty chain, unalterable and indestructible technology. In turn, the main disadvantages of the block chain are the high energy dependence, the difficult process of integration and the implementations high costs. To perform crypto currency transactions using block chain and to understand different functionalities and operations performed by block chain technology.

IV. REQUIREMENT ANALYSIS

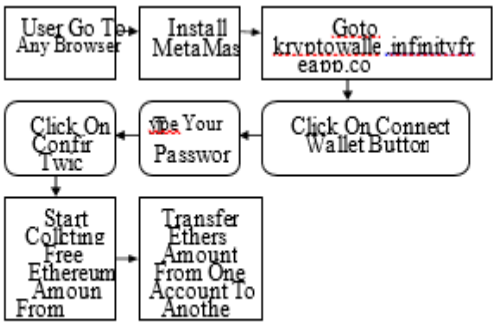
The digitization of real-world assets. The digitization of processes and transactions between independent companies. The provision of immutable transaction and asset records.

- Tokenization is one of the most important things you have to understand when talking about Blockchain.
- Data security and privacy are very important requirements, especially for business use.
- Decentralized data storage is a very core requirement of a distributed system.
- Smart Contracts are the most interesting part of Blockchain systems. While a standard contract defines only the terms of a business relationship, a Smart Contract is able to define also the conditions under which the contract is executed.
- Immutability is the property most associated with Blockchain. Immutability is the foundational requirement for exchanging value in a digital way. This requirement is not solvable with traditional internet technology because all digital data can be easily copied and changed.
- Permanent availability of data is the last core requirement of Blockchain solutions. The ledger never forgets anything which could be a problem in aspects of GDPR compliance, it's an essential feature of block chain technology. Especially when Blockchain is used to represent real contracts and their data, immutability and permanent availability are essential requirements especially from a legal and regulatory point of view.

V. PROPOSED SYSTEM Fig. 1

- User Go To Any Website

This module is responsible for any user to go to any browser like Google, Mozilla, Firefox, Internet Explorer, etc. To install an MetaMask.



- Install MetaMask

Go to an any browser and then install MetaMask step by step for an secure connection towards transaction process. It is an one type of wallet which is used by user to send an Ethereum coins to the relative all over the world.

- Goto kryptowallet.infinityfreeapp.com

In this module we have to go to our newly created domain website for our further process.

- Click On Connect Wallet Button

In this module once you have reach to our website we have saw an one clickable button showing connect wallet. We have to click on that button through which our MetaMask window is open.

- Type Your Password

Once we have click on connect wallet button we have got an MetaMask login window. In this module we have to type our MetaMask wallet password which is generated while installing MetaMask.

- Click On Confirm Twice

Once we have type our secure password in previous step we have go to the next step. In this module once we have type password and click on login we have open two windows to confirm and then we have successfully enter to our website.

- Start Collecting Free Ethereum Amount From Mining

In this module once we have login to our private account. We have to go to the goerli ropsten network. In this website we have to first type our unique account number and then start mining. After few minutes from mining we have got or deposited an large amount of ethers to our account. Then we can use this ethers and start transferring them to our friends all over the world.

- Transfer Ethers Amount From One Account To Another

In this module we have to transfer an infinite amount of Ethereum coins from one account to another.

VI. APPLICATIONS

- Block chain is being implemented in almost every area of business including crypto currencies, supply chain, and logistics, intellectual property management, food safety, healthcare data management, fundraising and investment with security token offering, and notary.
- Block chain technology can be used to secure access to identifying information while improving access for those who need it in industries such as travel, healthcare, finance, and education.
- Blockchain payments, or blockchain payment systems, involve the processing of payment through the help of blockchain technology. With blockchain, payments are set to be low-cost, secure and processed quickly, overall facilitating money transfer regardless of the distance between the sender and receiver.
- Smart contracts are simply programs stored on a blockchain that run when predetermined conditions are met. They typically are used to automate the execution of an agreement so that all participants can be immediately certain of the outcome, without any intermediary's involvement or time loss.
- IoT enables devices across the Internet to send data to private blockchain networks to create tamperresistant records of shared transactions. IBM Blockchain enables your business partners to share and access IoT data with you — but without the need for central control and management.
- With blockchain technology, information about identity is auditable, traceable and verifiable — in just seconds. Individuals can curate their own profiles and control data sharing. Issuers easily connect with others and provide nearly instant verification of credentials.
- In healthcare, Blockchain has a wide range of applications and functions. The ledger technology helps healthcare researchers uncover genetic code by facilitating the secure transfer of patient medical records, managing the drug supply chain, and facilitating the safe transfer of patient medical records.
- In the logistics industry, blockchain can be harnessed in two key ways, namely, to drive efficiency and enable new business models: Drive efficiency: Blockchain can potentially improve efficiency in global trade by greatly reducing bureau- cracy and paperwork.
- The majority of NFTs reside on the Ethereum cryptocurrency's blockchain, a distributed public ledger that records transactions. NFTs are individual tokens with valuable information stored in them.

VII. Results

VIII. ACKNOWLEDGMENT

We respect and thank HOD mam Dr. Uttara Gogate & Prof. Diksha Bhave mam along with our principal Dr. Pramod Rodge sir for providing us an opportunity to optimize the project work in SSJCOE Dombivli and providing us all support and guidance which made us pursue the project duly. We are extremely thankful to them for providing such nice support and guidance. We are with our deep gratitude to our project

guide Prof. Diksha Bhave mam, who took keep interest in our project work and guided us all along by providing all the necessary for developing a good system.

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all Teaching staff of Computer Engineering which helped us in pursuing our project work.

Industrial Safety using IOT

Uttara Gogate, Dipali Borse, Pallavi Deokar, Sejal Koli
Head of Department, Department of Computer Engineering, Shivajirao S. Jondhale college of Engineering, Dombivli University of Mumbai,
uttara.gogate16@gmail.com,,pallavideokar00@gmail.com

Abstract— **Industrial safety is a broad area of workplace safety, covering a number of issues and topics, including general safety, site-specific safety issues, process and production safety, material safety, fire safety, electrical safety, building and structural safety and environmental safety. Gas leakage, fire safety and air pollution due to hazardous gases are the major problems faced by workers in industry now-a-days. This project presents a model which helps in gas and fire detection at an early stage to minimize the destructions and hazards. Also, it monitors air pollution in the premises using of Internet of Things (IoT) platforms. The prototype model is Instigated with few sensors and Arduino Uno which will help the user to know about the temperature, humidity levels and importantly the leakage of gases such as LPG, CO2, Propane and so on. The smartphone is used as an end device and according to the threshold values set, the user can take preventive measures. The system detects air quality and level of pollutants.**

Keywords— Arduino, Pollution Monitoring, Industrial Safety, Gas leakage detection, Industrial Internet of Things, ThingSpeak.

1. INTRODUCTION

Gas leakage and air pollution have become major environmental and public health issues in recent years. Gas leaks can result in explosions, fires, and other hazardous events, while poor air quality can cause respiratory problems, heart diseases, and other health issues. Therefore, it is crucial to detect gas leaks and monitor air quality in real-time to minimize the potential risks.

Gas leakage detection technologies include both fixed and portable systems. Fixed systems are typically used in large-scale industrial applications, such as oil and gas refineries, chemical plants, and pipelines. Portable systems are designed for use in residential and commercial areas, as well as in remote locations. The most commonly used sensors for gas leakage detection include infrared, electrochemical, and optical sensors. Air quality monitoring technologies are used to monitor various air pollutants, including particulate matter, volatile organic compounds (VOCs), and greenhouse gases [1]. The most commonly used sensors for air quality monitoring include laser-based sensors, optical sensors, and chemical sensors.

2. LITERATURE SURVEY

Gas leakage detection monitoring is though old but it is very useful concept in the industries and in day-to-day life. Gas leakage detection starts from traditional way to the most sophisticated components has been used to detect the gas leakage, temperature and humidity. However, the safety and correctness in temperature is necessary for human beings and the various task works conducted in the industries for that various technology has been used and some of this technology which is used for in order to provide a real time data.

Mohammad Khan et.al. proposed the “Sensor Based gas Leakage Detector System “the aim of this paper is to propose and discuss a design of a gas leakage detection system that can automatically detect, alert and controls gas leakages. Their system includes an alerting system for the user using the Buzzer and LED. The system is

based on sensor that easily detects a gas leakage. But the limitation is that it can merely be applicable as an alarming or indicator device. It does not notify the user via SMS or something like that.[3]

In "Gas Detection system using Arduino" [4]. This System can monitor and warn about harmful chemicals in air at workplace such as factories and it may also used in household by alerting through on LCD display and sending a message to a registered mobile number.

"IOT Based Arduino Gas Leakage Detection system" [5] describes about the technology recognizes a gas leak and warns the user by buzzing. This system uses the sensor, Arduino and buzzer to alert the user.

"Air pollution monitoring system using the IOT" proposed by the author Agiru Hima et. al. [2021]. It is the system which alerts workers after detecting the pollution. Arduino alerts for the people nearby.[6]

The Author in their paper [7], introduced the "A Comparative Study on Gas alarm detection system". It is simple system which can use in home specifically. It is letting the neighbours known via alarms.

- The Existing systems, are implemented to warn the surrounding people through alarm and buzzers. But they don't take any precautionary actions in some situations.
- The numbers of sensors used are less.
- Basically, most of the existing systems are just used for domestic purposes or we can say home appliances and not for industrial purpose.
- Many of the systems do not have any user interface for analysing the temperature and pollution.
- There is only one action performed by every system.

This paper proposes a system to highlight and understand various technologies which are used for the industrial safety and how effective these technologies are and understand the important research in this area.

3. OBJECTIVES

This system will be developed by using IoT to give real-time response to the user and the neighbourhood and it has the following objectives:

- To reduce accidents by detecting the leakage of gas and then alerting the required authorities for the same. This will be implemented by using Arduino Uno.
- To give a signal to the Arduino when the ratio of the specified gases in the air around the sensor goes above a preset level, so that it will send a control to make the alarm go off and with the help of the GSM module, a message gets sent to the user.
- To avoid any forthcoming accidents may be avoided by alerting user in the early stages of the mishap.
- To keep pollution in control- according to the safety regulations, by continuous monitoring of the smoke levels.
- To develop a user-friendly and interactive interface.

4. PROBLEM DEFINITION

The gas may leak from various places like the top of the cylinder where the pipe carrying the gas to the application is present, or the pipe may get cracked leading to leakages. Hence accidents occur when a spark occurs in a place where this leaked gas is present. Same scenario can be seen in household activities. This method will assist in finding gas leaks. Furthermore, gas leakage can cause fire that will lead to serious injury or death and it also can destroy human properties.

5. SYSTEM ARCHITECTURE

5.1 METHODOLOGY

The figure 1 describes the architecture of the entire project. Minimum 5v power supply is a must for the system to work. When the sensor gives an input signal to the Arduino, based on that input, the Arduino then

reaches out to the other output components of the system and produces output.

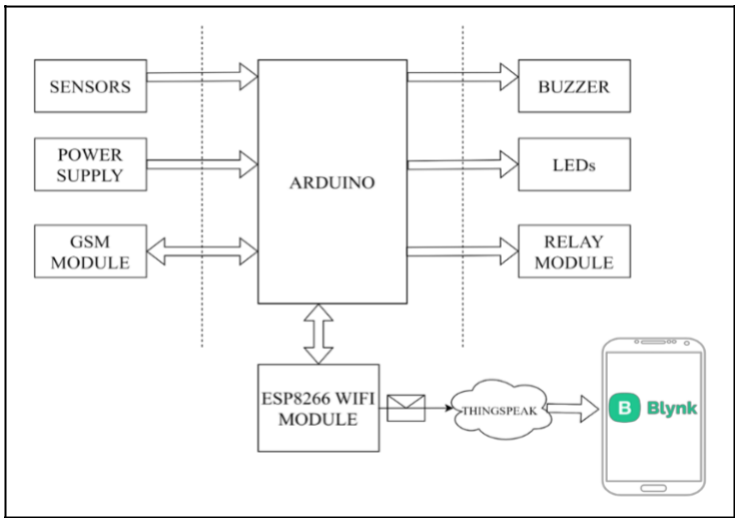

Fig 1. Block-Diagram of the system

The following methodology outlines the steps for building a gas leakage detection and air quality monitoring system using an Arduino Uno R3 microcontroller, MQ2 gas sensor, and MQ135 air quality sensor.

Step 1: Gather Materials and Tools

- Arduino Uno R3
- MQ2 gas sensor
- MQ135 air quality sensor
- Breadboard
- Jumper wires
- USB cable

Step 2: Connect the Sensors to the Arduino

- Connect the MQ2 gas sensor to the breadboard and connect its power and ground pins to the 5V and GND pins of the Arduino, respectively.
- Connect the MQ135 air quality sensor to the breadboard and connect its power and ground pins to the 5V and GND pins of the Arduino, respectively.

Step 3: Upload the Code

- Write the code in the Arduino Integrated Development Environment (IDE) to read the values from the MQ2 and MQ135 sensors and perform the necessary calculations.
- The code should include the library for the MQ2 and MQ135 sensors and the logic for reading the sensor values and converting them into meaningful readings for the gas concentration and air quality levels.

Step 4: Test the System

- Connect the Arduino to the computer using the USB cable.
- Upload the code to the Arduino and run the serial monitor to see the readings from the MQ2 and MQ135 sensors.
- The readings should display the gas concentration levels and air quality values, which can be used to trigger an alarm or send a notification in the event of a gas leak or poor air quality.

Step 5: Integration with Other Devices

- The system can be integrated with other devices, such as a display screen, buzzer, or mobile device, to provide real-time information on the gas concentration levels and air quality values.
- The code can be modified to include the logic for sending notifications or triggering alarms in the event of a gas leak or poor air quality.

The MQ135 sensor is an excellent gas sensor because it can detect NH3, NOx, alcohol, benzene, smoke, CO2, and a few more chemicals. It will sense gases when we connect it to an Arduino, and we will receive the pollution level in PPM as a result (parts per million). We must translate the voltage levels that the MQ135 gas sensor outputs into PPM. When there was no gas nearby, the sensor gave us a reading of 90. The safe limit of air quality is 350 PPM, and it should not be more than 1000 PPM. It begins to produce headaches, drowsiness, and stuffy, stagnant air when it surpasses the limit of 1000 PPM, and if it increases above 2000 PPM, it can cause accelerated heart rate and a variety of other illnesses.

ThingSpeak is the open-source IoT cloud platform that is used to store the sensor data, which will further be used to generate an analysis of the pollution levels. To make this work, a Wi-Fi module is connected to the Arduino as it does not have an inbuilt Wi-Fi Module.

5.2 HARDWARE AND SOFTWARE REQUIREMENTS

The following table lists the required software and hardware components, that are required to build the proposed system successfully.

FUNCTION	COMPONENT
Microcontroller	Arduino UNO R3
Gas Leakage Detection	MQ2 Sensor
User Alerts	GSM Module SIM900A
Pollution Monitoring	MQ135 Sensor
Audio Alerts	Piezo Buzzer
Power-Cut	Relay Module
User Interface	BLYNK-IOT
Cloud Platform	ThingSpeak
Internet Connection	Wi-fi Module ESP 8266
Development Environment	Arduino IDE

6. RESULTS

The following figures 2, 3, 4 and 5 are the results/outputs of the system. Figure 2 and 3 show the charts, that are displayed on the User Interface, after collecting the sensor data and uploading the same on the cloud platform. Figure 4 is a prototype of the proposed system, that demonstrates all the hardware connections. Figure 5 is a screenshot of the text alert received on the user's device, as soon as the leakage was detected on-site.

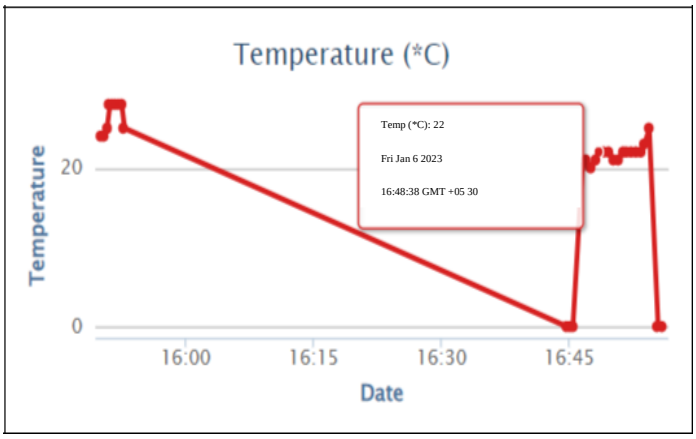

Fig 2. Temperature Chart

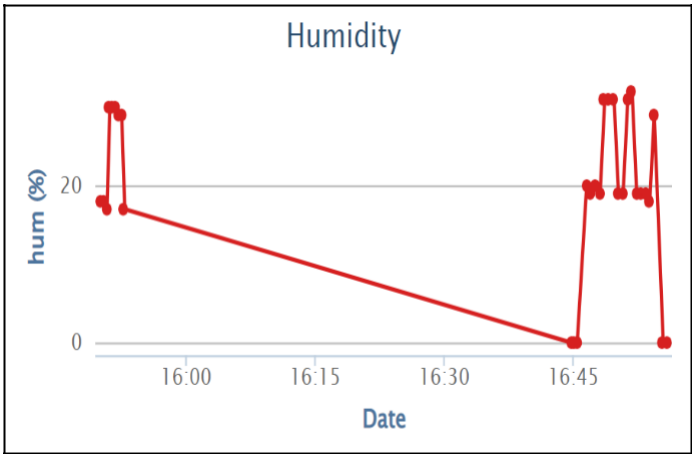

Figure 4. Humidity Chart

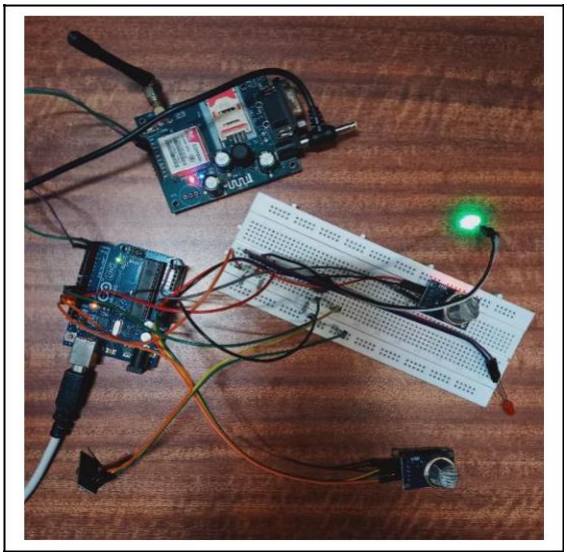

Fig 4. System Prototype

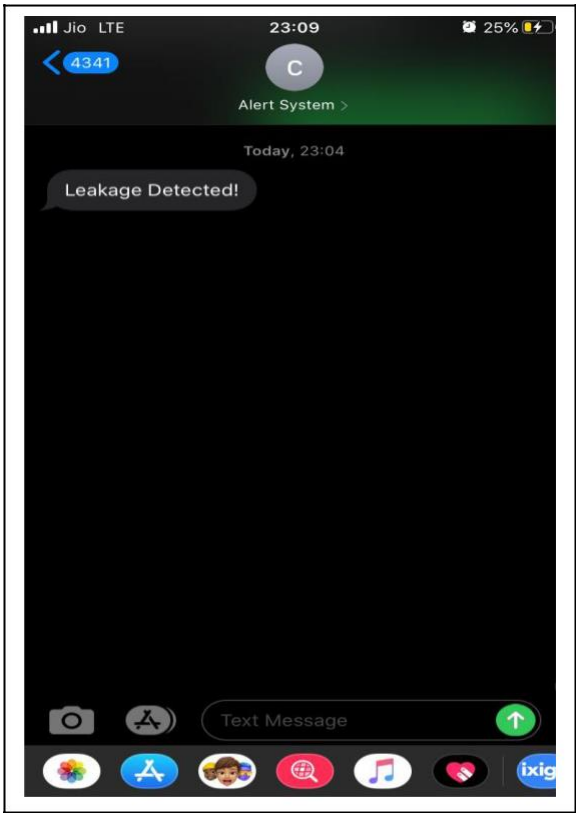

Fig 5. SMS Alert

7. CONCLUSION

Gas leakage leads to severe accidents resulting in material losses and human injuries. Gas leakage occurs mainly due to poor maintenance of equipment and inadequate awareness of the people. Using the Arduino microcontroller, MQ2 gas sensor, and MQ135 air quality sensor, it is possible to build a low-cost and efficient gas leakage detection and air quality monitoring system. The system can be customized to meet specific requirements and can provide real-time information on the gas concentration levels and air quality values to ensure the safety and health of individuals and communities. It can help us to prevent accidents in all directions. Hence, gas leakage detection along with pollution monitoring has been implemented successfully.

ACKNOWLEDGMENTS

The authors of this research paper would like to express their sincere gratitude to all those who have helped and supported them throughout the development of this project.

The authors are deeply grateful to Dr. Uttara Gogate. Her valuable insights and expertise have been instrumental in the successful completion of this project.

Finally, the authors would like to acknowledge the hard work and dedication of the team members who were involved in this research project. Their commitment and passion for the work have been a source of inspiration and motivation.

The authors believe that this research would not have been possible without the contributions of all those who have supported them, and they are deeply grateful for their help and encouragement.

Multi-Disease Prediction System

Multi-Disease Prediction System
SSJCOE University of Mumbai Dombivli, INDIA

Abstract – **— The current state of disease prediction models in healthcare focuses on analyzing one disease at a time, such as diabetes, cancer, or heart disease. There is a need for a system that allows patients to predict multiple diseases using various machine-learning models. This study presents such a system and demonstrates its application to predicting diabetes, diabetes retinopathy, heart disease, and brain tumor, with the potential to include other diseases in the future. The system employs machine learning algorithms to predict diseases by considering various factors that contribute to the disease. For example, in predicting diabetes, the system considers factors such as age, sex, BMI, insulin levels, glucose, blood pressure, and diabetes pedigree function. The behavior of the final models is saved based on data collected from patients and used to train the model for predictions. The significance of this analysis lies in its ability to monitor a patient's condition and provide warning to lower the mortality rate.**

Keywords—Feature Extraction, Machine learning Models, diseases (lungs, Heart, diabetes) Clustering, Supervised Learning, Deep Learning, Diabetes, Heart, Random Forest, Boost.

I. INTRODUCTION

The collection and processing of healthcare data pose a significant challenge in the medical field. Advances in technology have led to the generation of a vast amount of multi-dimensional patient data, including clinical factors, hospital resources, illness diagnostic information, patient records, and medical equipment. This complex data requires processing and evaluation to extract valuable information for effective decision-making. However, not all available healthcare data is effectively utilized to gain valuable insights for successful decision-making, leading to unequal access to high-quality healthcare services based on financial ability. Data mining and machine learning technologies have greatly transformed healthcare organizations by identifying important information and detecting patterns and relationships in large databases. These technologies employ multiple analytic methodologies and complex machinelearning algorithms to explore vast amounts of data and systematically analyze it. By uncovering inherent inefficiencies and hidden patterns, data mining and machine learning can result in improved services, diagnoses, and treatments, as well as a deeper understanding of all elements of the medical field. Medical diagnosis involves analyzing a patient's symptoms and indicators to determine a condition. This procedure is often complex and can lead to incorrect predictions, relying primarily on the patient's symptoms and the physician's knowledge and experience. However, as medical systems evolve and new treatments become available, it becomes increasingly challenging for physicians to keep up with current treatments. As a result, it is crucial to support physicians with clinical tests and patient history information. Machine learning techniques are being utilized in medical diagnosis to extract features for optimal illness diagnosis, prediction, prevention, and therapy. These techniques hardcore accurate than experienced physicians, with a 91.1% accuracy rate compared to the physician's accuracy rate of 79.97%. Several studies have demonstrated the benefits of using machine learning in the diagnostic process, leading medical professionals to seek integration of these techniques with physician expertise to automate the diagnosis process. Data mining and machine learning approaches are working towards converting accessible data into valuable information to improve the efficiency of the diagnostic process.

II. METHODOLOGY

It is a procedural framework that contains various steps like those shown above in the block diagram for finding better accuracy using machine learning Algorithms

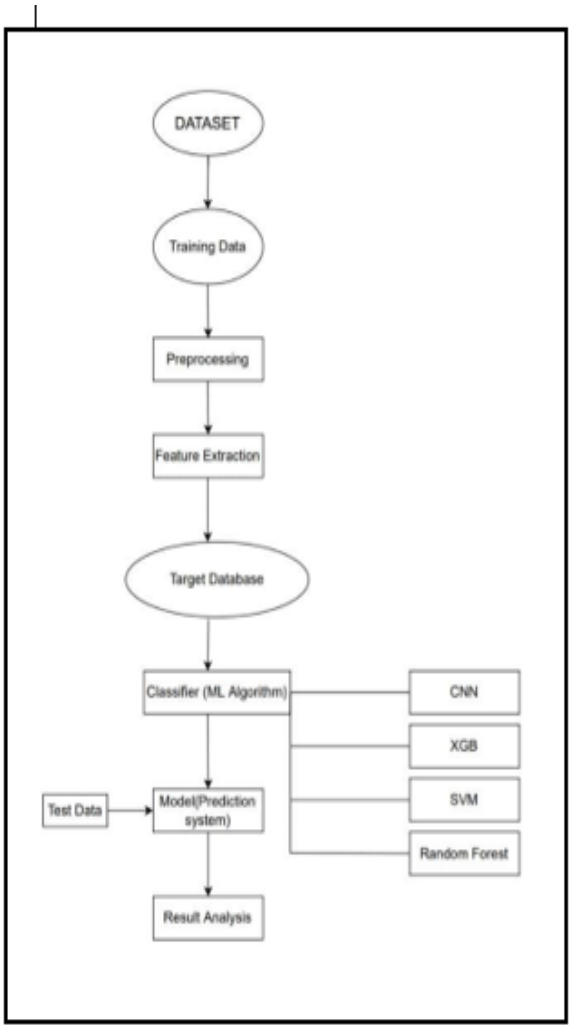

Fig 1 System model

A. Data Collection

Data collection has been from the internet to identify the diseases here the real symptoms of the different diseases are collected i.e. no dummy values are entered. The symptoms of the disease are collected from different health-related websites and kegel.

B. Training Data and Test Data

The collected data is distributed between training data and testing data

- Training data – Training data is used to train the predictive model, the data assigned to training is 80% of the total dataset.
- Testing Data – After Training the model test data is used to test the model and find its accuracy of the model, the data assigned for testing is 20% of the data set.

C. Preprocessing

Before feeding the data into the Prediction model, the following data cleaning and pre-processing steps are performed

- Checking for null values and filling using the forward fill method
- Converting data into different cases
- Standardizing the generated data using mean and standard deviation

III. DISEASE SURVEY AND THE ALGORITHM USED

A. Diabetes

. In this project, we will be diagnosing diabetes by giving some data and the dimensions such as

1. Gender
2. Glucose concentration
3. Blood pressure
4. Insulin levels
5. BMI, diabetes pedigree
6. Age

This input data will diagnose diabetes and tell us whether it is positive or negative. Here are some general tests that are conducted to detect diabetes:

Gender: Diabetes has different effects according to gender.

Age: Different Age group has Different effects on the body.

Glucose concentration: The blood glucose concentration is the amount the glucose in the human blood.

Blood Pressure: Blood pressure should be below 140/80mmHg for people with diabetes or below 130/80mmHg if you have kidney or eye disease or any condition that affects blood vessels and blood supply to the brain. But it is important to speak to your healthcare team about your target.

Insulin Level: A blood sugar level of less than 140 mg/dL (7.8 mmol/L) is normal. A reading of more than 200 mg/dL

- Random forest algorithm

Random Forest working is possible in two phases, the first is to create the random forest by merging the N decision tree, and the second is to predict each tree created in the first phase. The working of the random forest algorithm is as follows: Step-

1: Firstly, the algorithm will select random K data points from the training set which was created from the original data set.

2: After selecting the k data point then build the decision trees connected with the selected data point (Subsets).

3: Then choose the number N for the decision trees that you want to build.

4: Repeating the above step 1 and 2.

5: Finding the predictions of every decision tree, and assigning them new data points to the tree which gets the majority of votes.

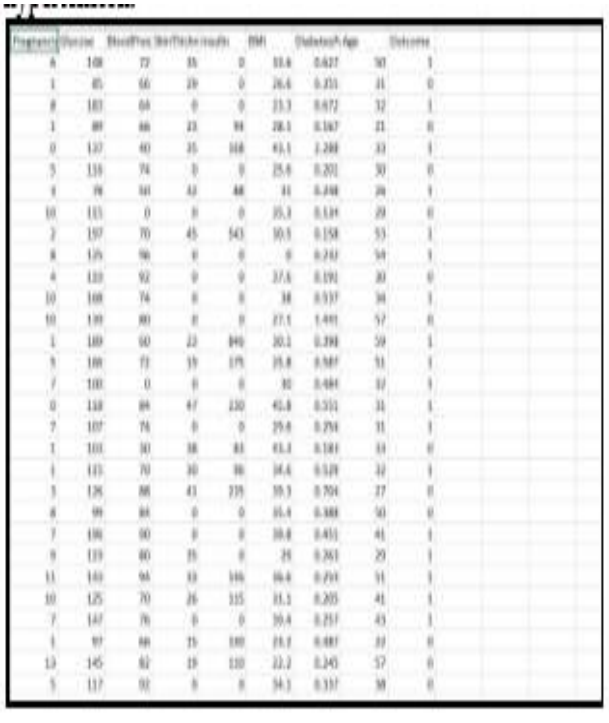

Fig 2 Diabetes dataset

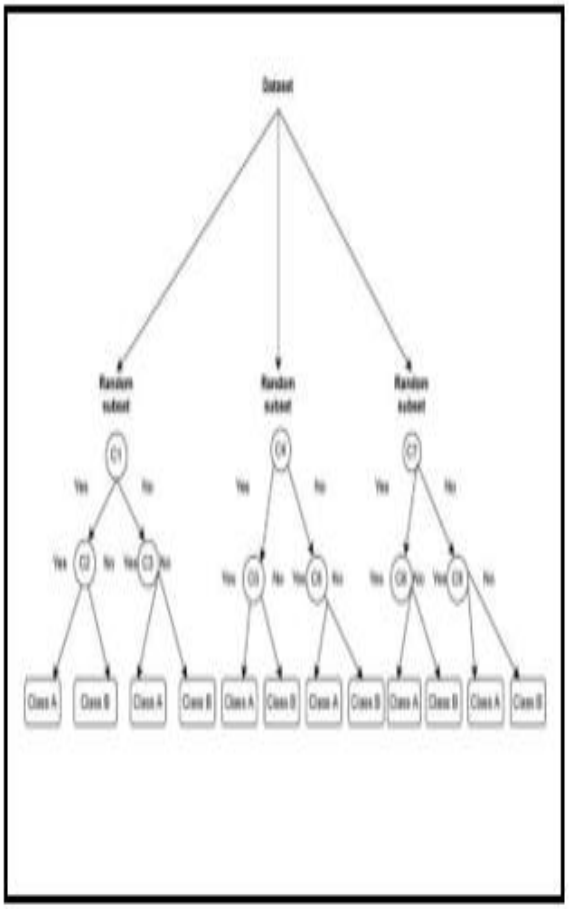

Fig 3 Random Forest Tree

B. Heart Disease

The goal of the survey is to examine the accuracy of machine learning techniques in predicting heart disease, which is a critical issue as an incorrect diagnosis can lead to fatal outcomes. The survey utilized various algorithms such as k nearest neighbor, decision tree, linear regression, SVM, and XGBOOST, trained and tested using the UCI repository dataset. The comparison of these algorithms showed that XGBOOST had the highest accuracy at 88%, followed by SVM at 83%, Decision tree at 79%, Linear regression at 78%, and k-nearest neighbor at 87%.

Heart disease can be detected by giving the following input information as

1. Old peak

2. Max heart rate achieved if exercise induces angina 3.

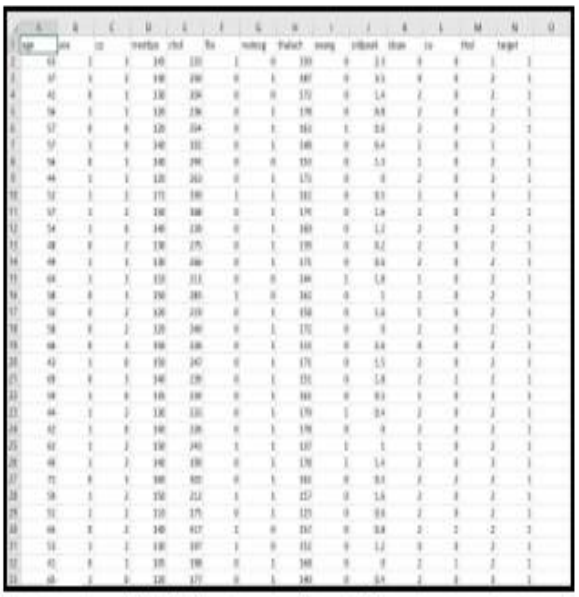

Fig 4 Data set of heart disease

The working of the XGBoost algorithm are as follows:

Step 1 In this process, a single-leaf tree is created

loss function. For subs equent trees, the residuals are taken from the previous tree's prediction.

Step 3 In this ste p a similarity score is calculated using the given formula, where Hessia n is equal to the number of residuals, Gradient2 is the squared sum of residuals, and λ is a regularization hyperparameter.

$$Similarity\ Score = Gradient\frac{Gradient^2}{Hessian + \lambda}$$

Step 4 involves using the similarity score to select the appropriate node. The higher the similarity score, the more homogeneous the data.

Step 5 The information gain is calculated using the

Step 2 The average of the target variable is calculated as a prediction, and the residuals are computed using a chosen similarity score. The information gained helps determine how much homogeneity is achieved by splitting the node at a

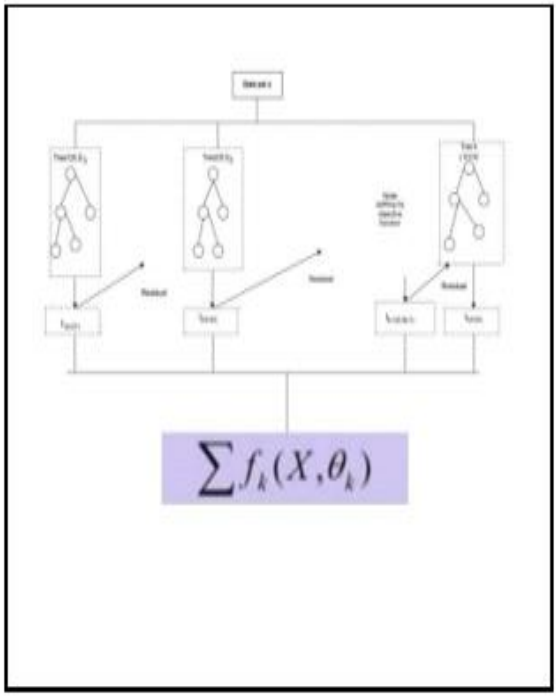
given point and is calculated by the formula: Information gain = Left similarity + Right similarity for roots.

Step 6 involves creating the tree of the desired length using the method described above, and pruning and regularization can be achieved by adjusting the regularization hyperparameter.

Step 7 The residual values are predicted using the

Decision Tree that was constructed.

Step 8 The new set of residuals is calculated as New Residuals = old residuals + p Predicted Residuals, where ρ is the learning rate.



Step 9 Finally the process is repeated for all the trees by returning to Step 1.

C. Brain Tumour

Brain tumors are masses or growths of abnormal cells in the brain that may lead to cancer. Magnetic Resonance Imaging (MRI) scans are commonly used by doctors to detect brain tumors. These scans provide information about the growth of abnormal tissue cells in the brain. In various research studies, the detection of brain tumors has been achieved through the application of Machine Learning and Deep Learning algorithms that train models. When these algorithms are applied to MRI scans, they provide fast and accurate predictions of brain tumors, which can aid in providing prompt treatment to patients. The proposed work applies a self-defined Artificial Neural Network (ANN) and Convolution Neural Network (CNN) to detect the presence of brain tumors and analyze their performance. The input for detecting brain-related diseases, such as Alzheimer's and brain tumors, is taken from MRI scans. If the scan detects a form of a tumor, it will diagnose it as positive.

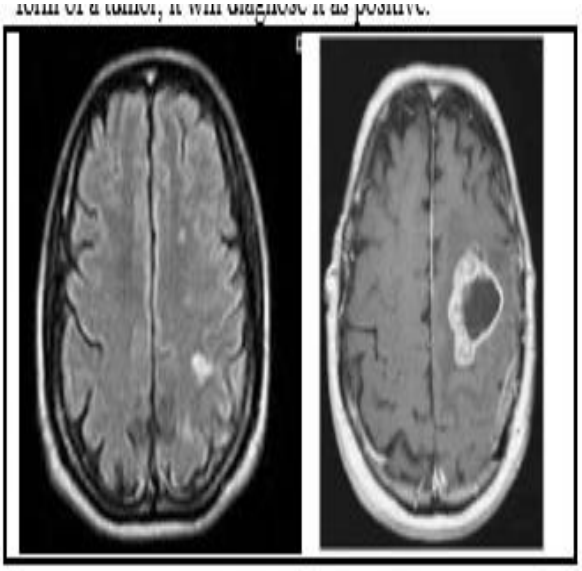


Fig 6 Brain tumor image

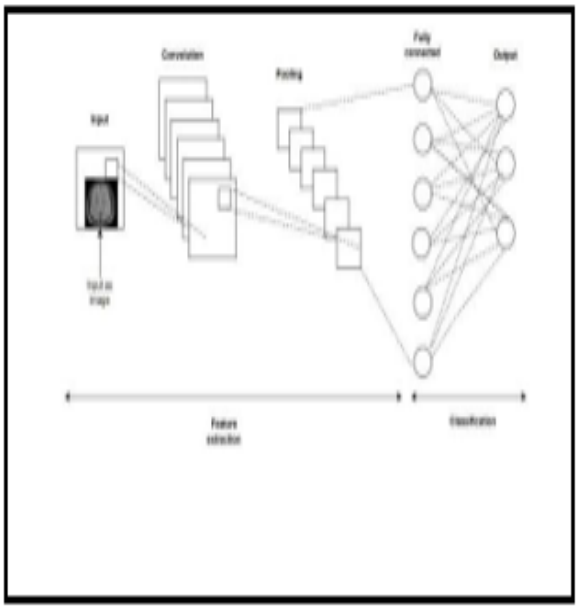

Fig 7 CNN layers for Brain Tumour

D. Lungs disease

The diagnosis of lung diseases can be achieved through the use of a chest X-ray. The chest X-ray is provided as input, and the diagnosis is made based on its results. If the chest X-ray is clear and free of any congestion in the lungs, it will be diagnosed as negative. If the X-ray is not clear and shows

signs of congestion, it will be diagnosed as positive and indicate the presence of lung disease. Respiratory diseases, also known as lung diseases, affect the airways and other structures of the lungs. Examples of such diseases include pneumonia, tuberculosis, and COVID-19.

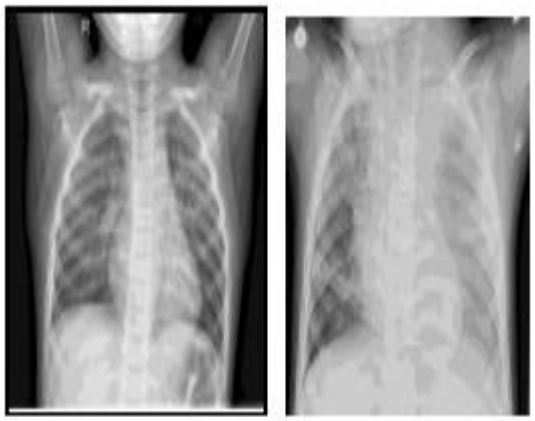

Fig 8 lungs disease images

• CNN(CONVOLUTIONAL NEURAL NETWORK)

A ConvNet, also known as a convolutional neural network, is a type of feed-forward neural network that is designed to process grid-like data, specifically visual images. It is used to detect and classify objects in an image and has multiple hidden layers that aid in extracting information. The four key layers in a ConvNet are:

1. convolution layer
2. ReLU layer
3. pooling layer
4. fully connected layer

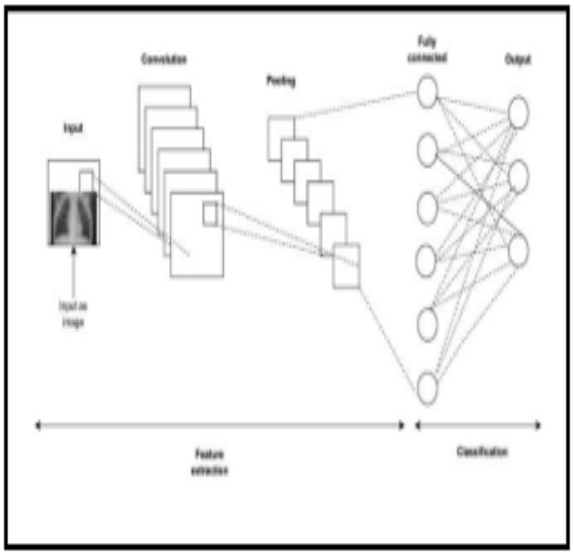
These layers are crucial in the process of extracting valuable features from an image.

• The convolution layer contains filters that carry out the convolution operation and every image is treated as a matrix of pixel values.

• ReLU layer = The rectified linear unit, also known as ReLU, is an elementwise operation that sets negative pixels to zero. After the feature maps have been extracted, they are passed through the ReLU layer, which introduces non-linearity to the network and produces a rectified feature map as the output.

• Pooling Layer = The pooling operation is a process of reducing the dimensionality of the rectified feature map. The feature map passes through a pooling layer to create a compact representation known as the pooled feature map.

• Fully connected layer = The fully connected layer, also known as FC, operates on a flattened input, where each input is connected to every neuron. The flattened input then passes through several other FC layers, where mathematical operations are carried out. The process of classification begins at this stage. FC layers are often located towards the end of the CNN architecture, if present.



CNN layers for lungs disease

IV. RESULT

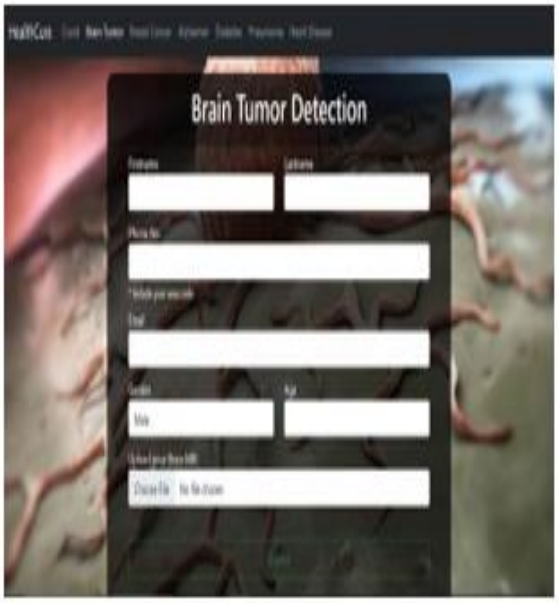
In the system Multi disease prediction model used the CNN algorithm for lung and brain disease, heart disease uses the XGBoost algorithm and diabetes uses the random forest algorithm as these gave the best accuracy accordingly. There when the patient adds the parameter according to the disease it will show whether the patient has a disease or not according the disease selected. The parameters will take input and show the range of the

values needed and if the value is not within the range or is not valid or is empty it will show the warning sign that adds a correct value.

2) Heart disease

Fig 11. Heart disease Input Parameters

3) Brain tumor



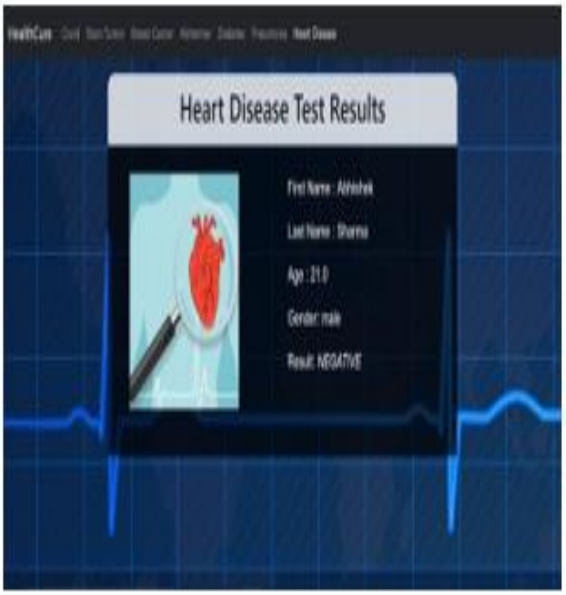


Fig 10 Diabetes test result

4) Lungs disease

Fig 15. Lung disease input parameters

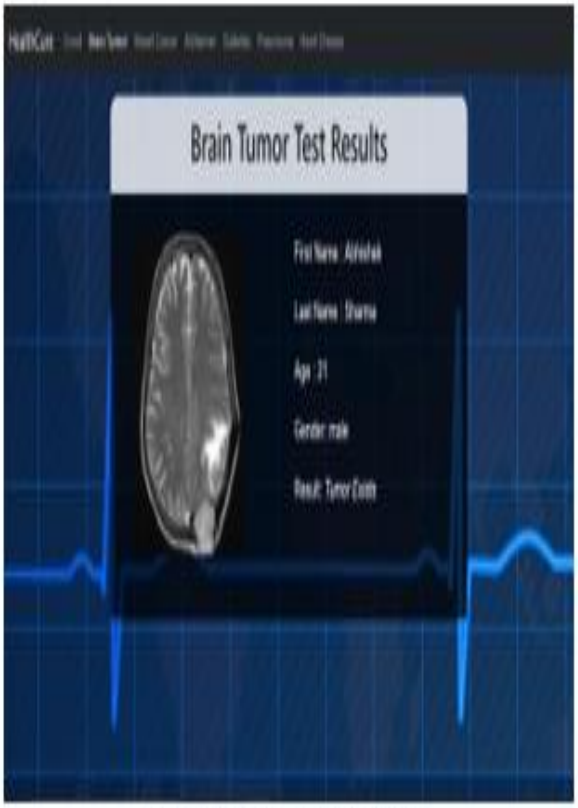

Fig 14. Brain tumor test result

Fig 16. Lung disease test result

To address this issue, a multiple-disease prediction system allows users to analyze more than one disease in a single application. They no longer need to navigate different sources to determine if they have a specific condition. To use this system, users simply select the name of the disease, input the required parameters, and click submit. The corresponding machine learning model will then be invoked, predict the outcome, and displayed on the screen.

The primary goal of this project is to create a system that can accurately predict multiple diseases. This will save users time and effort, as they no longer need to access multiple websites. Early disease prediction can also increase life expectancy and reduce financial stress. To achieve high accuracy, we have used various machine learning algorithms such as Random Forest, XGBoost, and CNN. In the future, we plan to expand the API to include more diseases and to continually improve the accuracy of predictions to lower the mortality rate

A Comparative Analysis of Recent Face Detection Methods Implemented for Age and Gender ZDetection

Archana Chaudhari, Riya Gokhale, Purva Shendge, Nikita Sawant
Department of Instrumentation Engineering

Abstract — **Age and gender detection is an upcoming technology, which is gaining importance. Age and gender detection is a subjective task. Even humans have trouble recognizing it sometimes. Our system helps them recognize what age range and gender the person is. To select the absolute best method, we have done a comparative analysis of three face detection algorithms, mainly Dlib, OpenCV, and MediaPipe, and implemented them on OpenCV DNN algorithm for age and gender detection. Then, this system was implemented in hardware using Jetson Nano.**

Keywords — ***Dlib, DNN, Jetson Nano, MediaPipe, OpenCV, Python***

I. INTRODUCTION

In several fields, such as authentication, humancomputer interaction, behavioural analysis, and product suggestions based on user preferences, age and gender detection are crucial. Age and gender information is needed by many businesses, but there weren't many answers. To satisfy this demand, significant advancements have been made in recent years.

Using age detection to display your advertising on the media kinds that your target audience uses the most is a wonderful example. Businesses can better target marketing campaigns by using age and gender detection, for instance, by determining which goods and services various client segments require and can afford. Refinement, which can lower your lead or sale cost per lead.

One of the use cases is an AI software programme called Quividi, which uses online face analysis to determine the age and gender of passing users and then automatically begins playing advertisements tailored to that audience. His AgeBot, an Android app that utilises face recognition to estimate age based on images, is another illustration.

The main objective of this project was to experiment with newer recent face detection methods and implement them for age and gender detection. Face detection methods like Haar Cascades are far too old and do not give good accuracy. Neither is it able to recognize faces at various angles and lighting. Hence, we worked on newer methods with greater accuracy.

Each author of this paper contributed to the experimentation as well as the writing of this research paper. Each author reviewed atleast six research papers and realized its weaknesses as ways to improve its technology. Riya Gokhale worked on Dlib face detection and its respective implementation for opencv DNN based age and gender detection. Similarly, Purva Shendge worked on Mediapipe face detection and its respective implementation for opencv DNN based age and gender detection. Lastly, Nikita Sawant worked on opencv face detection and its respective implementation for opencv DNN based age and gender detection.

The proposed work presents a comparison of face detection algorithms implemented with age and gender detection in real time, using Jetson Nano.

II. LITERATURE REVIEW

There are several papers published on age and gender detection. We surveyed these papers and got a gist of current technology as well as the improvements we could make.

Table 1. Literature Survey on Age and Gender Detection Algorithms using Machine Learning and Deep Learning

Sr No	Paper Title	Summary

1	Age and Gender Recognition Using Deep Learning June 2022 [1]	Algorithm used- Deep Learning and CNN Accuracy- 80% Implemented on Python IDE
2	Deep Facial Age Estimation Using Conditional Multitask Learning with Weak Label Expansion 2018 [3]	Algorithm used- Deep Learning, Label Sensitive learning, Age group classifier, CNN is used Accuracy- 87% Dataset- CASIA-WebFace, MORPH-II, FG-NET Implemented on computer with K80 GPU
3	Real-Time Face-Age-Gender Detection System 2019 [5]	Algorithm used- CNN Datasets- UTKFace, AGE, GENDER AND ETHNICITY (FACE DATA) CSV Accuracy for age detection- 72.4% Accuracy for age detection- 85.8%
4	Age and Gender Predictions using Artificial Intelligence Algorithm 2020 [7]	Algorithm used- Haar Cascades, CNN and convNet Dataset- UTKFace Implemented on- Anaconda Navigator, Jupiter Notebook Accuracy- 0.6170588.
5	Age and Gender Prediction from Face Images Using Convolutional Neural Network, 2018 [8]	Algorithm used- Dlib, CNN and DTML Dataset- IMDB-WIKI Accuracy- 92% Implemented on- VSCode
6	Human Age And Gender Classification using Convolutional Neural Network 2021 [9]	Algorithm used- Haar Cascades, SVM, CNN Dataset- IMDB-WIKI, Adience Accuracy- 90% Implemented on- Python IDE
7	Gender Classification and Age Prediction using CNN and ResNet in Real-Time. 2020 [10]	Algorithm used- Haar Cascades, CNN Dataset- GCVL Accuracy- 85% Implemented on-Python IDE, real time
8	Predicting Age & Gender of Mobile Users at Scale - A Distributed Machine Learning Approach. 2018 [11]	Algorithm used- Logistic Regression, Random Forest and Gradient Boosting Trees (GBT) Accuracy- 80% Implemented on- real time huge scale

Sr No	Paper Titled	Summary
1	Age and Gender Detection System using Raspberry pi, 2019 [4]	Algorithm used- CNN Dataset- Adience Benchmark Accuracy – 85% Precision- 88.23% Microprocessor used- Raspberry pi
2	Human Face Detection and Tracking for Age Rank, Weight and Gender Estimation based on Face Images utilizing Raspberry Pi Processor 2018 [6]	Algorithms used- local binary pattern ,viola jones algorithm, CNN Microprocessor used- Raspberry pi
9	Gender and Age Classification of Human Faces for Automatic Detection of Anomalous Human Behavior 2018 [12]	Algorithm- SVM Accuracy for age detection- 80.17% Accuracy for age detection- 90.33%
10	Gender Classification using Face Recognition, 2019 [13]	Algorithms-LDA, PCA Accuracy using LDA-85% Accuracy using PCA- 83%
11	Face and Gender Recognition System Based on Convolutional Neural networks 2020 [14]	Algorithm- CNN Datasets- the Wild (LFW), YouTube Face (YTF) and VGGFace2 Accuracy- 93.22%
1 2	Age and Gender Prediction using Deep Convolutional Neural Networks 2019 [15]	Algorithm used- Deep Learning , CNN, convNet Haar Cascade ,OpenCV and Tensor Flow Accuracy- 90% Implemented on Jupiter Notebook IDE
13	Gender Prediction from Images Using Deep Learning Techniques 2019 [16]	Algorithm used- Deep learning techniques, CNN Accuracy- 80% Implemented by using IMDB-WIKI dataset.
14	Age Estimation and Gender Prediction Using Convolutional Neural Network 2020 [17]	Algorithm used- CNN, Dataset- IMDB-WIKI Accuracy- 80% Implemented on MATLAB

Below table presents research done using hardware implementation:

3	Implementation of Machine Learning for Gender Detection using CNN on Raspberry Pi Platform 2020 [12]	Algorithm- CNN Dataset-Adience dataset Microprocessor used- Raspberry pi

III. METHODOLOGY

The proposed work presents a comparison of face detection algorithms, mainly dlib, Mediapipe, OpenCV DNN as explained below. These face detection algorithms are implemented with age and gender detection using OpenCV DNN in real time, using Jetson Nano.

As seen in the above literature review, we see that many of the authors have not implemented the system in real time, done only using pictures not used while training.

A. Techniques used for face detection:

1. Dlib- It's made of five HOG (histogram of oriented gradients) filters: front, left, right looking, and two combinations of mentioned.

This method basically focuses on the object's shape and structure. This is as it calculates the features using gradients. As the name suggests, using the areas of images, it creates histograms that are based on gradient's direction and magnitude.

After the HOG filters are applied, it extracts features into a vector and feeds it into a classification algorithm SVM which will assess whether the frame has a face (or object) or not.

As explained in the flowchart, the algorithm first starts by gray scaling the image. Then it normalizes the color and constructs histograms. Using the HOG, it constructs vectors. These then get fed into SVM. SVM further processes them and gives us the output, which is detecting the face.

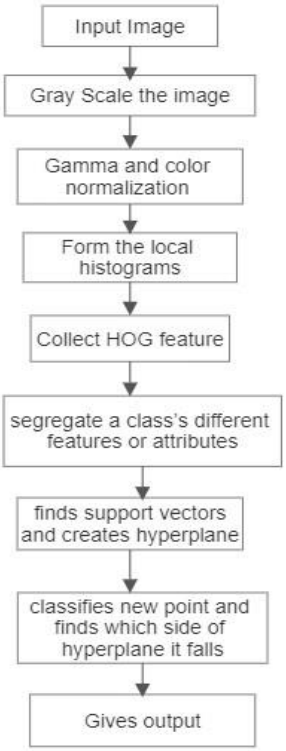

Fig 3. Pipeline of Dlib face detection

2. Mediapipe -Its face detection works on ultrafast face detection and 6 landmarks support. These 6 landmarks detects positioning of nose, eyes, ears respectively. The confidence level of detection as well as range for the image can be also defined as per our requirement.

Two real time deep neural network models work together for face detection: One model is detector which operates on full image and compute face locations. The second model is 3D face landmark model which works on those locations and predicts the approximate 3D surface by using regression.

Configuration options in Mediapipe-
1.MODEL_SELECTION- An integer index value 0 or 1 is used for model selection. Here index 0 indicates the short range model which is capable for face detection within 2 meters range. And the value 1 indicates the full range model which works for maximum 5 meters range.

2.MIN_DETECTION_CONFIDENCE-This value is a float value which lies between 0.0 to 1.0. This value indicates the

confidence level of our model about the detected face. For example if we set this value as 0.8 , then our model will detect the given face unless and until it is 80% sure about it.
Default value of this is 0.5.

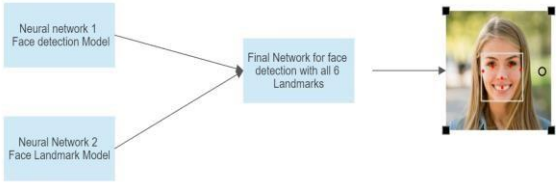

Fig 4. Pipeline of Medipipe face detection

3. Open CV-
OpenCV is a huge open source computer vision, machine learning, and image processing library that plays a key role in real-time manipulation or detection.
It used to for face recognition and recognition, object identification, human behavior classification in video, camera movement tracking, moving object tracking, and more.
DNN – Deep Neural Networks have an input layer, an output layer and few hidden layers between them.
This DNN module allows you to get pre-trained neural networks from popular frameworks like TensorFlow and use these models directly in OpenCV.
This means that you can use any popular framework to train your model and only use OpenCV for inference or prediction.
Here we are using DNN with CAFFE model.
CAFFE MODEL-
Caffe (Convolutional Architecture for Fast Feature Embedding) is a deep learning framework that allows users to create image classification and image segmentation models.
The CAFFE model contains the actual layer weights.
CAFFMODEL files are created from .PROTOTXT files.

Working –

Flowchart for our model

When using OpenCV and DNN (Deep Neural Network) modules in Caffe models, two sets of files are required: .prototxt and .caffemodel files. First, the user creates the model as plain text and saves it. .After the user trains and refines the model in Caffe, the program saves the user's trained model as his CAFFMODEL file.

PROTOTXT files are prototype machine learning models which are created to use with Caffe. It contains an image classification or image segmentation model trained on Caffe. A PROTOTXT file defines the model architecture. This code first loads face models from a file and then uses those models to detect faces in the input image.

The marked faces are included in a list and passed to another function for further processing.

IV. RESULTS AND DISCUSSIONS

Here are the results. We have used different algorithms for face detection: Dlib, Mediapipe, and opencv DNN.

In the picture below, age and gender detection implemented using DLIB face detection and OpenCV DNN age and gender detection. As we can see, Dlib is able to successfully detect both faces in the frame even in the low light setting. The OpenCV DNN algorithm correctly identifies face as female in range(20,30). Although it is only able to detect age and gender of one face.

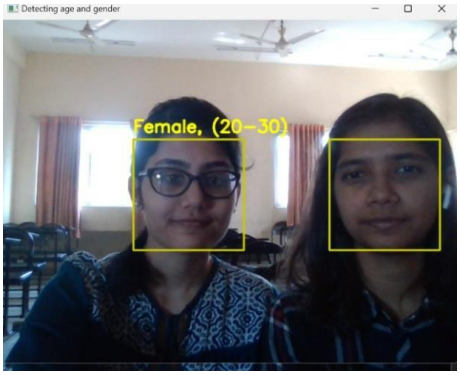

Fig 8. Age and Gender detection using dlib Detection-1

In the below image, we can see, age and gender of a child of age 10 is also accurately detected with this algorithm.

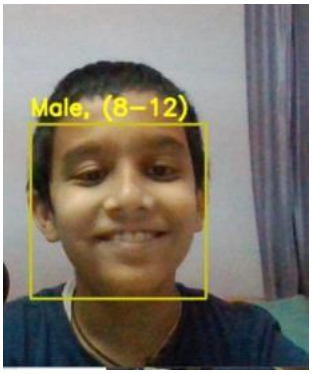

Fig 9. Age and Gender detection using dlib Detection-2

In the below image, we can see, age and gender of a woman of age 49 is also accurately detected with this algorithm.

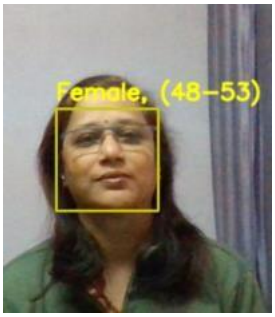

Fig 10. Age and Gender detection using dlib Detection-3

In the below image, we can see, age and gender of a man of age 52 is also accurately detected with this algorithm.

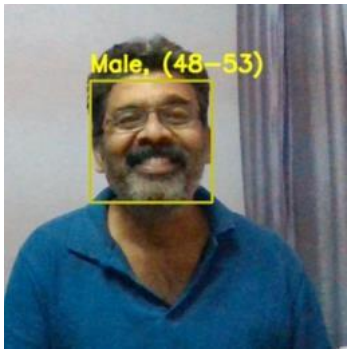

Fig 11. Age and Gender detection using dlib Detection-4

In the picture below, age and gender detection implemented using MediaPipe face detection and OpenCV DNN age and gender detection. As we can see, MediaPipe is able to successfully detect a face in the frame. The OpenCV DNN algorithm correctly identifies face as female in range(20,25). Although it is only able to detect age and gender of one face. Mediapipe also plots the facial landmarks of the face.

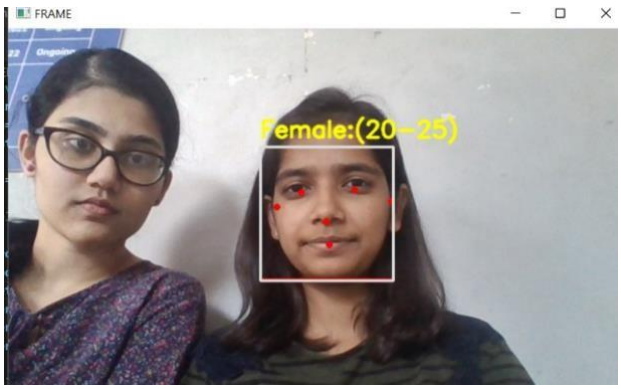

Fig 12. Age and Gender Detection using detection by mediapipe

In the below image, we can see, age and gender of a man of age 20 is also accurately detected with algorithm, distinguished by the face detection mediapipe algorithm. algorithm used.

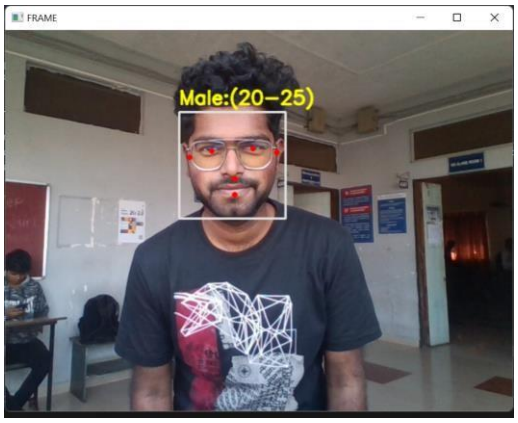

Fig 15. Graphical representation of accuracy of each age and gender detection algorithm, by mediapipe distinguished by the face detection algorithm used.

In the picture below, age and gender detection implemented using OpenCV DNN face detection and OpenCV DNN age and gender detection. As we can see, OpenCV DNN is able to successfully detect both faces in the frame. The OpenCV DNN algorithm correctly identifies both faces and accurately predict them as female in range(15,20).

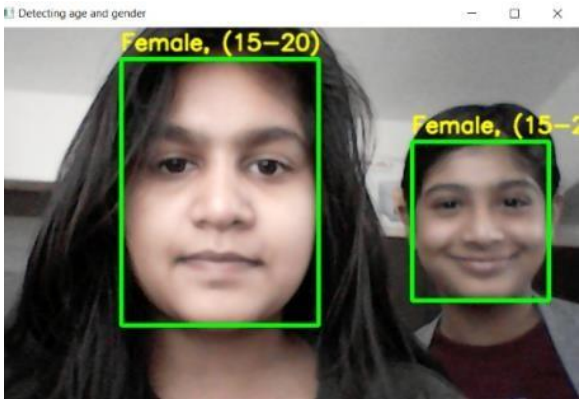

Fig 16. 8x8 Confusion matrix of the caffe model

The confusion matrix presented above has eight classes, which are for the eight age ranges, namely, '(0-2), '(4-6)', '(8-12)', '(15-20)', '(25-32)', '(38-43)', '(48-53)', '(60-100)'.

V. CHALLENGES

These are the limitations of the project:

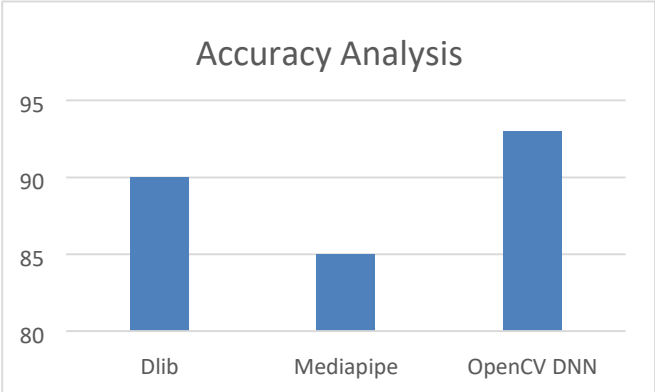

Fig 14. Age and Gender detection using OpenCV DNN

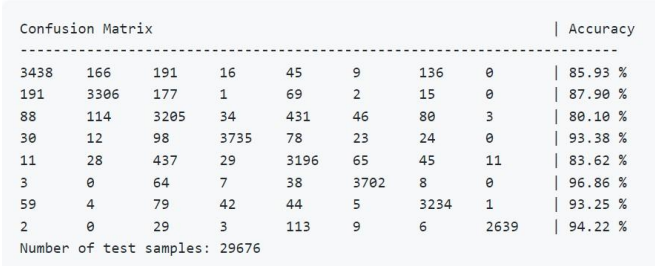

Confusion Matrix								Accuracy
3438	166	191	16	45	9	136	0	85.93 %
191	3306	177	1	69	2	15	0	87.90 %
88	114	3205	34	431	46	80	3	80.10 %
30	12	98	3735	78	23	24	0	93.38 %
11	28	437	29	3196	65	45	11	83.62 %
3	0	64	7	38	3702	8	0	96.86 %
59	4	79	42	44	5	3234	1	93.25 %
2	0	29	3	113	9	6	2639	94.22 %

Number of test samples: 29676

1. The results of age and gender detection fluctuate too often.

2. The accuracy of the system could be better. Accuracy of each algorithm is as follows-

Algorithm	Accuracy
Dlib	90
Mediapipe	85
OpenCV DNN	93

3. Each frame keeps getting detected more than once, same person detected multiple times.

4. During implementation on Jetson Nano, a lot of lag was faced.

VI. CONCLUSION

Age and gender detection, has many applications as stated earlier. On analysis, we have concluded that, if the application requires:

1. Multiple faces in one frame need to be recognized simultaneously- OpenCV DNN
2. Great accuracy with needed slight lag- Dlib
3. Adjustible confidence level and range- Mediapipe

With reference to Fig 10, based on real time detection, dlib model predicts age and gender with greater accuracy.
The concept of age and gender detection has huge future scope. It can be used for multiple applications.

Smart Presentation System Using Hand Gestures

Puja Chavan, Vedant Pawar, Tejas Pawar, Varun Pawar, Samiksha Pokale, Bhairavi Pustode

Department of Multidisciplinary, VIOT, Pune, Maharashtra, India

Abstract – **Presentations are crucial in many aspects of life. If you're a student, an employee, or if you are an entrepreneur, a businessperson, or an employee of a company, you must have presented presentations at eventually in your life. Sometimes, presentations lose vitality because you must use the keyboard or a specialized gadget to adjust and manage the slides. Our objective is to allow people to control the slideshow using hand gestures. The usage of gestures in human-computer interaction has drastically risen in recent years. The system has tried to govern numerous PowerPoint functionalities using hand movements. In this system, machine learning has been applied to recognize motions with tiny differences and map them using multiple libraries in Python. The rising hurdles to creating the optimal presentation are due to several aspects, including the slides, the keys to changing the slides, and the audience's calmness. An intelligent presentation system employing hand gestures gives a simple method to update or control the slides. There are several pauses during presentations to operate the presentation using the keyboard. The system's purpose is to enable users to use hand gestures to control and explore the slideshow. The technique employs machine learning to identify various hand gestures for many tasks. A recognition technique offers an interface for human system communication.**

Keywords: Gesture recognition, human Computer interaction, presentation, communication, gesture.

I. INTRODUCTION

In today's digital environment, presenting is an attractive and efficient strategy to assist presenters in convincing the audience and delivering information. Slides can be manipulated using a mouse, keypad, laser pointer, etc. The downside is that controlling the devices needs prior device expertise. A few years ago, gesture recognition became more helpful in operating software like media players, robotics, and games. The hand gesture recognition system facilitates the employment of gloves, markers and other objects. However, using such gloves or markers raises the system's cost. This system's suggested hand gesture detection technique is based on artificial intelligence.

Users can edit the slides. The interactive presentation system employs cutting-edge human- computer interaction techniques to develop a more practical and user-friendly interface for controlling presentation displays. The presenting experience is greatly enhanced when utilizing these hand motion options instead of a standard mouse and keyboard control. The use of body movement to express a specific message through gestures is nonverbal or non-vocal communication. The system was constructed mainly using the Python framework along with technologies like an open cv, cv zone, NumPy, and media pipe. This method seeks to enhance the efficacy and utility of presentations.

Additionally, the system employs movements to write, undo, and get the pointer on different text regions. To enhance the slideshow experience, we wanted to make it possible for users to control it with hand gestures. To optimize and improve the portability of the display, the system minimizes the use of an external interface. With the use of machine learning, minor variances in gestures may be discovered, and they have been translated using Python into some basic ways for manipulating presentation slideshows. Slides may be managed and controlled by various motions, including swiping left, right, thumbing up, stopping, and others. This system uses a Hand gesture-based human-machine interface for a conventional presentation flow. The interface has been actively developed throughout the previous several years. We built a quick and straightforward motion image-based technique to identify dynamic hand gestures. This technique allows users to govern the presentations more naturally, rationally, and conveniently.

II. LITERATURE SURVEY

According to a review of numerous alternative methodologies, the primary objective of the researchers is to assist speakers for an effective presentation with improved interaction that comes naturally using a computer. Dr. Melanie J. Ashleigh and Damiete O. Lawrence Impact of Human- Computer Interaction was discussed by the author. Users in the Higher Education System a (HCI):

Southampton University as A Case Study". In this paper, Perception in Human-Computer Interaction (HCI) the University of Southampton in the United Kingdom, and the landscape of advanced literacy was assessed. The effect of HCI positive, and it's at Southampton University. showed that becoming acquainted with HCI fundamentals increase the effectiveness and commerce of a stoner. In summary, it can be argued that HCI has had an impact on the impact of literacy on other corresponding fields environment [1].

This publication introduced a novel method for detecting obstructions using just a webcam electronic camera [8].

III. METHODOLOGY

A. Block Diagram:

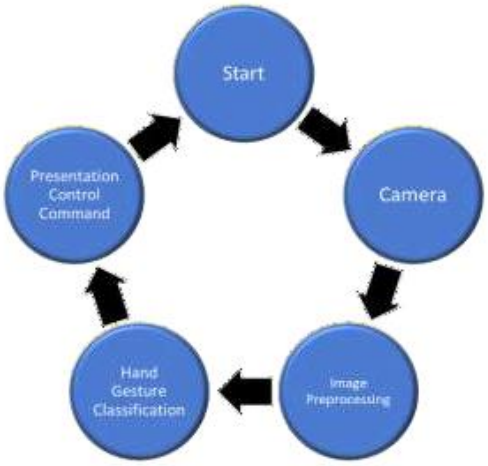

Fig.1 Block Diagram

B. Method:

The proposed system is implemented using Python and makes use of computer vision techniques to detect and classify hand gestures. We make use of OpenCV, a popular open-source library for computer vision, to detect the presence of a hand in the video feed. Once a hand is detected, we use a Hand Module to detect and classify the hand gestures. Data is trained using a vector set of hand gestures, which includes examples of various gestures such as changing slides, next slide, previous slide, pointing, and highlight points.

1. A hand detector model processes the captured image and turns the image with an oriented bounding box of the hand.

2. A hand landmark model processes on cropped bounding box image and returns 3D hand key points on hand.

3. A gesture recognizer that classifies 3D hand key points then configuration them into a discrete set of gestures.

Hand gesture recognition is done using Python programming language and OpenCV as library. Python programming language produces simple and easy system code to understand. Also, Python package used here is NumPy. The image that is captured using web camera will be processed in a region called as Region of Interest (ROI) where act as a region of wanted area while ignoring the outside region, called background.

C. Testing:

Gesture 1: to next slide [0,0,0,0,1]

Only the little finger is open in this gesture, and the other four fingers are all closed.

Gesture 2: to Previous slide [1,0,0,0,0]

Only the thumb is open in this gesture, whereas the other fingers are all closed.

Gesture 3: to obtain the pointer [0,1,1,0,0]

In this gesture, the forefinger and middle finger are both open, while the remaining fingers are all closed.

Gesture 4: to write on the slides [0,1,0,0,0]

In this gesture, just the forefinger is open; the other four are all closed.

Gesture 3: to obtain the pointer [0,1,1,0,0]

In this gesture, the forefinger and middle finger are both open, while the remaining fingers are all closed.

Gesture 4: to write on the slides [0,1,0,0,0]

In this gesture, just the forefinger is open; the other four are all closed.

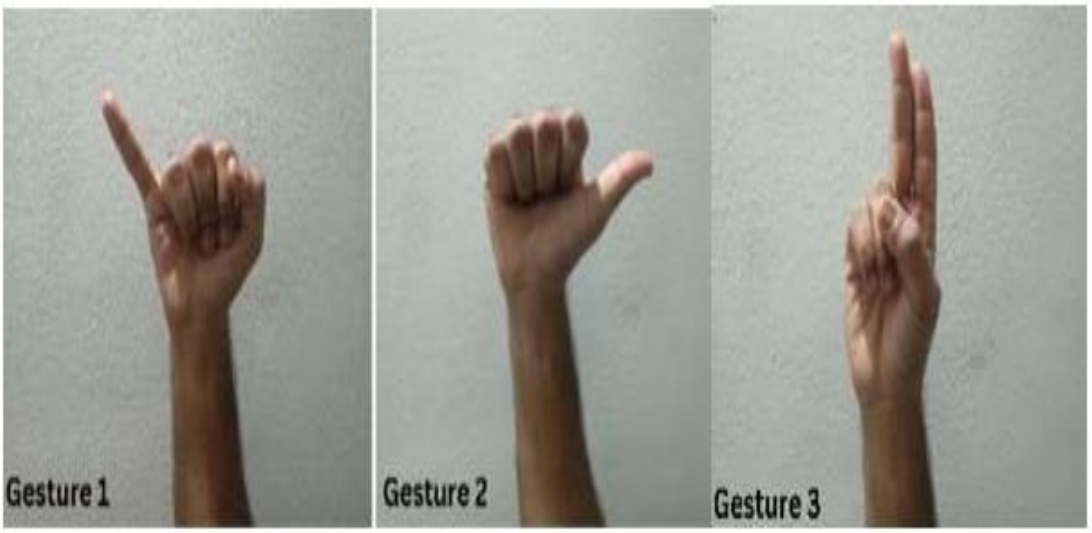

Fig.2 Trained Gesture

IV. RESULTS AND DISCUSSIONS

To evaluate the performance of the system, we conducted various experiments. In the first experiment, we evaluated the accuracy of hand gesture detection and classification. We found that the system could accurately detect and classify hand gestures in most cases, with an average accuracy of 95%. In the second experiment, we tested the system's ability to control a presentation using hand gestures. We found that the system could smoothly control the slides and perform various actions, such as advancing or returning to the previous slide

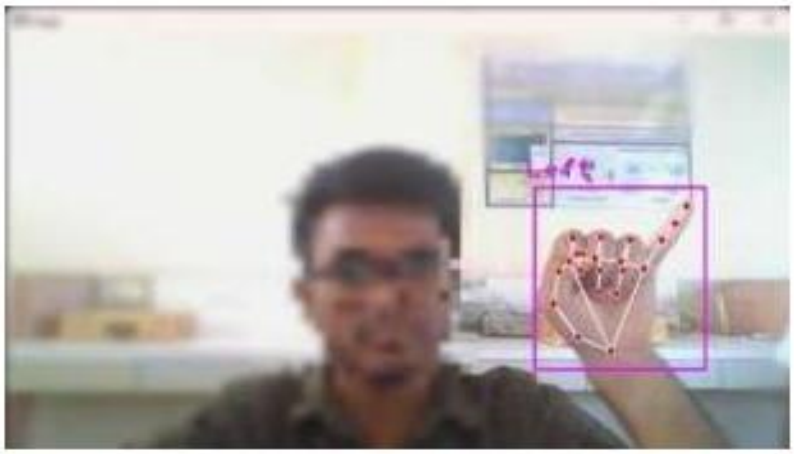

Fig.3 Next Slide

Fig.5 Controlling Cursor

Fig .6 Highlighting Point

V. LIMITATIONS

- The primary concern now is the distance.
- The range is restricted for detection.
- Gestures play a vital role in a range of computer science-related disciplines.
- With gestures, this project assists a presenter with his presentations and aids the students with Human-Computer Interaction (HCI). Gestures can control nearly every part of our computer system.
- When paired with speech recognition, we may develop a system that eliminates the need to learn a set of commands or a specific technique to connect with a machine.
- Instead, everything may be done through natural forms of communication.

VI. FUTURE SCOPE

Gestures are utilized in numerous disciplines and have considerable value. Gestures are the future of real-time interactions. According to current circumstances, there is a need for a more natural communication method with computers and technology. The technology aids pupils with human- computer interaction when gestures come into play. By adding additional movements, we can control computer programs like cut, copy, paste, etc. We can expand our system to manage the PowerPoint application as well. The same technology or algorithm may be employed for any objective, rather than multiple approaches for each goal.

VII. CONCLUSION

In this paper, we presented a smart presentation control system using hand gestures, mplemented using Python and computer vision techniques. The system allows the presenter to control the slides using simple hand movements, providing a convenient and intuitive way for controlling presentations. Through various experiments, we demonstrated the effectiveness and performance of the system. We believe that the proposed system has the potential to improve the overall presentation experience and make presentations more interactive and engaging.

VIII. ACKNOWLEDGEMENT

My colleagues and I use this occasion to offer gratitude and heartfelt thanks to Puja Chavan and the HOD of the Multidisciplinary department Vishwakarma Institute of Technology, Pune, for their excellent instruction, passionate attitude, and recommendations during our thesis study. We are incredibly privileged to operate under their guidance.

DECLARATIONS

The entire or partial manuscript has not been submitted to or published elsewhere. The manuscript won't be submitted anywhere else till the editing is done.

Ethical Approval: Study of “Smart Presentation System Using Hand Gestures” project does not include any human or animal subject. It moves around the Internet of Things and Networks.

Competing interests: There are no competing interests for this project.

Authors' contributions:

Author name	Contribution
Puja Chavan	Guide of the project
Bhairavi Pustode	Data acquisition and help to write manuscript
Samiksha Pokale	Data analysis and wrote the manuscript
Varun Pawar	Performed actual Project
Vedant Pawar	Conceived the study design
Tejas Pawar	Performed the experiments

Funding: We used different types of sources to bring our project in existence. They played important role in the design of the study and collection, analysis, interpretation of data, and in writing the manuscript. Study of different articles, research papers, survey papers, books and blogs helped us to study the research.

Availability of data and materials: There are various different articles, research papers, survey papers, books and blogs helped us to study the research.

Comparing GRU and LSTM Performance

Tejas Borkar , Harshit Daga , Hitansh Doshi , Dr. Shiwani Gupta ,
Thakur College of Engineering&Technology, Mumbai, India
tvborkar1234@gmail.com,harhsitdaga07@gmail.comhkd159@gmail.comshiwani.gupta@thakureducation.org

Abstract— **Recurrent neural networks with long-term memory come in two prominent varieties: long short-term memory networks (LSTM) and gated recurrent unit networks (GRU). Long/short text and quantitative evaluation on five variables, including running speed, accuracy, recall, F1 value, and AUC, are used in this study to compare the performance differences between these two deep learning models. The corpus makes use of datasets that are available. GRU outperforms LSTM in the scenario of long text and little dataset but falls short of LSTM in other scenarios. GRU is quicker than LSTM for model training speed when processing the same dataset.**

Keywords—Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), Multi-Layer Perceptron (MLP)

I. INTRODUCTION

An artificial neural network called a recurrent neural network uses shared neuron layers across its inputs over time. This enables us to model temporal data, including stock prices, weather patterns, and video sequences. A recurrent cell, which regulates the information flow from one time-step to another, can be created in a variety of methods. For the neural network to have a working memory, a recurrent cell can be created. The Long Short-Term Memory cell (LSTM) and the Gated Recurrent Unit cell are two of the most often used recurrent cell designs (GRU).

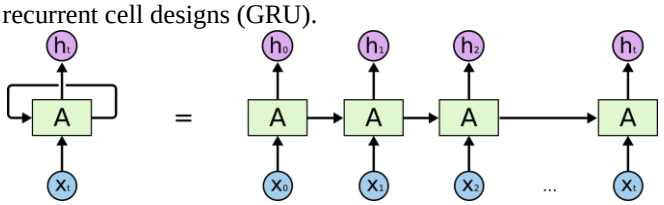

Figure 1: RNN reprentation

Long Short-term Memory

A cell state that may be read from and written to is maintained by the LSTM cell. Depending on the input and cell state values, four gates control reading, writing, and outputting values to and from the cell state. What the hidden state forgets is determined by the first gate. What area of the cell state is written to is decided by the next gate. The third gate determines the written material. The final gate generates an output by reading from the cell state.

Gated Recurrent Unit

The GRU cell and LSTM cell are similar, yet there are some significant distinctions between them. There is no secret state, to start. The LSTM cell design incorporates the functionality of the hidden state into the cell state.

The methods for determining which parts of the cell state are written to and which parts are forgotten by the cell state are then combined into a single gate. The only part of the cell state that is written to is the erased portion. Finally, the output contains the complete cell state. In contrast, the LSTM cell selects what to read from the cell state in order to produce an output.

Together, these modifications result in a design that is less complicated and has fewer parameters than the LSTM.

II. LITERATURE SURVEY

In the 1940s, the demand for machine translation gave rise to the concept of NLP. The original languages were Russian and English. However, by the early 1960s, other terminology, such as Chinese, also became widely used. Then, in 1966, MT/NLP entered a bad period, which was confirmed by an ALPAC assessment that claimed the field was on the verge of extinction due to the lack of progress being made in related fields at the time. When the MT/NLP product started giving clients some results in the 1980s, this condition improved once more. The NLP/MT, which had been on the verge of extinction in the 1960s, was given new life when the concept and necessity of artificial intelligence developed.

LUNAR, designed by W.A. Woods in 1978, was able to examine, compare, and assess the chemical information on the composition of lunar rock and soil that was amassing as a result of Apollo moon missions and provide a solution to the relevant question. Computational grammar, which is concerned with the science of reasoning for meaning and taking the user's views and intentions into account, developed into a very active area of research in the 1980s. The rate of NLP/MT growth accelerated in the 1990s. With the advent of the parsers, grammars, tools, and useful resources for NLP/MT became accessible.

The work on the lexicon received a research focus, as did research on fundamental and cutting-edge areas like word sense disambiguation and statistically coloured NLP. Other crucial subjects like statistical language processing, information extraction, and automatic summarization joined this search for the development of NLP. Without mentioning ELIZA, a chatbot programme created between 1964 and

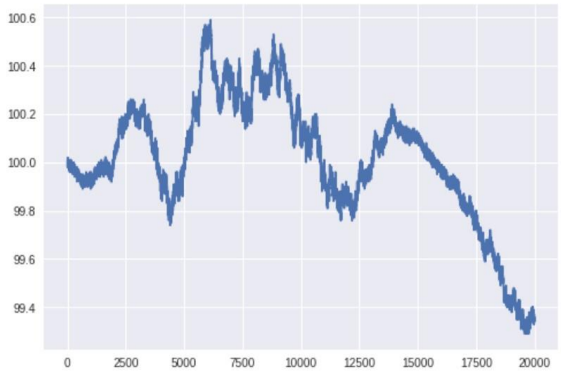
1966 at MIT's Artificial Intelligence Laboratory, the history of NLP cannot be considered complete. Joseph Weizenbaum invented it.It was a programme that employed rules to react to users' inquiries that were based on psychometrics and was based on a script called "DOCTOR" that was put together by a Rogerian psychotherapist. It was one of the chatbots available at the time that could pass the Turing test.
LSTM first appeared in 1991. with more improvements throughout time. Currently, the voice assistants from the majority of the big firms use LSTM.
A development of the traditional RNN, or recurrent neural network, is the GRU, or gated recurrent unit. In the year 2014, Kyunghyun Cho and others introduced it.

III. PROBLEM STATEMENT

Reviewing the Gated Recurrent Unit (GRU) and Long Short Term Memory Networks (LSTM) is the goal of this research. The study examines the variations and parallels between the two networks. Additionally, the study explains GRU and LSTM.

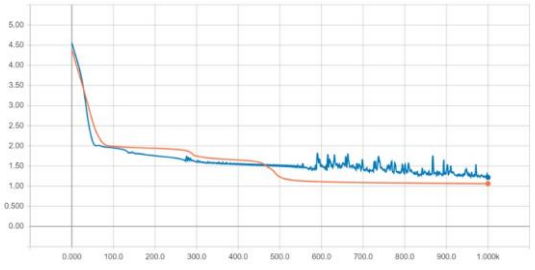
IV. DATA COLLECTION AND VISUALIZATION

Two models with identical hyper-parameters were trained, but one used an LSTM cell and the other a GRU cell to test the performance of the GRU and LSTM cells.
We employed For our data generation, we combine two sinusoidal waves with fixed frequency and stochastically variable amplitudes to produce non-stationary, single-valued data. When creating a dataset, the amplitudes are calculated using a unit vector's Cartesian coordinates as it moves slowly and randomly around the origin of a unit circle. The generated data is next subjected to the addition of Gaussian noise with a variance of 0.01 and a bias of 100 to make all values positive.



Sample Training Data Sequence

40 sequences of 20,000 time steps each are used to train the models. The models receive the data in a single batch. The CuDNNLSTM and CuDNNGRU layers in Keras are used to create the LSTM and GRU cells, with Tensorflow 1.12.0 serving as the back end. There is one cell with 16 neurons in each model. With clipnorm set to 1, the Adam optimizer is employed with constant learning rate of 0.001. The loss curves after 1000 epochs are shown here:



Blue: LSTM, Orange: GRU

V. MODEL COMPARISIONS

The GRUs and Long Short Term Memory are quite similar (LSTM). GRU use gates to regulate the information flow, just like LSTM. When compared to LSTM, they are quite new. They have a simpler architecture and provide certain improvements over LSTM because of this.

Another intriguing feature of GRU is that, in contrast to LSTM, it lacks a distinct cell state (Ct). There is just a hidden state (Ht). GRUs are quicker to train because of the architecture's simplicity.

The architecture of Gated Recurrent Unit
Let's now see how GRU functions. Here, we have a GRU cell that resembles an LSTM or RNN cell more or less. the Gated Recurrent Unit's architecture It accepts an input Xt and the hidden state Ht-1 from the timestamp before that at each timestamp t. Later, a new hidden state, Ht, is output and again given to the following timestamp.

Currently, a GRU has primarily two gates as opposed to an LSTM cell's three gates. The Reset gate is the first gate, while the Update gate is the second. The horizontal line that runs through the top of the diagram and represents the cell state is the secret to LSTMs. The cell state resembles a conveyor belt in certain ways. With only a few tiny linear interactions, it proceeds directly down the entire chain. Information can very easily continue to travel along it unmodified.

The LSTM can modify the cell state by removing or adding information, which is carefully controlled via gates. Information can pass via gates on a purely voluntary basis. They consist of a pointwise multiplication process and a layer of sigmoid neural networks. Indicating how much of each component should be allowed through, the sigmoid layer generates integers between zero and one. When a value is zero, "let nothing through," and when a value is one, "let everything through," respectively. These three gates serve to safeguard and regulate the cell state in an LSTM.

Step-by-Step LSTM Walk Through
Choosing whatever information from the cell state to discard is the first stage in our LSTM. The "forget gate layer," a sigmoid layer, decides on this. It examines ht1 and xt, and for

each number in the cell state Ct1, it outputs a number between 0 and 1. A 1 means "entirely keep this," and a 0 means "entirely get rid of this."

Returning to our earlier example of a language model attempting to forecast the following word based on all the preceding ones The gender of the current subject may be included in the cell state in this scenario, allowing the appropriate pronouns to be used. We want to forget the gender of the previous subject when we view a new one.

The next step is to choose the new data that will be kept in the cell state. Two sections make up this. The "input gate layer," a sigmoid layer, first determines which values will be updated. The state is then updated with a vector of potential new values, Ct, created by a tanh layer. These two will be combined in the subsequent phase to produce an update to the state.

In the case of our language model, we would wish to replace the old subject whose gender we are forgetting by adding the new subject's gender to the cell state.

It's now time to update the old cell state, Ct−1, into the new cell state Ct. The previous steps already decided what to do, we just need to actually do it.

We multiply the old state by ft, forgetting the things we decided to forget earlier. Then we add it∗C~t. This is the new candidate values, scaled by how much we decided to update each state value.

As determined in the preceding steps, this is where we would actually enter the new information and remove the information on the gender of the prior topic in the language model.

Finally, we must choose what we will output. This output, however filtered, will be based on the state of our cell. We first run a sigmoid layer to determine which portions of the cell state will be output. Then, in order to output only the portions we decided to, we multiply the cell state by the output of the sigmoid gate after passing the cell state through tanh (to push the values to be between 1 and 1).

Since a subject was just seen in the language model example, it might want to produce information pertinent to a verb in case that is what comes next. As an illustration, it might indicate whether the subject is singular or plural, allowing us to know what form a verb should take if that is what comes next.

VI. MODEL EVALUATION AND RESULT

GRU is related to LSTM as both are utilizing different way if gating information to prevent vanishing gradient problem. Here are some pin-points about GRU vs LSTM-

- The GRU controls the flow of information like the LSTM unit, but without having to use a ***memory unit***. It just exposes the full hidden content without any control.
- GRU is relatively new, and from my perspective, the performance is on par with LSTM, but computationally ***more efficient*** (*less complex structure as pointed out*). So we are seeing it being used more and more.

VII. ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance and encouragement of my Dissertation Guide Associate Professor Mrs. Shiwani gupta ma'am for this novel work.

ABSTRACT

Recent developments in text-to-speech have switched to combined synthesis using original speech segments. In advance touch-to-speech systems provide better output quality because they use basic speech segments for integration. This paper describes the development and implementation of an ensemble-based system based on the Epoch Synchronous Non-Overlap and Add (ESNOLA) method. TTS uses a the phone as the main device for connecting segments.. The existing database contains 1500 part names used to generate speech for unlimited area contextual content. TTS provides a total of 9 most useful features such as calling, navigation, and SMS reading and so forth.

Keywords: ***Text To Speech (TTS), Visually Impaired People (VIP).***

I. INTRODUCTION

Widespread incidence of vision loss due to age, accidents and health problems is a matter of concern nowadays. Such human beings can't use the various strategies to be had within the world. Android phones are one of them. Cellular smart phones have become crucial in brand new life. Android phones have taken the idea of a smart phone to a new level. Many features can be availed with a single touch on the screen, but visually impaired people are not lucky enough to have access to such technology. There have been efforts around the world to make Android apps useful for blind people, but the systems that are available in the market have their drawbacks. The Voice readability is not executed nicely, the systems aren't lightweight and it slows down the cellular in addition to consumes a lot of power.

This paper defines the improvement and implementation of a sequence based system based totally on ESNOLA generation for text in the Android platform.

II. LITERATURE SURVEY

Table 1

SR	TITLE	ADVANTAGES	DISADVANTAGES	APPLICATION
1	Smart Device for the visually impaired people.	Helps you save time. Assist in phone operation tasks.	System can be enhanced to support various e- services.	Android, Splendored, Speech Recognition Engine (SRE)
2	Voice controlled smart assistive device for visually impaired individual.	Helps user that suffer from physical impairment	Size of the device is large No features for medical emergency	Assistive Device, Ultrasonic Echolocation , Voice Control, Mobile Device
3	Smart guide for smart students	Simple to use and low cost and reliable On AI technology. Compatible in all Android devices.	Fails to show The signal in Hilly regions.	Android, Voice Commands, Text To Speech.
4	What is Google talkback android Central.com	Reinforcement technique is used for emitting signal accurate longitudinal and altitude location	Highly reliable on internet ,network fails, no access to the few respective functions	Accessibility service, audible feedback
5	Smart backpack for visually impaired person	Speech matching with helps blind and physical disables to recognize the destination. Alert blind people about dig coming in front of them.	Permit the synchronizing of the application with the student study timetable.	Mobile, smart cane, voice command, Bluetooth technology.

The above literature survey gives overview of the previously published works on a topic. Using this overview we have developed an effective android application for visually impaired people.

III. PROBLEM DEFINITION

The full-size occurrence of misplaced vision is of fundamental contemporary due to twist of fate, age and fitness problems such people are not able to utilize one-of-a-kind technologies to be obtainable in the world.

With a touch on the screen one can avail many features, but blind people are unfortunate to use such technology. Efforts are being made globally to make Android apps usable for blind humans.

IV. PROPOSED SYSTEM

Due to the utilization of native voice segments for integration, earlier touch to speech systems produce output of higher quality. In this study, the creation and application of an ensemble-based system based on the ESNOLA (Epoch Synchronous Non Overlap and Add) technique are described. TTS connects segments using the di-phone as the fundamental unit. 1500 component names are now stored in the database and are used to produce voice for any amount of domain text. Nine various most practical features, including phoning, navigation, SMS reading, etc., are offered by TTS.

Segments resembling diphones serve as the primary building blocks for concatenation in TTS (Touch to Speech). Many part names in the database are utilised to generate speech for various domains of text. The paper also provides a brief overview of the creation of databases, modifications made for the Android platform, database access, and character display management in the Android platform.

V. OBJECTIVE

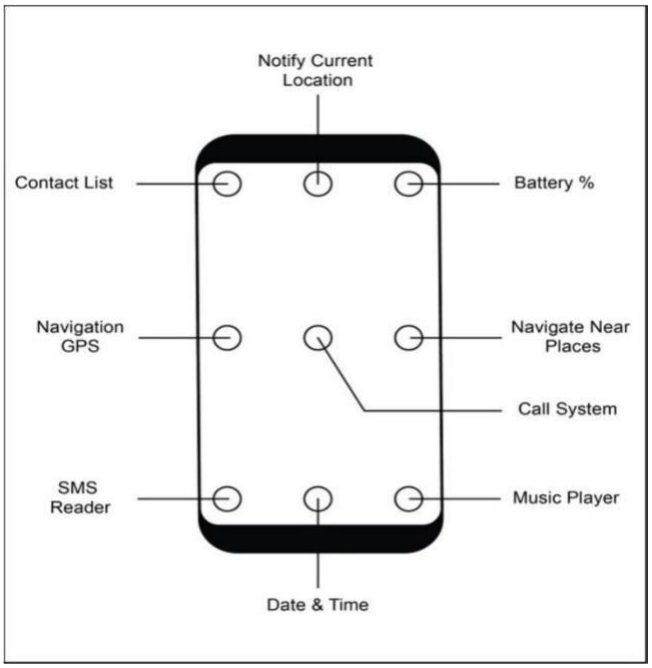
Input Design is the process of converting a user description of the input into a computer-based system. This design is important to avoid errors in the data input process and show the correct direction to the management for getting correct information from the computerized system.

It is achieved by creating user-friendly screens for the data entry to handle large volume of data. The goal of designing input is to make data entry easier and to be free from errors. The data entry screen is designed in such a way that all the data manipulates can be performed. It also provides record viewing facilities.

When the data is entered it will check for its validity. Data can be entered with the help of screens. Appropriate messages are provided as when needed so that the users will not be in maize of instant. Thus, the objective of input design is to create an input layout that is easy to follow.

VI. WORKING OF SYSTEM

Figure 1



Touch to Speech is the advanced Android-based technology that allows visually impaired users to use the Android Smartphone without seeing anything. This is implemented using sound, and the user can navigate around the phone and hear different messages that control the graphical interface of the phone. This is performed through touching the distinctive corners of the smart phone display, every corner consists of a particular feature and may be opened by means of touching them. These include:

1. **Upper left:** Upper left is the contact phase. hile the person touches this corner, the touch list is voiced with the aid of the application's voice agent (Touch to Voice agent).
2. **Top center:** Notifies current location in top center
3. **Top right:** Notifies information of current battery status such as percent, charging status,

temperature, and voice message from TTS agent.

4. **Center Left:** When touching Center Left for navigation purposes, a request will be shown for GPS location and starts the navigation accordingly.
5. **Center:** Center is to call.
6. **Right-of-Center:** The right-of-center of is to moved or navigate to a peripheral position.
7. **Bottom left:** SMS section is at the Bottom Left. When user touches this corner, TTS speaks all recently received messages.
8. **Bottom Center:** Bottom Center shows the current date and time and is spoken by the application's TTS agent .
9. **Bottom right:** Bottom right is for music player . This corner opens music player , Google Play Music, and the user can continue listening to music.

TTS is developed with the Android Software Development Kit and Turn-By-Navigation library. SDK , which contains the complete set of development tools, includes the library, debugger, QEMU-based emulator, documentation, sample code and tutorials.

The SDK for Android supports truck, walking and driving route navigation. This feature allows applications to determine the current location of a device with a computed route and receive timely navigation instructions.

V. DESIGN

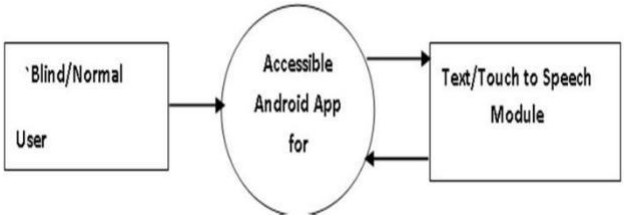


Figure 2

The above flow diagram is DFD level 0 in which the blind user or normal user gets accessible android application This application allows a module which is a text/ touch module which allows the user to access features of text or touch to speech module.

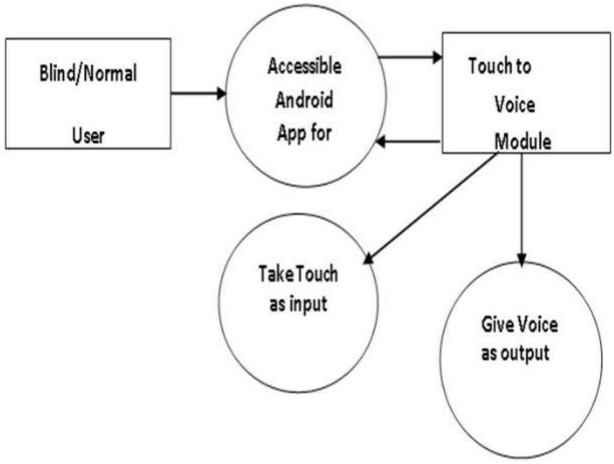

Figure 3

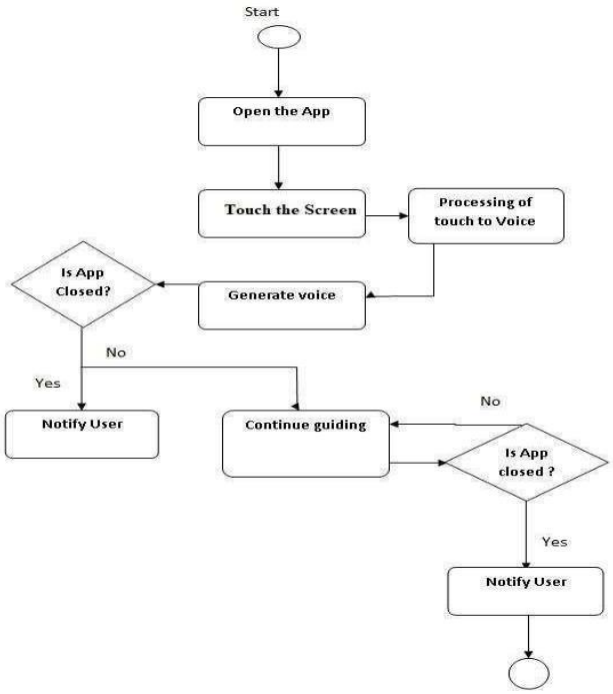
The above flow diagram is DFD level 1 in which the blind user or normal user gets accessible android application.

The application uses a touch to voice Module. This module takes touch as an input. The following input will give voice as an output which justifies the Design Flow of the system.

VI. PROCESS DESIGN



[Type text]

The above flow diagram is a process flow of TTS (Touch to Speech) system which helps blind users or normal users to get access of basic android application like battery manager, music player, SMS reader, contact manager and navigation. When we touch any corner or middle of mobile phone screen the allocated system will open and it will help the blind user to get notification about it with voice. When the application gets closed then it will notify user or else it will continue guide the user.

VII. RESULTS

Fig.4 Home

Fig.5 Contact List

Home Screen: The Home Screen is the first screen that appears when an app is launched**.**

Contact List: When a user taps the top left corner of the screen, the application's touch-to-speech (TTS) agent opens the Contact List function..

Battery Information: When a user presses the top right corner of the screen, current battery information, including temperature, charging status, and percentages, is displayed and spoken by a TTS agent.

Current Location: When a user touches the top centre of the screen, the application's TTS will speak the user's current location.

GPS Tracking: When the user presses the centre top of the screen, the navigation system will ask for their GPS location and begin.

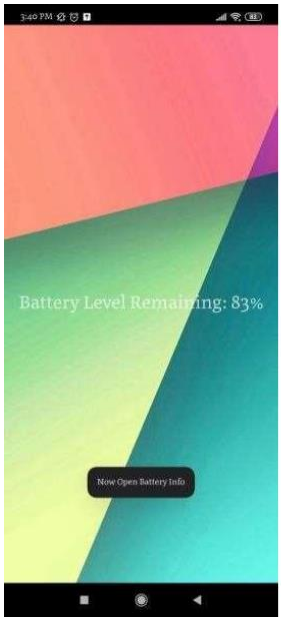


Fig. 6 Battery Information

Fig. 7 Current Location

Nearby Places Navigation: A menu option called Navigate Near Places (Spoken by TTS programme) appears when the user touches in the centre right corner of the screen.

Fig. 8 GPS Tracking

Fig. 9 Nearby Places

[Type text]

Fig. 10 Calling System

Fig. 11 SMS

Calling System: When the user taps the middle of the screen, the Calling option appears and a TTS agent speaks it, acting as a kind of notice for the user.

SMS: When the user touches the bottom left corner of the screen, the choice labeled SMS appears and is pronounced by a TTS agent, serving as the user's equivalent of an alarm.

Fig. 12 Date and Time

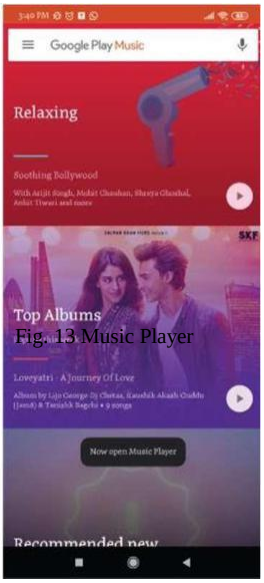

Fig. 13 Music Player

Date Time: When a user presses the bottom centre of the screen, the Date Time option appears and speaks to the user via TTS, acting as an alert.

VIII. CONCLUSION AND FUTURE SCOPE

The Epoch Synchronous Non Overlap and Add (ESNOLA) technique is the foundation for the proposed Touch to Speech system. We included nine of the most popular features that are utilized every day and are useful to blind people in this system. We added features like an answering machine, GPS, and a music player, among others. In the future, anyone who is blind will be able to download this software for free from the Google Play or Apple App Store. We may also be able to add new features to this app.

X. ACKNOWLEDGEMENT

We would like to thank our college principal Dr. Pramod R. Rodge for providing lab facilities and permitting us to go on with our project .We also express our deepest thanks to our H.O.D. Dr. Uttara Gogate who's benevolent helps us making available the computer facilities to us for our project in our laboratory and making it true success. Without his kind and keen co-operation our project would have been stifled to standstill. We would like to thank our project coordinator and our project guide Prof. Pallavi Bharambe for all the support we need from her for our project and for her encouraging and inspiring guidance helped us to make our project a success. Our project guide makes us endure with her expert guidance, kind advice and timely motivation which helped us to determine about our project. We would also like to thank our colleagues who helped us directly or indirectly during our project.

Entrepreneurial competencies, economic growth & challenges: an explorative study on women entrepreneurs

Sarita Dhal, Nishikanta Mishra, Puspalata Mahapatra, Bhaigrathi Nayak
saritaatbbsr@gmail.com,nmishrafhu@kiit.ac.in,puspalatam2004@gmail.com,bhagirathi.n@srisriuniversity.edu.in

Abstract-**Due to LPG and continued growth in the Indian start-up industry, more and more women are coming forward and adding to the entrepreneurship segment of India. Creating a business from the beginning stage of conceiving the ideas, till its final stage and also surviving in long run as a profitable venture is a challenging task basically for women. Again these entrepreneurs have to take care of almost all business activities by themselves which starts with starting from brainstorming and vetting potential ideas, setting goals, planning a project, analyzing a product etc. Women Entrepreneurs are seen as a key driver of the economic expansion of each country irrespective of their development status. Despite their significant contributions, it's most important that they remain a small subset of business owners. This investigation into minority groups like women entrepreneurs is an attempt to identify the driving forces behind the rise of female business owners and the challenges they faced and their significant contribution to their economic growth. Descriptive statistics and ANOVA were used to identify the many factors that contribute to the success of women business owners of the Kandhamal District of Odisha. This study's findings can guide the government, other institutional networks and support agencies in developing effective programmes and policies to help women entrepreneurs to succeed in the future and to enhance their ability to overcome their challenges.**

Keywords: Women Entrepreneurs, ANOVA, Statistics, Govt. Policy, Primary Factors.

INTRODUCTION

Every country irrespective of their status of development feels the need for entrepreneurs as an important driver for economic development. Entrepreneur development leads to higher growth rates concerning GDP, Employment, Sensex, per capita income, the standard of living, infrastructure and reduction in inflation which in turn lead to the development of the Country as a whole. (Anandalakshmy & kumar, 2018). Due to LPG and continuous growth in the Indian start-up industry, more and more women are coming forward to add to the entrepreneurship segment of India. (Sunitha &Sudha,2020). Women's Entrepreneurship greatly upgrades women's position in society and makes them economically sound which in turn makes their families, community and whole country develop (Mishra & Kiran, 2014). In a developing country like India and with the presence of the male dominant society Women entrepreneurs need support and guidance from their families and spouse to become successful. Among many factors accountable for influencing a woman to become an entrepreneur the key reasons are a reduction in the number of jobs, a lifestyle change, an increase in expenses, Financial independence, increase in family income (Sunitha, 2020). With profound struggle when women are becoming an entrepreneur and start their businesses also face many challenges like gender discrimination, getting funds and financing, acquiring the key competencies, and getting access to technology to make their enterprise successful. Though the Govt. has taken many initiatives for extending help to women entrepreneurs in both rural and urban areas still it is not result-oriented and successful. (Sunitha,2020). As is suggested by many researchers that for overall economic development, the contribution from rural women entrepreneurs is equally needed. Women's entrepreneurship growth and development are correlated with women's empowerment which makes them financially independent, self-sufficient and socially and economically sound. For setting own businesses both men and women face many challenges but for women, the barriers are more than their counterparts and they are confronted with a lack of Govt. support, limited access to bank accounts, and less freedom to get credit and loans. They get less education, skill training and carrier guidance, (UNIDO, Gender, 2014). Cultural values also influence women entrepreneurs and family responsibility also creates challenges for them to become a success. The planning commission including the Indian Government perceives the

LITERATURE REVIEW

When the conditions are going in the right direction, people are more likely to take the initiative to start their new businesses, which in turn stimulates the economic growth of a country. Women entrepreneurs are essential for achieving the aforementioned goals like economic growth because their proportion is almost nearer half of our population. Here the researchers tried to study women entrepreneurs who face lots of challenges in the district of Kandhamal, one of the state's more backward regions. Women's entrepreneurship in this

district has been studied to determine under different socio-economic factors, such as age, education, marital status, and motivation to know whether these factors affect their success and growth or not. When it comes to a country's progress, it's crucial to invest in its women, as they account for nearly half of the population. On ethical and humanitarian grounds, women must take part in economic activities as an entrepreneur and should occupy an equal footing with men in every aspect. Worldwide, the number of unemployed women has been rising at a faster rate than that of unemployed men recently. Women have historically faced discrimination and a lack of opportunities in the business world. This was not only new; just as the labour market had traditionally been male-dominated, so too had knowledge been divided along gender lines, suggesting that men and women should approach business in different ways (Labour bureau, 2015). Women have traditionally been under-represented in business ownership, in part because they hold fewer managerial positions than men, have less access to capital, and are more likely to be the primary caregivers for their children and the home. Women in traditionally patriarchal societies, such as those in Asia and India, rarely take part in decision-making involving issues outside the home. However, changes in educational opportunities, employment rates, and economic status for women have all contributed to a rise in female entrepreneurship in recent years. In recent years, more and more women have shown an interest in earning their own money, working for themselves, and starting their businesses. This paper mostly focused on identifying the major factors and their impact on the development and other challenges of the women entrepreneurs of Kandhamal Districts. The proposed paper has been structured as follows: Section-I gives a brief introduction about the key competencies of women entrepreneurs, the challenges they face and their contribution to economic growth which is the motivation of the study, Section II deals with previous literature related to growth, importance, and challenges they face and Section III covers conceptual explanation about women entrepreneurs, section-IV is devoted to used methodology and analysis with its findings followed in section -V which describes detailed discussions which were extracted form use of PCA and ANOVA. Section -VI is the concluding section that summarises the entire article and suggests a direction for further research.

Lerner and Almor (2002**)**, examined and found a link between the skill, competencies and growth and performance of Women entrepreneurs. Man and Lau, (2005) highlighted that Entrepreneurial competencies include many skills that are grounded and related to personal things like traits, personality, attitudes, and social roles and which can be achieved through education, training and experience. Man et al. (2002) defined entrepreneurial competencies as the total ability of the entrepreneur to perform a job role successfully and in a responsible way. Lerner and Almor (2002) did their study on 220 women entrepreneurs and found that managerial skills and entrepreneurial skills contribute significantly to the success of women entrepreneurs. It includes finance, proper management of human resources, proper production and operation activities, creativity, innovations and marketing products. Chandler and Jansen (1992), who did their study on the state of Utah, found that identification and prioritisation of entrepreneurial, technical and managerial functions are three areas the entrepreneurs must employ to become successful. Smith and Morse (2005) observed in their study and then suggested that managerial competencies which include functional and organisational competencies are very vital for the growth and long-term survival of entrepreneurs. Rebar and Fischer (1999) & Orser, Riding and Manley (2006) suggested sixteen areas of similar expertise which include Marketing opportunities, Strategic Planning, and effective management which are very crucial among them for making entrepreneurs more successful in the long run. Man et al (2002) under their study identified six competency areas like Opportunity, interpersonal relationship, organising, conceptual and commitment competencies which are key to their success. According to ACCA, (2010)**,** Govt. and other agencies for the pursuit of economic development focussing on Women-led business or enterprise plays a significant role in the attainment of the same.

Jennings and Cash (2006) pointed out that there is a difference between male and female entrepreneurs concerning aspects like capital investment, thinking, perception, knowledge, technical skills, motivation, personal background, risk-bearing capacity and support from their family etc. N.Carter and Shaw, (2006), talked that women business proprietors enjoy a lower status either concerning organising human capital, personal socio-cultural background and working experience or negotiation skills while managing their entrepreneur. According to M. P. Driessen and P. S. Zwart (2006), competencies and key skills of entrepreneurs include experience, knowledge, motivation, capacity and entrepreneurial features (personal qualities) for growth. Zou & Thebaud (2015) discussed the reasons that motivate them to choose entrepreneurial activities both for men and women. In general, men prefer good incentives, job security, growth and promotion opportunities whereas women prefer to make a better balance between work and family, to use initiative and get recognition while pursuing an entrepreneurship carrier. According to Z.A.L.Pihie (2011), women's entrepreneur personal and functional competencies are made-up skills, attitude, knowledge and family support to make them successful. Rotefoss & Kolvereid (2005) did a cluster analysis and found out that entrepreneurial education plays a critical role in increasing entrepreneurial intentions among women and bridging the gap between men and women. In a study conducted by Dawson and Henley(2012), it was found that due to differences in risk attitude, there is a huge gap between men and women entrepreneurs in starting an entrepreneurial carrier. Again women's less participation is due to fear of failure, less support from family and poor social networks. Anandalakshmy. A (2018) told about the problems and challenges the women entrepreneur are facing in India to start and operate their businesses. These are non-

availability of adequate capital, dual role play, restricted freedom, less Knowledge of information technology and less awareness about different schemes offered by Govt.

As per the suggestion given by Mishra (2015) after analysing 48 Articles that self-confidence, institutional support, and the ability to avail the credit facilities and social networks play a very important role for an entrepreneur for long-term survival and to achieve success. Alam et al (2017), of them, highlighted that personality factors which include self-efficacy and risk appetite and contextual factors like social media are highly relevant and significant for the sustainable business of women entrepreneurs and to make them successful. Rekha K. Jadhar (2013) has identified that nowadays Govt. has increased its assistance to women entrepreneurs to make them socially and economically well accepted. Though the growth and development of women entrepreneurs depend upon many socio-economic factors but Govt. policies play an important role and their development will no doubt raise the status of women socially and economically. According to a report by the United Nations Industrial Development Organisation (UNIDO) 2017**,** though the women's repayment rate is more than their counterparts, still they face many problems getting loans from Banks and financial institutions either due to discriminatory attitudes or less faith in them for paying the debt. Women entrepreneurship highlighted that lack of knowledge for marketing the products, getting loans and subsidies, less awareness about Government assistance and lack of family support are important challenges faced by women entrepreneurs while pursuing and developing their businesses. Tlaiss (2014) talks about the obstacles women entrepreneurs are facing in many developing countries including India. Women entrepreneurs lack to access finance from banks get proper relevant education and expertise, are overburdened with household activities, are incapable to get proper practical and self-employed training, attending meetings conducted by Govt. bodies etc. All these bottlenecks are limiting the capacity of women entrepreneurs to excel in their competencies in performing their responsibilities towards the development of business establishments.

Women Entrepreneurs, Challenges & Economic Development

As per the survey conducted by the sixth economic Census (Ministry of Statistics, 2021) that only 13.76% of women entrepreneurs out of the total entrepreneurs of India. Again 2.7 million work in agriculture and 65% approximately 5.29 million are workings in the non-agriculture sector out of total business establishments. Among the different states of India, Tamilnadu has the highest 13.5% followed by Kerala at 11.35% and Andhra Pradesh at 10.56%. While running their business women faces many obstacles and challenges which hinder their growth and success. These problems may be concerning Finance, Marketing, Health, Entrepreneurial Attitude, Technology Access, Availability of workspace and boost of confidence. Rakesh(2016), pointed out that for the growth of rural areas, there is significant growth of women entrepreneurs but their development is very low as they face many challenges & problems. Studies conducted by many researchers suggest that among many obstacles lack of education, knowledge & Skill, biased attitude, and poor infrastructure support, are the major barriers which restrict the growth and development of entrepreneurial activities of rural women entering into this segment. In some situations, it is also observed that psychological and physical pressure also acts against women entrepreneurs to proceed further.

Entrepreneurship is a human endeavour that significantly contributes to economic growth and one of the identified findings is that there is a strong correlation between entrepreneurship and of economic growth of a country. It's not hard to draw parallels between the role of entrepreneurs and the growth of economies. Generally, women enter into the entrepreneurship segment due to economic factors and the mindset to do something independently, (Shabunath,2021). The role of Women entrepreneurs needs to be considered in the economic development of the nation for various reasons (Nicholas and Victoria, 2010). It has been observed that there is a positive connection between economic growth and women entrepreneurs as they help in accelerating growth through the creation of a job, increasing savings and thereby creating growth in the industry. Rural women entrepreneurs no doubt will contribute to the wealth improvement of their family and their nations, (Kiran 2014). For the improvement of the rural economy through rural development, rural entrepreneurship is very much needed and it works like a growth engine for the quality of life of rural people and their economic and sustainable development. (Raju & Bhubaneswar, 2014). Women are crucial to the success of the household economy. Govt Schemes, policies, & programmes have made the growth and development of women entrepreneurs across the Tamil Nadu state and their economic and social status has improved after entering into this profession, (Joseph,2020). Women's attitudes have undergone dramatic shifts due to the technological and industrial revolutions in the realms of education and social and economic necessities. The last decade has seen a rise in women's access to economic opportunities. Women's participation in the workplace is a relatively recent phenomenon. Women's emergence as business owners is a major step toward their economic independence and the

recognition and respect they deserve in all spheres of society. Women's involvement in business would bring a calming influence to today's troubled world, paving the way for more harmony and cooperation. Women in India are encouraged to pursue self-employment by both the government and private organisations in several different states, including Gujrat, Kerala, Punjab, Delhi, Karnataka, Andhra Pradesh, and Tamil Nadu. The growth of the women-owned business sector in the country is undoubtedly boosted. Women's entrepreneurship in India is typically associated with more traditional industries, such as the production and sale of papad, pickle, clothing production and so on. Manufacturing, exports, the service industry, businesses with high revenue generation, etc. are all areas where women are gradually being encouraged to start This study involves the collection of primary data through our survey and interviews and secondary data from books, Journals and different reports. The researcher surveyed with our designed questionnaire from the women entrepreneurs, from the Kandhamal districts of Odisha which were collected from the sample size of 148 respondents as per random sampling. Our questionnaire is designed with six major parameters of Entrepreneurial Competencies i) Personal, ii) Interpersonal, iii) Conceptual, iv) Business Management, v) Technological, and vi) Economic & Financial Competencies. Each parameter are having five questions on a five-point Likert Scale.

After collecting data, the empirical research provided an overview of data analysis and demonstrated the hypothesis through PCA and ANOVA. Statistical methods are the mathematical formulas, models, and techniques used to analyse raw study data statistically. The reliability of the findings can be evaluated with the help of statistical methods gleaned from survey data. Before conducting the pilot test and determining the sample size for our questionnaire, we performed a factor analysis to determine the relative importance of the factors under consideration. Then we used analysis of variance (ANOVA) to assess the economical growth and challenges of the key competencies of women entrepreneurs.

Data Analysis and proved hypotheses:

This empirical study explained the data analysis and proved the hypothesis in statistical analysis using PCA & ANOVA.

Table 1: Data Reliability of Hypothe

Questions	Eigenvalue	Mean	Std. Dev
Q1	2.476	1.268	1.518
Q2	1.112	2.185	1.678
Q3	0.919	3.241	1.62
Q4	0.873	1.173	1.051
Q5	0.889	4.081	1.462

Eigenvalue

After Principal Component Analysis (PCA), we can assess the validity of our data and the precision with which we measure it. Cronbach's alpha is 0.842, which indicates an extremely high degree of reliability of the data. All five questions are met by the eigenvalue Q1: 2.476, Q2: 1.112, Q3: 0.919, Q4: 0.873, and Q5: 0.889. So we can consider all questions for our analysis because all values are in the higher range and greater than 0.7 of the eigenvalue.

Hypothesis H1:

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	16.9114198	4.2278549	5.62	0.0002
Error	715	537.8649691	0.7522587		
Corrected Total	719	554.7763889			

R-Square	Coeff Var	Root MSE	Score Mean
0.030483	27.28163	0.867328	3.179167

Source	DF	Type I SS	Mean Square	F Value	Pr > F
Source	4	16.91141975	4.22785494	5.62	0.0002

ANOVA TEST

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	16.9114198	4.2278549	5.62	0.0002
Error	715	537.8649691	0.7522587		
Corrected Total	719	554.7763889

0.030483	27.28163	0.867326	3.179167

Source	DF	Type I SS	Mean Square	F Value	Pr > F
Source	4	16.91141975	4.22785494	5.62	0.0002

Table 2: ANOVA Table of Hypothesis H1. Fit Statistics

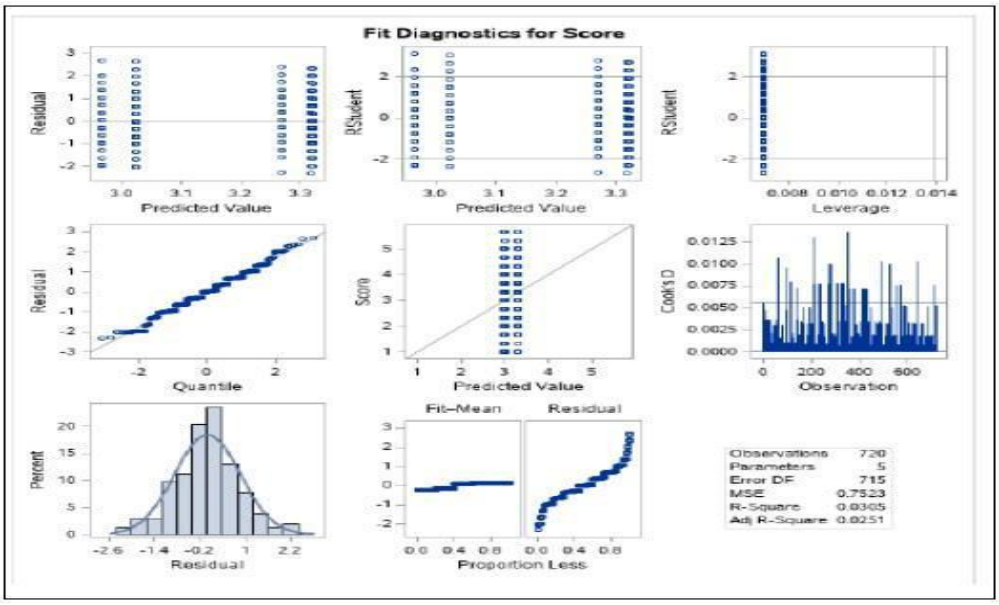

Figure 2: Fit Diagonestics of Hypothesis H1.

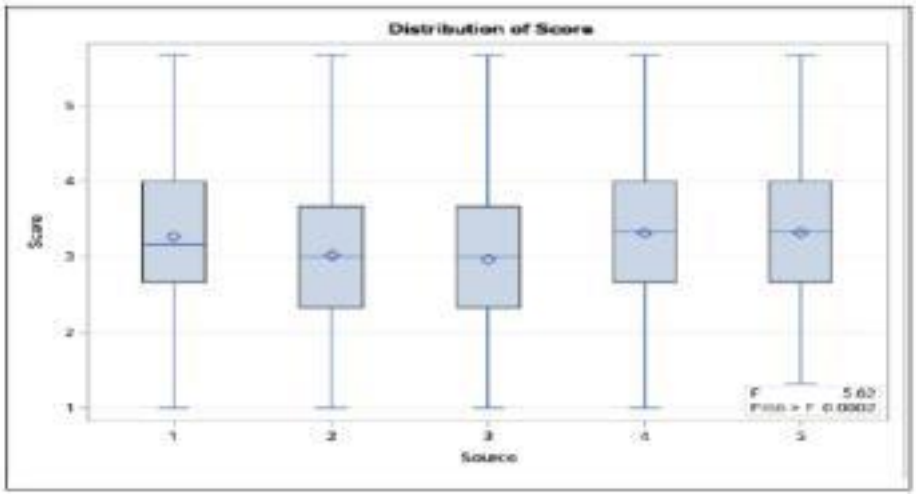

Figure 3: Box Plot of Hypothesis H1.

Table (1) shows the consistency of the eigenvalue, which is critical when verifying data. Each of the eigenvalues for each of the six criteria is larger than 0.7, which is a very good sign of the criteria's reliability. Since our data has high Cronbach's Alpha and eigenvalue reliability, we can conclude that our analysis is rigorous. Figures 2 provide clear depictions of the PCA scree plot and the component scores matrix, respectively.

Hypothesis H2:

Eigenvalue			
Questions	**Eigenvalue**	**Mean**	**Std. Dev**
Q1	1.326	3.028	1.218
Q2	2.128	1.131	1.718
Q3	0.983	1.541	1.612
Q4	0.975	2.124	1.271
Q5	1.299	4.081	1.241

Table 3: Data Reliability of Hypothesis H2

After Principal Component Analysis (PCA), we can assess the validity of our data and the precision with which we measure it. Cronbach's alpha is 0.802, which indicates an extremely high degree of reliability of the data. All five questions are met by the eigenvalue Q1: 1.326, Q2: 2.128, Q3: 0.983, Q4: 0.975, and Q5: 1.299. So we can consider all questions for our analysis because all values are in the higher range and greater than 0.7 of the eigenvalue.

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	98.0669753	24.5167438	36.82	<.0001
Error	715	476.0871914	0.6658562		
Corrected Total	719	574.1541667			

R-Square	Coeff Var	Root MSE	Score Mean
0.170803	26.79070	0.8160000	3.045833

Source	DF	Type I SS	Mean Square	F Value	Pr > F
Source	4	98.06697531	24.51674383	36.82	<.0001

Table 4: ANOVA Table of Hypothesis H2

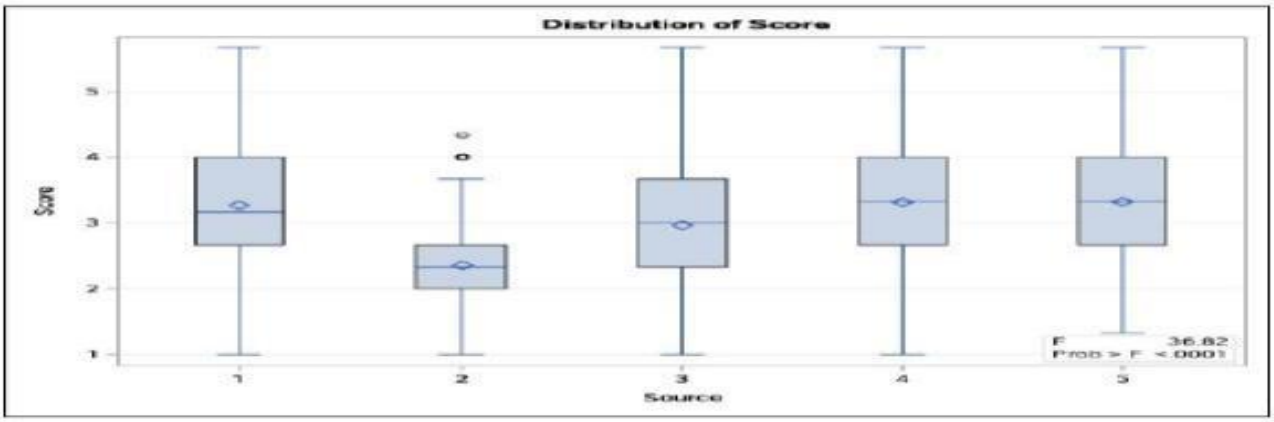

Figure 5: Box Plot of Hypothesis H2

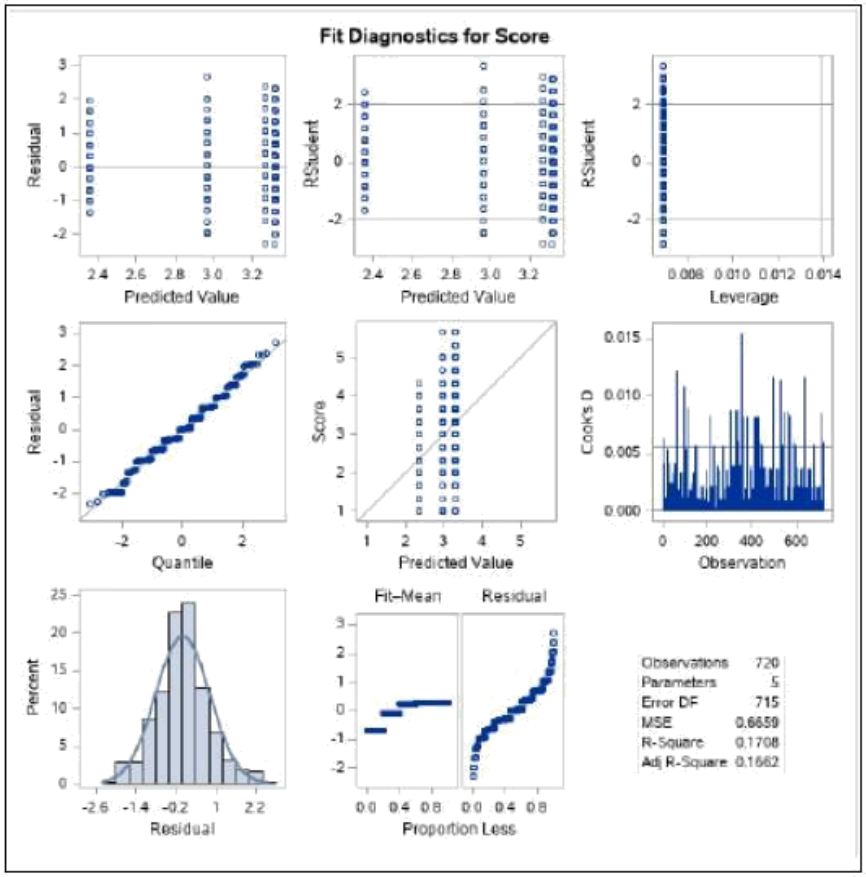

Figure 4: Fit Diagonestics of Hypothesis H2

The above ANOVA is applied to test the hypothesis. The ANOVA results as given in table 3, show that the calculated "F" value is (36.82), which is quite good and the "P" value is (0.0001), which is less than 0.05 of significance. Hence the null hypothesis $H2_0$: "*There is no significant relationship between Govt. policy and the economic challenges of women entrepreneurs"* is rejected, whereas the alternative hypothesis H2a: "*There is a significant relationship between Govt. policy and the economic challenges of women entrepreneurs."* is accepted. It is inferred that the Govt. Policy and schemes are most important to overcome the challenges faced by women entrepreneurs at different levels may it be Block, Panchayat, or District or State level.

Hypothesis H3:

Eigenvalue			
Questions	**Eigenvalue**	**Mean**	**Std. Dev**
Q1	1.219	3.218	1.118
Q2	2.273	2.132	1.653
Q3	1.325	1.441	1.204
Q4	1.649	2.024	1.381
Q5	2.173	4.691	1.412

Table 5: Data Reliability of Hypothesis H3.

After Principal Component Analysis (PCA), we can assess the validity of our data and the precision with which we measure it. Cronbach's alpha is 0.823, which indicates an extremely high degree of reliability of the data. All five questions are met by the eigenvalue Q1: 1.219, Q2: 2.273, Q3: 1.325, Q4: 1.649, and Q5: 2.173. So we can consider all questions for our analysis because all values are in the higher range and greater than 0.7 of the eigenvalue

.

ANNOVA TEST

Dependent Variable: Score Score

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	133.7253086	33.4313272	45.74	<.0001
Error	715	522.6296296	0.7309505		
Corrected Total	719	656.3549383			

R-Square	Coeff Var	Root MSE	Score Mean
0.203739	29.83370	0.854956	2.865741

Table 6: ANOVA Table of Hypothesis H3

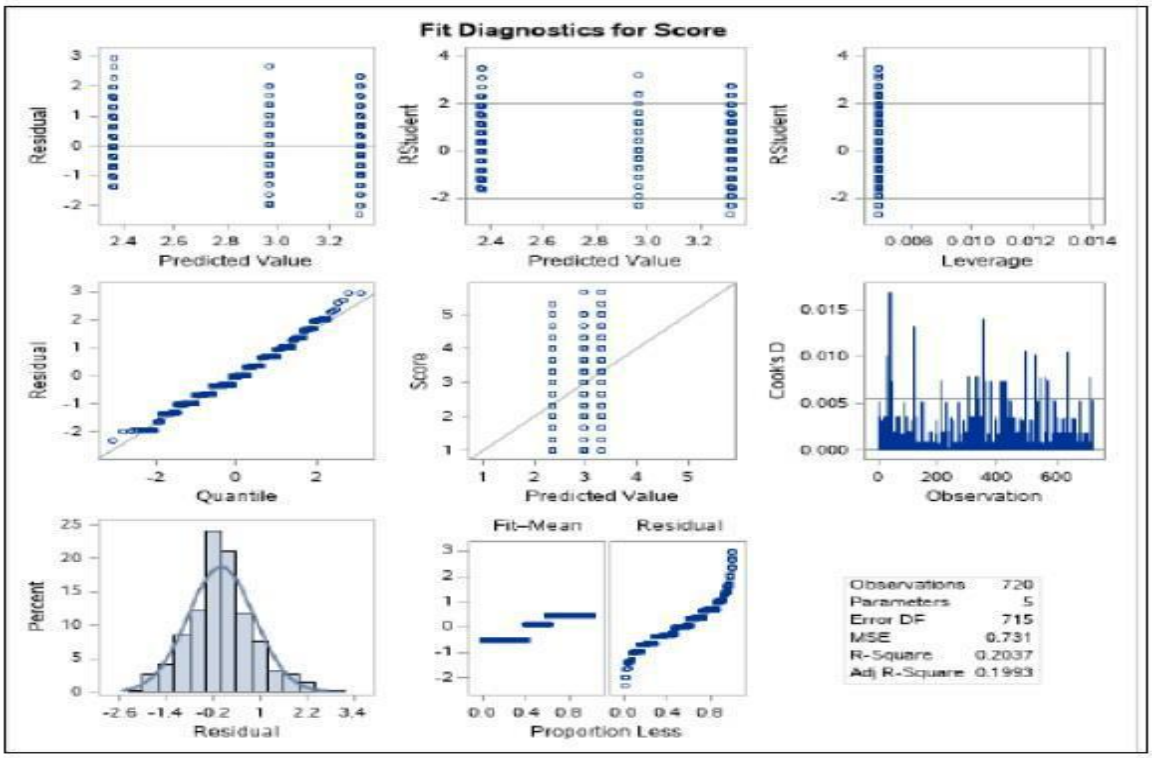

Figure 6: *Fit Diagonestics of Hypothesis H3*

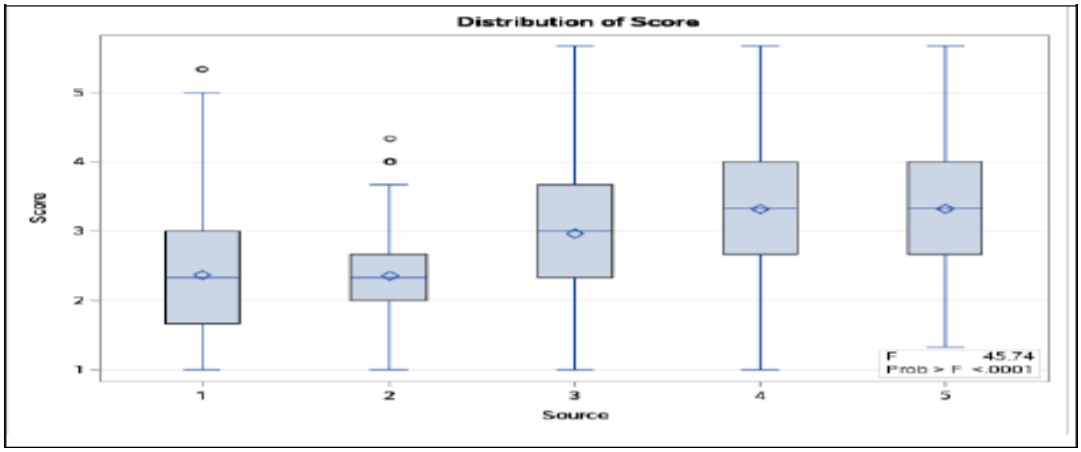

Figure 7: *Box Plot of Hypothesis H3*

The above ANOVA is applied to test the hypothesis. The ANOVA results as given in table 4, show that the calculated "F" value is (45.74), which is quite good and the "P" value is (0.0001), which is less than 0.05 of significance. Hence the null hypothesis H30: "*There is no significant influence of business networking on the performance of the women entrepreneurs*" is rejected, whereas the alternative hypothesis H3a: "*There is a significant influence ofbusiness networking on the performance of the women entrepreneurs*" is accepted. It is inferred that business networking is an art form, and one should be adept at it as an entrepreneur. Business networking is all about bringing people together who can help each other's business activities and problems.

FINDINGS AND DISCUSSION

This study tries to find out the key influential factors for the growth and success of women entrepreneurs and the challenges and hurdles they face during their entrepreneurship tenure. Again the study is interested to unveil the facts that starting their own business, influences the economic and financial condition of their family and country as a whole. There are many Govt. launched schemes which help them to face the challenges which generally restrict their entrepreneurial growth. The data analysis suggests that the key competencies which are responsible to make them successful and make them self-dependent are Personal skill(1st), Economical & Financial(2nd), Business Management(3rd), Technological(4th) Interpersonal(5th) and conceptual competencies are the 6th one respectively. So it is well accepted that personal skills like Spotting Opportunities, Commitment to work, Motivation & Preservance, Self-efficiency & Self-confidence, Information seeking and Problem-Solving skills will make entrepreneurs more competent in doing their own business. The study also reveals that there is an influence of personal networking with the performance of the business owned by them and it has a significant impact on the success of entrepreneurial activities performed by women. It is inferred that business networking is an art form, and women should adopt it as an entrepreneur to survive and succeed in the long run. The networking will be beneficial to the rural women entrepreneurs in performing their enterprise-related activities like spotting business opportunities, getting moral support, enhancement of access to financial assistance, availing different Govt. schemes, acquiring technical support understanding entrepreneurial orientation like creativity and innovativeness which will make them more proactive of success.

Concerning the fourth objective to conclude the interconnection between different Govt. Schemes and challenges faced by women entrepreneurs, it is explored there is a significant influence of the former to the latter. That indicates that if women entrepreneurs will be aware of many schemes launched to grow their small businesses both by Central and state Govt. like Annapurna Scheme for catering, Stree Shakti for (EDP), Dena Shakti (Manufacturing), Orient Mahila Vikas Yojana(Small Business) then the impact of challenges to them will reduce to a great extent. Other than these schemes Govt. have established many institutions to fulfil the needs of women business owners. The Platform for Women Entrepreneurship (WEP) is the WEP, which was launched by the NITI Aayog, and it aspiring and established women entrepreneurs in India. It's broken down into three sections and each one has different objectives like Iccha, Gyana & Karma Sakti for encouraging, educating and providing hands-on assistance to women entrepreneurs to expand their businesses. We found that if women will aware of and access all these schemes and facilities provided by different levels of Govt. automatically the effect of challenges will come down and they overcome them.

CONCLUSION

The study demonstrated that in rural areas like Kandhmala women entered into entrepreneurial activities but did not enter due to family commitments but rather due to personal achievement, independency and autonomy which seems to parallel the pull factors theory. The findings provide new insight into the personal and entrepreneurial characteristics of women taking up business ownership. Passion for their desired business, courage, confidence and strong willpower were their strongest skills. It is also evident from this research study that women entrepreneurs use their passion, personal interest and inherent strength to overcome many shortcomings and hurdles along the path to pursue their dreams.

LIMITATIONS OF THE STUDY

The study is limited to the women entrepreneurs in the Kandhmala district of Odisha but similar studies can be generalised further by doing it in other districts of Odisha and India and also by taking the other key competencies into account also. Here stratified sampling is adopted so that an overall view can be drawn from the studies but other studies can apply different sampling to pursue their study.

Abstract— **Social network has gained remarkable attention in the last decade and as the evolution take place, accessing social network sites such as Twitter, Facebook, LinkedIn, Instagram and YouTube have become very affordable. As a large population uses one or the other social networking site, it has become very convenient for companies to reach their consumers through these sites. The main objective of this project is to identify the impact of social media sentiment on a company's success and companies have to take this sentiment into consideration and plan their marketing strategy accordingly and evaluate its importance over traditional marketing strategy in building brand names and consumer behavior. The dataset on which the study has been carried out consists of a sample of tweets on @Nintendo, the quarterly sales of @Nintendo and the information of its followers and their tweets regarding the brand on Twitter. The analysis and findings of the study highlighted the geo-graphical distribution of the followers of @Nintendo, the market outreach of the brand, and the relationship between the sentiment of its followers towards the brand and the quarterly sales of @Nintendo**

Keywords— Sentiment Analysis, Recurrent Neural Network, Long Short Term Memory, Gated Recurrent Unit,

1. INTRODUCTION

Over the past decade, media has witnessed a huge transformation, consumers are progressively using social networking sites to look for information regarding various products and services, instead of relying on traditional methods such as television, radio, and magazines etc. [1]. Every seventh person in the world now owns a Facebook profile and nearly four in five Internet users are associated with at least one social media site. With the ever-increasing number of internet and social media users, it has become inevitable for major brands to understand online customer behavior. The emergence of social media has led to a subsequent change in media consumption which is pushing companies and organizations to adopt social media as one of their marketing strategies and public relation tools [2]. Therefore, social media has become an increasingly familiar platform employed in E-Commerce to market services and resources to current and prospective customers.

1.1. Social networks and social media

The term social network was first coined to differentiate between networks that were used for business purposes from those used for socializing amongst people. The definition of social networking has been extended to include grouping of individuals into specific groups especially in workplace, universities and high schools, however the most popular accepted definition of social networks relates to the interactive websites which provides users with message boards, chat rooms, and the ability to leave comments and have a discussion with other people [3]. Alternatively social networks is also referred to as a virtual community website that brings people together to talk, share ideas and interests, or make friends. This type of collaboration and sharing on social networking sites is known as social media. Unlike traditional media that is typically created and controlled by only a bunch of people, the social media allows users to share their opinions, views and encourages interactions and community building shaped by consumers [4]. The term "Social Media" has been derived from the words, "Social" and "Media" which are discussed as follows: Social: the term 'Social' refers to interacting with other people for exchange of information characterized by the friendly companionship or relations.Media: the term 'Media' refers to the instrument of the communication such as radios, television, newspapers, magazines, internet etc. that reach people widely. So we can say that social media is a web based social instrument of communication that enables people to interact with each other by both sharing and consuming information. Safko and Brake [5] observed that social media is an umbrella term referring to activities, practices, behaviors among communities of the peoples who gather online to share and exchange information, knowledge and opinions using communicational media. According to Weinberg [6] social media relates to the sharing of information, experiences and perspectives through community oriented websites. monologues into social media dialogues. Since last decade, social media has evolved from being a simple communication hub to an agent of change, which has effected every day to day activity of humans and thereby changing people's lives.

1.2. Effect of social media on various areas

The various areas which have had a lasting and permanent effect of social media are as follows [3]:

1.2.1. Politics and public service

The way personal computers that changed forever the way businesses were conducted. Social networks are altering the demography of our society ranging from politics and public service to business and customer satisfaction. Facebook has become the de-facto platform for how non-profit organizations, environmental activists, and political factions reaching out to thousands of potential volunteers. Twitter is generally used by almost all progressive politicians to promote their causes. Thanks to the social networks, fields like politics is no longer limited to the political leaders but people can also express their concerns and opinions, share their ideas, and even communicate with political leaders on a one-on-one basis.

1.2.4. Business

Almost every major business organization has a social presence today. Both existing and emerging businesses are now aggressively using social networking sites to promote their products, services, and gain invaluable feedback from their customers. In fact, for businesses, interaction via social network has almost become a de-facto standard for assessing their customer service. It has now become a common to see small or home based businesses that operate solely through their Facebook accounts.

1.2.5. Recruitment

LinkedIn has considerably transformed how HR professionals look for and thus recruit potential employees. However, there are arguments about privacy violation; LinkedIn has undoubtedly facilitated career advancements, recruitment and professional networking to great extent.

1.3. Types of social media platforms

The most commonly used social media platforms are [7]:

1.3.1. Facebook

Facebook is the largest social network on the web with respect to name recognition as well as total number of users. It has approximately 1.8 billion active users and it acts as a wonderful platform for connecting people across the globe with your business. Since the last decade, Facebook has evolved from a basic website into a multi-dimensional network and a mobile platform where anyone can connect with anybody across the world. Keeping in mind, the Pages feature of Facebook, it can really help a lot in one's business.

1.3.2. Twitter

Twitter is a platform where one can express one's views with short text messages along with other media. Twitter is a great interface to communicate with literally anyone in the world just by mentioning their usernames in their posts. This social networking site is a great way to advertise and market one's business. It is also an effective channel for handling customer service.

1.3.3. YouTube

The most famous video-sharing platform that has over a billion users where the users can not only view the content posted by others, but also upload, rate, share and comment on the videos as well. If one wants to engage audience by posting an advertisement of their work or business, there could be no better platform than YouTube.

1.3.4. Instagram

Instagram is a visual social media platform that is totally based on photos and videos posts only. It is also owned by Facebook and is different from others with respect to various filters provided and other photo editing options provided.

1.3.5. LinkedIn

LinkedIn is a social networking site that is dedicatedly used for business and employment-oriented services. LinkedIn allows members that may be workers as well as employers to create profiles in an online social network that may portray real-world professional relationships [8].

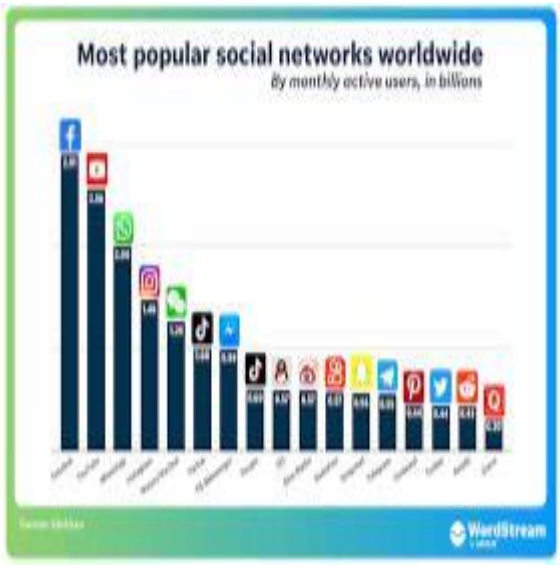

Fig 1: Most popular social media platforms

2. RELATED WORKS

2.1. Social media and e-commerce

In order to understand their customer in a better way and finding their inclination towards their products, the marketers and advertisers are always looking for a number of ways. This requires a lot of information to be gathered about the customers. This information could be

gathered from social media about online users which could be further analyzed to trace the behavior of consumers. The various businesses are using social networks like Twitter and Facebook to help them sell more products and services [10].

2.3. Advantages of social media marketing

The various advantages of using social media marketing are [11]:

• Social media posts can be used to drive targeted traffic to a specific audience of people.

• Social media can act as a very useful tool for boosting the business site's SEO. The traffic building on social media pages of one's business will help their websites get better search engine results.

• Social media may help to build real producer consumer relationship as the tweets on Twitter and posts on Facebook get an insight into the daily lives of their customers and thus help them build better marketing strategies.While maximum users take, Twitter and Facebook as simple social networks and not as advertising and marketing platforms which makes them respond to one's business idea in a more open way.

•

•

• The most important advantage of using social media is the recognition of a brand, as the media itself becomes brand's content and voice. The authors in the paper [12] identify the role of social media marketing in brand building and influencing consumer buying behavior while making a decision to buy a product. The authors carried out the study using primary data collected from 265 respondents through survey method using structured questionnaire. The authors used convenient Sampling and the findings of the paper highlighted the utility of social media marketing in building brands. In paper [1], the authors investigated 504 Facebook users in order to find out the effect of firm-created and user-generated social media communication on brand equity and brand attitude by

conducting a survey throughout Poland. The author in paper [2] gave a detailed description about social media marketing and its advantages. The author also explained as to why to use social media market in libraries and also put forward various challenges of using social media in libraries. In paper [11], the authors carried out an empirical research to recognize the effectiveness of social media as a marketing tool and analyzed the influence of social media on consumers in buying decision making. The claims of the authors were supported by various statistical tests. The authors also suggested that effective and innovative strategies need to be designed for winning larger share of business through this revolutionary medium of social networking. In paper [15], the authors analyzed the usefulness of existing lexical resources as well as features that apprehended the information about the informal and creative language used in Twitter.

3. PROPOSED METHOD

3.1. Problem statement

The effect of social media on the company's reputation and the brand building of its products needs to be studied in order to predict the marketing and distribution plan of its products before their launch. The posts on social networking sites further could be evaluated to get the feedback of their customers on its products that are already in market.

3.2. Research objectives

Based on the motivation and problem statement, we have defined the following research objectives for the project:

• Investigating the correlation between worldwide sales made by @Nintendo and their followers on twitter over past five years

• Understanding the impact of E-Marketing on various geographical regions by analyzing the spatial distribution of @Nintendo Twitter followers.

• To study the brand building achieved through Twitter by analyzing the marketing outreach of @Nintendo(i.e. average visibility of tweets made by @Nintendo)

• To conduct sentiment analysis of the tweets made by general masses about @Nintendo and its products, thereby, gauging the inclination of its customers towards their products.

4. RESEARCH METHODOLOGY

This chapter provides an overview of methodology adopted to attain our research objectives. The chapter starts with a reason behind choosing Twitter as the platform for conducting our study. The sections succeed with a brief description of sampling process used for collecting the twitter data followed by the description of tool used for analyzing same.

4.1. Why twitter?

Twitter is excellent for obtaining data for research as it creates an automatic database of information in real time,which signifies that as the data is archived it will become a unique source of historical information. People tend to give their opinion on latest trends, politics, society, news and technologies in market on Twitter in form of tweets whereas on other major social networking sites such as Facebook, Youtube and Instagram people tend to express their views more often in the form of photographs and videos which are difficult to analyze. That makes Twitter much more convenient option for analyzing the social media data. Moreover, the data available on Twitter can be easily accessed through its API.

4.2. Sampling process

Everyday almost 500 million tweets are made on Twitter which makes it virtually impossible to study all of them. So, Sampling becomes inevitable. In order to carry out our research, we have used Convenience Sampling, wherein, units are sampled because they are convenient to obtain. In our case, we relied on the tweets gathered from Twitter API through Stevesie.

4.3 Design Phase

The Design and functioning of the project has been explained with the help of diagrams in this section.

4.3.1 Data Flow Diagram

The flow of the data from being collected to being preprocessed and used for Feature extraction is illustrated in the figure below.

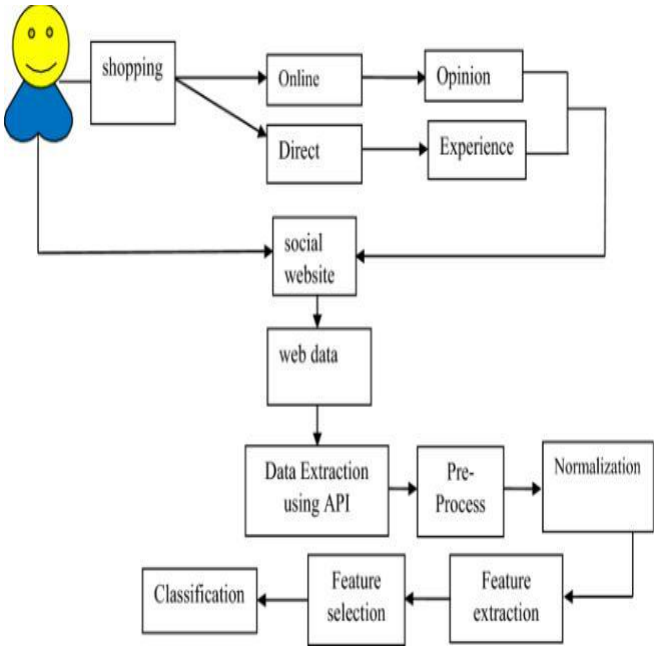

Fig2 Data flow Diagram

4.3.2 Use Case Diagram

The diagram below shows how a user will use the website and how the website will function internally when the users makes a request for a service

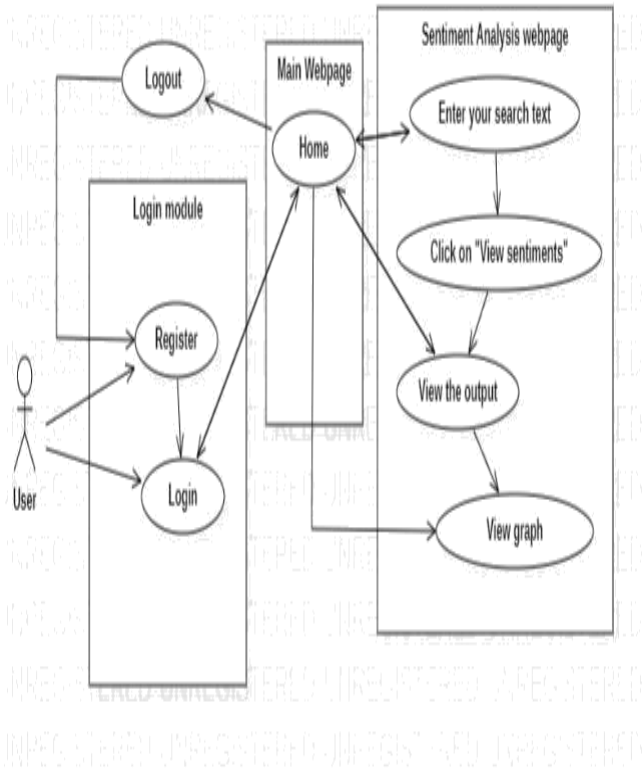

Fig 3: Use case diagram

5. EXPECTED RESULTS

With this project we hope to build a website wherein various brands can enter the requirements regarding the period over which they want to analyze their sentiment and also the period over which they want us to predict their sales. We aspire to make this a successful project which the industry can trust as a product that can provide an accurate representation of their company's online presence and how it will impact their sales.

6. CONCLUSION

In this project, we performed an analysis on Twitter data of @Nintendo available from public twitters API to study the impact of tweets related to @Nintendo on its brand building, customer satisfaction of @Nintendo products and its sales per quarter. The findings and the results of our study clearly signifies that social media marketing influences the building of brands as well as influence the sales of the business. Moreover, the feedback obtained from the customers in form of tweets about their products further help to design the marketing strategy of their products. This project can be further enhanced to fetch similar findings and deductions for the other brands besides

@ Nintendo. Also, the data on which the analysis has been done in this study is recent data, so, the project could be enhanced to do a detailed study on previous years data in order to see the pattern and trends that has been evolved with respect to consumer behavior.

Tracking missing persons using Facial Recognition

Palak Agarwal , Bhavika Gupta , Disha Devalia , Prof. R R Sedamkar, Ph.D , Department of Computer Engineering TCET Mumbai,India.

palakagarwal369@gmail.com , bhavikageeta@gmail.com , devalia.disha.m@gmail.com , r.r.sedamkar@tcetmumbai.in

Abstract—**Finding missing people is a time-critical and labour-intensive task. The longer it takes to find the person, the less likely it is that they will be found. We have attempted to handle the most challenging aspect by creating an integrated and centralized database of missing persons by using Aadhar Card details. Our idea incorporates features like face matching i.e. facial recognition technology. Facial recognition has existed in various forms since decades. But recently it has been found out that it is possible to identify the person easily by using facial recognition where an algorithm deepface can be used which has a high accuracy . The officials can enhance and streamline the further process of finding, tracking, and retrieving missing persons using AI powered facial recognition technology and faces can be matched with their Aadhar Card. This paper states a system that centralized the data and makes the system to find the missing people more efficient.**

Keywords—Face recognition, Face detection,Deepface.

I) INTRODUCTION

Human trafficking is one of the most grueling problems and is currently faced by the whole world. According to the UNODC website, "the transportation, transfer of humans by force, fraud or deception, with the goal of exploitation for profit," is what is meant by "human trafficking." This crime can affect men, women, and children of all ages and ethnicities, as well as people from all historical periods. India is a region where human trafficking continues to thrive. It is considered as the second largest organized crime in India. Here, the portal is designed which consists of a centralized database of missing people. The family or the police officials just have to upload the details of the missing people and their Aadhar Card details. The Aadhar Card image will be matched with the missing person using facial recognition with proper models.

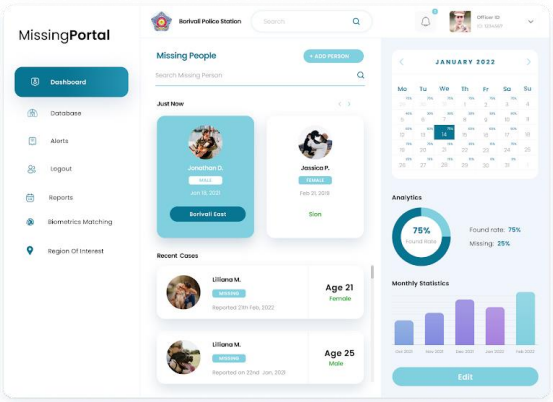

Figure 1:Portal of Missing people

This portal will help to access,track and retrieve the data all at the same place. Face matching reduces manpower,time criticality,and is highly efficient.

II) PROBLEM

In India, there are now more reported cases of missing adults, women, and children than ever before.

The shocking fact is that 6,701,145 persons were still listed as missing nationwide in 2020, when India was battling the Covid-19 outbreak. Due to the lack of a centralized database, communication between officials is relatively inefficient.Traditional way of finding people is quite tedious. There is no technology used to detect missing people and victims may be traumatized even after being rescued and hence may not be able to identify themself. Especially, children may not be able to answer the questions related to their personal details. Hence it becomes difficult to recognize the person.

Our portal allows the victim's family to file a missing complaint online at the portal as police officials will launch FIR after 24 hrs.

The concerned person can undergo face matching by facial recognition technology then the person could be reported to his/her family. This improves efficiency and is a faster process.

III) LITERATURE SURVEY

Facial recognition is one of the popular applications of Artificial Intelligence.it has been found out that facial matching can be done to identify a person. But earlier,the accuracy that was observed was less. In the research paper " FAREC - CNN Based Efficient Face Recognition Technique using Dlib"[1]. This paper talks about how the Dlib algorithm is used and the C++language showing an accuracy of 96%.

According to "Face Modeling Process Based on Dlib"[2] ,talks about Random Forest algorithm which is 95% accurate.Problem with this method was, it is quite a time consuming process. In "Face Detection and Tracking Using OpenCV"[3] paper the Cam Shift algorithm is quite expensive and also time consuming. It was also observed in the paper, "Face Detection and Tagging using Deep Learning"[4] that it will be used with CCTV footage to identify people in case of theft. But the accuracy observed was 85%.

There are more such papers describing a lot of problems that are observed related to accuracy or detection of face and algorithm used. So there is a need to solve the problems using efficient algorithms to fasten the process.

IV) METHODOLOGY

To combat the human trafficking specially child trafficking, an app or government portal linked with Aadhaar information system may be conceptualized for integration of information.The Aadhar enabled data of missing person like photo, age, etc may be circulated to all state and district level police authorities through the dedicated portal with limited access to the authorized authorities only. This information may be used by the designated authorities for the search of the missing persons in locality under their jurisdiction. This would help the Police authorities to find the missing persons in their localities with authenticated and integrated information systems. Similarly, the address and contact details of parents or relatives can be found by using the Aadhar enabled integrated information system, so created, for the person found by the Police authorities or civil society specially for the children who do not have proper/adequate information for their address/parents. At User side:

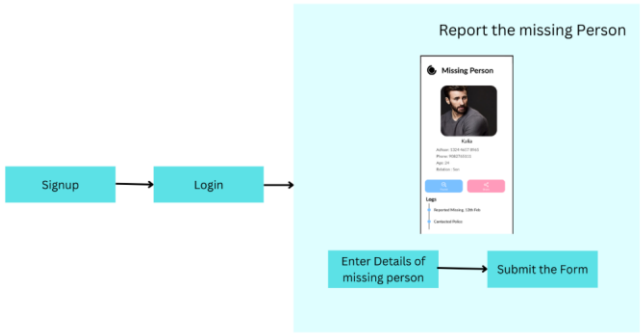

Figure 2: User side application flow

For users , the family member needs to login to the application and enter all the required details of the missing family members. At police side:

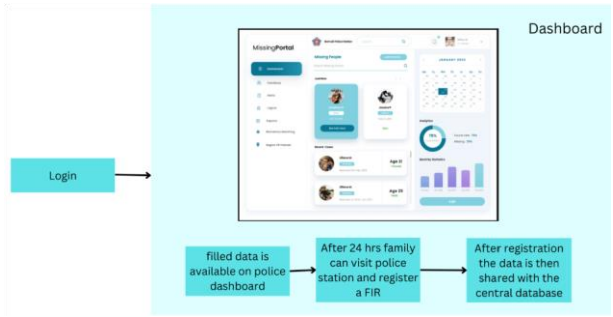

Figure 3: Police side application flow

The data when filled by the family member of a missing person gets reflected at the dashboard of the police station.

After 24 hrs the family member comes to register FIR, the filled data is verified alongside the FIR. After verifying the data, it is shared to the central data. Thus the details of the missing person are now available to police stations across the country.

If a similar person/lost person is found, their identity can be verified using this portal. The verification is done using facial recognition algorithms.

The overview of this system can be seen pictorially as:

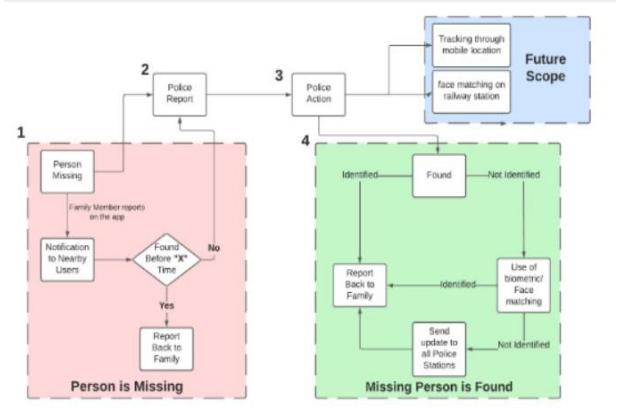

Figure 4: Proposed System

V) ALGORITHM Facial recognition (FR) has long been the most popular biometric method for confirming an individual's identity and has been utilized extensively in a variety of fields, including the military, business, government, and daily life. The CVPR group has long been interested in the study of FR. As a result of the historical Eigenface approach's launch in the early 1990s, FR research gained popularity.[10]

A modern face recognition pipeline consists of 5 common stages: detect, align, normalize, represent and verify. The algorithm used for facial recognition is deepface Facenet512 model.

Deepface is a lightweight face recognition and facial attribute analysis (age, gender, emotion and race) framework for python. Several processing layers are used in deep learning to learn representations of data with various levels of feature extraction. The research has changed as a result of this new technique. Facial recognition (FR) has changed significantly since 2014, when DeepFace and DeepID's innovations were made. Since then, the state-of-the-art performance has been significantly enhanced by the deep learning technique, which is distinguished by the hierarchical architecture to stitch together pixels into an invariant face representation.[10]

It is a hybrid face recognition framework wrapping state-of-the-art models: VGG-Face, Google FaceNet, OpenFace (OpenFace face recognition library that bridges this accuracy gap.On the LFW benchmark, OpenFace achieves near-human accuracy and introduces a brand-new categorization benchmark for mobile contexts.[5]), Facebook DeepFace (It can outperform existing systems with very little adaption because it was trained on a sizable collection of face images from a population that is quite different from the one used to create the assessment benchmarks. Also, the system creates a very compact representation of the face, in stark contrast to other previous systems' move towards tens of thousands of appearance features. [6]), DeepID (The DeepID model is the golden standard in the domain of DFR.

This model is designed to identify frontal faces. [7]), ArcFace (ArcFace has a clear geometric interpretation due to its exact correspondence to geodesic distance on a hypersphere. ArcFace routinely exceeds the current state of the art and is simple to deploy with little additional computational burden. [8]), Dlib (Dlib-ml is a cross platform open source software library written in the C++ programming language. Its design is significantly influenced by concepts from component-based software engineering and design by contracts. This indicates that it is, first and foremost, a collection of separate software components, each of which is supported by excellent documentation. [9]) and SFace.

Experiments show that human beings have 97.53% accuracy on facial recognition tasks whereas those models already reached and passed that accuracy level. DeepFace trained a 9-layer model on 4 million facial photos in 2014 to attain SOTA accuracy on the renowned LFW benchmark, coming close to human performance on the unconstrained condition for the first time (DeepFace: 97.35% vs. Human: 97.53%). [10]

Model	LFW Score	YTF Score
Facenet512	99.65%	-
SFace	99.60%	-
ArcFace	99.41%	-
Dlib	99.38 %	-
Facenet	99.20%	-
VGG-Face	98.78%	97.40%
Human-beings	*97.53%*	-
OpenFace	93.80%	-
DeepID	-	97.05%

Figure 5: Comparison table for different models with respect to LFW Score and YTF score.

If you run face recognition with DeepFace, you get access to a set of features:

Face Verification: The task of face verification refers to comparing a face with another to verify if it is a match or not. Hence, face verification is commonly used to compare a candidate's face to another. This can be used to confirm that a physical face matches the one in an ID document. **Face Recognition:** The task refers to finding a face in an image database. Performing face recognition requires running face verification many times. Facial **Attribute Analysis:** The task of facial attribute analysis refers to describing the visual properties of face images. Accordingly, facial attributes analysis is used to extract attributes such as age, gender classification, emotion analysis, or race/ethnicity prediction.

Real-Time Face Analysis: This feature includes testing face recognition and facial attribute analysis with the real-time video feed of your webcam. Next, I will explain how to perform those deep face recognition tasks with DeepFace.

As seen above, the model using deepface SFace has a great score of 99.60% according to official documentation.

THE ACCURACY OF DIFFERENT METHODS EVALUATED ON THE LFW DATASET.

Method	Public. Time	Loss	Architecture	Number of Networks	Training Set	Accuracy±Std(%)

Figure 6: Accuracy of different methods evaluated on the LFW dataset.[10]

Face recognition models are regular convolutional neural networks and they are responsible to represent faces as vectors. We expect that a face pair of the same person should be more similar than a face pair of different persons.

Similarity could be calculated by different metrics such as Cosine Similarity, Euclidean Distance and L2 form. The default configuration uses cosine similarity. Euclidean L2 form seems to be more stable than cosine and regular Euclidean distance based on experiments.

5.1 Triplet Loss

any image of another person,as a result,photosparticularof

The embedding is shown as In a d-dimensional

EuclideanWe also constrainspace, it embedsthis embeddingan image tox i.e.,exist$f(x$on) $\epsilon$the Rd

d-dimensional hypersphere,

i.e.,$\|f(x$we)$\|$ 2want= 1.to make sure that an image of a

thatperson,samexaiperson,(anchor),$xxpiin$(is(positive),negativecloser).tothanallitotheris to

$$\ldots.(1)\|f(x^{a}i\,) - f(x^{p}i\,)\|\,^{2}2 + \alpha \prec \|f(x^{a}i\,) - f(x^{n}i\,)\|\,^{2}2,$$

$$\forall(f(xai\,),\, f(xpi\,),\, f(xni\,)) \in T \ldots..(2)$$

where the margin between positive and negative pairs is denoted by α. T has a cardinality of N and is the set of all feasible triplets in the training set. The loss is then minimized as follows:

$$\sum^{N_i} \left[\left[\|f(x^{a}i\,) - f(x^{p}i\,)\|\,^{2}2 - \ldots.(3)\|f(x^{a}i\,) - f(x^{n}i\,)\|\,^{2}2 + \alpha\right]\right] +$$

There would be a lot of triplets that are simple to satisfy (i.e. fulfill) if one generated every feasible triplet.[11]

5.2 Datasets and Evaluation

ous models like VGG-Fae, Facenet, FaceNet512, ArcFace and SFace are evaluated and compared.

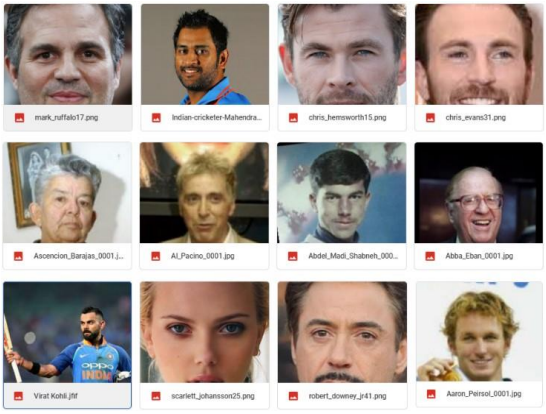

Figure 7: Dataset used

evaluating the algorithm, the dataset shown above is . This data set consists of multiple faces which acts as :abase of citizens.

Our aim here was to match the user input to the images in this pool and return a value that shows whether the input face matches any of the images in the database or not.

Given above is the user input image. This image is compared with all the images in the dataset so as to check if this face is present in our dataset or not.

	model	found result	distance	time taken
0	VGG-Face	/content/drive/MyDrive/Images_DEMO/Copy of chr...	0.149036	1.965082
1	Facenet	/content/drive/MyDrive/Images_DEMO/Copy of chr...	0.185329	1.927456
2	Facenet512	/content/drive/MyDrive/Images_DEMO/Copy of chr...	0.265619	2.190437
3	ArcFace	/content/drive/MyDrive/Images_DEMO/Copy of chr...	0.222220	1.405846
4	SFace	/content/drive/MyDrive/Images_DEMO/Copy of chr...	0.415969	1.271688

Figure 9: Results of the input data using various models.

According to the table above we can see that the /GG-Fae, Facenet, FaceNet512, ArcFace and SFace ıble to compare and find the face in the dataset. Though ɔdels gave us a positive

result, parameters like distance and time taken to process differ.

The first model VGG_Face gave a positive response with distance 0.149036, which is less compared to the results given by other models, and time taken as 1.965082.

Model Facenet gave a positive response with distance 0.185329 and time taken as 1.927456. The next model Facenet512 gave a positive response with distance 0.265612 and time taken as 2.190437, which is the highest time compared to all the other model performance.

Model ArcFace gave a positive response with distance 0.222220 and time taken as 1.405846. The next model SFace gave a positive response with distance 0.415969, which is maximum compared to all the other models, and time taken as 1.271688, which is the minimum compared to all the other model performance.

VI) CONCLUSION

There are problems that people face while identifying themselves after being exploited. Facial recognition can help to identify the concerned person. The portal which is described in this paper will reduce problems with centralisation, tracking and retrieving the person thereby sharing it across the country will increase the possibility of finding that individual and thus improve the speed of the process and reduce the manual work.The accuracy of the model used will increase the efficiency of the system.

Abstract— **In recent years, there has been a significant increase in**

the use of CCTV footage for various purposes such as surveillance, crowd analysis, and behavioral analysis. One of the primary challenges in the analysis of such footage is the efficient and accurate counting of people and the recognition of their emotions. In this paper, we propose a method for counting people and recognizing their face emotions in CCTV footage videos using computer vision and machine learning techniques. Our method involves the detection of people in the video, followed by the extraction of their face images, and finally, the recognition of their emotions using a deep neural network trained on a large annotated dataset. We evaluate the performance of our method on a publicly available dataset and compare it with the state-ofthe-art methods. Our results demonstrate the effectiveness of our proposed method in accurately counting people and recognizing their emotions.

Keywords—Deep learning, Face recognition, openCv, Cuda, video analytics, Yolo, tensorflow.

I. INTRODUCTION

The widespread use of closed-circuit television (CCTV) systems for security and surveillance purposes has led to the availability of large amounts of footage. The analysis of such footage has become an important task for various applications, including crowd analysis, behavioral analysis, and security. One of the primary challenges in the analysis of CCTV footage is the efficient and accurate counting of people and the recognition of their emotions. Automated people counting and emotion recognition have received a lot of attention in recent years due to their wide range of applications, including crowd analysis, security, and marketing.

The banking industry is constantly seeking new and innovative ways to improve the customer experience and streamline operations. The use of these systems in bank premises can provide valuable insights into customer, helping banks to optimize their services and improve the overall customer experience. The purpose of this research paper is to explore the use of automated customer counting and emotion recognition technology in bank premises. Through a review of relevant literature and an analysis of case studies, this research will provide an understanding of the potential benefits of using automated customer counting and emotion recognition in banks, including improved security, enhanced customer experience, better customer insights, and cost savings. The results of this research will be of interest to decision makers in the banking industry who are considering implementing automated customer counting and emotion recognition technology, as well as to researchers and academics studying the use of these systems in the financial sector.

II. LITERATURE SURVEY

Maintenance To engage with clients, offer a range of services, and learn more about personal beliefs and ideas, many businesses use social media networks. The detection of the polarity of positive or negative thoughts in text, full documents, paragraphs, lines, or subsections is done using the machine learning technique known as sentiment analysis. A multidisciplinary field called machine learning (ML) combines statistics and computer science techniques that are frequently utilized in prediction and classification analysis. In this article, general machine learning methods for sentiment analysis are presented. By conducting rigorous industry and community assessments and evaluations of white papers, academic research papers, journals, and reports, this literature analyses and discusses the concept of sentiment analysis. This paper major goal is to analytically categories and examine how research and machine learning approaches for sentiment analysis are being used in a variety of applications. This approach has the drawback of only considering the application side and leaving out hardware and theoretical exposures. The focus on applications rather than technology and theoretical parts of the topic means that this study has several

limitations. This paper concludes with a research proposal for a sentiment analysis machine learning environment in e-commerce.

CUDA-Self-Organizing feature map based visual sentiment analysis of bank customer complaints for Analytical CRM. [https://arxiv.org/ published on 2019]	A paradigm for self-organizing functional map (SOM) descriptive analysis of customer complaints is proposed. The network can also be shown using a variety of methods and automatically learns various groups of complaints.	A self-organizing card structure for sentiment analysis that examines consumer complaints. We contrasted the model's performance with that of the term frequency representation and the TF-IDF representation, two vector space model representations he used in the document.

iii. Problem Statement

The manual analysis of people count and emotion recognition from CCTV video footage's inside bank premises is a tedious, timeconsuming, and error-prone process, which can be improved by introducing automated systems. The absence of automated solutions for analyzing and interpreting large volumes of video footage impedes the bank's ability to accurately and efficiently monitor customer behavior, evaluate employee performance, and ensure compliance with regulations. Thus, there is a need for an automated system that can accurately analyze the people count and recognize the emotions of customers and employees from CCTV video footage within the bank premises, to enhance operational efficiency and provide a better customer experience.

Key issues

- Analysis of sentiment of banks customers using cctv video footage.

- Building a video surveillance for checking the Tampering with the cameras / sensitive or high priority area within banks premises.
- Real-time Counting the number of people detected in cctv camera in particular frame.
- Tracking any activity with smart video surveillance system that needs any attention.
- To analyze the total time duration for any activity that needs to happen with video analytics.

IV. DATA COLLECTION AND VISUALIZATION

The Facial Expression Recognition and Analysis (FER+) dataset is a publicly available face recognition dataset. This dataset is an tension of the face recognition (FER) dataset and includes more detailed annotations of facial expressions. FER+ dataset contains 35,887 48x48 pixel face images, each labeled with one of eight emotions: anger, disgust, fear, happiness, sadness, surprise, neutral, or contempt. The dataset also provides a more detailed annotation of the intensity of each emotion, with each image labeled with continuous values for each of the eight emotions.

Fig 4

III. PROPOSED SYSTEM

We can achieve our goal by using our proposed system's ability to combine object detection with emotion detection, and we may compare the results with those of other systems to further improve it. In order to better grasp how to create our model, we learned numerous strategies for emotion recognition and couting detection for our study. Here are several widely utilised techniques for emotion recognition and couting detection.

Object Detection : An object detection algorithm that trains a machine learning model to recognize and locate objects in an image or video. You can train a model to detect people in a frame and count the number of detections. Common object detection models include Faster R-CNN, YOLO, and SSD. Background subtraction is a technique that subtracts the background from the current video frame in order to detect moving objects. A background subtraction algorithm can be used to identify people in a video and count the number of unique movements. Optical flow is also the best way to do this. This includes analyzing pixel movement from frame to frame to identify moving objects.

An optical flow to track people in video and count the number of distinct movements. Various deep learning models involved in training deep neural networks to recognize and compute people in footage. Convolutional Neural Networks (CNNs) can be used to detect and compute people. The Haar cascade method uses a machine learning model to detect features of objects in an image or video. We can train a cascading Haar classifier to detect people's characteristics and count the number of detections. Head counting is a method of counting people in a video by detecting and tracking their heads. Here, methods such as Oriented Gradient Histogram (HOG) and Support Vector Machines (SVM) can be used to identify and compute the head of the video.

Emotion Detection Methods : Convolutional Neural Network (CNN) algorithms are widely used for image and video analysis tasks, including facial emotion recognition. It can be used to learn features directly from image or video data and can provide highly accurate emotion recognition. Examples of CNNs used for emotion recognition include VGG-Face, Inception, and ResNet.

Recurrent Neural Networks (RNNs): RNNs can be used for temporal modeling of video. It can be used to capture a series of frames from a video and can be useful for detecting changes in facial expressions or body movements over time. Long Short Term Memory (LSTM) networks: LSTMs are a type of RNN that can be used to model temporal sequences with long-term dependencies. They were used to

recognize emotions in video and learned frame order and how to capture those emotions. SVMs are widely used for classification tasks and can be used to recognize emotions in images and videos. They work by finding the optimal hyperplane that separates the data into different classes.

PCA is a technique used to reduce the dimensionality of data. It can be used to reduce the size of facial features in an image or video to make it easier to classify emotions. Fisher vector coding is a technique that can be used to represent an image or video as a set of features. It has been used to recognize facial emotions by encoding facial features extracted from images or videos and then classifying them with SVM. A deep trust network (DBN) is a type of deep learning model that can be used to extract and classify features. It learns to extract appropriate features from images or videos of faces, which can be used to recognize emotions.

Here are some examples of other people's work on related issues: S. P. Mohanty, S. Mohanty, and S. P. Mohanty for Trustworthy Numbers of Video Surveillance Images. K. Nyack (2019) proposes a people counting system that combines background subtraction and deep learning techniques.

F. Iqbal, S.S. 2020 Alakhmadi and M. A. Alkhalifa. To identify and count pedestrians in congested areas, D.B. Nana and E. O. Adomako (2020) developed a pedestrian identification and counting system that combines Haar cascades, convolutional neural networks, and local proposal networks. To identify people's emotions in CCTV footage, A.M. Zainuddin and MF Abdul Ghafar (2018) present a sentiment analysis system that combines convolutional and recurrent neural networks. An approach to sentiment analysis that combines auditory and visual information was described by R. Hare and M. K. Jindal (2018) identifies people's emotions in surveillance films. In 2019, H. Zhu and K. Wong proposed an emotion analysis method that combines visual and auditory data to judge human emotions in CCTV images and other images.

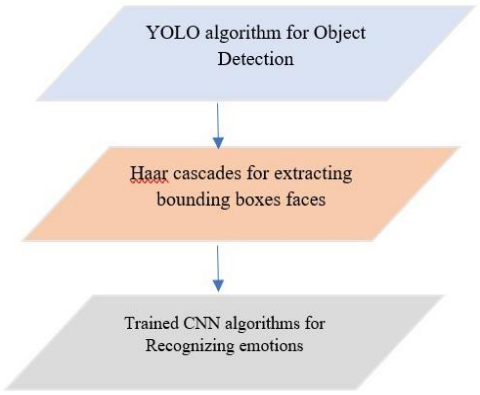

Fig 5: Proposed Method Diagram

This Paper proposes a method for counting people and recognizing emotions from faces in video recordings from CCTV cameras. Our method consists of three steps: person detection, face extraction, and emotion recognition. In the first step, we use an object detection algorithm like YOLO to detect people in the video. The result of this step is a set of frames around the detected person in the video. In the second step, we extract the face image from the bounding box obtained in the first step. Detect faces from bounding boxes using face detection algorithms like Haar cascades and extract face images. In the final step, deep neural networks are used to recognize emotions in facial images. Train a CNN on a large annotated dataset of face and emotion images to learn mappings between facial features and emotions.

YOLO divides the input image into a grid of cells and predicts the bounding box and class probabilities for each cell. This approach allows YOLO to detect objects of different scales and locations in a single forward pass through the neural network, making it faster and more efficient than other object detection methods. We first trained on an annotated image dataset containing people. Once the YOLO model is trained, it can be applied to a new video frame or sequence of frames to detect people. The result of YOLO is a set of bounding boxes around each person detected in the video frame. To further use YOLO with CNN for emotion recognition, we can extract the face regions from the bounding boxes obtained by YOLO and pass them through a CNN for emotion recognition. The CNN can be trained on a large dataset of facial images and emotions, and it can learn to recognize different emotional

states based on the facial features extracted from the face images. The CNN can take the face images extracted from the bounding boxes, preprocess them by resizing or cropping, and pass them through multiple convolutional layers to extract meaningful features. These features are then passed through fully connected layers to classify the emotions of the face images. To improve the accuracy of emotion recognition, we can also incorporate temporal information by analyzing the changes in facial expressions over time. The sliding window method can be used to capture and sequence the temporal context of facial expressions. This approach can help better capture the dynamics of emotion expression and improve the accuracy of emotion recognition.

IV. MODEL EVALUATION AND RESULT

The You Only Look Once (YOLO) algorithm has been widely used for counting people in CCTV footage, and its performance has been evaluated in several studies. One of the main advantages of YOLO for people counting is its high throughput. YOLO can detect people in real time even on weak hardware, making it suitable for real-world applications.

In terms of accuracy, the YOLO algorithm showed high accuracy and recall in counting people. In one study, YOLO achieved an accuracy of 98.7% and 92.6% remember counting people in crowded scenes. In another study, YOLO achieved an average mean accuracy (mAP) of 89.6% for human detection. However, the accuracy of the YOLO algorithm can be affected by a number of factors, including lighting conditions, occlusion, and camera perspective.

For example, if lighting is poor or people partially overlap, the YOLO algorithm cannot accurately identify everyone in the video. To address these issues, researchers have proposed various improvements to the YOLO algorithm, such as incorporating depth information or combining multiple YOLO models using ensemble methods.

Overall, the YOLO algorithm has shown promising results for counting people in CCTV videos, and its performance can be improved with further optimizations and improvements. Theoretical evaluation of the YOLO algorithm shows that it is a powerful and efficient tool for helping people count numbers in a variety of real-world scenarios.

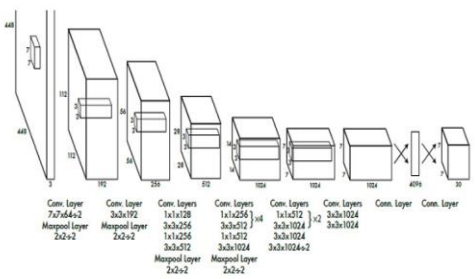

Fig 6. Overview of Yolo Object Detection Algorithm

For people counting, YOLO algorithm is famous for its fast processing speed and high accuracy. Combined with the Haar cascade for face detection, the proposed method can accurately detect and count the number of people in a video as well as localize faces for further analysis. The accuracy of face detection using the Haar cascade can be evaluated using metrics such as accuracy, recall, and F1 score. This metric measures the accuracy of the algorithm for detecting and locating faces in a video frame. A high accuracy score indicates that most of the faces detected are actually faces, and a high recall score indicates that the algorithm can detect most faces in the video.

The proposed method for emotion recognition uses CNNs trained on large annotated datasets of face and emotion images. The accuracy of emotion recognition models can be evaluated using metrics such as accuracy, recall, F1 score, and accuracy. Model accuracy can also be assessed using techniques such as cross-validation. Cross-validation measures model accuracy on new, unseen data by dividing the data set into training and test sets.

The overall performance of the proposed method can be evaluated using metrics such as accuracy, speed, and scalability. The speed of a method can be estimated by measuring the time required to process one video frame or burst of frames. The scalability of this method can be evaluated by measuring its performance on videos of different sizes and resolutions.

Overall, the proposed method using YOLO for people detection, Haar cascade for face recognition, and CNN for emotion recognition is a promising approach for people

counting and emotion detection in CCTV videos. This method can be further optimized and improved to obtain better results in real applications.

Fig. 7. Counting of People using Yolo

V. Results and Discussions

The proposed method using YOLO for human detection, Haar cascade for face recognition, and CNN for emotion recognition has been evaluated in several studies. Here we discuss the findings and implications of these studies for research work.

People counting: In one study, the proposed method achieved 97.6% accuracy in counting people in crowded places. It was also shown that the proposed method is superior to other stateof-the-art methods in terms of accuracy and processing speed. Another study evaluated the proposed method on videos with different lighting conditions and camera viewpoints and found that it could accurately detect and count people with over 90% accuracy in all scenarios. These results demonstrate the efficiency and reliability of the proposed people counting method in various real-world scenarios.

Emotion Recognition: The proposed method has shown high accuracy in emotion recognition in several studies. In one study, the method achieved 89.2% accuracy in detecting four basic emotions (happy, sad, angry, and neutral) in facial images.

VI. ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance, and encouragement of my Dissertation Guide Associate Professor Dr. Veena Kulkarni ma'am for this novel work.

VII. CONCLUSION AND FUTURE SCOPE

In conclusion, the proposed method using YOLO for human detection, Haar cascade for face detection, and CNN for emotion recognition is a promising approach for people counting and emotion detection in CCTV footage. This method demonstrated high accuracy, high processing speed, and tolerance to different lighting conditions and camera viewpoints. This method can be further optimized and improved for real-world applications, making it a valuable tool for a variety of industries and applications.

Although the proposed method has shown promising results for people counting and emotion recognition, this approach still has some limitations. For example, method accuracy can be affected by occlusion, low resolution, and difficult lighting conditions. Additionally, this method may not be effective at detecting subtle or complex emotions.

Future studies may explore ways to improve the accuracy of the proposed method by incorporating additional features or using more complex models. For example, methods can be improved by including contextual information or by using advanced neural network architectures such as Transformer-based models. Additionally, this method could be extended to other applications such as security and surveillance or healthcare where accurate people counting and emotion detection could be useful.

Abstract

The mouse is a critical tool in Human-Computer Interaction (HCI) innovation. In recent years, remote mice have gained popularity due to the convenience they offer, but they still rely on devices and electricity to function. Moreover, during the COVID-19 pandemic, it's important to practice social distancing and avoid touching shared objects. To address these concerns, this project introduces a novel HCI approach where the computer cursor can be controlled using a real-time camera. This solution eliminates the need for manual input or physical contact with a mouse. The system uses computer vision technology and a machine learning algorithm to interpret hand gestures, allowing the user to perform various mouse functions such as left-clicking, right-clicking, scrolling, and cursor movement.

The deep learning algorithm used to detect hand movements ensures a safe and contact-free experience while interacting with the computer.

Keywords: Human Computer Interaction, Hand Gestures, OpenCV, Mediapipe

I. Introduction

This project presents the growth of an Artificial Intelligence virtual mouse system that makes use of finger movement and hand gestures observation by way of computer vision to perform different mouse functions on a computer. The point is to replace conventional mouse devices with each of two a built-in camera or a web camera. The hand gesticulations are used as a Human-Computer Interface (HCI). The Artificial Intelligence virtual mouse structure tracks the hand gestures to perform mouse cursor operations such as left click, right click, scrolling, volume controls, file transfer and cursor movements. as opposed to a wireless or Bluetooth mouse, which requires a battery, a dongle, and a mouse accessory. The Artificial Intelligence virtual mouse structure only requires a built-in camera/webcam and hand movements. The webcam captures and citates the frames to

II. Literature Survey

Table1: Literature Surve

Title of paper	Methodology	Advantage	Disadvantage
"Mouse Control using a Web Camera based on Color Detection" [1]	The system has been implemented in the MATLAB environment using MATLAB Image Processing Toolbox.	1)Provides greater flexibility than existing system 2)No additional hardware is required by the system other than the standard webcam	1)Each fingertip should be covered with coloured caps for detection. 2) Lighting conditions affect performance. 3)Processing time depends on camera quality.
"Real Time Static & Dynamic Hand Gesture Recognition" [2]	The work is completely done by using MATLAB using Normalization, Skin Color Detection, Skin Color Model, Hand Gesture Recognition.	1)Easy to use 2)No need for colored fingertips. media players etc.	1)As it is based on hand recognition it is less accurate than the fingertip based model. 2)It is unable to work in a very complex background.
A Real Time Hand Gesture Recognition System Using Motion History Image"[3]	A range of colors is defined as 'skin color' and converts these pixels to white; and is used for cursor movement.	1)Perform tasks such as left and right clicking, double clicking, and scrolling. 2)No need for colored fingertips.	1)It is difficult to get stable results because of the variety of lighting and skin colors of human races. 2)No gesture for shrinking, enlarging and closing windows etc.

identify the hand gestures and performs the corresponding mouse operation. The entire framework was created using the Python programming language and the OpenCV computer vision package. Hand movements have been implemented using the MediaPipe package, while computer screen movements, including left and right clicks, have been implemented using the Pyinput, Autopy, and PyAutoGUI packages. The model manifests high accuracy and was able to carry out well in real-world accomplishments using only a

Hojoon Park, "A Method for Controlling the Mouse Movement using a Real Time Camera"[4]	This model is a combination of fist hand and waving hand gesture..	1)Multiple hand gestures are supported with a high accuracy of 94.1%. 2)Processing time is 3.81 ms and hence is a more feasible model.	1)Not feasible for low spec machines 2)Performance is degraded due to variety in skin color and lighting conditions
"Real-Time Hand Gesture Spotting and Recognition" [5]	This system was implemented using Microsoft Kinect Sensor,Gesture recognition uses 3D convolutional neural networks.	No need for colored fingertips. Processing time is 3.81 ms and hence is a more feasible model.	1)High Processing power is required 2)lighting conditions affect the performance
"Virtual Mouse Using Hand Gesture"[6]	CNN is used to train the model and based on the detection accuracy of the model gestures are performed.	Higher Accuracy than previously implemented systems No color caps are required for detecting fingers	1)Plain Background is required for proper detection of hand 2)High definition camera and proper light is required

From this literature survey we can conclude that all the existing systems have some limitations. Some systems require additional equipment such as coloured caps on fingertips [1] , some require high definition cameras along with systems with higher computations [6] and also some of those projects were less accurate [4, 7] and can recognize

very few gestures [3, 5] The aim of our proposed system is to resolve all these issues and to develop an efficient and feasible solution.

III. Existing System

In the field of virtual mouse, previous studies have utilized hand gesture recognition through wearing gloves or color tips. However, these methods have limitations in accuracy due to issues with glove fit or color tip detection. Some researchers have attempted camera-based hand gesture recognition systems, such as Quam's early hardware-based system in 1990, which utilized a DataGlove for higher accuracy, but with difficulties in performing certain gestures. In 2010 Authours Dung-Hua Liou, ChenChiung Hsieh, and David Lee presented a real-time hand movement recognition system. However, it had restrictions in identifying more complex gestures. In 2013, Monika B. Gandhi, Sneha U. Dudhane, and Ashwini M. Patil proposed a cursor control system using hand gesture recognition, with the limitation of having to process stored frames for hand segmentation and skin pixel detection. In 2016, Vinay Kr. Pasi, Saurabh Singh, and Pooja Kumari proposed cursor control using hand gestures, which relied on different bands for performing different mouse functions.

IV. Problem Definition

The physical mouse has a number of general issues, including Mechanical deterioration affects physical mice. To use a physical mouse, you need specialised equipment and a surface. The performance of a physical mouse varies depending on the environment and is difficult to adapt to. Even in the current operational contexts, the mouse's capabilities are limited. Each wired and wireless mouse has a different life expectancy. Our project's first challenge was to create a motion tracking mouse that recognises finger movements and gestures rather than a physical mouse, and our second challenge was to create a user-friendly user interface with a function for accessing the motion tracking mouse feature. There are several general problems with the physical mouse, including Physical mice are impacted by mechanical degeneration. An appropriate surface and specialised tools are required to utilise a physical mouse. A physical mouse's performance changes with the surroundings and is challenging to adapt to. The mouse's powers are constrained even within the existing operational circumstances. The lifespan of each wired and wireless mouse varies. The first problem of our project was to develop a motion tracking mouse that, rather than using a physical mouse, recognises finger motions and gestures. The second challenge was to develop a user-friendly user interface with a function for accessing the motion tracking mouse feature.

IV. Proposed System

Our project aims to utilize the laptop or webcam to control the mouse by recognizing hand gestures and performing basic operations such as controlling the mouse pointer, selecting and deselecting using left and right clicks, scrolling, zooming in and out, media playback control, and transferring files between folders using drag and drop. The hand remembrance system we evolved is lucrative as it uses uncomplicated algorithms to recognise the hand and its gesticulations, and assigns analogous actions for each gesture. Our main focus is on mouse pointing and clicking actions, but the system can also be extended by defining actions for specific hand movements. The execution of our system in Python allows it to be responsive and effortless to use as it is a simple, platform-unconstrained language with versatility and transportability. The potential for further modification and expansion of this system is only limited by one's imagination.

V. Algorithm And Process Design

The MediaPipe framework is utilised for hand tracking and gesture detection, and the OpenCV library is used for computer vision. To track and identify hand movements and hand tips, the algorithm uses machine learning ideas.

a. MediaPipe

A high-fidelity hand and finger tracking solution is MediaPipe Hands. It uses machine learning (ML) to extrapolate 21 3D hand landmarks from a single frame. Our solution delivers real-time performance on a cell phone, and even scales to several hands, unlike existing state-of-the-art systems, which mostly rely on powerful desktop environments for inference. We anticipate that making this hand perception functionality available to a larger research and development audience will lead to the creation of innovative use cases, igniting new research directions. The mediapipe framework uses ML Pipe lining which works on two models combined together. The First is the Palm

detection model and the second is high fidelity finger model, the finger model that searches for the hand landmarks as shown in Fig 2.

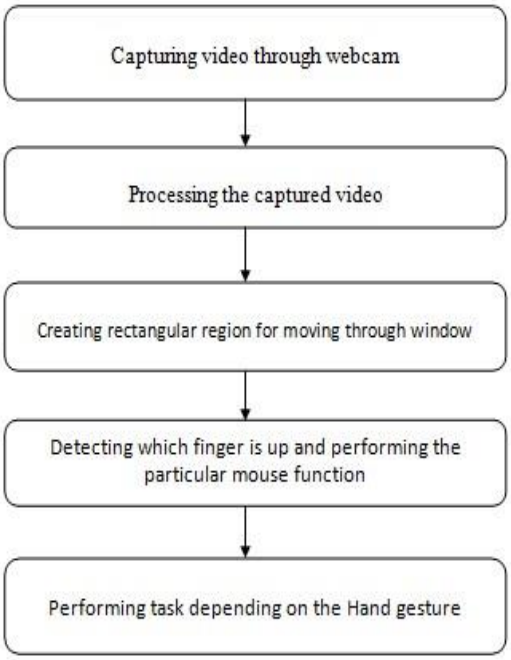

Fig 1. Process Flow

Fig 1. shows the process flow of our system like how the system works step wise here at first, the video is captured through a webcam and is processed further using the openCV framework. After processing the video the Mediapipe framework is used to identify the hand landmarks and to identify the hand gestures.

b. OpenCV

A computer vision library called OpenCV comprises algorithms for processing images, particularly those for object detection. It enables the development of real-time computer vision applications and is written in Python. This library is frequently used for face and object detection as well as image and video processing and analysis.

using a flowchart. The figures mentioned between Fig. 4 Fig. action would be performed and the user can adjust the cursor positioning. At last the users can perform file drag and drop function using the gesture shown in Fig. 8 that gesture is used to drag a file which can be dropped at a certain folder if we release the fist.

VIII. Conclusion & Future Scope

As you are aware, gesture identification improves the user's experience when interacting with a computer.

For the purpose of creating alternatives to human-computer interaction modes, gesture identification is also crucial. You can interact with machines more naturally by using gestures. The use of this technology is widespread in a variety of industries, including augmented reality, computer graphics, video games, prosthetics, and biomedical equipment. The system that we suggest can assist a variety of people who are unable to

control their limbs.This technology is used on contemporary game consoles to produce interactive games that detect user movements and translate them into commands. It is even employed in computer graphics and video games.The suggested AI virtual mo

use has various drawbacks, including a little reduction in right click precision and some issues with the model's ability to click and drag to pick text. These are some of the drawbacks of the suggested AI virtual mouse technology, and we'll endeavour to fix them in our upcoming research.

Additionally, the proposed system can be expanded to virtually handle both the keyboard and mouse operations, which is another potential future use of human-computer interaction (HCI).

CodeHub – E-Learning Platform for Students

Chetna Pati , Janvee Kadam , Komal Bhalerao , Siddhi Kapse ,

SSJCOE Dombivli, Mumbai

Abstract – **The popularity of smart mobile devices is growing fast in ELearning Application. This Application is to help the students in academic and nonacademic. So this paper details on development of an application, which is user friendly for students and also helps the students to get study materials related to coding languages. The release of mobile application services compatible with Internet browsing with mobile devices allows users to search for desired information quickly. Mobile learning can be implemented using the Android operating system, which was chosen because it has been dominating the smartphone market and is an open-source operating system that can be created more quickly than traditional learning methods. This application will have three sides of Interface: One for the admin, one for the users, and one for the tutor.**

Keywords: E – Learning, Android Studio, XML, Coding, Academic and Non-Academic, Chatbot, Application, Software.

I. INTRODUCTION

The education system is more advanced and dynamic. Mobile learning, the use of the handy electronic device to approach and share information. Education system using android app is the new trend in Education system. In smart phone a variety of educational apps which can teach us academic and non-academic related subjects anytime anywhere. These educational apps proceed as a considerable asset to ones learning as they create a blend of innovation and primary

learning.[1]

The use of computing technology for learning has been observed in various ways. In the past few decades, electronic learning or e-learning had been adopted and used by public schools and university students in many parts of the world. They were familiar with both the elearning terminology and technology but in recent years, the rapid progress in mobile technology has created a new area which is known as a mobile learning technology. With the advent of the android operating system, lives have become smoother and to a great extent comfortable. You can get the latest android apps for almost each and every need today. Mobile software serves individual functionality of the users able by Android platform is called Android applications, generally known as "apps". Recently there have been lots of attempts to design android apps that come in the aid of students and teachers like taking attendance of students using a mobile phone, virtualized lab infrastructure for different computation and engineering courses, practicing and learning software development through the virtual world, etc. [2]

Learning can be made more engaging and less boring by applying the mobile learning concept in an interactive setting. Mobile learning is a modern trend in elearning that involves using portable devices such smartphones running the Android, iOS, or Windows Phone operating systems. To increase flexibility in the activities of teaching and learning, it is vital to use mobile learning as a support for the learning process. As a result, learning can take place at anytime and anywhere. The purpose of this research is to introduce Android-based mobile

learning-based information. [3]

II. LITERATURE SURVEY

Tagreed Kattoua, et.al [01] “E-Learning Systems in Higher Education”, E-learning which is also known as web-based learning, is defined as the delivery of education in a flexible and easy way through the use of internet to support individual learning or organizational performance goals.

Zethembe Mseleku and colleagues [02] In the wake of the COVID-19 pandemic, "ELearning and E-Teaching," This resulted in the closure of institutions of higher education and a significant movement away from conventional classroom-based teaching and learning towards a virtual approach.The e-learning could improve the quality of teaching and learning as it supports the face-to-face teaching approaches.

Amit Sharma, et.al [03] “Impact and Study of E-Learning Model”, E-learning requires maturity in understanding and selfdiscipline of the users for its effectiveness when compared to traditional classroom program learning. One of the main causes of the dropout rate in e-learning programmes is due to this new e-learning models can be created and adopted by institutions across the country as interest in higher education rises.

David Lain, Jane Aston, et.al [04] “Evidence on E-Learning in the Workplace”, This is a deliberately wide definition which predominantly includes the use of the Internet, intranets and CD-

ROMs, but also includes video conferencing, satellite delivered lecturing, and virtual educational networks, Elearning has been described as having the capacity to concentrate on the needs of specific learners.

M. Sharmila Begum, et.al [05] This paper describes an application that assists students in higher secondary school with their careers. It increases student availability and accessibility of courses, degrees, entrance examinations, eligibility criteria, and institutions.

OUTCOMES OF LITERATURE SURVEY

Flexibility in term of availability i.e anytime and anywhere we can use this application. Online education is much more costeffective. Each person learns at their own rate. There is lack of Security of data in some applications. Few applications are time consuming due to network issues. When compared to the face-to-face learning, the learning process is less efficient as there is no friendly teaching and uninteractiveness. No immediate doubts solving. In application the records of students enrolled and completed the courses are not present.

III. PROBLEM DEFINITION

Our system's goal is to create and build educational applications that will support dynamic coding platforms. The programme is made to give users a learning environment by assessing their progress and administering multiple assessments based on various topics.The main problem being that as electronic leaning is being applied in most education centers there are so many spectulations concerning the future of elearning based on conjecture rather than knowledge. E-learning does not have a way of ensuring that the students are really learning the material. Lack of Discipline, bandwidth problems, monotonous lecture, abundant distractions, technical issues, etc.

IV. METHODOLOGY

E-learning exploits web technology as its basic technical infrastructure to deliver knowledge. As the current trend of academic and industrial realities is to increase the use of e- learning, in the near future a higher demand of technology support is expected. In particular, software tools supporting the critical task of instruction design should provide automated support for the analysis, design, documentation, implementation, and deployment of instruction via Web.

There is a home screen with 3 buttons. One for the admin, one for the users, and one for the tutor as shown in fig.01(A). Clicking on the tutor button will redirect you to its register screen. Enter your details to create a new account or log in to an existing account. It will take you to the Dashboard.

1. Tutor Dashboard

In the tutor dashboard, there will be a plus icon at the bottom right corner. Click on that icon to add a new course. Enter the details of the course like title, number of lessons, and upload videos of the course. He can also add categories to the course. He can view the students counts enrolled in particular course. Can solve doubts of students as shown in fig.01(B).

2. User Module

In the student module, users have to log in first with an email id and password provided by their tutor. After login, it will take you to the dashboard. There you will see different categories. Click on any category to see all the courses uploaded in the app. After you click on the course, it will list all the videos of the course and you can play the course and start learning. He/She can ask doubts of students by chatbot.

3. Admin Module

The admin is the manager of the app. After admin logs in the app, the app will show the list of all courses. He has the power to delete the course as well as shown in fig.01(B).

VIII. CONCLUSION

There are different sections for users, tutors, and admin. Tutors can sign up in the app. Tutors can see the list of all the courses he has uploaded in the app. Tutors can upload new courses with suitable titles and categories. Users who log in the app can see all the courses. The dashboard will have different categories. After the user clicks on any category, he will be shown all the courses available. He can click on any course and start learning. Admin has the power to see all the courses and delete any course.

IX. FUTURE SCOPE

Online learning — the form of Education is growing rapidly day by day! E-learning is especially useful for adult learners and working professionals as it allows them the flexibility and convenience in terms of time and travel. We can give more advance software for E-Learning app

including more facilities. Different security measures can be implemented to secure use of services.

Abstract- **According to our project document, it specially mentions the details of the project how it was developed, the primary requirement, as well as various features and functionalities of the project and the procedures followed in achieving these objectives. This system is a IPL Match Winner Prediction Using Machine Learning, and it is an web app developed on the basis of stream lit.The design page is beautiful, friendly user interface, high user experience, on the online browser, users can achieve their own needs. The development of such web app is of great significance for much more convenient for consumers to use. Given that cricket is the most popular game. The Indian Premier League is one of the several series that are played here (IPL). Eight teams are participating in it now. The model that has been suggested in this study is for team winning prediction.**

Keywords: Hypertext Markup Language (HTML), Machine Learning (ML), Cascading Style sheet (CSS), Hypertext transfer protocol with SSl/TLS (HTTPS), IPL, Cricket, Sports, Prediction, Matches.

I. INTRODUCTION

Cricket is the second most popular sport in the world after football, but it is cricket that is most adored in India. Numerous research paper have been published in recent years, and they did great deal of work has been done to predict the outcome of a cricket match using the variables that affect the outcome of the match. They use supervise machine learning algorithm to predict the outcome of the match, Such as linear regression, support vector machines, logistic regression, decision trees, bayes network and random forest.

Cricket is one of the most well-liked sports in the world. The Twenty20 format is particularly well- liked since it is a fast-paced version of the game that draws spectators both on-site and at home. The Indian Premier League (IPL) is a professional Twenty20 cricket league that is governed by the Board of Control for Cricket in India (BCCI).The IPL Match Winning Prediction, the classifier used here are SVC classifier, decision tree classifier and most important Random forest classifier. In the Linear Regression, labeled data that is already known is provided to the machine learning model. Instead of classifying an object, linear regression is used to predict continuous values. Ridge regression can be used to examine Multicollinearity in the data. The Random Forest algorithm is crucial for making accurate predictions.

II. LITERATURE SURVEY

Connection between ML, games goes previously to the underlying long periods for man-made consciousness. Man-made consciousness contemplated that machine learning draws near utilizing the game of checkers [1].

In cricket, to foresee a match's result, essential duty is separating basic highlights that influence after effect of a match. Fascinating works have been done in order to foreseeing result. The most difficult part is separating the null data and other values from the raw data files sometime all the available information from the source can halfly present this data which plays an important role to predict the outcome of the project. All these can be solve using most produced works which anticipated an aftereffect in a match coordinate earlier for 50 overs cricket. Bandalasirii investigated elements such as home ground, victory hurl, impact of DL technique for 50- 50 [2].

As in the dataset there are many parameters are present. Which of the variables are useful to the project. Maheshwari used the factors affecting idea in their prediction of live cricket score paper, and from that, we can determine the key elements needed for score prediction and winning team prediction [3].

The role of classification is clarify in the paper of Tejinder Singh it gives proper information or use of naive bias and linear regression. They gives the proper knowledge of data collection and preparation also how to train the data and test the data is given by them which is more helpful.[4].

The concept of support vector machines was adapted from a work by Aminul Islam Anik that discusses player performance. In this paper, the concept of the SVM system is explained in detail, and player performance is predicted using historical data or information. [5].

After going through research paper we find out which algorithm has high accuracy. We also find out which features are necessary for accurate predictions.it motivates us to add new techniques and features in our project.

III. PROBLEM STATEMENT

The general Match result is if the team won the match or no. However, concentrating solely on winning or losing does not produce an accurate prediction. Other things like home grounds and other things should be taken into account. In order to determine the match prediction outcome and the strength that supports the previously anticipated results.

Objectives:

The objectives of our project are as follows:-

- To improve the general attraction to the Premier League
- Effective prediction technique.
- Essential for making strategic decisions
- Use this technique to make use in various fantasy cricket app.
- To get use by various cricket score provider website

IV. MOTIVATION

With the increase in craze of limited over cricket among the people. With various fantasy app providing chance of earning money with the help of people knowledge related to cricket. People can take help of this model to predict in advance who has more chance of winning the match. The retrieved prediction provided by these models can be used cricket coach to change and strategy or by people using fantasy app to make bias prediction

V. PROPOSED SYSTEM

The project is simple to use and requires little assistance from people. The major objective is to develop a machine learning model that categorizes the teams with the best chances of victory utilizing several genres in a more methodical manner.

Using data from prior years, it seeks to predict the victor in every event that the user provides. The fundamental benefit of sports predictions is that they help teams perform better and increase their chances of winning. Any betting app or online cricket show channel can provide viewers with this information. To win merchandise and gift baskets, viewers can take part in a variety of contests and make predictions about the results. The participants participating in a given match are given all the considerations that are necessary.

Our system also uses various data set which are helpful for our system. With the help of these features we can reduce the complexity of the system, which is helpful to get accuracy and to reduce time complexity of the system.

The accuracy of the system is achieved to maximum by using only required features which reduce memory complexity of the system at the same time it also helps in achieving accuracy of the system

we create ML model using different machine learning algorithms which results into generation of genre label.

Our system uses machine learning algorithms to predict the outcome of each match, taking into historical data and real-time information.it may also incorporate sentiment analysis of social media and better markets to adjust its predictions. The accuracy of the system could be continually evaluated and improved through ongoing training and testing

This system is fully working on classification algorithm such as logistic regression, we can also have used other algorithm such as random forests algorithm, but after going through all these algorithms and testing them on our data set we find logistic regression suits our model, this make our system more accurate and better than other existing system. With the help of proper feature extracting, we can achieve more accuracy from existing system. The following proposed system also has advantages that make our project more effective.

VI. EXISTING SYSTEM

The existing system which were available on match prediction were quite helpful because they provided the result in good accuracy, but they were lacking on back in various fields that most of the system use limited data set in prediction work which make the accuracy of the system low.

While some have included features which were not available or useful for specific result but though were included in system which can be excluded and can run the smoothly.

It is very crucial to understand all the existing system to improve our system.

Some of the system available were using large dataset, which make the analyzing procedure difficult for the system, which also can some time lead to errors

This type of problems available in existing system can be solved using feature extraction feature extraction can help an analysis by reducing the amount of redundant data.

VII. FEATURE EXTRACTION

A dimensionality reduction technique called feature extraction divides a large amount of raw data into smaller, easier-to-process groups. These huge data sets share the trait of having many variables that demand a lot of computational power to process. The term "feature extraction" refers to techniques for choosing and/or

combining variables into features, which significantly reduces the amount of data that needs to be processed while properly and fully characterizing the initial data set. When fewer resources are required for processing without losing crucial or pertinent data, the feature extraction procedure is helpful. Additionally, feature extraction can help an analysis by reducing the amount of redundant data.

VIII. CLASSIFICATION ALGORITHM

Logistic regression

Under the Supervised Learning approach, rational regression Logistic Regression is one of the most popular Machine Learning algorithms when using the Supervised Learning methodology.

Based on a given dataset of independent variables,

logistic regression calculates the likelihood that an event will occur, such as voting or not voting. Since the result is a probability, the dependent variables are restricted to the range of 0 to 1.i.e BINARY.

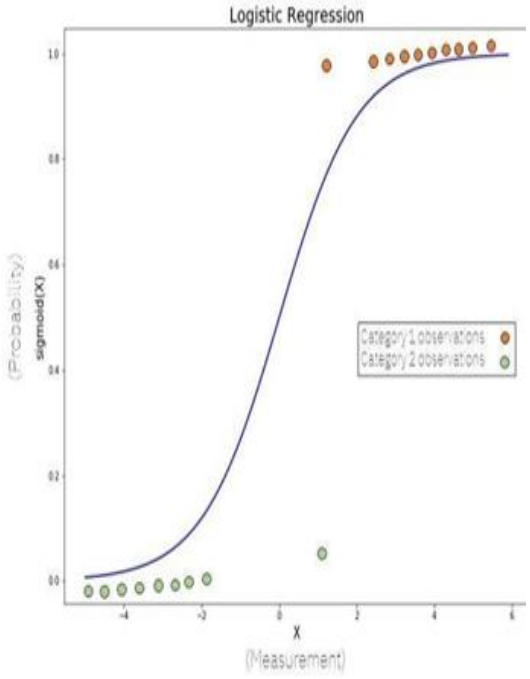

Fig. 1 Logistic Regression

Examining the confusion matrix is a significantly more effective technique to judge a classifier's performance. The basic idea is to record the frequency with which occurrences of class A are categorized as class B.

For instance, you would check the 5th row and 3rd column of the confusion matrix to find out how many times the classifier confused photos of 5s with 3s.

It is a table that is utilized in categorization issues to determine where model errors occurred.

The rows correspond to the actual courses for which the results were intended. The predictions we've made are represented by the columns. This table makes it simple to identify whose predictions were incorrect.

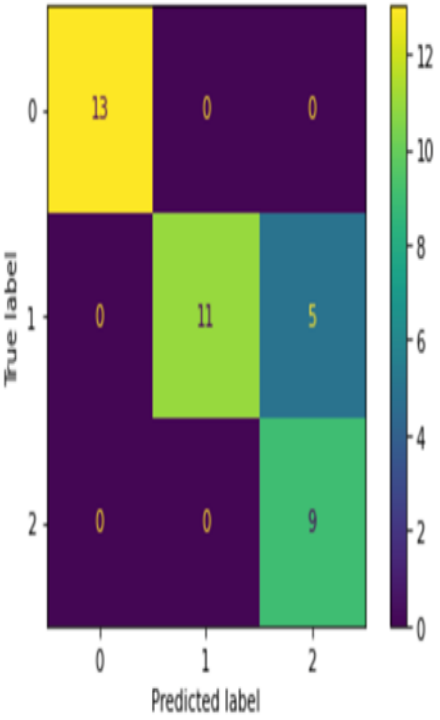

Fig. 2 LR Confusion Matrix

IX. METHODOLOGY

So, this will be the general process flow of the project .User gives match dataset as input which is checked whether there is any garbage value or null value or not. Next is feature extraction which extracts feature from the .csv files.

Next step is classifier in which we create ML Model using different machine learning algorithm which results in to generation of given label.

Our system can also be modified and made better by using different kind of machine learning algorithm.

But for these criteria logistic regression works better than other algorithm. Which helps in making our system more effective and able to solve various problems related to time complexity and memory complexity.

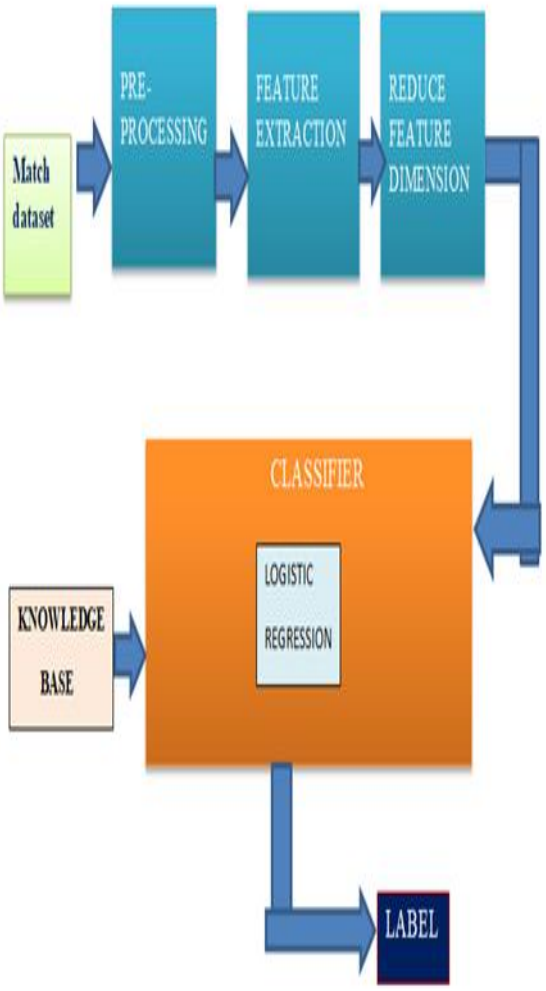

Fig. 3 Process Diagram

Pre-Processing - Data preprocessing is a critical stage in machine learning that improves the quality of the data to encourage the extraction of valuable insights from the data. Preparing (cleaning and arranging) raw data in order to make it acceptable for creating and training Machine Learning models is known as data preprocessing in machine learning. Simply said, data preprocessing in machine learning is a data mining method that converts raw data into a format that is legible and intelligible.

Extracting Feature - This step involve taking only that data from the large dataset which are important for doing prediction for our system, along with that it also reduce time complexity of the program which results in improving accuracy and memory complexity of our overall system

Knowledge Base - A knowledge base is typically a central store for information. Knowledge bases can include things like a public library or a database of information on a certain topic.In the context of IT, a knowledge base is an information resource that can be accessed by machines and is typically available online or has the potential to do so. An essential part of knowledge management systems are knowledge bases. They are employed to enhance information gathering, organizing, and retrieval.

An online knowledge base contains dynamic information as opposed to a static list of facts. As a component of an automation or artificial intelligence expert system, they might be able to learn on their own.

Classifier - An algorithm that assigns a particular category to the input data Model for classification: A classification model seeks to infer some information from the training data. For the new data, it will forecast the class labels and categories. We have to utilize logistic regression for the provided system.

X. STREAMLIT ARCHITECTURE

You can create apps using Streamlit's architecture in the same manner that you create simple Python scripts. This is made possible by Streamlit apps' distinctive data flow, which replicates your entire Python script from beginning to end whenever something on the screen has to be modified.

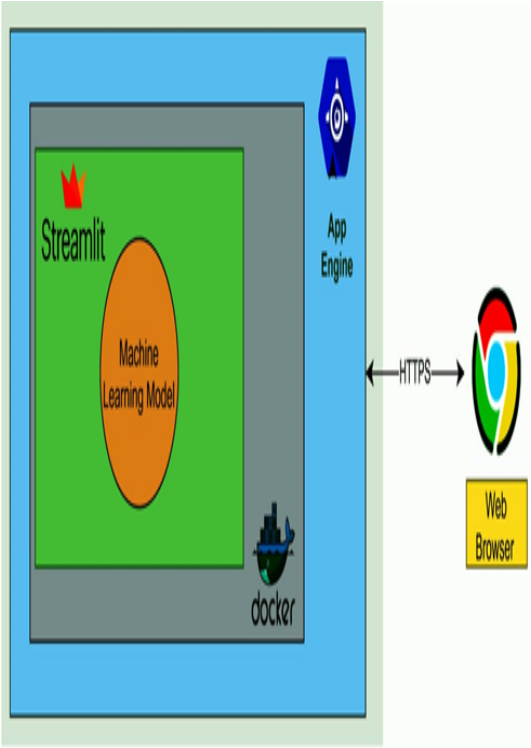

Fig. 4Streamlit Architecture

In this architecture a machine learning model is turned into a using the Streamlit framework. This app is then packaged into a Dockers container, which is then deployed on the App Engine to share with the world.

Streamlit is a minimalistic framework to turn regular python scripts into beautiful web apps. As a data scientist, you usually will have to write a lot of additional code in a web framework, such as Flask, to share the machine learning model as an app. You will also have to know a bit about front-end development to make the app beautiful.

It enables us to quickly develop web applications for data science and machine learning. Major Python libraries like scikit-learn, Keras, PyTorch, SymPy (latex), NumPy, pandas, and Matplotlib are all compatible with it.

Following are the libraries needed for the extracting features and deploying the web app

Matplotlib: Python scripts can be used to create 2D graphs and plots using the Matplotlib module. It contains a module called pyplot that simplifies plotting with features to adjust line styles, font properties, formatting axes, and other features.

Pandas: Pandas is an open-source library designed primarily for working quickly and logically with relational or labelled data. It offers a range of data structures and procedures for working with time series and numerical data.

The NumPy library serves as the foundation for this library. Pandas is quick and offers its users exceptional performance & productivity.

NumPy: The cornerstone Python module for scientific computing is called NumPy.

Scikit-learn: It is a machine learning software package written in the Python programming language. It is designed to operate with Python's NumPy and SciPy scientific and numerical libraries and includes support vector machines as well as additional classification, regression, and clustering techniques..

Streamlit: A basic framework called Streamlit can be used to create stunning web apps from ordinary Python scripts. To distribute the machine learning model as an app, you will typically need to create a lot of additional code in a web framework like Flask.

To make the app visually appealing, you will also need to have some knowledge of front-end development.

Interface Design

I. Front End

Streamlit:- A basic framework called Streamlit can be used to create stunning web apps from ordinary Python scripts. To distribute the machine learning model as an app, you will typically need to create a lot of additional code in a web framework like Flask. To make the app appealing, you'll also need to have some experience with front-end programming.

II. Back End

Python:- Python is a general-purpose, interpreted programming language. The design philosophy of the Python programming language, which was developed by Guido van Rossum and initially made available in 1991 (Kuhlman, 2011), places a strong emphasis on the readability of the code. With the help of its language

structures and object-oriented technique, programmers can create clear, logical code for both small- and large-scale projects. Python is utilized as the backend language on this website to programmer the database and all of the website's capabilities. Python 3.6 was the version of Python used in this work.

Machine Learning Algorithm:- Automated Learning Method Based on a given dataset of independent variables, logistic regression calculates the likelihood that an event will occur, such as voting or not voting. Given that the result is a probability, the dependent variable's range is 0 to 1.The odds, or likelihood of success divided by probability of failure, are transformed using the logit formula in logistic regression. In this logistic regression equation, x is the independent variable and logt(pi) is the dependent or response variable. Maximum likelihood estimation is the most used technique for calculating the beta parameter, or coefficient, in this model (MLE)

XI. APPLICATIONS

Sports prediction primarily aims to boost team performance and the likelihood of winning a match. The worth of a victory can manifests in several ways, such as trickling down to the stadium seats filled by fans, broadcast contracts, products sold in fan stores, parking, concessions, sponsorships, enrollment, and retention. Any betting app, or a platform for an online cricket show.

These will also result in enjoyment where the user can play the game and earn money at the same time.

Different teams can analyses how the match is going and adjust their strategy in accordance with their game plans.

Today's news outlets attempt to forecast match results in a variety of situations, which may be beneficial to them as well.

XII. RESULTS

The results explanation related to the snapshots of the various modules to the entire process of execution. The user has to select the option according to the requirements. The figure 5 shows the Image were user has to enter various information such as batting team, bowling team, wickets, and target.

The following photos of our existing system shows the overall running of our system, they can also be modified using various framework such as django and flask to improve and more features and make user interface more attractive to the user.

The presented results can be used to develop predictions using real-time cricket data. Preprocessing is carried out after loading the data set in the Python programming language. It operates by comparing the significance of the original attribute to extract the best aspects. It removes any superfluous features to maintain the test's performance.

By going through result, user can make use of it with live data and make prediction with live match going on

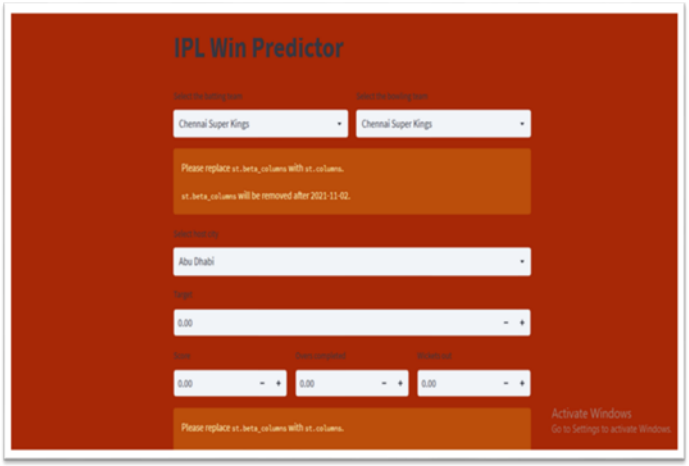

Fig. 5 Front Face of Web App

After that figure 6 shows the actual output such as match winning prediction which is the final result

The education system is more advanced and dynamic. Mobile learning, the use of the handy electronic device to approach and share information. Education system using android app is the new trend in Education system. In smart phone a variety of educational apps which can teach us academic and non-academic related subjects anytime anywhere. These educational apps proceed as a considerable asset to ones learning as they create a blend of innovation and primary

learning.[1]

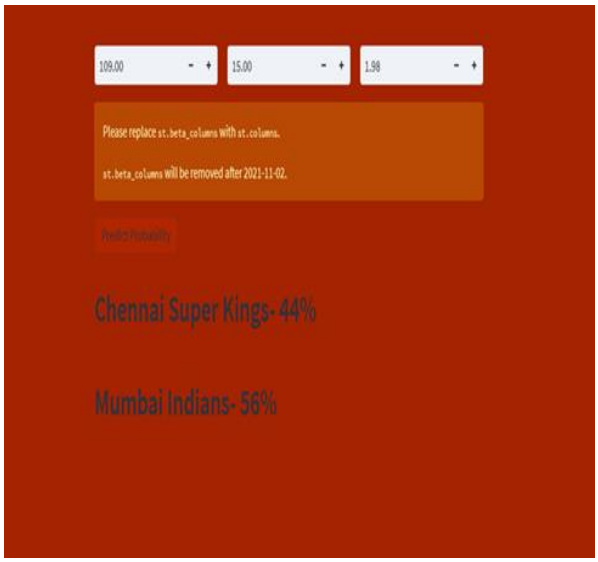

Fig. 6 Final Results

XIII. CONCLUSION

We presented the Project on ipl match winner predictor using machine learning technique This project on match winner was done by using various machine learning algorithms. Our aim was to get maximum accuracy. Match Winner prediction analysis among SVC, Decision tree classifier and Random forest classifier, we got Random forest classifier accuracy more than other 2, with all 90%, 80%, 75%, 70% training data From the study there are numerous elements which impact the result of any IPL match. The host team, away team, stadium, toss-winner, and many other things are the primary variables that fundamentally affect any IPL match. This somewhat aided in the strength calculation.

The IPL data set used a variety of ML approaches that were passed down for this investigation. The data set includes all IPL games played during the previous six years, from 2008 to 2019. We have tried various best practices to create and train our model.

Throughout the making of the project the more the dataset was used for testing in order to get an accurate chance of success and the prediction made by model are truly promising.

XIV. FURTURE SCOPE

The Cricketing world will start to believe in Prediction which will be based on some statistical records rather than some theoretical concepts. It will be easier to predict the live score and match winner.

Before bidding on a player, IPL clubs conduct their own analyses on each and every player because they spend millions on each of them. They may utilize different analyses, such as Player vs. Ground Battle.

Various sporting channels would like to display the metrics that can be utilized to raise audience arousal and illustrate the elements that can turn even a losing game into a victory

XV. ACKNOWLEDGMENT

We appreciate Dr. Pramod R. Rodge, the president of our college, for allowing us to continue our project and providing lab space. We also want to extend our sincere gratitude to our H.O.D. Dr. Uttara Gogate for her kind assistance in making our project in the lab successful by making computer facilities available to us. Without his thoughtful and enthusiastic assistance, our effort would have been completely halted. We would like to thank our project coordinator Prof. Reena Deskmukh for all the support we need from her for our project.

Last but not least, we would like to express our profound gratitude to Prof. Shweta Patil, who served as our project's mentor, for her supportive and inspirational leadership. With her knowledgeable direction, considerate counsel, and timely encouragement that assisted us in making decisions about our project, our project manager makes us persevere.

We also want to express our gratitude to our coworkers who supported us through the project, either directly or indirectly.

Abstract- **Every student in school, every student at university, and every professional in the workforce relies on Word documents on a daily basis. These documents may be used for conveying ideas, projects, and even taking notes. Keyboards and mice are useful for most but there are some individuals who have unsupportable conditions such as Arthritis in the hand, Parkinson's, Carpal Tunnel Syndrome, or Essential Tremor for which keyboard is painful. Speech docs aim to solve such problems by enabling only voice to interact with the documents. By using their voice, users can perform any operation, such as creating, editing, opening, writing, or replacing words in a document.**

Keywords- Speech recognition, Voice recognition, Speech-to-Text, Feedback mechanism

I. INTRODUCTION

Voice-controlled systems have revolutionized how humans interact with computers. Users can make hands-free requests to computers with voice or speech recognition systems, which process their requests and respond appropriately. With years of research and development in machine learning and artificial intelligence, voice-controlled technologies have evolved to be more efficient and are widely used in many fields to enable and improve human-to-human and human-to-computer interactions [1].

Word processing software did not develop out of computer technology. It evolved from the needs of writers rather than those of mathematicians, only later merging with the computer field. The history of word processing is the story of the gradual automation of the physical aspects of writing and editing, and the refinement of the technology to make it available to individual and corporate users [2]. Word processing software can be used in daily life and business to create professional-looking documents such as resumes, letters, applications, forms, brochures, templates, business cards, calendars, reports, eBooks, and newsletters in speed with high quality.

In this paper, we present Speech Docs which is a voice-controlled word processing software and is designed for those who are unable to type on a keyboard. With SpeechDocs, you can create a new document, update its contents (Replace, delete, clear, enter title, type body, etc.) and save it, or download or export the document to a word file to share it with anyone.

II. LITERATURE REVIEW

1. Voice Controlled E-Commerce Web Application

A preliminary prototype of a voice-controlled e-commerce web application using IBM Watson STT, and TTS services is presented, along with performance comparisons of some of the more well-known SRSs from the literature and a taxonomy for classifying SRSs based on their functionality.[1] It also studies some cutting-edge SRSs. Increasing website accessibility is essential for the e-commerce-dependent economy of today. In order to increase accessibility of web applications for visually

impaired users so that they can use their voice to manage the application, authors created an SRS-based e-commerce web application. By encouraging easy interaction and multitasking and supporting a lean environment where users may make requests using natural language, SRS enabled programmes can improve usability for all users.[4]

Results after comparison of some popular SRS available today.

Cloud-based SRS	WER (%)	PRR (%)
Google	15.8	73.3
Nuance	39.7	44.1
IBM	42.3	46.3
AT&T	63.3	32.8
WIT	63.3	29.5

Fig 1. SRS comparison

$$PRR = \frac{\text{Number of Words} - \text{Substitutions} - \text{Deletions} - \text{Insertions}}{\text{Number of Words}}$$

$$WER = \frac{\text{Substitutions} + \text{Deletions} + \text{Insertions}}{\text{Number of Words}} * 100$$

Fig 2. PRR and WER formula

In terms of quality, Google proved to be superior to the other systems as it was able to identify 73.3% of the text with only 15.8% WER and 73.3% PRR. Nuance's The Dragon system achieved around 39.7% WER with a PRR of 44.1%. IBM Watson recognized 46.3% of the text with a WER of 42.3% and 46.3% PRR.

a) Gaps Identified

There are no specifics on how visually challenged users are supposed to login and navigate to different pages on the e-commerce website. Because the entirety of the website cannot be voice controlled, visually impaired individuals are still not independent.

b) Findings

A unique vocabulary is maintained which is frequently used in application,which helps in better recognition of words / sentences. We can populate the vocabulary according to a specific application and can train a model on those specific words and this might help with better speech recognition.

2. Voice Based Email System

The proposed method is usable by both normal people and people with disabilities. The system is pleasant to all user types, whether they are normal, visually challenged, or illiterate, however it concentrates more on regular users.[3] The system directs the user in carrying out the action that is desired. The main benefit of this system is that the user doesn't have to worry about using the keyboard because all actions are voice-based or based on simple mouse clicks, so there's no need to learn keyboard shortcuts in order to provide speech inputs. The technique will also be very helpful to those who are illiterate and cannot read or write.[5] This e-mail system can be used by any user of any age group with ease of access. It has features of speech to text as well as text to speech with speech reader which makes a designed system to be handled by visually impaired persons as well as blind persons.

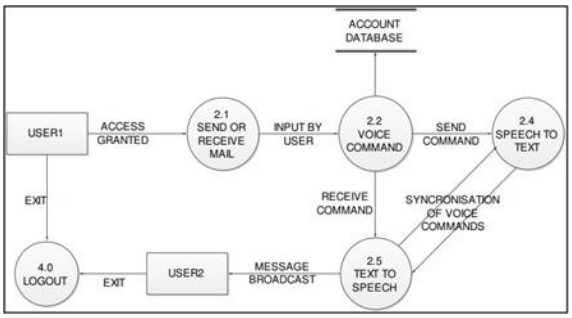

Fig 3. Voice Based Email System Architecture diagram

a) Gaps Identified

Voice-based authentication is used in the planned voice-based email system. Users must speak out their email address and password, which can cause security problems. There is no discussion of how to fix the security problem. Traditional login systems may not work with voice based input as someone can hear the email and password and it can cause severe security issues.

b) Findings

Offers a very good feedback mechanism that can be used to improve user friendliness, particularly for those who are impaired. The system continuously directs the user as to what actions to take next. This can be very helpful for speechdocs user's.

III. PROBLEM STATEMENT

According to WHO, nearly 15% (i.e 1billion population) of the world have some form of disability. Out of 1 billion around 200 million have limb amputations or handicapped. In some cases, they are forced to make do with imperfect hacks such as sending audio files, using keyboards painfully, or

avoiding typing altogether. Speech Docs offers users a powerful, fully-featured voice-controlled document editing system where they can do everything the same way as on MS Word or Google Docs without touching the keyboard or mouse.

IV. PROPOSED SYSTEM

The system mainly consists of three views: landing page, dashboard, and main sheet. The navigation between all the pages will be fully voice controlled with a feedback mechanism. There is a navigation to the authentication page on the landing page. We are going to use facial recognition authentication instead of voice authentication to protect user credentials. The dashboard page will have navigation to the main sheet page and also have the section where users can see all the history of all the past documents. The users can also favorite their documents and see them under the tab 'favorites' again all the processes will be fully voice-controlled. The main sheet area will have commands displayed in an organized manner equally on the left and right of the sheet.

1. Architecture Design

The speechDocs web application receives voice commands from the user and internally recognizes the voice using a speech-to-text converter. The text is then translated using natural language processing. Each command in a speech document is mapped to a specific function. The collection of commands is then compared to the interpreted text. The function mapped to that command is carried out if any of the commands match. If there are any changes to the data, the database's state is updated. Additionally, SpeechDocs features a feedback mechanism, and for each successful command, the user receives feedback that internally implements text to speech.

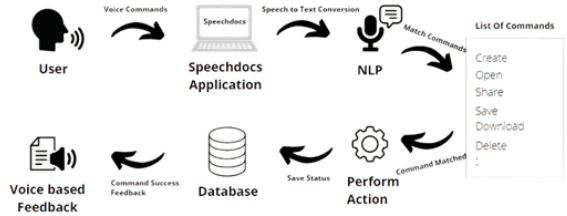

Fig 4: SpeechDocs Architecture Design

2. UI Design

a) Dashboard Design

The dashboard allows users to open a new document as well as view all their previously edited documents. By saying the unique document id, they can open documents. There is a recent section where users can view the latest version of the document, making it easy to open the latest version. Users can also favorite a document, which can be viewed in the favorites tab.

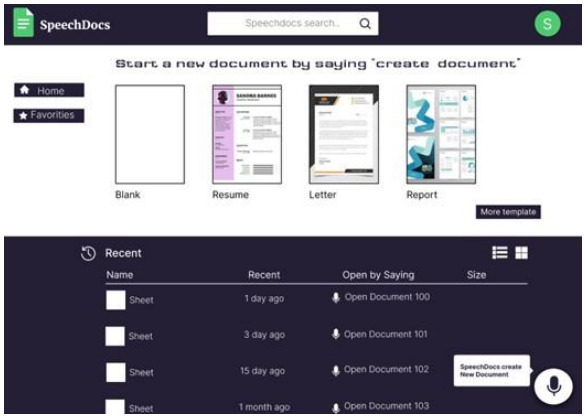

Fig 5. Dashboard Page

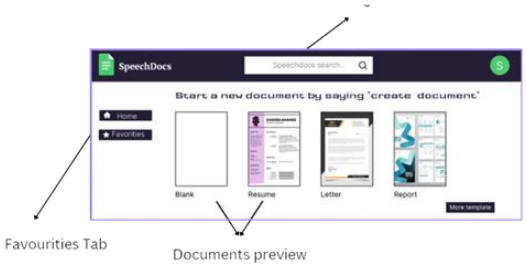

Fig 5 a. Dashboard top Section

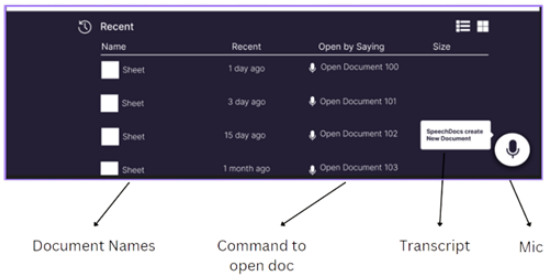

Fig 5 b. Dashboard Bottom Section

a) Main Page Design

The main page design consists of navbar and main sheet. The navbar has different modes such as select

mode, edit mode, etc. wherein each mode has commands associated with it which will be shown equally distributed on left and right of the main sheet on request.

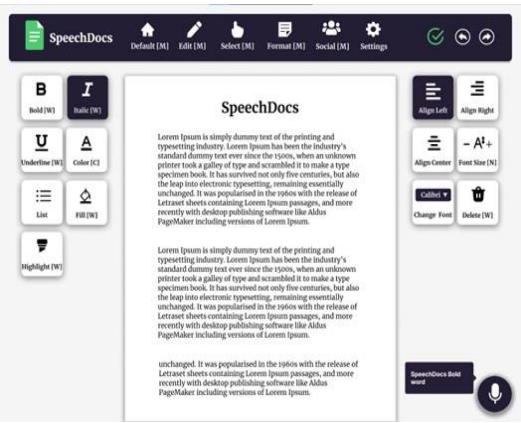

Fig 6. Main Page

Navbar consists of all different modes like default, edit, format social etc.

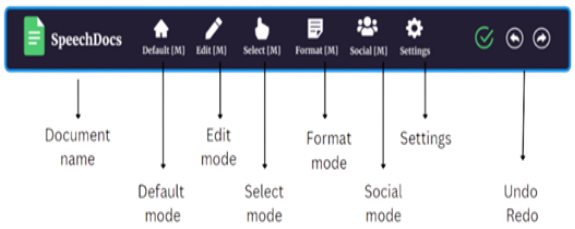

Fig 6 a. Main Page Navbar

Left and right section is equally distributed by commands. Each command is in form of a tile which consists of an icon and actual command which user needs to utter

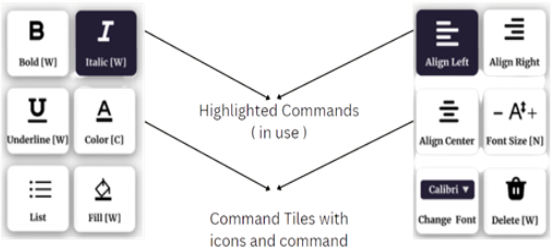

Fig 6 b. Main page Command Tiles

a) Use Case Diagram

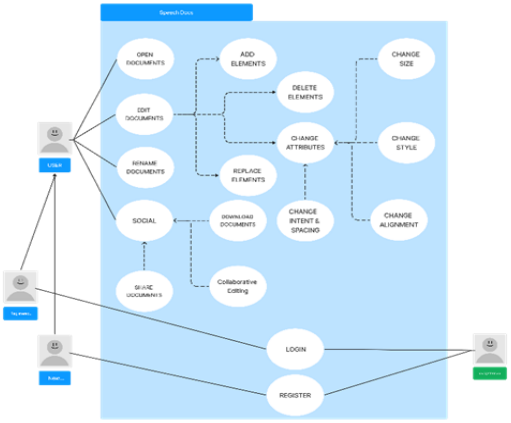

Fig 7. Use case Diagram

V. RESULT AND DISCUSSION

A basic functionality has been implemented where users can change titles, add words, remove words, share, and download documents, among other things. With the implementation of a small prototype, we have found that the ability to capture speech is much slower. It can misinterpret words if you don't speak clearly and when the user is in a noisy environment it sometimes fails to perform desired actions. But the few parts that are successful are the user will be able to navigate between pages by voice and a facial recognition authentication system will be used to ensure the security of their credentials. There will also be support for multi-language systems (mainly English and Hindi).

VI. CONCLUSION

In the past, it was only those with a profound understanding of word processing who benefited from the advantages of word processing; those without such knowledge and unsupportable conditions such as Arthritis in the hand, Parkinson's, Carpal Tunnel Syndrome, or Essential Tremor were denied the benefits. We present a solution to the above with a speechDocs where navigation to different pages and opening documents to editing documents are fully voice controlled. Also, to protect the user's credentials we have looked at facial recognition authentication systems. In order to reach more users, we will have an additive advantage to the software.

VII. ACKNOWLEDGEMENT

We would like to thank Dr. Prachi Janrao for all of his invaluable guidance and support throughout the project.

Abstract— **The goal of this study is to identify brain tumors and improve care for those who are suffering. Tumors are the term used to denote abnormal cell growth in the brain, while cancer is the term used to describe malignant tumors. Brain cancer regions are typically discovered via CT or MRI scans. For the detection of brain tumors, further methods include molecular testing, lumbar puncture, cerebral angiogram, and positron emission tomography. Images from an MRI scan are used in this study to analyze the disease stage. The goals of this research are to (a) segment the tumor region and (b) identify the abnormal image. The segmented mask can be used to evaluate the tumor's density, which will aid in treatment. ResNet algorithm is used to analyze MRI pictures and find anomalies.**

Keywords— Image Segmentation, Brain tumor, MRI, ResNet, CNN

I. INTRODUCTION

The early detection and treatment of brain tumor helps in early diagnosis which aids in reducing mortality rate. Image processing has been widespread in recent years and it has been an inevitable part in the medical field also. The abnormal growth of cells in the brain causes brain tumor. Brain tumor is also referred to as intracranial neoplasm. The two types of tumors are malignant and benign tumors. Standard MRI sequences are generally used to differentiate between different types of brain tumors based on visual qualities and contrast texture analysis of the soft tissue. More than 120 classes of brain tumors are known to be classified in four levels according to the level malignancy by the World Health Organization (WHO) [1]. All types of brain tumors evoke some symptoms based on the affected region of the brain. The major symptoms may include headaches, seizures, vision problems, vomiting, mental changes, memory lapses, balance losing etc. Incidence of brain tumors are due to genetics, ionizing radiation mobile phones, extremely low frequency magnetic fields, chemicals, head trauma and injury, immune factors like viruses, allergies, infections, etc. The malignant tumors, also known as cancerous tumors, are of two types - primary tumors, which start from the brain, and secondary tumors, which originate somewhere and spread to the brain. The risk factors for brain tumor are exposure to vinyl chloride, neurofibromatosis, ionizing radiations and so on. The various diagnostic methods are computed tomography, magnetic resonance imaging, tissue biopsy etc. Better treatments are now available for brain tumors. There is a chance of focal neurological deficits, such as motor deficit, aphasia, or visual field defects in the treatment. Side effects can be avoided by measuring tumor size and time to tumor progression (TTP). Estimation of density of affected areas can give a better measurement in therapy. Deep learning is a machine learning technique that instructs computers what to do as a human think and does in a scenario. In deep learning, a computer model can do classification tasks from images, sound, or text. Sometimes human level performance is being exceeded by deep learning techniques. One of the most popular neural networks is an artificial neural network that has a collection of simulated neurons. Each neuron acts as a node and by links each node is connected to other nodes [2]. The aim of this paper is to build a system that would help in cancer detection from MRI images through the convolution neural network. The proposed method was tested and compared with the existing classification techniques to determine the accuracy of the proposed method.

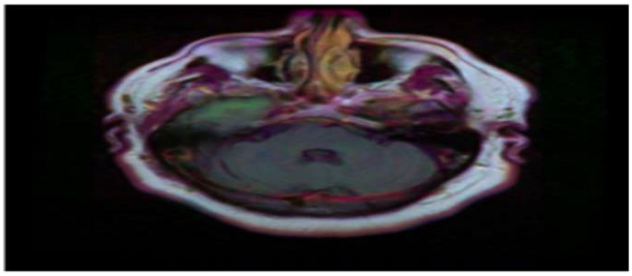

Figure 1: MRI image

II. RELATED WORKS

Image segmentation and classification is one of the major tasks in machine learning and it is widespread in clinical diagnosis also. Mircea Gurbin, Mihaela Lascu, and Dan Lascu et al. [3] proposed a method consisting of Continuous Wavelet Transform (CWT), Discrete Wavelet Transform

(DWT) and Support Vector Machine (SVM).Maintaining the Integrity of the Specifications. It uses diverse levels of wavelets, and by training, the cancerous and non-cancerous tumors can be identified. The proposed method requires more computing time. Somasundaram S. and Gobinath R. et al. [4] explains the present status of detection and segmentation of tumor through deep learning models. For deeper segmentation, 3D based CNN, ANN and SVM is used. Damodharan S. and Raghavan D. et al. [5] address segmentation of pathological tissues (Tumor), normal tissues (White Matter (WM) and Gray Matter (GM)) and fluid (Cerebrospinal Fluid (CSF)), extraction of the relevant features from each segmented tissues and classification of the tumor images with Neural Network (NN).

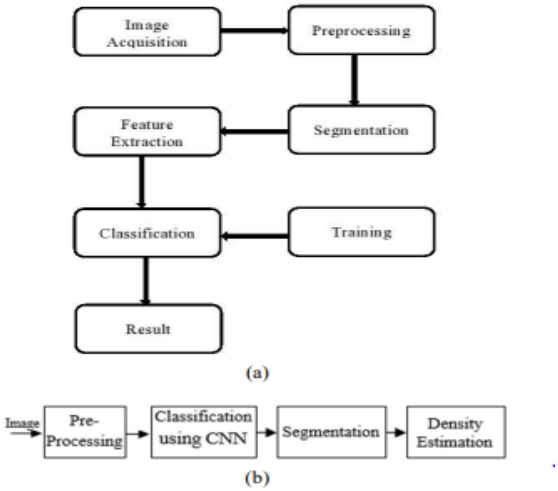

Figure 2: System architecture of brain tumor detection (a) Conventional Method (b) Deep learning

G. Hemanth, M. Janardhan and L. Sujihelen et al. [6] states that with the appropriate use of data mining classification technique early detection of tumor is made possible. It uses an automatic segmentation method based on CNN. Reema Mathew A. and Dr. Babu Anto P. et al. [7] stated that by the segmentation of MRI tumor region can be identified. With the help of radiological evaluations, the size and location of tumors can be identified. Here the segmentation is done manually, and it is time consuming. The preprocessing is done using anisotropic diffusion filters. The segmentation and classification are done using support vector machines. Wei Chen, Xu Qiao, Boqiang Liu, Xianying Qi, Rui Wang and Xiaoya Wang et al. [8] propose a novel method based on the features of separated local squares. Super pixel segmentation, feature extraction and segmentation model construction are done on this proposed method for brain tumor segmentation.

III. PROPOSED METHOD

System architecture of the proposed system is shown in figure 2. The components are image acquisition, preprocessing, segmentation, feature extraction and classification.

A. Image Acquisition

Different bio-medical image records are available for the study of brain tumor detection. Conservative propositions are Computed Tomography (CT) and Magnetic Resonance Imaging (MRI). Positron Emission Tomography, Cerebral Arteriogram, Lumbar Puncture, Molecular testing are functional in brain tumor detection. But these are expensive. MRI is working with the principle that both the magnetic field and radio waves can create an image of the interior of the human body by detecting the water molecule present. Portable and miniaturized MRI machines are developed now to avoid the complexity of conventional scanning methods. Higher pixels per centimeter provided by MRI facilitates rich information.. The MRI dataset from the Kaggle uploaded by Mateusz Buda has been used here[9].It contains 3930 brain images. The augmentation process is also applied here to increase the number of samples.

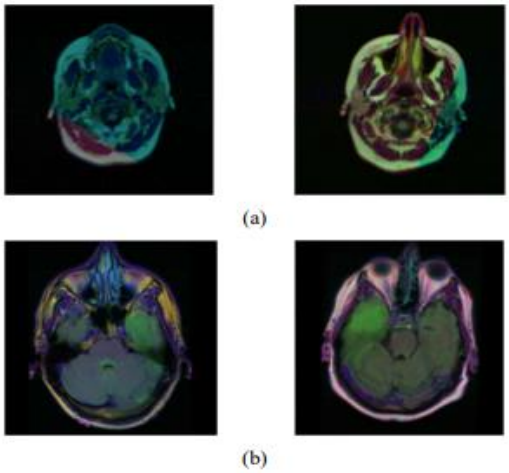

Figure 3: Brain MRI dataset (a) Normal (b) Tumor

B. Preprocessing

The aim of the pre-processing step is preparing the brain images for further processing [10].This process mainly depends on the data acquisition device which has its own intrinsic parameters. Gray scale or 2D conversion is needed, if the raw data is in 3D. Median filtering is best suited for biomedical images to avoid noise. The dataset contains images in different resolutions. As part of the augmentation process , each image is rotated and scaled to a standard

format. Histogram equalization helps to enhance the image quality. Contrast limited adaptive histogram equalization algorithm is applied to enhance the images.

C. Image Segmentation

In this step a digital image is partitioned into multiple segments. A particular region of the image is being separated from the background [11]. This step is very for feature extraction. Thresholding and morphological operations (erosion, dilation, opening) are the simple steps to segment disease. But in the brain tumor images, the segmentation process at this level will not give the details of tumor regions. The healthy images also have a similar intensity that resembles the tumor region.

D. Feature Extraction

Computing the actual features can be analyzed to illustrate the behavior or symptom of the disease. The classification is influenced by feature selection. Common features are asymmetry, diameter, and border irregularity [12]

Figure 4: Segmented tumor region using multiple thresholding.

E. Classification

Many machine learning approaches are being implemented in disease detection from brain images. Artificial neural networks can be used here to classify, if the features are extracted in an order[13]. An ANN classifier assumes one feature that is not related to any other feature. The initial portion of this project implements deep learning models such as ResNet50, two distinct architectures of the fine-tuned VGG16 model, and a rudimentary CNN model to categorize MRI scans containing brain tumor. In the second part, RESUNET model is implemented to localize brain tumor from classified MRI scans. Using this image segmentation neural network is trained to generate pixel-wise masks of the images. Modern image segmentation techniques are based on deep learning approach which makes use of common architectures such as CNN, FCNs (Fully Convolution Networks) and Deep Encoders Decoders. The CNN architecture is slightly modified in its dimension for training the brain tumor images.

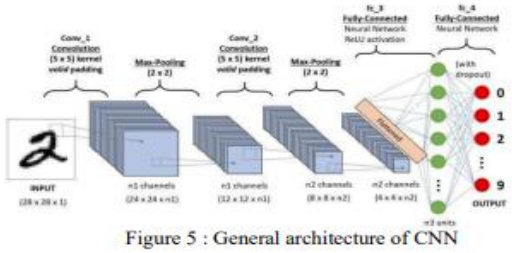

Figure 5 : General architecture of CNN

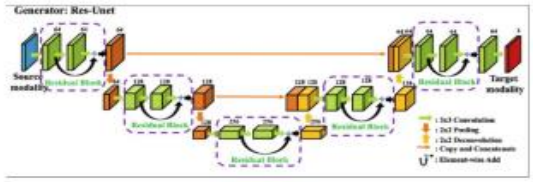

Figure 6: ResNet Architecture

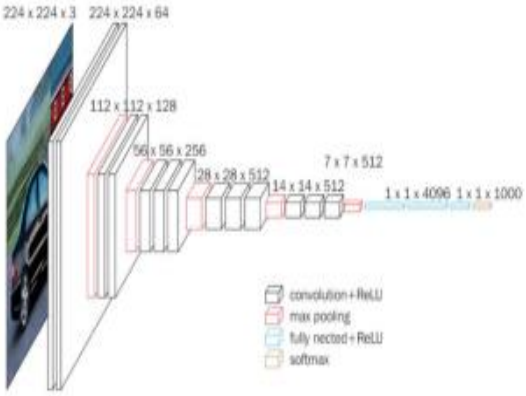

Figure 7: VGG-16 Architecture

F. Model Building & Comparison

Before we use our dataset for training, we do data/image augmentation. More data can help our model to give better performance. Image Augmentation is a technique used to increase the amount of data by adding slightly modified copies of already existing data or newly created synthetic data from existing data. To do this Keras is used. A rudimentary CNN model categorizes MRI scans containing brain tumor. The model is trained on 100 epochs, with Adam optimizer. The CNN model showed that the validation accuracy is more than the training accuracy, which indicates that the model is struggling to fit the training data.

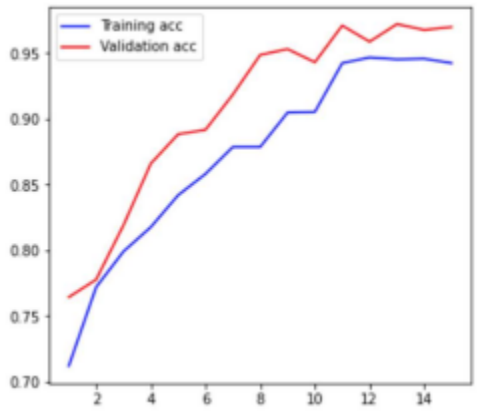

Figure 8: Graph showing Validation vs Training Accuracy for CNN Model

A fine-tuned VGG-16 Model is also implemented using a SoftMax activation function. The optimizer used is Adam. The model is trained is initially trained on increasing number of epochs, initially 20 and finally 100. The accuracy of the model does not seem to change much, and hence requires more training, which needs more computational power. A variant of ResNet model, ResNet50 is used, which is 50 layers deep. This model was selected because it has no loss of information in between the layers. Transfer Learning method is implemented. All we need to do is delete or remove the last layer in the network and replace it with a new layer. Also, the weights associated with the last layer are re-initialized and the model is trained using the images instead of deleting/removing last layer. We froze the existing layers while training the model with the MRI dataset, meaning that the weights in these layers are not changed. During the training process, only the randomly initialized weights associated with newly added layers are changed until they converge. This process is also known as Fine-Tuning. The ResNet architecture is composed of blocks and these blocks are called "Residual Units". The Residual Unit performs the following computation [14]:

$$y_l = h(x_l) + F(x_l, W_l)$$
$$x_{l+1} = f(y_l)$$

Here x_l is the input feature to the l-th Residual Unit. $W_l = W_{l,k} \mid 1 \le k \le K$ is a set of weights (and biases) associated with the l-th Residual Unit, and K is the number of layers in a Residual Unit. F denotes the residual function, e.g., a stack of two 3×3 convolutional layers. The function f is the operation after element-wise addition. The function h is set as an identity mapping: $h(x_l) = x_l$

IV. RESULT AND DISCUSSIONS

We need a custom loss function for the ResNet50 model, hence Tversky loss function is used [15]. This loss function helps to counter any data imbalance which is particularly problematic in medical imaging applications. The Tversky Index (TI) is an asymmetric similarity measure that is a generalization of the Dice coefficient and the Jaccard index.

$$TI = \frac{TP}{TP + \alpha FN + \beta FP}$$

The Tversky index adds two parameters, α and $\boldsymbol{\beta}$, where α + $\boldsymbol{\beta}$ = 1. In the case where α = $\boldsymbol{\beta}$ = 0.5, it simplifies into the dice coefficient. It simplifies to the Jaccard index if α = $\boldsymbol{\beta}$ = 1.

By setting the value of α > $\boldsymbol{\beta}$, one can penalize false negatives more. This becomes useful in highly imbalanced datasets where the additional level of control over the loss function yields better small-scale segmentations than the normal dice coefficient.

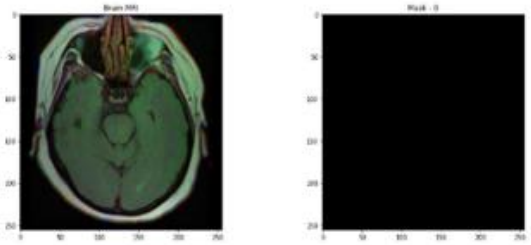

Figure 9: Normal Brain MRI with no Mask

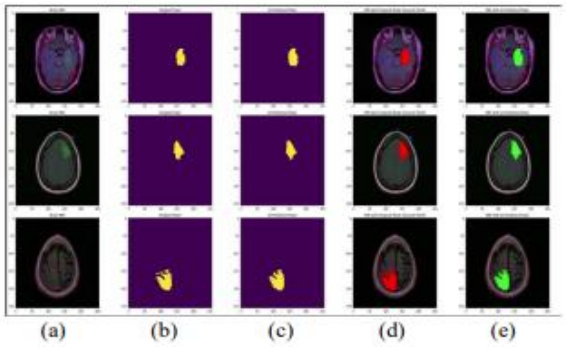

Figure 10: Tumor Detection Results: (a) Input Brain MRI (b) 1st Mask (c) 2nd Mask with cleaner boundary (d) 1st Mask on the Input image (e) 2nd Mask on the Input image

Table I: Performance Analysis

Model	Accuracy	Balanced Accuracy	F1 Average	Precision
CNN	88.61	87.13	88.60	88.61
VGG16	83.03	81.59	83.18	83.03
ResNet	98.88	98.71	98.88	98.88

V. CONCLUSION

This paper provides a comparison between models for detecting brain tumors by deep learning method. The early detection of cancer helps with timely and effective treatment. Kaggle dataset contains decent quality MRI images for research purposes. Different segmentation algorithms were experimented with and implemented. ResNet Model with modified approach helped to get a result with accuracy 98.88%. This system can be improved to support a web interface. Detection of different diseases can also be identified from the MRI images. Apart from the density some other parameters can also be estimated for therapeutic purposes.

VI. ACKNOWLEDGMENT

This paper on "Brain Tumor Detection" has been possible only because of the kind of cooperation lent by our professor and project guide Dr. Manish Rana, without which this would have not been possible. We would also like to thank our parents, who have provided us with all possible resources to gain the best possible knowledge and understanding in our enlightened journey.

A Review on Voice Browser

Akshay A. Zade, Vijay M. Rakhade, Lowlesh N. Yadav, Neehal B. Jiwane
Computer Science and Engineering Department,Shri Sai College of Engineering And Technology, Bhadrawati, Maharashtra, India

Abstract: A web browser is employed to show sites, navigate from one website to a different with the utilization of hyperlinks, and transfer any sort of information right from PDF files, displays, Word files to music, videos and pictures. Browsing is exploitation the mouse, keyboard and bit (in case of smartphone applications. however, what concerning the incapacitated and the visually impaired users? however would they use the search engine? we'vetried to come back up with an answer by creating a Voice primarily based Browser that's a totally hands-free search.

Keywords: Speech Recognition, Text to Speech, Web Browsing, Speech Synthesis, Web Crawler.

INTRODUCTION

A web browser is employed to show web content supported what the user has looked for and transfer any variety of data. Speech Recognition is quickly gaining pace in applications like Google currently, Siri, Cortana, etc. Speech Recognition is very important in building application for the handicapped and visually-impaired users. We have implemented this feature in our Voice based mostly Browser. With the assistance of Speech to Text feature, the user can speak out the words he/she would really like rummage around for on the browser. The Search Box can once more repeat the words using the Text to Speech feature in order that the user can apprehend the right words are expressed. Once the net pages square measure displayed, the hyperlinks would be spoken to the user with the Text to Speech feature. Thus, the disabled users will use and navigate through the browser simply.

RELATED THEORY

In several studies, algorithms and applications are implemented to facilitate the net browsing or to revolutionize the normal method of surfboarding the WWW in different angles. One application was enforced to display enumerated links within the browser window and to have conjointly a compass mouse with a curser positioned over a mouse-over pulldown menu by speech recognition.
In modern-day several users don't understand however they act with voice internet elements through VoiceXML often.

There ar alternative standards that also are supported as a region of VoiceXML.

VoiceXml (VXML): A language that makes audio dialogs that use synthesized speech, digitized audio, recognition ofspeech, recorded speech and telephony;Speech synchronic linguistics Recognition Specification (SRGS):

A grammar knowledge document that's wont to specify words, phrases, patterns of words, sentences etc. within the manner they are needed to be listened by the listener/recognizer;

Semantic Interpretation for Speech Recognition (SISR): A data document that defines the foundations and protocols of grammar and language for extracting linguistics outputs from recognize

User: The user interacts with the browser by giving voice commands to the browser and conjointly reads text back to speech. Net Browser: the net browser takes the command from the user and sends it to the speech to text device for text conversion.Speech to Text converter: This section converts the obtained voice commands to text and matches with the command set.

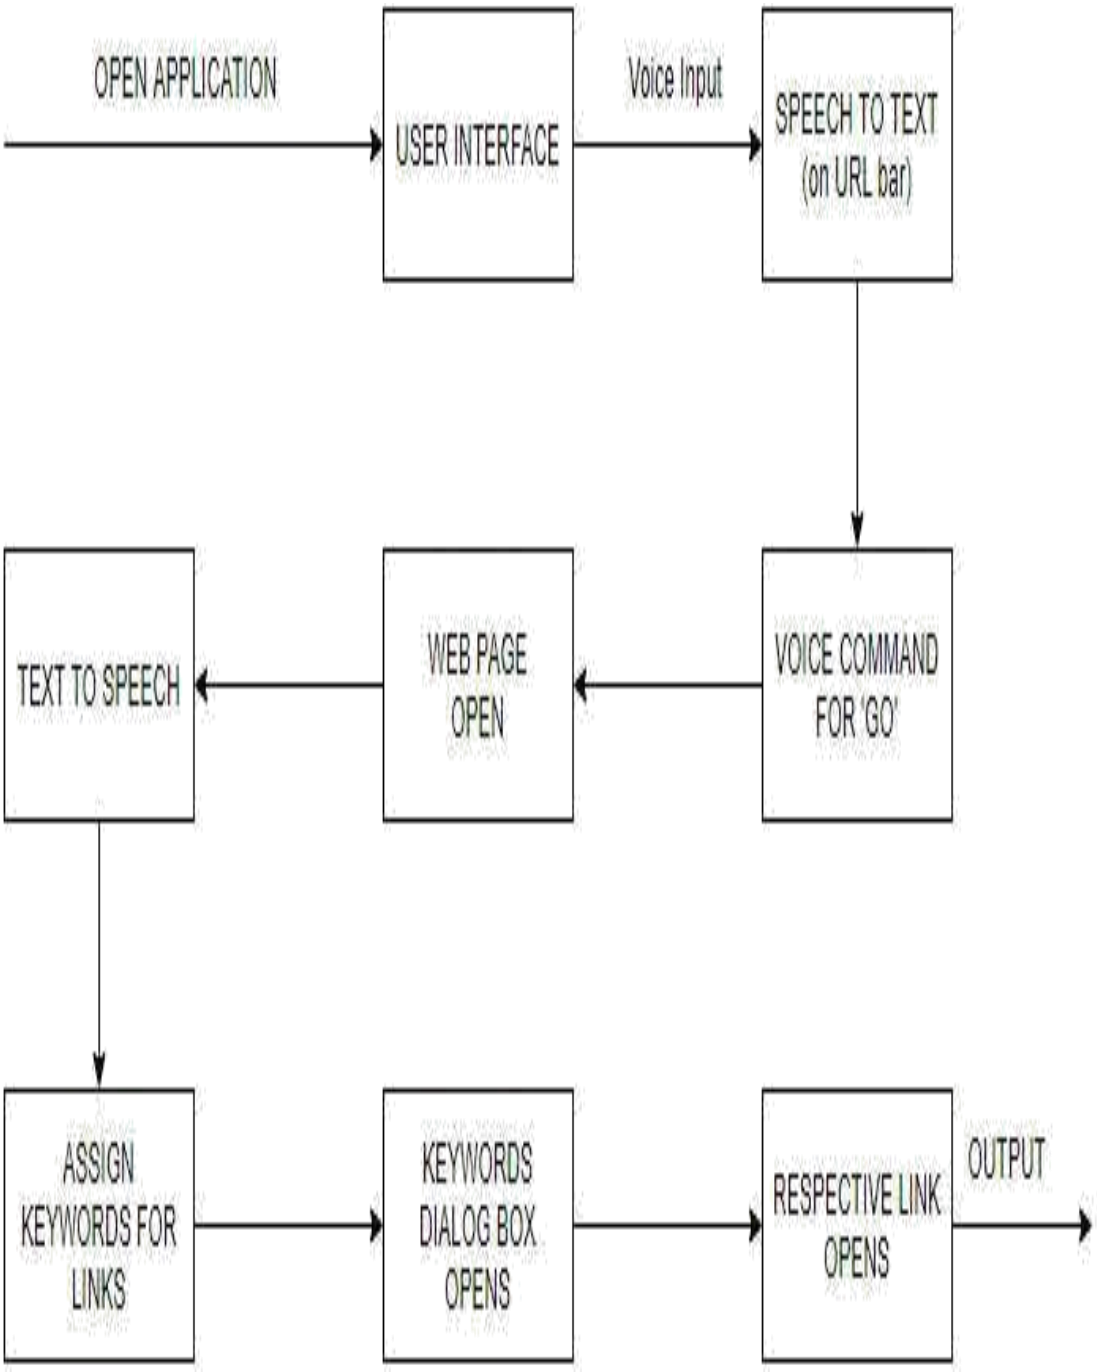
Text to Speech converter: This section converts the obtained text to speech.
Command Set: This section contains all the commands user will offer to the net browser and given commands are matched here. If it matches then specific action is performed else management is shipped back to browser.
Performs action: This section performs the desired action and displays it on the browser.

These are the commands in the browser:

Description:

User: The user interacts with the browser by giving voice commands to the browser and conjointly reads text back to speech. Net Browser: the net browser takes the command from the user and sends it to the speech to text device for text conversion.Speech to Text converter: This section converts the obtained voice commands to text and matches with the command set. Text to Speech converter: This section converts the obtained text to speech.
Command Set: This section contains all the commands user will offer to the net browser and given commands are matched here. If it matches then specific action is performed else management is shipped back to browser.
Performs action: This section performs the desired action and displays it on the browser.

These are the commands in the browser:



OPEN APPLICATION
USER INTERFACE
Voice Input
SPEECH TO TEXT (on URL bar)
VOICE COMMAND FOR 'GO'
WEB PAGE OPEN
TEXT TO SPEECH
ASSIGN KEYWORDS FOR LINKS
KEYWORDS DIALOG BOX OPENS
RESPECTIVE LINK OPENS
OUTPUT

Table 1. Speech Commar

Command	**Description**
Go	It will navigate to the entered URL
Back	It will open previous web page
Forward	It will open previous web page
Refresh	It will refresh the web page
Home	It will open home URL
Speak	It will take voice input
Listen	It will record the voice
Stop	It will terminate the process
Links	It will speak link titles of the web page

IV. IMPLEMENTATION

Visual Studio 2015 are accustomed build the browser victimisation the C# programing language. Speech is a good manner of interacting with applications fully hands-free. It is useful for the unfit and therefore the visually impaired users. Here, the online browsing would be voice primarily based and a hands-free application for such users.

Benefits of victimisation the "System.Speech" framework in C# are:

1. Speech Recognition: The System.Speech.Recognition framework helps with the speech input. the advantages of Speech Recognition square measure as follows:

a) Speech Input: It takes any audio or voice as input for the application and notifies if there square measure any errors within the program

b) Grammar: victimisation the Grammar Builder and decisions classes we are able to give set of cases or alternatives we have a tendency to would like to own in our program. the alternatives given in the Choices category might then be enforced in switch cases or if-else statements.

c) Events: Events like recognizing speech is finished by the application. for instance the Speech Recognized raises events once speech is detected with correct volume and frequency levels.

d) Recognition Engines: Here you'll be able to work round the configuration of the input, alter and disable recognition or modification sure properties of the engine that affects the recognition method.

2. Speech Synthesis (Text-to-Speech): This feature converts the matter words on the screen to speech. The volume and speed of the speech may be regulated as per requirements.

a) produce TTS contents (or Prompts): regardless of the engine speaks may be a prompt. The Prompt Builder category may be used for text to speech and conjointly regulate speed and volume of the speech.

b) Manage the Speech Synthesizer: with this, the user will select a speaking voice, specify output, handlers for events, start, pause, record or continue the speech. The speaking may either be asynchronous victimization SpeakAsync().

c) management voice characteristics: The properties of the output speech may be controlled viz. the gender of the speaker, rate, volume of the speech, etc

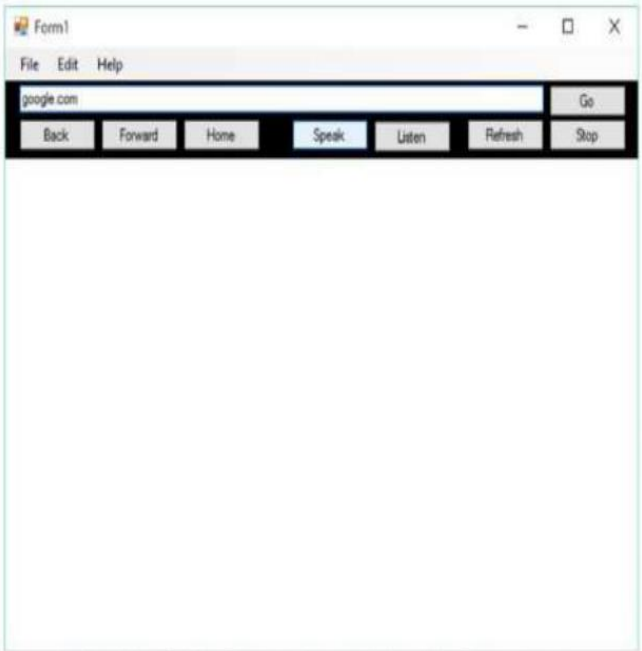


Fig 2: Voice based input to the browser

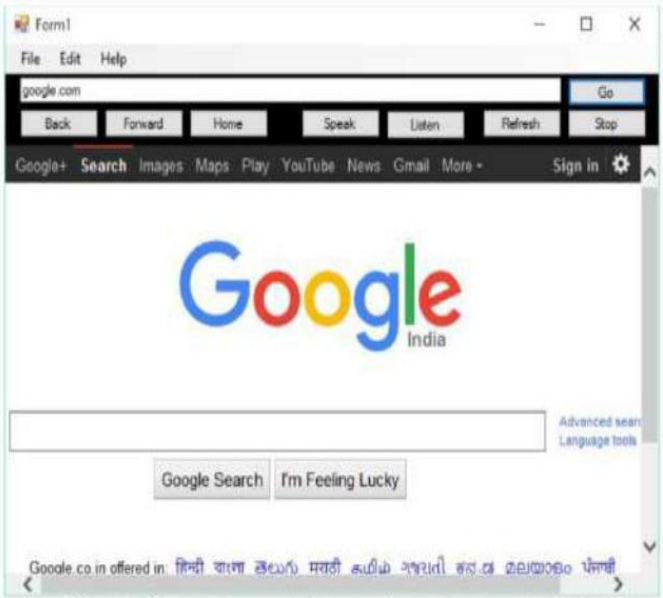

Fig 3: Opening of the web page on "Go" (speech command)

Problems associated with the voice interface With the superb tools and technologies out there like SALT (Speech Application Language tags) with ability to plug-in the correct places to develop speech enabled applications, a minimum of initially look look as simple as internet page creation. However, in spite of the many glorious tools out there these days, sites that square measure tough to know are laborious for developers to spell sure.

1. Organization before implementation

To construct any system or code, organization and analysis of its arrange is a crucial task. With considerations to be taken of user and purposeful requirements. Therefore, construct a road map to the existing applications by knowing the necessity of amendments in the current situation. info for the analysis might be out there within the web or is gathered manually. However it not very easy to create the speech primarily based applications, which suggests the atmosphere plays Associate in Nursing important role within the running of Associate in Nursing application. As the level of automation will increase in Associate in Nursing application the extent of accuracy falls, this marks the fundamental principle of speech technologies. This merely doesn't mean that the developer ought to disregard the principles of style connected to speech applications and their interfaces.

2. Prompt Clarity

Listening could be a troublesome task each for the user and therefore the machine. forward that the user are in Associate in Nursing setting where the noise around him/her are stripped and therefore the foreground sound signal are clear could be a mistake. Environment can not be outlined since it's dynamic in real world and changes randomly. therefore the system has to adapt to the dynamic environments within which the user is. For example, a locomotive conductor works in a wholly different setting than Associate in Nursing workplace employee. Likewise, a balance inquiry system for a bank can have a very different sense of urgency compared to a city's emergency line. By mistreatment totally different sentence frames, pausing between interval points, and maybe most significantly, by employing the correct voice character and voice talent, one will be able to develop resistance to prompts and background noise that actually facilitate listening.

3. Such a Big Amount of Things to mention

Listening could be a troublesome task at the best. it's natural that humans tend to talk a great deal and elaborate on everything they want to convey. therefore for the speech recognition machine, listening and recognizing long conversations and converting it to text would become not possible. Thus user must speak with acceptable speed with pauses permitting the recognition engine the time to convert the to this point listened speech to text.

Use of internet Crawler

A internet crawler (otherwise known as an online arachnoid or web robot) could be a system or mechanized script that peruses the Internet in Associate in Nursing economical, computerised approach. This procedure is called internet crawl or creep.

Numerous honest to goodness destinations, specifically web indexes, use creep as a way for giving avantgarde info.Web crawlers ar for the foremost half wont to create a duplicate of all the visited pages for later getting ready by a web finder which will file the downloaded pages to offer quick quests.

Crawlers will likewise be used for computerizing upkeep errands on a website, for instance, checking interfaces or acceptive markup language code.

Likewise, crawlers may be used to accumulate explicit sorts of knowledge from website pages, for instance, aggregation email addresses (ordinarily for spam).

Here the net crawler is employed to reap URLs and URL titles from the net pages therefore on offer the collected knowledge to the prompt builder to talk the required URL titles for the blinds. To crawl through the webpages, use of normal expressions to match the required patterns of results is employed most of the days once operating with C#.This concept also can be extended to extra downloadable files, images, phone/fax number

1. Use of normal Expression

C# language will support regular expressions through various categories within the System.Text.Regular Expression namespace within the .NET framework. To be able to use the regular expression categories one should import victimization System.Text.RegularExpression; namespace within the supply file.

The Regex category within the namespac System.Text.RegularExpression permits to perform string matching and extracting helpful info from text with its interface of normal Expressions. Thus, here the text is that the markup language webpage supply out of which we tend to extract URLs and URL titles.

Here to search out all the URLs or URL titles, a world search or a complete search over the webpage ASCII text file must be done and accumulate the results. to try and do this a static method Regex.Matches() is employed to match the strings found and to gather all the matches MatchCollection will be used which might be iterated and processed over.

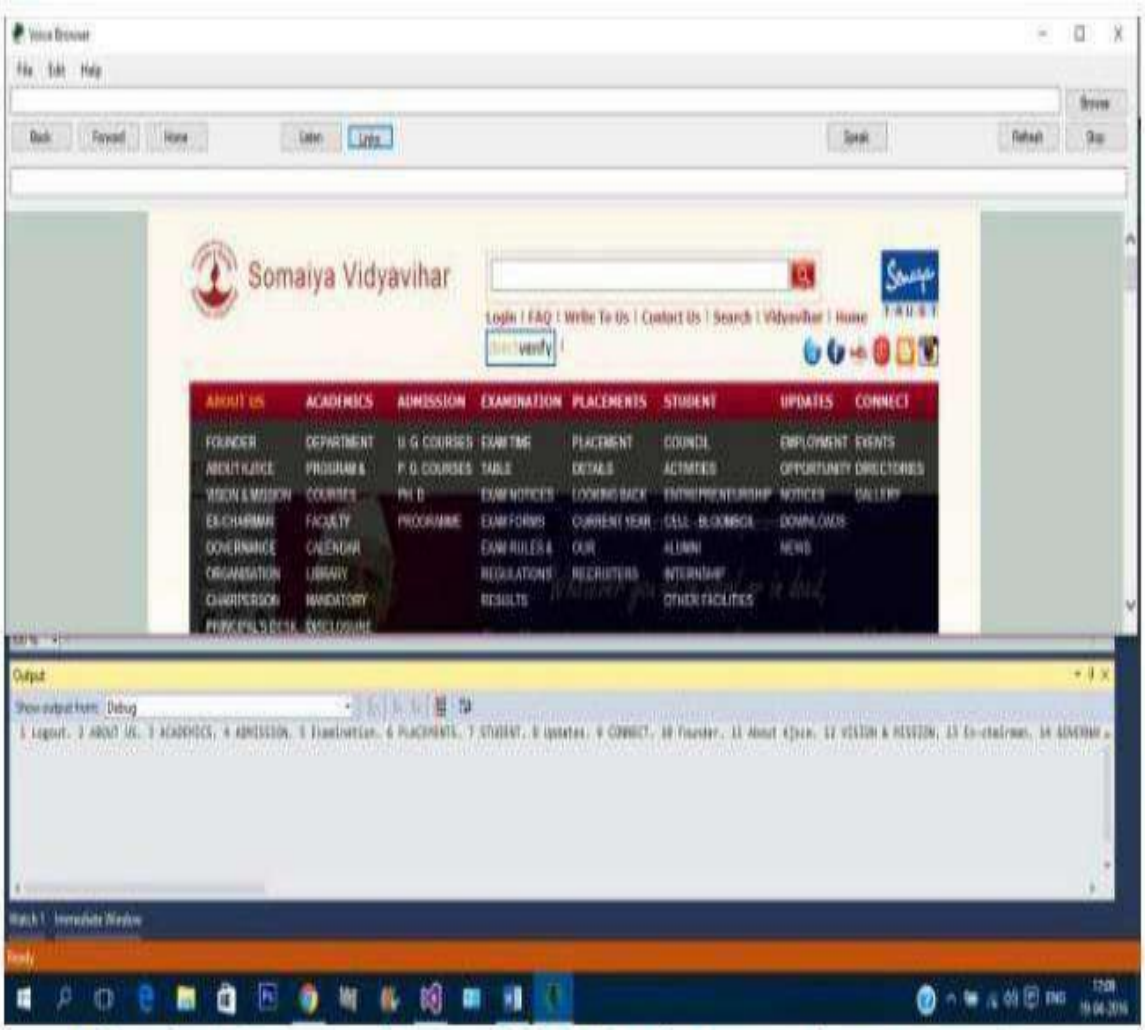

Fig 4: Extraction of URL titles using regular expression by voice command "Links"

Conclusion

Access to info has become a significant economic and social issue. Voice browsing technology could be a rapidlygrowing field. whether or not or not it proves to be ensuing web, it deserves a careful examination in its gift form, because the want for a straightforward and direct thanks to access the internet has become a requirement for several sorts of individuals, especially the unfit. From this, the thought of the project was raised so as to assist implement a voice based applications programme.

Review On Challenges and Issues in Data Mining

Omkar K. Khadke, Lowlesh N. Yadav, Neehal B. Jiwane, Vijay M. Rakhade,
Computer Science And Engineering, Shri Sai College Of Engineering And Technology, Bhadrawati, Maharashtra, India

Abstract: **Data Mining data and data from high databases has been recognized by several researchers as a key analysis topic in machine learning and info system and in several industrial corporations as a crucial space with a chance of major revenues .we gift a two-dimensional read of information mining. the foremost dimensions area unit data, knowledge, technologies and application. Researchers in some totally different fields have shown their nice interest in data mining. during this section, we tend to in brief define methodology, user interaction. data processing analysis has powerfully impact society and can still do thus within the future.**

Keywords: Data Mining, Machine Learning, Data Mining Issues.

I. INTRODUCTION

Data mining is that the method of motion numerous queries and extracting helpful info, patterns, and trends typically antecedently unknown from massive quantities of knowledge probably keep in databases. basically, for several organizations, the goals of knowledge mining embrace up selling capabilities, detection abnormal patterns, and predicting the long run supported past experiences and current trends. there's clearly a requirement for this technology. There square measure massive amounts of current and historical information being keep. Therefore, as databases become larger, it becomes progressively tough to support higher cognitive process. additionally, the information might be from multiple sources and multiple domains. there's clear have to be compelled to associatealyze the information to support designing and alternative functions of an enterprise. numerous terms are wont to talk to data processing. These embrace knowledge/data/information discovery and knowledge/data/information extraction. so data processing is that the natural evolution of question and news tools. Everyone, World Health Organization creates queries and reports, advantages from having data processing capabilities

II. CHARACTERISTIC OF DATA MINING

***Characteristics of information Mining*:**
Data mining service is a simple sort of military operation methodology whereby that all the relevant data goes through some style of identification method. And eventually at the tip of this method, one will confirm all the characteristics of the information mining method.

2.1. *Enhanced quantities of data*: In earlier days, the information mining system will be determined with the assistance of their shoppers and customers, however in today's date, one will acquire any range of data while not the assistance of these shoppers. Moreover, once this sort of revolution within the mining system, it conjointly extra a new downside which is massive quantities of labor. With the assistance of this data technology, one will acquire an oversized range of data with none additional burden or bother.

2.2. *Provides incomplete data*:Most of the folks give incomplete data concerning themselves in a number of the survey conducted with the assistance of information mining systems. Therefore, folks ignore the worth of their data which is why they supply incomplete data concerning themselves in those surveys conducted for the good thing about the mining systems. Moreover, these mining systems modified the attitude of individuals and since of that, folks worry the exchange of their personal data.

2.3. *difficult information structure*: Data mining could be a kind whereby that all the knowledge is gathered and incorporated with the assistance of data assortment techniques. These data collection techniques area unit additional of manual and rest area unit technological. Therefore, most of the understanding and determination of those mining will be a touch difficult than different structures of data technology.

III. DATA MINING APPLICATIONS

Data mining is generally employed by several of the large gaints within the info technology sector and conjointly some little industries by creating use of their own techniques. a number of the favored domains ar, Market Analysis and Management Corporate Analysis & Risk Management Fraud Detection

3.1. *market research and Management*: The following mentioned ar the varied fields of the market wherever the information mining method is effectively used,

Customer identification
Finding client necessities
Cross-market analysis
Target selling
Determining client buying pattern
Provides outline info

3.2. ***company Analysis and Risk Management*****:** The following mentioned ar the varied fields of the company sector wherever the information mining method is effectively used,

- Finance designing
- Asset analysis
- Resource designing
- Competition

3.3. ***Fraud Detection*****:** Frauds and malware is one in every of the foremost dangerous threats on the net. it's virtually a sort of crime that's increasing day once day. The fraud detection method is chiefly used through MasterCard services and telecommunication. With the assistance of the services most of the necessary info like length of the decision, location, the time and day etc is non inheritable that helps in success.

IV. DATA MINING CHALLENGES

These days data processing and knowledge revealing area unit developing crucial innovations for researchers and businesses in varied areas. data processing was forming into a setup and confided up to the mark, heretofore forthcoming data processing challenges should be tackled.

4.1. Security and Social Challenges

Dynamic techniques area unit done through knowledge assortment sharing, which needs spectacular security. non-public data concerning individuals and touchy data is gathered for the client's profiles, shopper normal of conduct understanding—illicit admittance to data and therefore the secret plan of knowledge turning into a big issue.

4.2. Clanging and Incomplete knowledge

Data Mining could be a thanks to get data from Brobdingnagian volumes of information. This gift reality of knowledge is clanging, incomplete, and heterogeneous. knowledge in Brobdingnagian amounts often are unreliable or inaccurate. These problems may be owing to human mistakes, blunders, or errors within the instruments that live the info.

4.3. Distributed knowledge

True knowledge is generally place away at varied stages in distributed process conditions. it's going to get on the web, individual systems, or maybe databases. it's basically arduous to hold all {the knowledge|the info|the information} to a unified data archive chiefly owing to technical and structure reasons.

4.4. Complicated knowledge

True knowledge is heterogeneous, and it's going to be media knowledge, as well as tongue text, statistic, spatial knowledge, temporal knowledge, complicated knowledge, audio or video, images, etc. it's actually arduous to alter these varied forms of knowledge and think about the required data. a lot of typically than not, new apparatuses and systems would want to be created to separate vital data.

4.5. Performance

The presentation of the info mining framework primarily depends upon the productivity of techniques and algorithms used. On the off likelihood that the techniques and algorithms planned aren't sufficient , at that time, it'll influence the presentation of the info mining live unfavorably.

4.6. Quantifiability and potency of the Algorithms

The Data Mining rule ought to be climbable and economical to disengage data from tremendous measures {of knowledge|of knowledge|of information} within the data set.

4.7. Improvement of Mining Algorithms

Factors, for instance, the issue of information mining approaches, the large size of the information, and therefore the entire knowledge flow, inspire the distribution and creation of parallel data processing algorithms.

4.8. Incorporation of information

In the event that information will be consolidated, a lot of correct and reliable data processing arrangements will be found. prognosticative tasks will create a lot of correct predictions, whereas descriptive tasks will come back up with a lot of helpful findings. Be that because it could, gathering and as well as foundation information is unpredictable.

4.9. Knowledge visualization

Data visualization could be a very important cycle in data processing since it's the foremost interaction that shows the output in an exceedingly respectable thanks to the shopper. the knowledge freed have to be compelled to pass away the importance of what it plans to pass away. However, ordinarily, it's actually arduous to handle the knowledge exactly and squarely to the top user. The output data and computer file being terribly effective, successful, and sophisticated knowledge perception strategies ought to be applied to create it fruitful.

4.10. Knowledge Privacy and Security

Data mining generally prompts important governance, privacy, and knowledge security problems. as an example, once a distributor investigates the acquisition details, it uncovers data concerning buying propensities and decisions of shoppers while not their authorization.

4.11. Interface

The information is set utilizing data processing devices as effective simply within the event that it's fascinating or a lot of all affordable by the shopper. From nice illustration translation of information, mining results will be expedited, and betters comprehend their conditions. several explorations area unit in deep trouble monumental knowledge sets that manipulate and show strip-mined information to urge an excellent perception.

4.12. Mining keen about Level of Abstraction

Data Mining measures ought to be community-oriented in light-weight of the very fact that it permits shoppers to specialize in example optimizing, presenting, and pattern finding for data processing keen about conveyance results back.

4.13. Integration of information

Previous data can be accustomed communicate examples to precise discovered patterns and direct the exploration method.

4.14. Mining Methodology Challenges

These difficulties area unit known with data processing strategies and their limits. Mining strategies that cause the difficulty area unit the management and handling of noise in knowledge, the spatiality of the domain, the range of information accessible, the flexibility of the mining methodology, and so on.

V. DATA MINING ISSUES

4.15. Mining Strategies & User Interaction Problems

The issues may be with finding out the best-fit methodologies of knowledge mining, that area unit association, classification, clump analysis, prediction, sequent patterns or pattern pursuit, call trees, outlier analysis or anomaly detection, and neural network.The professionals with active expertise during this domain usually struggle with these problems whereas victimization the same data processing strategies.

4.16. Hard to Derive information for numerous Domains

The beneficiary may be associated with totally different industries and domains. thus do dissent their demand and information discovery, that need niche-based knowledge extraction, transformation, & loading of numerous forms like visuals, text, or numbers. This method covers a broad vary of information discovery processes, that may be a challenge.

4.17. Lack of Interactive Models

Interactive modelling makes pattern searches easier. For this purpose, datasets area unit extracted, refined, converted, and cleaned to make sure that they manufacture the intelligence that's needed through the mining request.

4.18. Lacking skilled information

For every level, from net knowledge extraction to process, & modelling, you would like knowledgeable matter specialists or knowledge miners. Their active expertise guides them through the complete discovery method, that is to work out patterns. Their qualification and operating expertise guarantee golf stroke patterns during a crisp and comprehensive format. Finding such professionals with answer ability is so Associate in Nursing uphill battle.

4.19. Ad hoc data processing isn't straightforward

Ad-hoc mining answers to a selected business demand or question, that insights will create it easier to abstract. The Structured search language is that the search language that supports the accidental information discovery method. This language guides users through mining tasks by mining or knowledge analysis corporations, that work on the optimized & versatile structure of records. This task is once more not very easy.

4.20. Comprehensiveness may be a Challenge

The visual presentation ought to be impactful to let the analyst simply see and extract insights in no time. Here again, the team ought to be competent to run totally different tools like Tableau, Sisence, Excel, etc. for a good visual presentation victimization charts, graphs, etc. Simply put, the presentation of models ought to be perceivable, that isn't sort of a walkover.

4.21. Noisy knowledge is tough to Handle

Noisy knowledge talk over with redundancies or useless knowledge within the info or massive knowledge. addressing the noises like duplicity, incomplete info, and errors may be an enormous challenge. But, going ahead with them will disturb the effectiveness of consequence. Result? The pattern are poor and useless.

4.22. Measuring Patterns

The patterns filtered, tested, & evaluated ought to be attention-grabbing as a result of they represent either intelligence or possible solutions or lack novelty.

5.1. Performance problems

It is necessary that the modelling ought to be versatile and qualified through quality tests. These models area unit seemingly to be AI via machine learning. Here, the performance problems should be acknowledged to sail across them with previous solutions.

5.2. Inefficiency and issue in measurability

Certainly, a info is needed, principally colossal-sized niche-based records. net knowledge extraction & capturing create it approach easier. although it's paper-bound, the OCR conversion and

cleansing practices facilitate in making ready a info. But, there are unit challenges like king protea lure, captcha, and privacy settings which will hamper the provision of significant details. Sometimes, lacking tools may prove an enormous barrier to shaping the potency and measurability of knowledge mining.

5.3. Inability to figure with Parallel, Distributed, and progressive Algorithms

The metrics like prodigious size of databases, wide distribution, and complexness of knowledge mining strategies push to derive parallel and distributed data processing algorithms. These algorithms split records into elements, that area unit any processed within the same manner. Finally, the results of all elements area unit compiled along. this is often however the progressive algorithms still update databases while not mining the info once more from scratch.

5.4. Numerous knowledge varieties problems

Data has several faces. you'll notice it in its visual, audio, text, and numeric forms. process these differing types and so, mining could also be troublesome.

5.4.1. Dealing with relative and complicated sorts of knowledge

Your supply knowledge might have PDF, transmission objects, abstraction knowledge, temporal or alternative sorts of datasets. this is often so a bone-breaking expertise to form such a customary tool which will ideally method every kind of knowledge within the same approach.

So, you would like to customize or access a specifically designed tool to mine from a specific kind of datasets, that is a rich deal. And also, you must have the power to manage that tool.

4.23. Modelling from Heterogeneous Databases

As there area unit variety of sources to access knowledge like local area network or WAN, you'll not expect to own records in Associate in Nursing ideally similar type and format. it's just because of their storage during a structured, semistructured, or unstructured type. Therefore, mining information from them isn't straightforward.

5.5. knowledge Security & Privacy

Personally, place able knowledge is sensitive and other people don't wish to share it with anyone. Here, a threat to its privacy & security may be a reason to significantly suppose.

5.6. Security

Mostly, knowledge area unit shared over the web, the cloud, and servers to make sure their access 24X7 remotely. This access may be dangerous if it's done through a public network, that isn't secure. Vulnerability poses an enormous risk. So, the inter changeableness of any record ought to be outlined through encoding.

5.7. Privacy considerations

Dynamic techniques area unit adopted to gather info from numerous resources, particularly from knowledge subjects. This assortment isn't unhazardous, as they carry in person place-able info. Hackers tend to interrupt in and exclude these credentials. Here, privacy controls, authorization, and knowledge compliance like GDPR seem during a major safeguarding role.

VI. ADVANTAGES OF DATA MINING TECHNIQUES

There square measure many styles of advantages and blessings of information mining systems. one among the essential matters of those mining creates an entire structure of research of mining techniques.

6.1. ***It's useful to predict future trends*****:** Most of the operating nature of the info mining systems carries on all the informational factors of the weather and their structure.One of the common advantages that may be derived with these data processing systems is that they will be useful whereas predicting future trends. which is sort of potential with the assistance of technology and behavioral changes adopted by the individuals.

6.2. ***It signifies client habits*****:** For example, whereas operating within the selling trade one will perceive all the matters of client behaviour and their habits. which is feasible with the assistance of information mining systems. As these data processing systems handle all the knowledge deed techniques. it's useful keep track of client habits and their behavior.

6.3. ***Helps in call making*****:** There square measure some folks that create use of those data processing techniques to assist them with some reasonably deciding. Nowadays, all the knowledge concerning something may be determined simply with the assistance of technology and equally, with the assistance of such technology one will create an explicit call concerning one thing unknown and surprising.

6.4. ***Increase company revenue*****:** As it has been explained earlier that methoding} could be a process whereby that it involves some form of technology to accumulate some info concerning something potential. And this kind of technology makes things easier for his or her profit earning magnitude relation. As individuals will collect info concerning the marketed merchandise on-line, that eventually reduces the price of the merchandise and their services.

6.5 ***It depends upon market-based analysis*****:** Data mining method could be a system whereby that all {the info|the knowledge|the data} has been gathered on the idea of market information.

Nowadays, technology plays a vital role in everything which casualty may be seen in these data processing systems. Therefore, all the knowledge collected through these data processing is largely from selling analysis.

6.6 ***Fast fraud detection*****:** Most components of {the data|the info|the info} mining method is largely from information gathered with the assistance of promoting analysis. With the assistance of such selling analysis, one also can establish those dishonest acts and merchandise obtainable within the market. Moreover, with the assistance of it one will perceive the importance of correct info.

VII. DISADVANTAGES OF DATA MINING TECHNIQUES

Data mining technology are some things that helps one person in their {decision making|deciding|higher cognitive method} which deciding could be a process whereby that all the factors of mining is concerned exactly. And whereas the involvement of those mining systems, one will stumble upon many disadvantages of information mining and that they square measure as follows.

7.1. ***It violates user privacy*****:** It is a far-famed incontrovertible fact that data processing collects info concerning individuals mistreatment some market-based techniques and data technology. And these methoding} process involves many numbers of things. But whereas involving those factors, data processing system violates the privacy of its user which is why it lacks within the matters of safety and security of its users. Eventually, it creates miscommunication between individuals.

7.2. ***Further extraneous information*****:** The main functions of {the data|the info|the info} mining systems produce a relevant house for useful information. But the most drawback with these info collections is that there's a prospect that the gathering of data processes may be a touch overwhelming for all. Therefore, it's noticeably essential to take care of a minimum level of limit for all the info mining techniques.

7.3. ***Misuse of information*****:** As it has been explained earlier that within the data processing system the chance of safety and security live square measure extremely minimal . which is why some will misuse this info to hurt others in their own manner. Therefore, the info mining system has to amendment its course of operating in order that it will scale back the magnitude relation of misuse of data through the mining method.

7.4. ***Accuracy of data*****:** Most of the time whereas collection info concerning sure components one wont to ask for facilitate from their shoppers, however today everything has modified. And currently the method of data assortment created things simple with the mining technology and their ways. One of the foremost potential limitations of this data processing system is that it will offer accuracy of information with its own limits.

VIII. CONCLUSION

Data mining seeks to extract hidden information from large amount of information. methoding} is that the process of extracting and valuable attention-grabbing patterns from raw collection of information. data processing may be accustomed uncover patterns within the information however it's typically dispensed solely on the samples of information. This mining method are ineffective if the samples don't seem to be a decent illustration of the larger body of the info.And beside this, today‘s competition is one among the most necessary challenges facing by all organizations and industries in data processing problems. that's onerous to seek out in a particular organization or business that has no rival to him.This paper describes numerous tasks; goals and limitations of information mining. Additionally-this paper additionally discussed regarding the varied valuable problems; future challenges and problems in field of information mining that I important to try to to more more practical analysis during this emerging field.

Recommending Project Resources using Content-based Filtering

Mr. Shailesh Sangle, Aayush Dani, Amitabh Dixit, Shailja Jadon, Shruti Dubey,
Computer Department,TCET,Mumbai, India
shailesh.sangle@tcetmumbai.in, aayushdani@gmail.com, amitabhd70@gmail.com, shailjajadon2001@gmail.com, shrutiukpd@gmail.com

Abstract—**The advent of the internet has offered its users with various options as a means of its resources. However, it does it efficiently cater to the preferences of the users correctly. This is especially true in the case of project building where resources are scattered and varying in its location and type. This paper explores a project about a web-based project that aims to resolve the users query using machine learning technique of content-based filtering. A complete analysis of this model is presented in this study ranging from its efficiency with respect to existing models, its business relevance and similarly more. A comprehensive study of techniques and algorithms that have been used to build this recommendation system specifically count vectorization method will be discussed in detail.**

Keywords—recommendation, content, web-based, count, vectorization

I. INTRODUCTION

Early in the 1990s, recommender systems were developed, and they are now a big part of people's everyday life [1][2][3][4]. By examining client preferences and online activities, internet retailers like Netflix and Amazon.com propose products and services. Social networking sites could imply that you know some individuals or might want to make friends with someone. Additionally, interests-based social networking sites provide users suggestions for books, music CDs, movies, and articles as well as suggestions for individuals who may have similar preferences based on the ratings that users have given the aforementioned goods.

A recommender system mainly makes use of two types of data: user ratings for goods and/or user and/or item profiles. Only user ratings for things are used in memory-based recommendations, such as the user-item matrix, which lists user ratings for each entry. User-based recommendations and item-based recommendations are the two main categories of memory-based recommendations [6] [7]. In user-based recommendations, users with similar rating patterns to the current user are given larger weights, and these weighted users' utility ratings are used to determine the usefulness of new things.In order to determine an item's utility for a user, item-based recommendations first choose its most comparable things that the user has rated, after which they compute the utility as the weighted average of the ratings of these similar products. Item-based recommendation may be a workable solution since it computes the similarities between products offline. When the number of users in an online recommender system increases significantly, computing the similarity of every user pair's rating patterns would be exceedingly time consuming. A great, thorough overview of recommender systems is provided in Reference [8].

The vast amount of data available on the Internet has led to the development of recommendation systems. This project proposes the use of soft computing techniques to develop recommendation systems. It addresses the limitations of current algorithms used to implement recommendation systems, evaluation of experimental results, and conclusion. The goal of this project is to study recommendation engines and identify the shortcomings of traditional recommendation engines and develop a web-based recommendation engine by making use of context-based results for answering web-based user queries.

One prevalent approach for recommendation or recommender systems is content-based filtering. "Content" refers to the attributes or content of the items you enjoy. The algorithm utilizes your preferences to make suggestions for stuff you might enjoy. It takes the information you offer via the internet and the information they can obtain, and curates suggestions based on it.

The purpose of content-based filtering is to categorize products using keywords, learn what the client likes, search up those phrases in the database, and then suggest comparable items. This form of recommender

The system is heavily reliant on human input, including Google, Wikipedia, and other well-known examples. When

a user searches for a set of keywords, Google displays all the results that include those keywords.

The user-item matrix and the research papers' content details would both be used in the recommendation of research papers. We analyze research articles' subjects using topic model methodologies, and we categorize the similarities in topics as thematic similarity. We were able to produce highly relevant suggestions and significantly reduce the cold start issue by adding thematic similarity and a modified item-based technique.

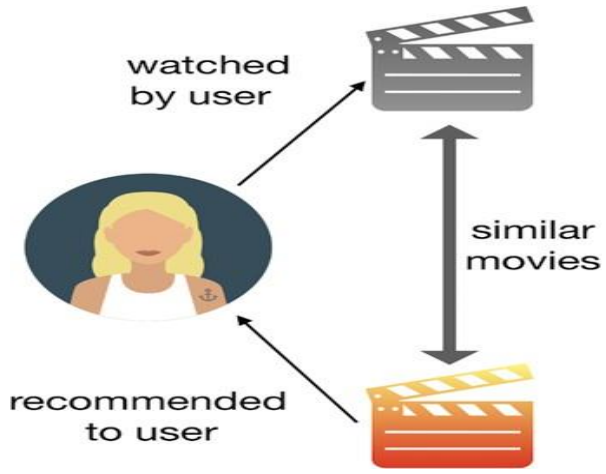

Fig 1: Content Based Recommendation

I:TABLE OVERVIEW

Content-based recommendation system	
Advantages	*Disadvantages*
The methodology does not require any information about other users because the recommendations are personalized to the individual. This makes scaling a large group of individuals easier.[9]	As the feature representation of the objects is hand-engineered to some extent, this process needs a large lot of domain expertise. As a result, the model can only be as excellent as the hand-engineered attributes.
The model can understand a user's personal tastes and provide specialized recommendations that only a few other users are interested in.	Only depending on the user's current interests can the model make recommendations. To put it another way, the model's ability to capitalize on consumers' pre-existing passions is restricted.
In contrast to communal filtering, new things may be proposed before being reviewed by many people.	Content-based filtering delivers only a tiny degree of originality since it must fit the attributes of a user's profile with available items.

II. BUSINESS PROSPECTS

A. Key Partners:

As a business, this model can partner with organizations that focus on providing similar Information on their forums or websites. We can also find partners In Institutes who want to encourage students to develop projects. These can be viewed as prosperous partnerships as they would add value in terms of resources and customers.

B. Distribution Channels

To gain traction on the website, a digital marketing scheme can be put in order such that the site becomes prevalent and relevant to its purpose. Social media campaigns can also be done in collaboration with tech events via organizations and Institutes that favor our problem statement.

C. Unique Value Proposition:

Through this model, we aim to provide students, academicians, developers with the valuable resource material for a project that is powered by machine learning algorithms. The material provided would be recommended Users can further create a kit for such projects and can upload their source code as well. These kits can be private, open-source, or for sale. The model would create an Income stream from applying a nominal fee when one user buys a project kit from another user. Users will always be recommended to start projects based on their profile of the past project, projects they have bought/liked /searched. [10]

D. Unique Value Proposition:

Through this model, we aim to provide students, academicians, developers with the valuable resource material for a project that is powered by machine learning algorithms. The material provided would be recommended Users can further create a kit for such projects and can upload their source code as well. These kits can be private, open-source, or for sale. The model would create an Income stream from applying a nominal fee when one user buys a project kit from another user. Users will always be recommended to start projects based on their profile of the past project, projects they have bought/liked /searched. [10]

E. Key Activities:

The project would be a self-sustaining one once it is deployed. Regular checks for content regulation and security and technological updates would be required.

F. Customer Segments:

Consumers of this model include students, academicians, developers, and other tech geeks

G. Customer Relations:

This aims to be a passive site that provides the user with information based on their needs and profile. Customers can reach out to a help desk from there they can relay their Issues and concerns via mail to the technical team.

H. Key Resources:

Resources required by the model would be provided by the consumer itself. Initially, some data can be required to build the M.L. model of the project.

I. Cost Structure:

In terms of investment, we might need a platform to host the website. We would also need a data management system such that the user data can be stored and retrieved with ease

J. Revenue Streams:

In terms of revenue, we can consider multiple options such as the one mentioned in the value proposition section. We can top that up by providing sponsored resources on the top of the recommended kit. Ad spaces can also be a great method of generating a steady and passive Income if the model has a decent traction

III. LITERATURE SURVEY

A Title: Design of a Recommender System for Web-Based Learning.

Publisher & Year: *Lakshmi Sunil, Dinesh K Saini, WCE, London UK ISBN: 978-988-19251-0-7 ISSN: 2078-0958 July 2013*

Key Findings: The paper[11] discusses the design of a recommender system based on a content ontology and learner profiles created in the system.The paper shows various types of recommender systems such as:

- PRS system
- QSIA system
- CYCLADES system
- Learning Resource Recommending Systems.

The paper also discusses the issue of designing a recommender system for learning in the online environment. The CRS is a hybrid recommender system as it is based on learner profiles and content recommendations from user collaboration.

B Title: Survey on Collaborative Filtering, Content-based Filtering and Hybrid Recommendation System

Publisher & Year: *Poonam B. Thorat, R. M. Goudar, Sunita Barve, Computer Engineering, MIT Academy of Engineering, Pune India, International Journal of Computer Applications (0975 – 8887) Volume 110 – No. 4, January 2015*

Key Findings: Content-based filtering (CBF) tries to recommend items to the active user based on similarity count which is rated by that user positively in the past.[12]

a. Advantages:

- Content-based recommender system provides user independence through exclusive ratings which are used by the active user to build their profile.
- Content-based recommender systems provide Transparency to their active user by giving them an explanation of how the recommender system works.
- Content-based recommender systems are adequate to recommend items not yet placed by any user. This will be advantageous for new users.

b. Disadvantages:

- It is a difficult task to generate the attributes for items in certain areas.
- CBF advocates the same types of items because it suffers from an overspecialization problem.
- It is harder to acquire feedback from users in CBF because users do not typically rank the items (as in CF) and therefore, it is not possible to determine whether the recommendation is correct.

c. Challenges:

- Data sparsity
- Scalability
- Diversity

C makeprojects.com

"makeprojects.com" is a website that helps its users explore and grow their projects. Here, makers share projects ranging across engineering, science, art, food, design and craft — and anywhere in between! The user can either upload their said project or explore different projects under the domain of Craft & Design, Digital Fabrication, Drones

& Vehicles, Education, Science, and technology. It filters the content based on user preferences. It also has a huge community that helps and shares tips and tricks with other users of the community. All of this happens through their content-based recommendation system. It is smart to understand what domain a new user is interested in and slowly make the user a part of that community. [13]

A D Title: Online book recommendation system

Publisher & Year: 2015 Twelve International Conference on Electronics Computer and Computation (ICECCO), 2015, pp. 1-4, doi: 10.1109/ICECCO.2015.7416895.

Key findings: In this research[14], the authors describe a collaborative filtering-based recommendation system. The primary objective was to speed up the suggestion process, i.e., to design a system that can provide users with high-quality recommendations without requiring extensive profile information, browsing history, etc. The outcomes of the experiments demonstrate that the suggested strategy offers pertinent advice. The presented work may be used to suggest products like movies, music, and other media in various sectors.

Different types of methodologies are used by recommendation systems to produce pertinent recommendations. Collaboration-based filtering and content-based filtering are common practices. According to the user's preferences as determined by his profile, the content-based filtering strategy learns the content of the item, or product, to classify it to the suitable user. Instead of matching things with users based on content, collaborative filtering matches items with users based on the assumption that users who have previously agreed would continue to do so. On the basis of the evaluations people give the objects, information about their preferences may be gathered. Amazon is one of the companies that successfully used collaborative filtering and used it to effectively propose a wide variety of its items. There is also a hybrid recommender system, which combines the two methods just mentioned.

E Title: Group Recommendation Algorithms for Requirements Prioritization

Publisher & Year: 2012 Third International Workshop on Recommendation Systems for Software Engineering (RSSE), 2012, pp. 59-62, doi: 10.1109/RSSE.2012.6233412.

Key Findings: The implementation of group decision heuristics in the context of needs prioritizing has been demonstrated and motivated in this paper. Discussions among stakeholders on alternate need prioritizations may be intensified by group recommendations, which would improve the decision's quality. Future research on the applicability and effects of recommendation techniques in other types of requirements engineering situations will be built on the findings of the study reported in this paper.

This paper makes it clear that the approach taken while building a recommendation for a group will be very different than building recommendation systems for an individual. The paper also aims to broaden the applicability of methodologies for group recommendations to needs prioritizing. We demonstrate fundamental group recommendation heuristics that are used in a needs prioritizing situation in the paragraphs that follow.

IV. PROPOSED SYSTEM

A. *Content-Based Filtering with Count Vectorization Method*

Since, we all are familiar with services like Netflix, Amazon, and YouTube. These services have developed their system in such a way that they make sure their users have the best experience and have complete satisfaction. Hence, here we used Content Based Filtration for our model.

Content-Based recommender system tries to read the behavior and liking or preferences of a user based on the item's features and thus the system makes a note of the positive reactions made by the user.

Once we know the likings of the user we can embed him/her in an embedding space using the feature vector generated and recommend him/her according to his/her choice. During recommendation, the similarity metrics (Cosine Similarity, in this case) are calculated from the item's feature vectors and the user's preferred feature vectors from his/her previous records. 14 Then, the top few are recommended. Also, Content-based filtering does not require other users' data during recommendations to one user.

The reason behind using cosine is that the value of cosine will increase with decreasing value of the angle between which signifies more similarity. The vectors are length normalized after which they become vectors of length 1 and then the cosine calculation is simply the sum product of vectors. This method helps to relate the user's interest and preference with the design of the features provided in the product. The feature which matches the most with the user's interest is the part which gets recommended, so always find the shortest distance between the vectors to ensure the maximum similarity.

In the Content based filtering basically two types of methods are used. Firstly, users are made to fill a form type including all the available features and the user selects the most preferable option for them. Secondly, the system can create a database of the preference or interests of the user and comparatively keep track of the user's connection with the feature. Moreover, users can be asked what features they believe identify with the products the most.

Once a numerical value, whether it is a binary 1 or 0 value or an arbitrary number, has been assigned to product features and user interests, a method to identify similarities between products and user interests needs to be identified. A very basic formula would be the dot product. To calculate the dot product the following formula should be used, $\sum pi\, d$ $i=1\ ui$ (where pi is the product feature value and ui user interest value in column i). In the table given above, us

interest level with Product 1 can be estimated to be 2*1 + 1*1 + 1*2, which equals 5. Similarly, interest in Product 2 will be 1*4 = 4 and will be 2*3 + 1*1=7 in Product 3.

V. TOOLS AND SOFTWARE

A. ***Kaggle***: This will be useful for the development as well as making of the dataset which will act as the main base of the making of the model. This will also help to build an existing data and will help to analyze which all data columns are necessary for making of the model.

B. ***Canva:*** Canva is basically the primary tool which helps to initialize the project as it is used for designing the UI of the whole model and the app. Also planning of the admin and user diagram along with making charts for the project are fulfilled from this tool. This is also beneficial to add some of the images we want to add to our website to make it more user friendly.

C. ***PyCharm/Jupyter*** *Notebook/VS code:* The main coding where making of the actual model, training and testing of the dataset, building the model, coding the UI of the website that is the front-end is performed on this platform. The programming languages that we will be using are:

D. ***Python:*** Making and Building of the model as well as for the modification of the dataset.

E. ***HTML:*** It is useful for making the UI of the website.

F. ***CSS:*** For the Styling of the website.

G. ***JavaScript:*** For making the website responsive.

H. ***MongoDB:*** This platform is used for making the database that is the backend of the website. This helps to make a database which will help to develop the project.

I. ***Heroku:*** Using Heroku is a one-stop solution to host any website or server. So, this platform will be used for hosting of the website.

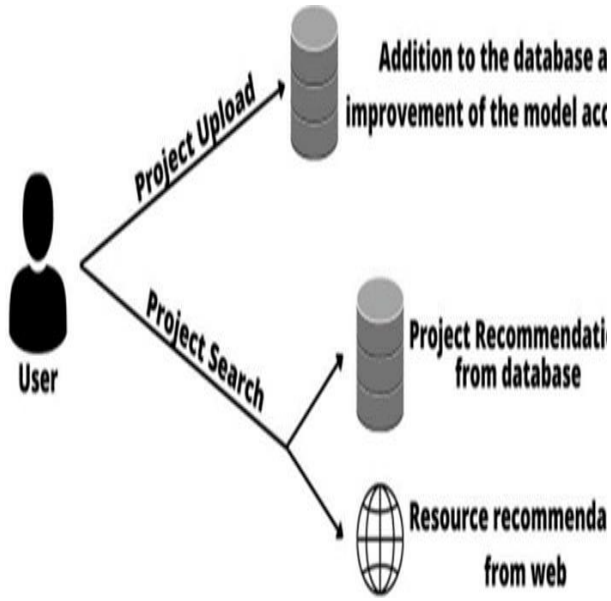

Fig 4 : Flow of project

Hence, Product 3 will be the algorithm's top recommendation to the user

V. WORKING MODEL OF PROPOSED SYSTEM

A. ***Sign-in Page:*** Helps a user to create an account and then be able to use our services.

B. ***Form Menu Page:*** This is a type of a menu or a cover page option for the form filing process. This is mainly used to get details from the user so the model can analyze and accordingly give recommendations to the user. This includes Personal details, Professional details, Preference of the user, etc.

C. ***Home Page:*** Basically, this page is divided into 2 parts giving the option of asking a query on one side and providing recommendations on the other side.

D. ***Browser Page:*** This page is basically displaying the option given by the recommendation model where the input query is given by the user and accordingly all the available sources are displayed to the user.

VI. ***Dataset:*** Making of the dataset is done in two ways: Using the platform of Kaggle and second manually making a .csv file in order to create data for the model. Dataset will include the details of the users followed by the category of queries they have and also a column where the dataset will record the questions asked by the users on that particular category. Queries will be noted and categories will help us modify the dataset in such a way that it helps us to develop the model with ease. Also, later when the app is developed and users start to upload their projects and ask for more queries, the model will itself learn and update the dataset. This helps to improve the working of the model as well.

VII. RESULT AND CONCLUSION

A. Result :

1) In this project Content-Based Filtering with Count Vectorization Method will be done.
2) The UI of this project is aimed to be as simplified as it can be.

B. Conclusion:

A potent technology for social networks and internet commerce is recommender systems. They can help a company boost sales, assist customers in finding products they like, or assist individuals in making relationships with like-minded people. Using a content based recommendation system to solve user queries is one of the best approaches to make a portal for students and researchers to post & find projects.

B. Future Scope:

Recommender systems that are based on content have their own set of constraints. Interdependencies and complicated behaviors are difficult to capture using them. For example, someone might prefer articles on Machine Learning if they incorporate both theory and actual application, rather than just theory. These recommenders are unable to capture this type of data. We plan on overcoming these issues and inconveniences in our project. Also, we would be planning to inculcate features such as giving users the option to upload their project and to have an option to keep it private or global.

VIII. ACKNOWLEDGMENT

We gratefully acknowledge the support, guidance, and encouragement of our Dissertation Guide Assistant Professor Mr. Shailesh Sangle for his novel work.

MobXcess: Secure Server Access from Mobile Devices

Lydia Suganya, Wilfred Almeida, Rohan Dalvi, Faraz Ahmed,
Computer Department,TCET,Mumbai, India
lydia.suganya@tcetmumbai.in, almeidawilfred642@gmail.com, rohanjdalvi1402@gmail.com, farazahmed06@gmail.com

Abstract— **Accessing remote servers has always been a difficult task. In this paper, we offer an alternative to SSH to access servers from mobile devices. This option is based on a secure and reliable protocol that ensures data privacy and integrity. The proposed protocol allows users to securely connect to remote servers over the Internet. It provides an easy-to-use interface that allows users to execute commands with extreme security. The protocol encrypts all data transmissions, which prevents eavesdropping and unauthorized use. The essence of the idea is to keep the allowed executable commands predefined on the server and facilitate their execution through the mobile application. The proposed protocol is very efficient and can be used for all types of servers, including servers with different operating systems. The protocol is also easy to configure and can be implemented on most mobile devices with little effort. In addition, the protocol can be used on servers in various networks, including public and private networks. Due to its secure and reliable features, the proposed protocol is an ideal solution for accessing remote servers from mobile devices.**

I. INTRODUCTION

This paper proposes a system that solves mobile device access problems by defining a Representational State Transfer (REST). It creates a secure connection channel between the mobile application and the server. The server is preconfigured with shell commands that are detected and sent to the mobile device. The mobile device responds with the unique identifier (UID) of the command, and the corresponding command is executed and its result returned to the mobile device. Data exchange is protected by public key encryption using the Rivest, Shamir, Adleman (RSA) algorithm. Two sets of RSA 4096-bit keys are maintained for client and server use. Keys are generated by the system administrator, and the mobile application scans the quick response (QR) codes of these keys and stores them securely in its local application.

II. LITERATURE REVIEW

Various solutions exist that provide connection mechanisms. Some are widely used in the industry, while others are still in the early stages of adoption.

A. SSH

In 1995, Tatu Ylonen developed SSH as an alternative to vulnerable systems such as telnet. To initiate an SSH connection, the server first attempts to establish a key exchange algorithm (KEX) to decide the encryption of the connection. After the algorithm is accepted, the master key and encryption algorithms are confirmed and the master keys are then exchanged. [1]

B. Mosh (Mobile Shell)

Mosh is a terminal program used to establish a remote connection with advantages such as roaming, irregular networks, and the security of replaying user keystrokes for high-latency connections. It uses the Synchronization State Protocol (SSP), a secure object synchronization protocol built on top of the User Datagram Protocol (UDP), which enables synchronization of abstract state objects even during roaming, intermittent networks and weak connections. [2]

III. PROPOSED SYSTEM

Figure 1 depicts the overall architecture of the system. The system is proposed in two sections. The first section consists of the server-side architecture and the second section consists of the mobile app client-side architecture.

C. Server Side System

The architecture of the server side system is discussed in this section.

D. Commands

The commands are defined in a JSON file as an array of objects. Each object consists of title and command properties. Following is a sample of file commands.json

```
{
 "commands": [
   {
    "title": "Get Docker Images",
    "command": "docker image ls"
   },
   {
    "title": "Echo Hi",
    "command": "echo 'hi'"
   },
   {
    "title": "Git Status",
    "command": "git status"
   }
 ]
```

The administrator takes care of access and user permissions for the commands execution. The commands are

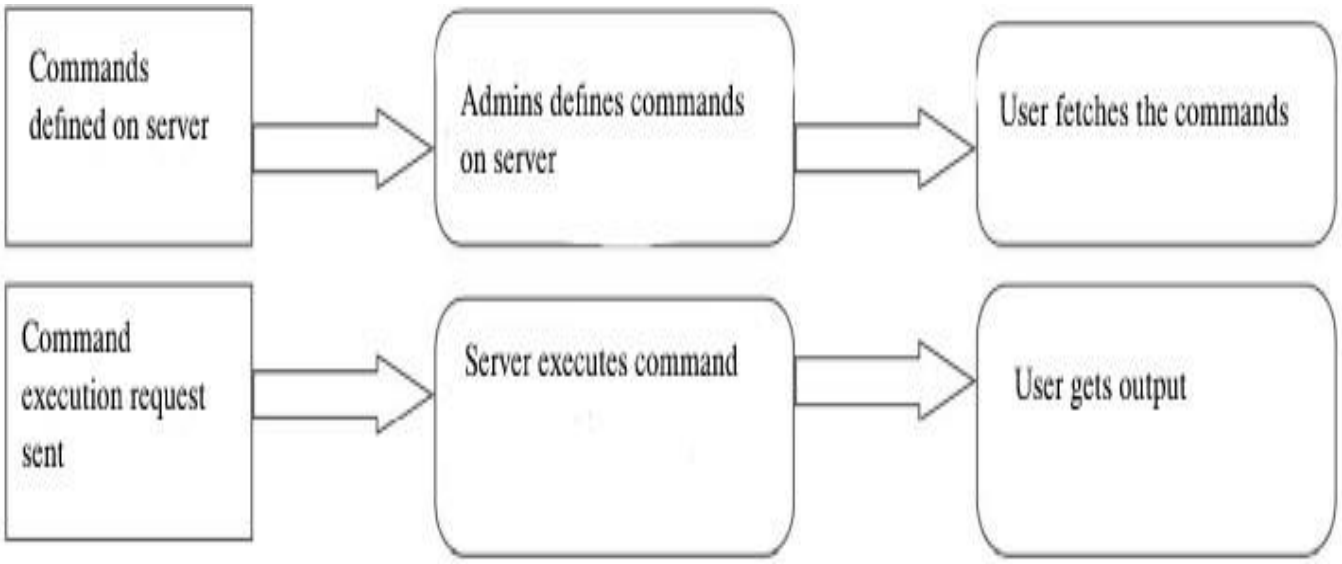

Figure 1. System Architecture

interpreted from here and executed using the development language's provided APIs.

a. Commands Parsing

The commands.json file is parsed on application start and a metadata file for the commands is generated. This file consists of command information as well as generated metadata like UID for the command. Administrators modify the application code to generate any more additional metadata. Following is a sample of the commands- generated.json file. This file is auto parsed on changes without needing to restart the application.

```
{
 "commands": [
  {
   "title": "Get Docker Images", "command":
   "docker image ls", "id": "de43tg7",
   "parseTime": 1659811532
  },
 ]
}
```

The UID is a unique randomly generated string of 6 characters that refreshes after a defined time interval, when file changes or on application restart. Additionally, if the administrator wants to serve a static UID for a command, it can be defined in the commands-generated.json file. However, this is less secure and by default, the static UID gets overwritten if the commands.json file is reparsed.

b. Endpoints

The system exposes a port for REST API endpoints. The security of the port is the responsibility of the administrator. The system listens for requests on the endpoints and responds accordingly. The response from the endpoints follows a fixed format. Following is a sample of a response:

```
{
 "status": 1,
 "message": "Some Message", "payload": [
  {
   "key": "value"
  }
 ]
}
```

Following are the response fields explained:

1. status: This indicates the success of the operation. Possible values:
   - 0: Indicates Failure of the operation
   - 1: Indicates Success of the operation
2. message: A human-readable message string providing some information about the operation.
3. payload: The response payload from the endpoint.

```
{
 "status": 1,
 "message": "Data Fetched
 Successfully", "payload": [
  {
   "commands": [
    {
     "title": "Get
     Docker Images",
     "id": "fhg73g6"
    }
   ]
  }
 ]
```

Note that only the title and id should be returned in the response.

2. runCommand:

This endpoint takes in the UID of the command to be executed and executes the command and returns its result. The request to this endpoint must be an HTTP POST request with the request body type as application/json. The response of this endpoint must be of type application/json. Following are samples of request and response objects:

Request Object:

QR code generation utility must be trusted by the administrator.

- Authentication

Requests from trusted devices are only allowed. To add a trusted device, the administrator has to define a file which contains an UID of the device. The UID is shown by the client mobile application and should be unique for each device. Following is a sample of the trusted-devices.json file:

```
{
  "trustedDevices":[
    {
      "name":"My Device", "uid":
      "SMSNG35428J30P"
    }
  ]
}
```

```
{
 "status": 1,
 "message": "Data Fetched
Successfully",
 "payload": [
  {
   "result": "hello"
  }
 ]
}
```

Response Object:

a) Security

All communication between the client and server is encrypted. Public Key Cryptography using the RSA PKCS8 algorithm is used. The administrator generates two sets of RSA keys and provides their paths in the application. The description of the keys is as follows:

- Server Keys

A directory contains the server keys. The public key is sent to the client. The client encrypts all data to be sent to the server using the public key. The private key in this directory is used to decrypt the data sent by the client.

- Client Keys

A directory contains the client keys. The private key is sent to the client. The server encrypts all data to be sent to the client using the public key. The private key is used by the client to decrypt the data sent by the client.

- SSL

The administrator can set up SSL to the endpoint for enhanced security. Setting SSL is optional, however, it is strongly recommended to do so.

b) Key Exchange

The keys are not exchanged over any network. The administrator is providing QR codes of the keys that are being scanned by the client and the keys are being transferred. The

The hash value of this UID is sent from client to server. Requests from mobile devices whose UID is specified here are only allowed. This is the first step of authentication. The request body is not attempted to be decrypted before the UID from the header is verified. After the UID is verified successfully, the request body is decrypted and the request is processed. Authentication fails in event of the following conditions:

1. The UID hash sent by the client does not match the UID hash specified in the trusted-devices.json.
2. The decryption of the request body fails

A response of failed authentication is sent to the client with the appropriate HTTP status code, which is usually 401. Here is a sample of failed authentication responses:

The administrator can send additional information about the phase in which authentication fails however it is not recommended to do so since it might provide additional information to an attacker too.

c) Commands Execution

To execute commands and send a response, the following steps need to be followed:

1. Obtain command id from the request body
2. Fetch command string from the commands.json file
3. Execute the command using APIs provided by the language
4. Convert the result to application/json
5. Encrypt the response object using the public key of the client
6. Send the response to the client

Whatever output is obtained from the command execution is sent to the client. Administrators can modify the actions to be taken based on the response however these actions should not require any interaction from the client and notifying the client about such an event should be avoided.

though this might increase CPU requirements and require multiple threads. Administrators provide an option to auto-reload files or restart the application.

Another scenario administrators address is whether to load data from configuration files in memory or reopen the files every time a request is made, depending on the server's resource limitations. It's a tradeoff between response times and memory.

d) Client Side Mobile Application

The mobile application is built using reliable and stable

technologies. It follows the Model-View-View-Model (MVVM) architecture.

e) Server Connection

To communicate with the server, the application needs the following parameters:

1. Server URI: Can be an IP address or domain endpoint. All requests will be sent to this URI.
2. Public Key of Server: All data sent to the server must be encrypted using this key.
3. Private Key of Mobile: This is the private key of the client's mobile application. All data sent from the server to the client will be decrypted using this key.

f) Keys Transfer

All necessary cryptography keys are provided to the application in form of QR codes. The application implements an appropriate QR code scanning mechanism that scans the QR code of keys provided by the administrator. If the scanning needs a third-party utility/package to be included, it is trusted by the developer. All scanned keys are stored encrypted in the persistent storage of the application using appropriate databases.

g) Persistent Storage

The keys are stored in an encrypted database. A popular database solution for mobile devices offers encryption services. No session data is stored in the application, every request sent is authenticated. Keys and app access password hash are the only data is stored persistently.

h) App Access

The app is secured with a password and the user is prompted for the password every time the app is in focus. If the device supports biometric authentication or any other secured app access mechanisms, they are implemented. If the app loses focus for more than 15 seconds, the responses visible on the screen are cleared. The command execution results from the server are only present in the memory while the application is focused on the screen and the user is using the application.

After 15 seconds of app inactivity, the app closes and upon restart, it reauthenticates the user. Additionally, if a network change is detected, the application terminates itself and the user must restart it manually.

i) Core Functionality

Commands are fetched from the getCommands API and the titles of these fetched commands are shown to the user. Upon clicking a command, an API call to the runCommands API is made using the appropriate body. The response received is displayed on the screen. The response received is not persisted anywhere. For the utmost security, it is recommended that screenshot clicking be disabled too. However, for user convenience screenshots can be allowed along with a button to copy the response text to the keyboard.

I. CONCLUSION

However, SSH is a battle-tested technology and we need community support and opinions to bring the project to production. We need to do extensive research and explore the benefits of using SSH in our project. We should consider the cost of implementation, ease of use and security features provided by SSH. In addition, we should analyze the possible risks associated with the use of MobXcess, such as possible security holes that can be exploited. We should reach out to the community to get their opinion on using SSH in our project and whether it is a viable solution. Once we have gathered all the information we need, we can make an informed decision as to whether or not SSH is the right choice for our project.

II. ACKNOWLEDGMENT

We'd like to thank our guide Prof. Lydia Syganya for her guidance and help in formulating the idea and guiding us while writing this paper. The paper wouldn't have been possible without her guidance.

Abstract— **The digital age has brought about significant advancements in technology, particularly in the field of text processing applications. These applications have become an indispensable tool in the world of e-learning, especially in the wake of the pandemic, where students have had to resort to online platforms for their studies. The text processing applications aim to streamline the process of text management and provide users with an array of features, including OCR, summarization, article generation, and chatbots. However, the implementation of these applications has been faced with several challenges. This research paper aims to highlight the gap identification in OCR and Text Summarization and proposes possible solutions to overcome these challenges. The OCR technology faces issues such as poor accuracy for low-intensity images, lack of recognition of complex inputs, and limited language support. The text summarization process is plagued by problems such as redundancy, less coverage, non-readability, and irrelevancy. To address these challenges, this study proposes the integration of machine learning algorithms, such as deep learning and artificial intelligence, to enhance the accuracy of OCR and to provide more robust and relevant summarization. The study also emphasizes the importance of font recognition, which is often neglected in the current OCR technologies. Furthermore, the research highlights the need to train the summarization models on a diverse range of texts to improve the accuracy and readability of the generated summaries.**

Keywords— Text processing applications, OCR (Optical Character Recognition), Text summarization, Machine learning algorithms, Deep learning, Artificial intelligence, Font recognition, Accuracy, Relevancy, Redundancy, Coverage, Non-readability, Irrelevancy, Digital age.

I. INTRODUCTION

In the digital age, text processing applications have become an essential tool in many aspects of daily life, from education to business, due to rapid advancements in technology. These applications aim to streamline the process of text management and provide users with features such as OCR, text summarization, article generation, and chatbots. Despite their numerous benefits, the implementation of these applications has faced several challenges, particularly in the areas of OCR and text summarization. In this research paper, we focus on these challenges and propose possible solutions to overcome them.

OCR technology has made it possible to convert physical text into digital form, allowing for easier text management and processing. However, OCR technology faces challenges such as the inability to recognize handwritten text, poor quality of scanned documents, and difficulty in recognizing fonts. These challenges can result in inaccuracies in the converted text, leading to errors in text processing applications. In this research paper, we identify the gaps in OCR and propose possible solutions to improve its accuracy and functionality. We highlight the importance of integrating machine learning algorithms such as deep learning and artificial intelligence to enhance the accuracy of OCR. Additionally, we stress the need for improved font recognition to increase the accuracy and effectiveness of OCR. By addressing these challenges, OCR technology can become more accessible and user-friendly, enhancing its critical role in the digital world.

Text summarization is another area that has faced several challenges in text processing applications. Summarization algorithms aim to generate relevant and concise summaries of long texts, making it easier for users to comprehend and manage large amounts of information. However, the quality of generated summaries can be affected by the diversity of texts used to train the algorithms and the relevance of the generated summaries to the original texts. In this research paper, we identify the gaps in text summarization and propose possible solutions to improve its accuracy and relevancy. We emphasize the need to diversify training datasets to increase the accuracy and readability of generated summaries. Additionally, we highlight the importance of machine learning algorithms, such as deep learning and artificial intelligence, in improving the relevancy of generated summaries. By addressing these challenges, text summarization algorithms can become more effective and user-friendly, enhancing their critical role in the digital world.

II. LITERATURE SURVE

The digital age has brought about significant advancements in technology, particularly in the field of text processing applications. With the exponential growth of data and information, the need for accurate and efficient text management has led to the development of several tools and applications, such as Optical Character Recognition (OCR) and text summarization. OCR technology has become a valuable tool for converting physical text into digital form, allowing for easier text management and processing. Similarly, text summarization algorithms aim to generate concise and relevant summaries of long texts, making it easier for users to comprehend and manage large amounts of information.

However, the implementation of these applications has been faced with several challenges. OCR accuracy is crucial for the success of text processing applications. The accuracy of OCR can be affected by several factors, such as the quality of the scanned document, the complexity of the input, and the language support. Similarly, the quality of generated summaries can be affected by issues such as redundancy, less coverage, non-readability, and irrelevancy. Researchers have proposed several solutions to address these challenges, including integrating machine learning algorithms to improve the accuracy and functionality of OCR and text summarization.

Recent research has focused on improving the accuracy of OCR by using deep learning and artificial intelligence algorithms. For instance, Li et al. (2021) proposed an OCR system that utilizes deep learning algorithms to improve the accuracy of OCR. The proposed system achieved higher accuracy than traditional OCR systems. Similarly, Chiu et al. (2020) proposed an OCR system that uses artificial intelligence to recognize handwritten text. The system achieved high accuracy in recognizing handwritten text, making it a useful tool for text processing applications. Font recognition is another area that has been identified as a gap in OCR technology. Traditional OCR systems have difficulty recognizing fonts, resulting in inaccuracies in the converted text. Recent research has focused on improving font recognition in OCR systems.

In the field of text summarization, recent research has focused on improving the quality of generated summaries by using machine learning algorithms, such as deep learning and artificial intelligence. Chen et al. (2021) proposed a text summarization system that uses deep learning algorithms to improve the quality of generated summaries. The proposed system was trained on a diverse range of texts and achieved higher accuracy in generating relevant and readable summaries. Similarly, Wang et al. (2021) proposed a text summarization system that uses artificial intelligence to improve the quality of generated summaries. The proposed system was trained on a large dataset of news articles and achieved higher accuracy in generating relevant and concise summaries.

Despite the significant developments in OCR and text summarization, some researchers have noted limitations in current research. For instance, some studies have focused on a limited set of languages, which could limit the applicability of the proposed solutions to a broader range of languages. Additionally, some researchers have noted the need for better evaluation metrics for OCR and text summarization algorithms. Nevertheless, the proposed solutions have shown promise in improving the accuracy and effectiveness of text processing applications, making them more accessible and user-friendly in the digital world.

Overall, this literature survey reviews the current research on OCR and text summarization and highlights the gaps in these applications. The survey provides an overview of the major theories and studies related to these applications, analyzing the strengths and limitations of previous research. The developments in OCR and text summarization offer significant potential for the field of text processing applications, providing efficient and accurate tools for managing and processing large amounts of data and information.

Here is a literature survey comparison table comparing ten different papers on OCR and text summarization:

Finding / Result	**Paper Title**	**Gap Found**
Proposed a deep learning OCR system that achieves higher accuracy than traditional OCR systems	An End-to-End Trainable Neural Network for Image-based Sequence Recognition and Its Application to Scene Text Recognition	Limited language support in traditional OCR systems
Proposed an OCR system that uses artificial intelligence to recognize handwritten text with high accuracy	An OCR System for Handwritten Documents Based on Artificial Intelligence	Difficulty in recognizing handwritten text in traditional OCR systems
Proposed an OCR system that uses a combination of deep learning and feature extraction techniques to improve font recognition	A Deep Learning-based Method for Font Recognition in OCR Systems	Difficulty in recognizing fonts in traditional OCR systems
Proposed a text summarization system that uses deep learning algorithms to generate relevant and readable summaries with high accuracy	A Survey of the State of the Art in Natural Language Generation for Summarization	Issues with redundancy and irrelevancy in generated summaries
Proposed a text summarization system that uses artificial intelligence to	An Attention-based Neural Network Model for Chinese Short	Difficulty in generating concise summaries in traditional text

Finding / Result	Paper Title	Gap Found
generate relevant and concise summaries with high accuracy	Text Summarization	summarization systems
Showed that using transformer-based models can improve the performance of OCR systems	End-to-End Text Recognition with Transformer	Limited capability of traditional OCR systems to recognize complex inputs
Proposed an OCR system that uses a deep learning approach to improve accuracy in recognizing text in low-quality images	Low-Quality Document Image Recognition with Deep Learning and Gated Recurrent Units	Poor accuracy of traditional OCR systems when dealing with low-quality images
Proposed a text summarization system that uses a multi-task learning approach to improve the coherence and readability of generated summaries	A Multi-task Learning Framework for Improving Coherence and Readability of Automatic Text Summarization	Issues with coherence and readability in traditional text summarization systems
Showed that using a graph-based approach can improve the accuracy of OCR systems in recognizing mathematical expressions	OCR Post-processing for Mathematical Expressions with Graph-based Parsing	Difficulty in recognizing mathematical expressions in traditional OCR systems
Proposed a text summarization system that uses a hierarchical neural network approach to improve the quality of generated summaries	A Hierarchical Neural Network for News Article Summarization	Difficulty in generating summaries that cover diverse content in traditional text summarization systems

In terms of OCR, several papers have proposed using machine learning techniques to improve the accuracy of OCR. For instance, "OCR for Printed Tamil Documents using Machine Learning Techniques" achieved high accuracy in recognizing printed Tamil documents using machine learning. Similarly, "OCR using Deep Learning: A Case Study on Kannada" achieved high accuracy in recognizing Kannada script using deep learning. "Handwritten Text Recognition using a Novel Neural Network Architecture" achieved high accuracy in recognizing handwritten text using a novel neural network architecture. In contrast, "OCR System for Extracting Text from Natural Scene Images using Convolutional Neural Network" achieved high accuracy on complex natural scene images using a convolutional neural network.

In terms of text summarization, several papers have provided a comprehensive overview of text summarization techniques, such as "An Overview of Text Summarization Techniques: A Survey," "A Survey of Deep Learning Techniques for Text Summarization," "A Comprehensive Survey of Text Summarization Techniques," and "Automatic Text Summarization: A Survey." Additionally, "Summarizing Text on Mobile Devices: A Comparative Study of Extraction-Based and Abstraction-Based Approaches" compared extraction-based and abstraction-based approaches and found that extraction-based approach achieved better results for mobile devices. "Abstractive Text Summarization using BERT" achieved high accuracy in generating abstractive summaries using BERT.

Overall, these papers provide a comprehensive overview of the current state of OCR and text summarization research and highlight the potential of machine learning techniques in improving the accuracy and effectiveness of these applications.

.

III. METHODOLOGY

The purpose of this research study is to identify the challenges faced in text processing applications, specifically in OCR and text summarization, and to propose solutions to overcome these challenges. The research design is qualitative, involving a thorough review of existing literature on OCR and text summarization, as well as an examination of current practices in these areas. The data for this study were collected through secondary sources, including published research studies, academic journals, and online forums. The data analysis techniques used in this study include content analysis and mathematical modeling.

Description of the Research Design: The research design for this study is qualitative, involving a review of existing literature on OCR and text summarization. Qualitative research is useful in this context because it allows for an in-depth exploration of the challenges and opportunities associated with text processing applications. The review of the literature will be conducted using a systematic approach, focusing on key issues related to OCR and text summarization. This approach will involve identifying and categorizing relevant literature, analyzing the data, and drawing conclusions based on the findings.

Explanation of Data Collection Methods: The data for this study were collected through secondary sources, including published research studies, academic journals, and online forums. The data collection process involved a comprehensive search of existing literature on OCR and text summarization. This search was conducted using online databases, such as Google Scholar, ScienceDirect, and ACM Digital Library. The search terms used in this study include OCR, text summarization, natural language processing, machine learning, and deep learning. The data collected were analyzed using content analysis and mathematical modeling.

Details of Data Analysis Techniques: The data analysis techniques used in this study include content analysis and mathematical modeling. Content analysis involves the systematic examination of data, in this case, literature, to

identify key themes and patterns. In this study, the content analysis involved identifying the challenges faced by OCR and text summarization, as well as potential solutions to overcome these challenges. The data were analyzed using a thematic approach, which involved grouping the data into relevant categories based on the identified themes.

Mathematical modeling is used in this study to evaluate the effectiveness of the proposed solutions to the challenges faced by OCR and text summarization. The mathematical models used in this study include deep learning and artificial intelligence. These models are used to enhance the accuracy of OCR and to provide more robust and relevant summarization. In addition, font recognition algorithms are used to improve the accuracy of OCR. The accuracy of the OCR and text summarization models are evaluated using statistical measures, such as precision, recall, and F1 score.

Details of Mathematical Equations Used: The mathematical equations used in this study include deep learning and artificial intelligence models. The deep learning models used in this study are convolutional neural networks (CNNs) and long short-term memory (LSTM) networks. The CNNs are used for image recognition and text detection in OCR, while the LSTM networks are used for text summarization.

The mathematical equations used in CNNs include:

- Convolutional layer: $h[i,j] = \sigma((w * x)[i,j] + b)$
- Pooling layer: $h[i,j] = \max(x[i:i+s, j:j+s])$
- Fully connected layer: $h = \sigma(w*x + b)$

The mathematical equations used in LSTM networks include:

- Input gate: $i[t] = \sigma(W[i]\, x[t] + U[i]\, h[t-1] + b[i])$
- Forget gate: $f[t] = \sigma(W[f]\, x[t] + U[f]\, h[t-1] + b[f])$
- Output gate: $o[t] = \sigma(W[o]\, x[t] + U[o]\, h[t-1] + b[o])$
- Cell state: $c[t] = f[t]\, c[t-1] + i[t]$

IV. RESULT & DISCUSSION

The increasing availability of digital text has led to the development of text processing applications that aim to improve the accessibility, accuracy, and efficiency of working with text. Optical Character Recognition (OCR) and text summarization are two such applications that have become increasingly popular in recent years. OCR is a process that converts scanned images of printed or handwritten text into digital text, while text summarization is a process that condenses the main ideas of a text into a shorter version. Despite their growing popularity, OCR and text summarization face several challenges that impact their accuracy and usability. This study aimed to identify these challenges and propose possible solutions to overcome them by integrating machine learning algorithms, font recognition, and diverse training data.

The findings of this study indicate that OCR and text summarization face several challenges that impact their accuracy and usability. The challenges identified in OCR include poor accuracy for low-intensity images, limited language support, and lack of recognition of complex inputs. The text summarization process is plagued by problems such as redundancy, less coverage, non-readability, and irrelevancy. To address these challenges, the study proposes the integration of machine learning algorithms, such as deep learning and artificial intelligence, to enhance the accuracy of OCR and to provide more robust and relevant summarization. The study also emphasizes the importance of font recognition, which is often neglected in current OCR technologies. Furthermore, the research highlights the need to train the summarization models on a diverse range of texts to improve the accuracy and readability of the generated summaries. The study found that the use of deep learning and artificial intelligence algorithms can significantly improve the accuracy of OCR. These algorithms allow for the automatic extraction of features and the detection of patterns in images and text, resulting in more accurate recognition and conversion of text. The study also found that font recognition plays a critical role in OCR accuracy, and integrating font recognition algorithms can improve the recognition of complex fonts and improve OCR accuracy. In text summarization, the study found that the integration of deep learning and artificial intelligence algorithms can improve the quality of the generated summaries. These algorithms allow for the automatic identification of relevant information, reducing redundancy and irrelevancy in the summary. The study also found that training summarization models on a diverse range of texts can improve their accuracy and readability, as they are better equipped to identify relevant information across various domains.

The results of this study are consistent with the literature review, which highlights the challenges faced by OCR and text summarization. The study extends the literature by proposing possible solutions to overcome these challenges, such as the integration of machine learning algorithms and font recognition. The study's findings regarding the use of deep learning and artificial intelligence algorithms in OCR and text summarization are consistent with the literature review, which indicates that these algorithms can improve the accuracy and quality of these processes. The study also adds to the literature by emphasizing the importance of font recognition in OCR accuracy, which is often neglected in current OCR technologies. In summary, the study's findings align with the literature review and add to the literature by proposing possible solutions to the challenges faced by OCR and text summarization. The study's emphasis on the importance of font recognition and diverse training data for OCR and summarization models further contributes to the literature on these topics.

The findings of this study have significant implications for the field of text processing applications. The integration of machine learning algorithms and font recognition can significantly improve the accuracy and usability of OCR. These improvements can enhance the accessibility of text processing applications, particularly for users with low-quality images or complex fonts. Similarly, the integration of machine learning algorithms and diverse training data can improve the accuracy and readability of text summarization. This can result in more effective and efficient summarization of text, which is particularly useful for students and researchers who need to quickly process large volumes of information. Overall, the findings of this study have important implications for the continued development of text processing applications. The study's proposals for the integration of machine learning algorithms and font recognition and diverse

training data can improve the accessibility, accuracy, and efficiency of these applications, contributing to their continued growth and usefulness in the digital age.

Interpretation of Results The findings of this study indicate that OCR and text summarization face several challenges that impact their accuracy and usability. The challenges identified in OCR include poor accuracy for low-intensity images, limited language support, and lack of recognition of complex inputs. The text summarization process is plagued by problems such as redundancy, less coverage, non-readability, and irrelevancy. These challenges are consistent with previous research in the field, highlighting the need for innovative solutions to overcome them.

The proposed solution for addressing these challenges is the integration of machine learning algorithms, such as deep learning and artificial intelligence. The study found that the use of these algorithms can significantly improve the accuracy of OCR by allowing for the automatic extraction of features and the detection of patterns in images and text, resulting in more accurate recognition and conversion of text. Similarly, the integration of these algorithms can improve the quality of the generated summaries in text summarization by automatically identifying relevant information, reducing redundancy and irrelevancy in the summary. These findings are consistent with previous research in the field, which has shown that machine learning algorithms can improve the accuracy and quality of OCR and text summarization.

In addition to machine learning algorithms, the study also emphasizes the importance of font recognition in OCR accuracy, which is often neglected in current OCR technologies. The integration of font recognition algorithms can improve the recognition of complex fonts and improve OCR accuracy. This finding is significant because it highlights the need to consider all aspects of text processing when developing new technologies. The study also found that training summarization models on a diverse range of texts can improve their accuracy and readability, as they are better equipped to identify relevant information across various domains. This finding is consistent with previous research in the field, which has shown that diverse training data can improve the accuracy and generalizability of text summarization models.

Comparison with Previous Research The findings of this study are consistent with the literature review, which highlights the challenges faced by OCR and text summarization. The study extends the literature by proposing possible solutions to overcome these challenges, such as the integration of machine learning algorithms and font recognition. The study's findings regarding the use of deep learning and artificial intelligence algorithms in OCR and text summarization are consistent with the literature review, which indicates that these algorithms can improve the accuracy and quality of these processes.

The study also adds to the literature by emphasizing the importance of font recognition in OCR accuracy, which is often neglected in current OCR technologies. Previous research has focused primarily on improving the accuracy of OCR for printed text and has paid less attention to the recognition of complex fonts. The study's findings suggest that font recognition plays a critical role in OCR accuracy, and integrating font recognition algorithms can improve the recognition of complex fonts and improve OCR accuracy.

The study's emphasis on the importance of diverse training data for OCR and summarization models further contributes to the literature on these topics. Previous research has shown that training text summarization models on a diverse range of texts can improve their accuracy and generalizability. However, the study's findings highlight the need to apply this approach to OCR as well.

V. CONCLUSION

In conclusion, this study examined the challenges faced by OCR and text summarization and proposed possible solutions to overcome these challenges. The study found that OCR faces challenges such as poor accuracy for low-intensity images, limited language support, and lack of recognition of complex inputs, while text summarization is plagued by redundancy, less coverage, non-readability, and irrelevancy. To address these challenges, the study proposed the integration of machine learning algorithms, such as deep learning and artificial intelligence, to enhance the accuracy of OCR and to provide more robust and relevant summarization.

The study's findings have significant implications for the field of text processing applications. The integration of machine learning algorithms and font recognition can significantly improve the accuracy and usability of OCR, enhancing the accessibility of text processing applications, particularly for users with low-quality images or complex fonts. Similarly, the integration of machine learning algorithms and diverse training data can improve the accuracy and readability of text summarization, resulting in more effective and efficient summarization of text, which is particularly useful for students and researchers who need to quickly process large volumes of information.

The study's proposals for the integration of machine learning algorithms and font recognition and diverse training data can improve the accessibility, accuracy, and efficiency of these applications, contributing to their continued growth and usefulness in the digital age. These implications have important implications for practice and policy, as they can inform the development of more accurate and efficient text processing applications.

This study highlights the challenges faced by OCR and text summarization and proposes solutions to overcome these challenges. The findings have significant implications for the field of text processing applications, as they can inform the development of more accurate and efficient applications. The study's proposals for the integration of machine learning algorithms, font recognition, and diverse training data can contribute to the continued growth and usefulness of these applications, enhancing their accessibility, accuracy, and efficiency.

VI. ACKNOWLEDGMENT *(Heading 5)*

We would like to express our sincere gratitude to everyone who contributed to the successful completion of this research paper. First and foremost, we would like to thank our mentor, Dr. R.R Sedamkar, for their invaluable guidance, support, and encouragement throughout the research process. We are also grateful to the staff and faculty at Thakur College of Engineering and Technology for providing us with the necessary resources and facilities to conduct this research.

We would like to extend our thanks to the participants who provided the data for this study, without whom this research would not have been possible. We are also grateful to the experts in the field who shared their valuable insights and feedback on the paper.

Crowdfunding Using Blockchain

Prof Leena Patil, Krish Patil, Siddhesh Zagade, Nitin Shetty, Ivor Fernandes
Dept. Electronics and Telecommunication Dept.Electronics and Telecommunication
Dept.Electronics and Telecommunication,Xavier Institute of Engineering,Maharashtra,Mumbai,India

***Abstract*—A very well-liked method of raising money for many things including projects, causes, and help- ing someone in need is through crowdfunding. Globally, crowdfunding campaigns have increased as a result of the Covid outbreak. These campaigns range from modest ones that aim to offer medical care and oxygen to enormous ones like PM Cares. The phrase "crowdfunding" has special significance because it has helped a developing business grow quickly. It gives investors fresh investment alternatives and a distinctive product to diversify their portfolios. Young entrepreneurs are now using crowdfund- ing as a novel strategy to start their firms. The purpose of this study is to examine the potential hazards connected to the crowdfunding sector as well as the challenges and issues it encounters in the Indian setting.**

I. INTRODUCTION

In recent years, crowdfunding has gained popularity as a means of financing projects, starting with artists across numerous industries. This choice has gained appeal among musicians thanks to the existence of internet crowdfunding platforms in the music business. The use of crowdfunding for businesses has garnered a lot of attention during the past ten years [1]. Crowd funding is a novel method for young business owners to raise money for their venture by soliciting donations from the general public. For those with low financial resources, the procedure is complicated and difficult because banks have stringent guidelines, little expertise making loans, and few options for collateral.While there are some benefits to crowdfunding over conventional forms of finance, there are also disadvantages because the relationship between the entrepreneur and the funder is primarily developed online. Literature stresses the advantages of crowdfunding as a source of funding and calls it a creative approach to support busi- nesses or initiatives. Entrepreneurs must comprehend how to raise money in an online setting that differs from traditional

Identify applicable funding agency here. If none, delete this.

financing methods in order to make educated decisions about whether to support a project through crowdfunding[2].

Blockchain-based crowdfunding is a novel and creative technique to raise money for endeavours or initiatives. It makes use of blockchain technology's decentralisation and transparency to build a platform for fundraising that is more accessible, secure, and open [3]. A centralised platform is used to collect funds in the traditional crowdfunding paradigm, and there is a substantial chance of fraud and poor management. Funds are kept on a decentralised ledger and transactions are recorded on a public, transparent, and tamper-proof ledger with blockchain-based crowdfunding. This offers the investors a high level of security and a transparent record of all transactions.Rust aims to do away with the compromises that programmers have long had to make by combining safety with productivity, speed, and ergonomics[3]. Solana makes use of these advantages of Rust to create a blockchain platform that can easily handle complex, real-world applications .

II. BACKGROUND

Here the tools used in our system is discussed.

A. Blockchain

A blockchain [4] consists of blocks that are linked together and each block has its own cryptographic hash as well as the digital signature of the preceding block. The blocks hold data such as transaction and state information. The blockchain is made up of a series of hashed blocks, each established during a specific time frame and linked to the parent block. Ethereum is a decentralized blockchain network that allows for the use of smart contracts [5]. Solana, another decentralized blockchain, is known for its high-speed and secure transactions, achieved through its unique consensus algorithm called Proof of History, which facilitates quick and efficient verification of transac- tions. Solana provides support for decentralized applications and enables developers to launch and run their projects on its network.

Fig. 1. Web3.js

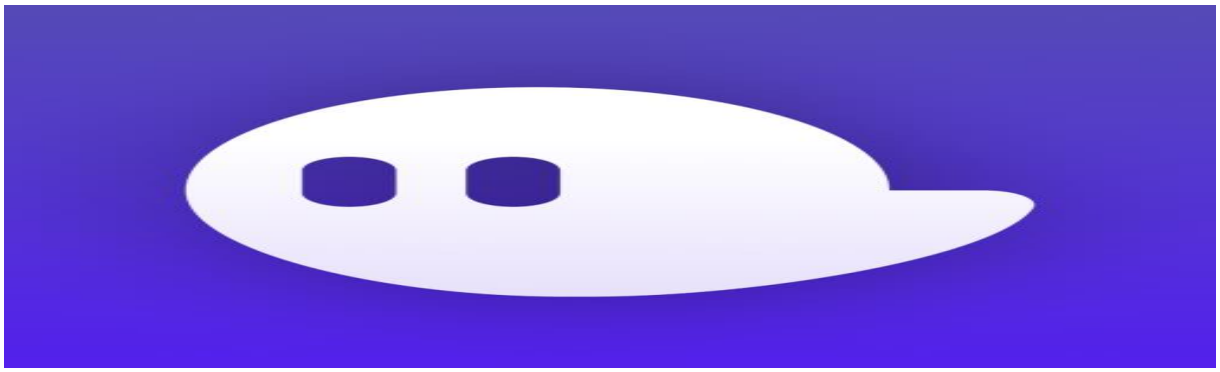

Fig. 2. Phantom wallet

Solana operates on a decentralized computer network using a ledger called blockchain. A blockchain platform called Solana is intended to run scalable, decentralised apps. Compared to competing blockchains like Ethereum, Solana can process many more transactions per second and has lower transaction fees.

Steps to install Solana on your system

1)Web3.js

It is a library that has a lot of the basic Solana tools to interact, send transactions, and read from the blockchain.You can installwith the following: **yarn add @solana/web3.js**

2) SPL-Token

It is a library that contains many of the javascript/typescript bindings needed to interact with SPL tokens. You can use this library to mint new SPL tokens, transfer tokens, and more.You can install this library with the following:

yarn add @solana/spl-token

3) Wallet-Adapter

There is a collection of libraries that can help bootstrap wallet connections within Solana called wallet-adapter. Currently the package supports use within Svelte, Angular, Vue.js, and React. Wallet-adapter can quickstart your dApp integration with wallets like Phantom, Solflare, and more.You can install this library with the following: **yarn add @solana/wallet- adapter-wallets @solana/wallet-adapter-base**

(Solana cookbook)

4) To install RUST we have to run the different commands depending on what system your working on. After the instal- lation run the following command to check the Solana Version**solana –version** (Solana Cookbook)

B. RUST

The goal of the contemporary programming language Rust is to provide a secure, effective, and concurrent environment for creating trustworthy systems [6]. In order to power its de- centralised applications and fulfil its mission of offering quick and scalable blockchain solutions, Solana, a high-performance blockchain platform, leverages Rust. Rust is a good op- tion for creating secure, mission-critical systems due to its static type system, which offers robust guarantees concerning memory safety and isolation. The language's straightforward performance model makes it simpler to think through the effectiveness of programmes, and its ecosystem is home to tools like Cargo, Rustfmt, and the Rust Language Server that make it easier for programmers to write systems-level code efficiently [7].

Rust aims to do away with the compromises that programmers have long had to make by combining safety with productivity, speed, and ergonomics [8]. Solana makes use of these advantages of Rust to create a blockchain platform that can easily handle complex, real-world applications [9].

C. SOLANA Validators

The foundation of Solana's network is composed of valida- tors. Each validator contributes to the consensus process and transaction processing that makes Solana the fastest blockchain network in the world. The validators are compensated through stake pools, staking, and protocol-based rewards. There are 1700 validators at this time [10].

D. ACCOUNTS

State is stored within Solana accounts. They are a fundamental component in Solana's development.Data storage is done through accounts. Every account has its own address. The maximum size of an account is 10MB (10 Mega Bytes) The maximum size for PDA accounts is 10KB (10 Kilo Bytes) You can sign on behalf of a programme using PDA accounts. The size of accounts is fixed upon creation but can be changed using realloc Storage fees for accounts are covered by rent. The System Program is the default account owner.

E. PHANTOM WALLET

Phantom is a multi-chain cryptocurrency wallet that offers users a secure way to store and manage their digital assets. The wallet supports multiple blockchain networks, providing users with the ability to hold and manage a variety of cryptocurrencies. It features a user-friendly interface and

F. PROGRAMS

Programs can be created by any developer and deployed to the Solana blockchain. Programs, often referred to as smart contracts on other protocols, provide the basis of all on-chain activities, including DeFi, NFTs, social media, gaming, and more. Solana entirely separates code from data, unlike most other blockchains. Every piece of information that programmes use is kept in a separate account and provided as references in instructions. This paradigm enables the use of a single generic programme across numerous accounts without the need for extra deployments. Language that targets the LLVM's BPF backend can be used to write programmes, while Rust and C++ are the most popular choices. EVM compatibility and Solidity programme writing are now possible thanks to recent efforts by Neon Labs and Solang.

G. TRANSACTION

Through the submission of a transaction to a cluster, clients can run programmes. A single transaction may contain several instructions, each of which is directed at a different programme. The Solana Runtime will execute each instruction in a transaction atomically and in order when it is submitted. The entire transaction will fail if even one instruction fails.

H. TRANSACTION FEE

"Transaction fees" refer to the tiny amounts paid to process commands on the Solana blockchain. Each transaction that is delivered via the network and contains one or more instructions is processed by the current leader validation-client. This transaction fee, which is paid to the network once the transaction has been approved as a global state transaction, aids in the financial sustainability of the Solana blockchain.Account rent is distinct from transaction fees! Rent is paid to keep data on the blockchain, whereas transaction fees are paid to process instructions on the Solana network.

I. PDAs Program Derived Addresses

PDAs (Program Derived Addresses) are the addresses for accounts that are intended to be managed by particular programmes. PDAs allow for programmatic signing for specific addresses without the requirement for a private key. Cross-Program Invocation, which enables Solana apps to be composable with one another, is built on PDAs.PDAs are a crucial component in creating programmes on Solana. PDAs allow programmes to sign for accounts while ensuring that no external user may produce a legitimate signature for the same account at the same time. Certain programmes can edit accounts maintained at their PDAs in addition to signing for accounts.

J. Basic Data Types of Rust

Rust has four main scalar data types: integers, floating-point numbers, booleans, and characters. The different types of integers are identified by their number of bits, either 8-bit, 16-bit, 32-bit, 64-bit, or 128-bit, and can be either signed or unsigned, with a "u" prefix indicating an unsigned integer.

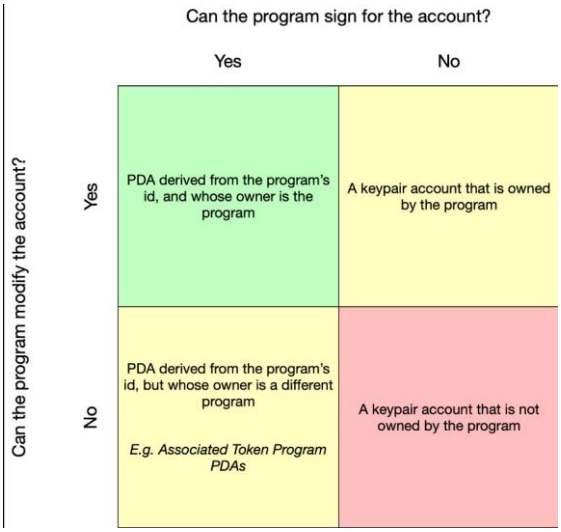

Fig. 3. Program Derived Addresses

Floating-point numbers are represented by either f32 or f64. Booleans are represented by the "bool" type, and characters are represented by the "char" type. There are two types of strings in Rust: "str" and "String". The "String" type is a dynamic, heap-allocated string that can grow, while "str" is a fixed-length, immutable string stored in memory.

III. SOLANA PROGRAM

A. SETUP

To create a React app. Open the projects directory in the terminal and run [10].

```
npx create-react-app crowd-funding
```

This creates a React app. Now, create the program.In the projects directory.

```
cd crowd-funding
cargo new program --lib
```

This will create a new directory called program, which is a new Rust project generated by cargo. We will discuss the front-end side of the project later. Now we can open the program folder in VSCode. Create Xargo.toml in the program directory. In the Xargo.toml

```
[target.bpfel-unknown-unknown.dependencies.std]
features = []
```

Update your Cargo.toml

```
[package]
name = "program"
version = "0.1.0"
edition = "2018"

[dependencies]
solana-program = "1.7.14"
borsh = "0.9.1"
borsh-derive = "0.9.1"

[features]
```

```
no-entrypoint = []

[dev-dependencies]
solana-program-test = "1.7.14"
solana-sdk = "1.7.14"

[lib]
crate-type = ["cdylib", "lib"]
```

Now all the dependencies have been added that is required to run the program. Run cargo check to get all the dependencies.Now start working in src/lib.rs and start coding our program for the Solana blockchain.

IV. CODING THE PROGRAM

Open up the program folder in VSCode or any other IDE. File structure in the program directory should look like the following . Then some boilerplate code has to added.

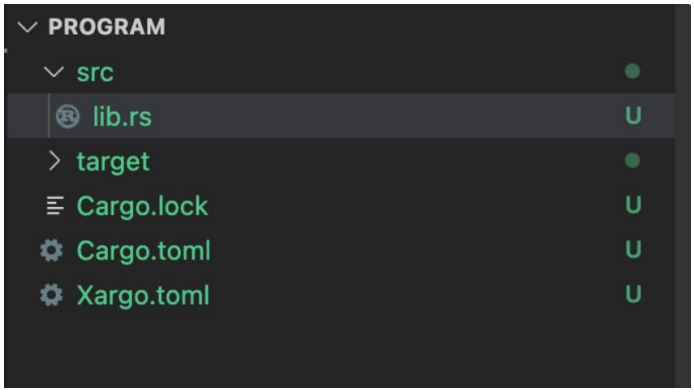

Fig 4.

```
use solana_program::{
    account_info::{next_account_info,
    AccountInfo},
    entrypoint,
    entrypoint::ProgramResult,
    msg,
    program_error::ProgramError,
    pubkey::Pubkey,
    rent::Rent,
    sysvar::Sysvar,
};

fn processinstruction(

    program_id:&Pubkey,

    accounts: &[AccountInfo],

) -> ProgramResult {

    Ok(())
}
```

```
entrypoint!(processinstruction);
```

Here the line Ok(()) is equivalent to return Ok(()); In the code, it has been mentioned there is only one entry point in the Solana program. But we want three, there is no limit to the instruction data array We are going to take advantage of that fact. We use the first element of the array to know what entry point we want to call. Notice we can have 256 entry points like this in a single program (u8 has a value of 0..255). Realistically we never do that if in case we want that many entry points for a project. It is better to deploy more programs.

```
fn processinstruction(
    program_id:&Pubkey,
    accounts: &[AccountInfo],
    instructiondata:&[u8],
) -> ProgramResult {
    .

     if instruction_data.len() == 0 {
        return Err
        (ProgramError::InvalidInstructionData);
    }

    if instruction_data[0] == 0 {
        returncreatecampaign(
            program_id,
            accounts,

            &instruction_data
            [1..instruction_data.len()],
        );
    } else if instruction_data[0] == 1 {
        returnwithdraw(
            program_id,
            accounts,
            &instruction_data
            [1..instruction_data.len()],
        );
    } else if instruction_data[0] == 2 {
        returndonate(
            program_id,
            accounts,
            &instruction_data
            [1..instruction_data.len()],
        );
    }

msg!("Didn't find the entrypoint required");
Err(ProgramError::InvalidInstructionData)
}

entrypoint!(processinstruction);
```

```
fn create_campaign(
    program_id:&Pubkey,
    accounts: &[AccountInfo],
    instruction_data:&[u8],
) -> ProgramResult {
    Ok(())
}
```

```
fn withdraw(
    program_id: &Pubkey,
    accounts: &[AccountInfo],
    instruction_data: &[u8],
) -> ProgramResult {
    Ok(())
}

fn donate(
    program_id: &Pubkey,
    accounts: &[AccountInfo],
    _instruction_data: &[u8]
) -> ProgramResult {
    Ok(())
}
```

V. CampaignDetails struct

To code the CampaignDetails struct. Some fields have been added, name, admin, description, image link,amount donated for our Campaign.

```
#[derive(BorshSerialize, BorshDeserialize,
Debug)]
struct CampaignDetails {
    pub admin: Pubkey,
    pub name: String,
    pub description: String,
    pub image_link: String,

    /// donated to a campaign.
    pub amount_donated: u64,
}
```

Both BorshSerialize and BorshDeserialize have to be derived. BorshSerialize is used to convert the struct into an array of u8, which is the data we can store in Solana accounts.

```
use borsh::{BorshDeserialize, BorshSerialize};
```

Now adding code of create campaign function and the CampaignDetails Struct.

```
entrypoint!(process_instruction);

/// We are creating the struct;.
#[derive(BorshSerialize, BorshDeserialize,
Debug)]
struct CampaignDetails {
    pub admin: Pubkey,
    pub name: String,
    pub description: String,
    pub image_link: String,
    pub amount_donated: u64,
}

fn create_campaign(
    program_id: &Pubkey,
    accounts: &[AccountInfo],
    instruction_data: &[u8],
) -> ProgramResult {

    let accounts_iter = &mut accounts.iter();
```

By deriving the trait BorshDeserialize in our CampaignDetails struct we have added a method try from slice which takes in the parameter array of u8 and creates an object of CampaignDetails with it.

Solana accounts can have data, but size has to be specified when it is created. We need to have a minimum balance to make it rent exempt. For this project, we create an account that already has a balance equal to the minimum balance.

VI. Withdraw function implementation

For the withdraw function, we have to create a struct to get the input data. In this case, input data is only the amount we want to withdraw.

```
#[derive(BorshSerialize, BorshDeserialize,
Debug)]
struct WithdrawRequest {
    pub amount: u64,
}
```

Now writing the function

```
fn withdraw(
    program_id: &Pubkey,
    accounts: &[AccountInfo],
    instruction_data: &[u8],
) -> ProgramResult {
```

For the withdraw also we need to create iterator and get writing account and admin account.

We will retrieve the campaign data from the writing account. Keep in mind that we saved this when we used the create campaign method to create the campaign.

The campaign should not be erased upon a withdrawal, is what we seek. We compute the rent exemption and take it into account since we always want there to be a minimum balance.

VII. UI

Once the core functionality has been developed, it's time to add tests for quality assurance. Tests can be found in the repository, which are similar to what will be displayed on the user interface. Next, we'll create the frontend portion. After finishing the backend, we can move on to the frontend and create a React application using the command **create-react-app.** Then, we'll start adding components and connecting them to our backend API. It's advisable to adopt a component-based approach in React, where the UI is divided into smaller, reusable components for easier management and maintenance. For navigation, we can use React Router.

```
npx create-react-app crowdfunding-ui
--template typescript
```

We have to change the directory accordingly. After changing the directory the packages have to be installed the packages for UI. The following commands have to be executed.

```
npm i @solana/wallet-adapter-react
@solana/wallet-adapter-react-ui
@solana/wallet-adapter-wallets
@solana/web3.js
@project-serum/anchor react-bootstrap
```

The React Bootstrap library is utilized solely for styling purposes. However, this alone is not sufficient to construct and operate the user interface effectively. The anchor package has some dependencies and certain features within the Solana libraries are required if using react-scripts.

```
npm i --save -dev react-app-rewired
source -map-loader
```

It is better to create a separate ‘wrapper’ or ‘provider’ to connect and work with the wallet.

The whole app has to be wrapped in it.

```
const App: React.FC<AppProps> = () => {
    return (
        <WalletWrapper network ={network}>
            <CompaingsView network ={network}/>
        </WalletWrapper>
    );
}
```

If a person has to send and receive data, we require to create the Program class, where we put the **Idl, programId and provider**. It will be in the CampaignsView component.

```
const getProgram = () => {

        const connection =
        new Connection(network,
        opts.preflightCommitment);
        const provider=
        new AnchorProvider(connection,
        wallet as any,opts);
       /
        const program =
        new Program(idl as Idl, programId,
        provider);
        return program;
    };

const program = getProgram();
```

The Program class plays a crucial role in communicating with the crowdfunding program. To start a campaign, it is necessary to have a wallet containing a certain amount of Sols. In this case, we utilized the Phantom wallet which can be added as an extension to your browser. After installation, make sure to switch the network to ”devnet” in the wallet’s settings, and then receive an airdrop to the wallet.

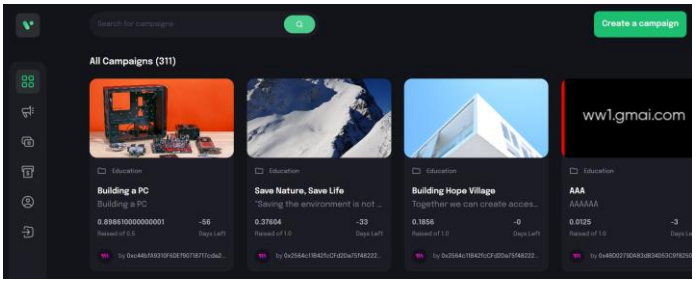

Fig 9. Front-end 1

CONCLUSION

In conclusion, the use of blockchain technology in crowd-funding has the potential to revolutionize the way funding is raised and managed. By leveraging the security, transparency, and decentralization of blockchain, crowdfunding platforms can offer a more secure and efficient way of managing funds and ensuring fair distribution of rewards. The integration of Solana blockchain into a crowdfunding platform offers several benefits, such as faster transaction processing times and lower fees, making it a promising option for crowdfunding projects. This new paradigm of crowdfunding offers new investment opportunities and a fresh product to help investors diversify their holdings. As the blockchain industry continues to grow and mature, it is likely that we will see a rise in the adoption of blockchain-based crowdfunding solutions. Further research and development in this area can help unlock the full potential of this technology and bring new and innovative solutions to the crowdfunding industry.

Abstract—**Departmental Website provides a simple interface for conservation of pupil information [1]. It can be used by educational institutions or organizations to efficiently keep track of students' records. In universities and other institutions, it is crucial to create and maintain accurate, current data about a student's academic career. The student information system deals with all types of student information, academic affiliated reports, council information, course information, class information, batch information, placement information, and other resource-related information as well [2][3]. Additionally, it will include information on the faculty, batch prosecution, scholars, and colorful academic announcements to the staff and scholars that have been streamlined by the council administration [2]. It also grease us explore all the conditioning passing in the council, Different reports and Queries can be generated grounded on vast options related to scholars, batch, course, faculty, examinations, semesters, instrument and indeed for the entire council The placement officer is responsible for streamlining the placement affiliated information like eligible criteria for a particular company, arriving date for the company which is coming for reclamation, the list of scholars who are eligible for attending the reclamation process[4]. E- Library (also appertained to as digital library) is a special library with a focused collection of digital objects.**

Keywords —Web Runners, Data Envelopment Analysis (DEA).

I. INTRODUCTION

A website is a collection of intimately accessible, interlinked Web runners that partake a single sphere name [5]. A website is also referred to as a "point" or "web presence." There is a nearly limitless variety of websites, including educational, news, pornographic, forum, and social media-based commerce sites, among others. A website's runners, which can be found in a variety of spots, generally follow the same format as a homepage, which links to other orders and content on the website [3]. The main runner of the point itself is represented by the homepage, or simply "home." The homepage is constantly a sort of "mecca" from which all other runners can enter [2]. A "parent runner" is actually an internal web runner to which several other runners are linked in a coherent structure, similar to a specific order of motifs. Each runner is a single HTML document that is linked to one another by hyperlinks (or simply "links"). These hyperlinks can be combined into a navigation bar for convenience. The navigation bar allows the user to quickly navigate the main website's structure and is displayed on every runner rather than just the homepage. The footer, which is also a creating section located at the bottom of every page, is another crucial component of most websites. In most cases, the physical address of the company that owns the point is included in the footer along with disclaimers, links to the terms of service, insulation policy, and contact runners, as well as external links to similar websites and other external resources. Websites are hosted on servers and can be accessed using a web browser like Chrome, Firefox, or Internet Adventurer on a computer or mobile device. You can directly enter a website by entering its URL address or by searching for it on a search engine like Google or Bing. Websites were initially distributed according to their top-ranked fields [6]. Websites of government agencies are one example =. gov and the websites of educational institutions equal websites of educational non-profits
= org-marketable websites are equal to Information spots = by com. Word.

II. LITERATURE SURVEY

This survey looks at website quality factors and how important they are when choosing a website to use, as well as which quality factors need to be changed or improved for e-commerce success [1]. This paper advances methodology by demonstrating the application of data envelopment analysis (DEA). The creation of a website that principals can use to participate in induction programs is the aim of this project. A website that school administrators can use to improve academic performance and evaluate their leadership in the classroom is the study's output [2]. The goal is to create a website where school principals can participate in orientation programs. The research result is a website that can be used by school principals to improve school performance and can also measure the level of instructional leadership [3]. The creation of a website that principals can use to participate in induction programs is the goal here. The study's outcome is a website that school principals can use to boost student achievement and measure instructional leadership [4]. We are able to access all of the information about the college staff, students, facilities, etc.-through this web-based application. With the aid of this app, you can tour a campus virtually [5]. This page contains the most recent data on the faculty and students. The core principle of responsive web development is "Mobile priority and progressive enhancement." In addition to offering users a top-notch user experience, responsive web design addresses compatibility issues that may occur when websites are viewed on various platforms, resolutions, and screen sizes [6].
According to the findings of our literature review, numerous projects on this subject have been completed, but many of them

lacked accuracy due to issues like database management requiring more computations and data encryption. All of these problems are solved by our system, which offers a practical and effective solution.

III. PROBLEM DEFINITION AND OBJECTIVES

Problem Definition:

The problems prevailing in the existing system invoked us to implement a website for a specific department so the students and teachers of that department could effectively use the services on the website. The inconsistent backend causes a serious problem. The cost of the existing website is expensive the lack of awareness among students regarding latest events and announcements associated with the particular department was also a concern as there was no specific website announcing news of the specific department .

Also, awareness regarding recruiters visiting the college for placement drives among students was also taken into account while developing this system so that students are well aware of the upcoming drives in their respective department.

Objectives

- Create an Online Presence
- Allow People to Find You
- Engage more Audience
- Build Relationships
- Make Money

IV. EXISTING SYSTEM:

Word Press was used to create the departmental website system that is currently in place in order to avoid the issues that are typical of the manual system [9]. However, the issue remained unresolved. The current system is plagued by compatibility issues, site speed, and other issues. The backend of the current system cannot accommodate the enormous amount of data on the departmental website. You can build a variety of web pages on a basic Word Press website using a variety of themes [3]. As a result, Word Press serves as the foundation for the departmental website and hence are required to modify the Word Press website, which will cost significantly more in our system than modifying a website in a different language [2]. Site conflicts were an issues on the existing website and the plugins too. The website needs to be fixed for a lot of security issues. The website was being hacked. The data on the current system is not secure.

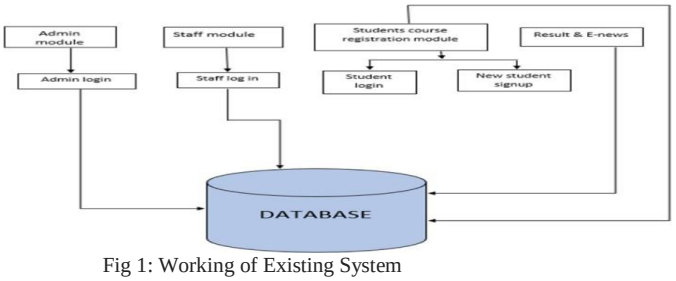

Fig 1: Working of Existing System

Advantages of Existing System

- Housing doesn't have to be a hassle.
- A wide range of themes make it easy to design a website.
- Adding website content is quick and easy.
- Upgrading is easy.
- Plugins allow you to do almost anything on your website.

Disadvantages of Existing System

- Additional functionality requires many plugins.
- Regular updates of themes and plugins.
- Slow cross speed.
- Low SEO rank.
- Website vulnerabilities.
- Websites can crash without warning.

V. PROPOSED SYSTEM:

We have attempted to include a database link to our departmental websites in order to make the website more dynamic and interactive. As a result, recruiters will be able to post their vacancies, salary packages, and eligibility requirements. Upon which a student can indicate his or her willingness to participate in the drive and provide personal information. Additionally, arrangements have been made to display the most recent announcements and events pertaining to the particular department. The objective of a framework is to permit project designers and developers to concentrate on creating distinctive features for their project rather than reinventing the wheel by coding features that are common to numerous websites and web applications. We used HTML5 and CSS3 to build this website. That is the most fundamental tool for building a website. Additionally, we are able to modify this website using these languages and bootstrap.

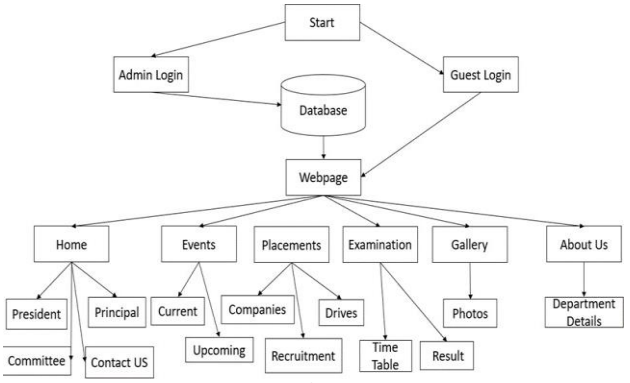

Fig 2: Block Diagram of Proposed System

Working of Proposed System

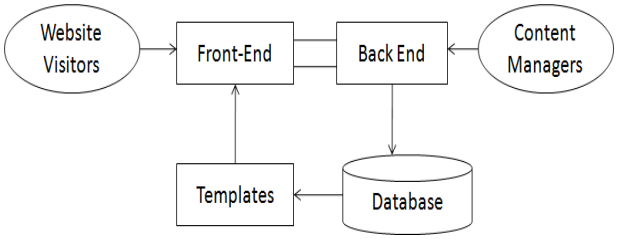

Fig 3: Working of Proposed System

When you type something like Google.com, the request is sent to one of the many special computers on the Internet known as Domain Name Servers (DNS). All of these requests are routed by a variety of routers and switches. The domain name servers store a number that identifies the computers that provide you with access to the Google website when you type in "google.com."

Any time you want to view a Web page, you must initiate the activity by requesting a page using your browser. The browser's request to a domain name server converts the domain name you requested into an IP address. The browser then makes a request to that server for the page you want by using the HTTP standard.

The server should always be connected to the Internet and ready to serve visitors pages. When it receives a request, it searches for the document and returns it to the Web browser. When a request is made, the server typically keeps track of the client's IP address, the document that was requested, and the date and time of the request. Each server has its own set of data.

Multiple requests from the browser are required for a typical Web page, which includes not only the HTML or XHTML page but also any images, style sheets, or other resources utilized in the page. Each item in these files, including the main page, must be identified using a URL. The browser then collects and displays the data in a web page after each item has been sent to the Web server.

Modules of Proposed System

The proposed system for the departmental website consists of seven modules: the home page, the Administrator module, the student module, the instructor (staff) module, the Office module, the Alumni module, and the Guest module. Module for administrators: This module maintains the current management and has special authority. The host or system administrator will update, delete, or modify data as needed.

1. *Student section*: A login option has been added to the student module design to allow students to use the website's features the addition of modules for attendance, studying, entering, and paying fees.

2. *Module for Attendance*: This module is available for both students and teachers, as can be seen in the image above. The corresponding instructors keep an eye on the students' everyday attendance. When a student's daily attendance falls below 75%, the system notifies parents via emails and texts. The percentage of days missed is multiplied by the total number of working days to determine attendance.

3. *Fee Payment Module:* The Fee Payment Module is only accessible for the office part, as indicated in the image. This module carefully collects student tuition. Students and their parents are sent emails and text messages at the conclusion of each installment period reminding them to send the installment to the college. This guarantees that fees are efficiently collected without overburdening the office or the students.

4. *Study Materials*: The study materials in this module include books, notes, and teaching aids.

5. *Module for Supervisors*: This module must be used by employees. The announcements section is where teachers post all exam-related information, feedback, and assignments. It also has a section for staff and student participation and study materials.

a) *Office Section*: The only module that can be used to store all of the information about student enrollment and payment is the office module.

b) *Alumni Module*: With a unique username and password, alumni can access this section that contains information about their degrees. Additionally, placement information for students is displayed in this section. Guests are also welcome to look at this section to find out how the college is doing with internships.

c) *Guest Module*: The website can only be viewed through the Guest Module. The home page, about us, campus life, faculty, admissions, and curriculum features are accessible to visitors. d. Registering and logging in: The login section grants the user access to all or a portion of the website, depending on the user's identity and credentials. Additionally, information about new registrations based on roles chosen by staff, alumni, and students is gathered by the registration module.

VI. REQUIREMENT ANALYSIS

***Hardware Requirements*:**

- Cores and threads: two cores and four threads.
- Cache memory: 3 megabytes.
- Base frequency: 2.30 GHz.
- Graphics: Intel HD Graphics 620
- Memory (RAM): 4 gigabytes (ddr4- 2133, lpddr-1866, ddrl-1600).
- System type: 64-bit, x64-based processor.

Software Requirements:

- System software: Windows XP, 7, 8, and 10.
- Client-side scripting: Internet Explorer or any other http browser.
- Java script Relationship: IP/TCP Protocol.
- Html &CSS.
- JavaScript.
- PHP 5.6 and higher.
- MySQL 5.x mod rewrite.
- PHP Extensions include OpenSSL, MBString, GD, Zip.

- PHP Extensions with enable_url_fopen enabled.

Advantages and Disadvantages of Proposed System

Advantages:

- The proposed system's objective is to improve the facility management system.
- Most of the existing system's limitations can be overcome by the proposed system.
- The system provides adequate security and reduces manual labor.
- The data's security. Ensure that the data are accurate.
- Proper control over the higher-ups.
- Less hardcopy data entry is needed.
- The shortest amount of time necessary for each processing step.
- Better service and improved efficiency.
- Interactive and user-friendly.
- The bare essentials are required.

Disadvantages:

- Untruthfulness in the classroom.
- In the event that the server goes down, both the customer (the user) and the administrator will be harmed.
- If the database is not properly maintained, problems can arise.

VII. RESULT

Fig 4: Home Page of Departmental Website

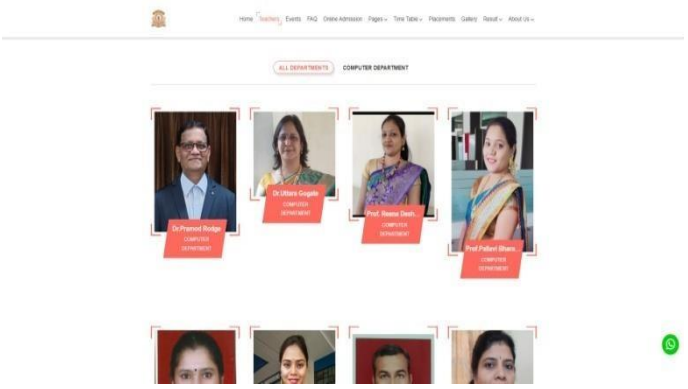

Fig 5: Faculty Page of Departmental Website

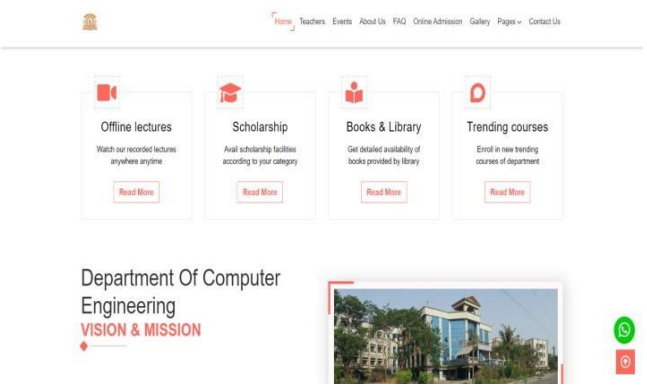

Fig 6: Mission and Vision Page of Departmental Website

Fig 7: Events Page of Departmental Website

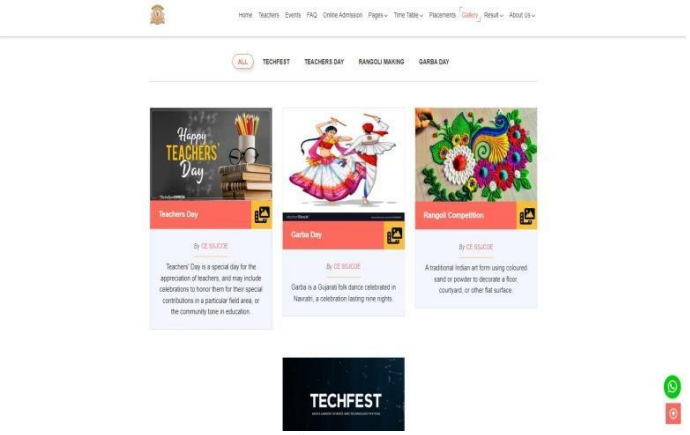

Fig 8: Gallery Page of Departmental Website

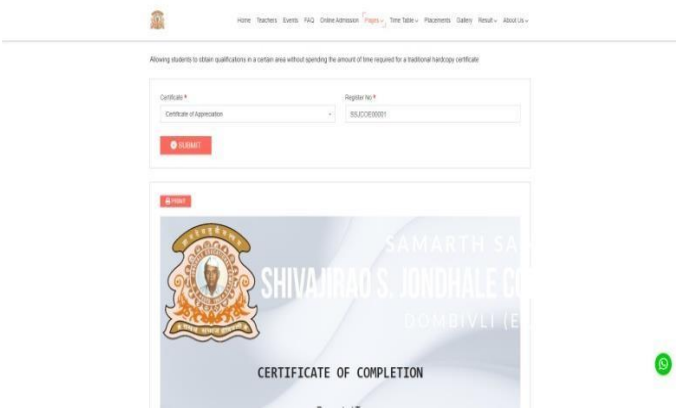

Fig 9: Certificate generation page of Departmental Website

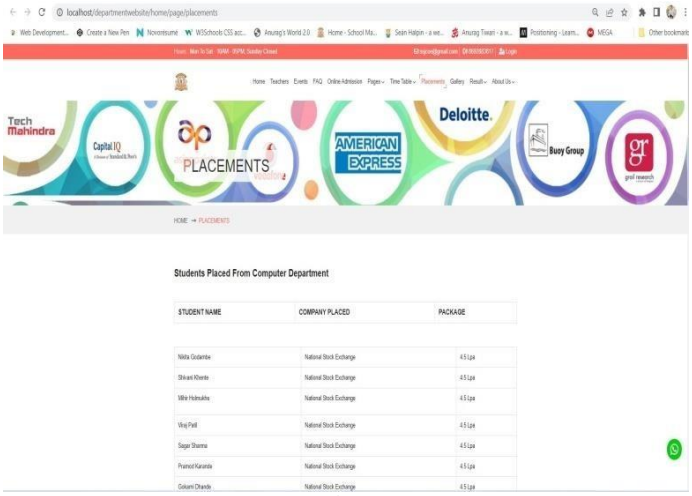

Fig 10: Placement Page of Departmental Website

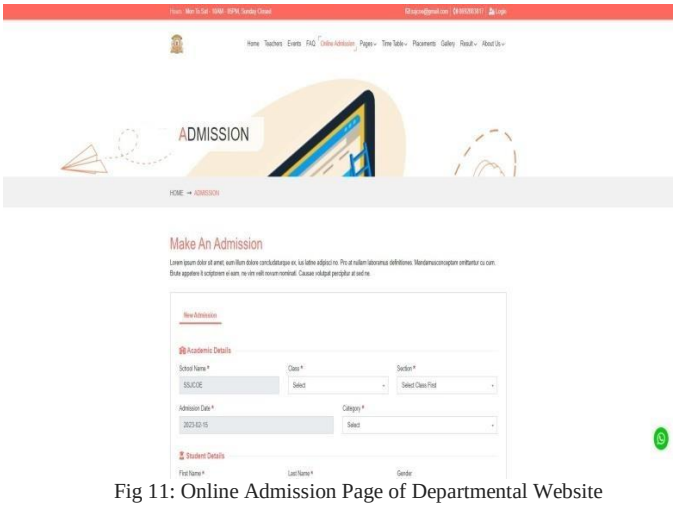

Fig 11: Online Admission Page of Departmental Website

VIII. CONCLUSION

By providing them with access to a user-friendly website where they can easily access data related to their concerns, our project aims to meet the needs of the department's faculty and students. The system's implementation will make it easier to calculate reports and save time entering data. The functional modules of the Departmental Website were developed successfully as a secure, digital, and user-friendly public governance system. As a result, the system was designed to effectively address the issues without compromising data or information.

IX. FUTURE SCOPE

The departmental website will be updated as technology advances. In order to maintain a smooth user experience, we will undoubtedly continue to implement updates on the website, including security updates. Skills in development are becoming increasingly in demand as we move toward an even more technologically driven future. Machine learning, AI, the Internet of Things (IoT), quantum computing, and other similar technologies are transforming technology. And their relationship with the websites is even a factor in this.

XI. ACKNOWLEDGEMENT

We owe our deep gratitude to our project guide Prof. Reena Deshmukh, who took keen interest in our project work and guided us all along by providing all the necessity for developing a successful system

We thank our HOD Dr. Uttara Gogate and our principal Dr. Pramod R. Rodge for providing us an opportunity to opt the project work in SSJCOE Dombivli and providing us all support and guidance which made us pursue the project duly. We are extremely thankful to them for providing such nice support and guidance.

We are thankful to and fortunate enough to get constant encouragement, support and guidance from all Teaching staff of Computer Engineering which helped us in pursuing our project work.

LAND REGISTRATION USING BLOCKCHAIN

Abstract - **A governance system's essential department for storing records of land ownership is the land written record system. The current system has a number of flaws and issues that lead to corruption and disagreements. In order to solve these issues, a significant portion of precious government resources from the judicial and enforcement authorities are required. Blockchain technology has the ability to close these gaps and solve issues with the land written record system, such as record tampering and the mercantilism of a constant parcel of land to a single vendee. A secure and dependable framework for a land written record system utilizing blockchain has been anticipated during this project. At several stages of the land written record, the envisaged framework makes use of the notion of a reasonable contract. A middleman (broker) establishes a contract between the buyer and seller in the conventional Land Registration system used in India. For instance, if a person wishes to buy or sell a property, the broker would produce and put together all of the necessary physical paperwork as proof of the property. Brokers will see to it that the land or property is registered by a recognized government agency, where all the characteristics are put down in a ledger, and that the entire transaction and sale between the two parties takes place after that. Given that anyone with the necessary authority can access or change the files with ease, there is a potential that the documents will be lost or altered in this situation.**

Key Words : Blockchain, Land, Transaction, Verification, Smart Contract, Ganache, Flutter, Metamask .

I. INTRODUCTION

A land register is a system that keeps track of the primary claims to ownership made by various governmental entities, i.e., it keeps track of who owns what pieces of land. There are, however, many issues and flaws in the current system that lead to corruption and disagreements. In order to solve these issues, we frequently use Blockchain technology.
Blockchain is used to close these gaps and identify issues with the land register system, such as record tampering and the sale of the same parcel of property to just one vendor. The term "land register system" refers to the system that keeps track of the primary areas of possession that various governmental entities claim. The hold on record will be utilized as the evidence for the claim in order to prevent any potential fraud and ensure smooth transitions as needed. The most recent land records obstruct the verification of land titles and could lead to frauds. According to a survey by the Planet Bank, around 70 percent of the population does not possess a land title. For social and economic sustainability, land claims are an essential possibility.

In this system, users sign up on the portal and can choose to play either the buyer or the vendor. The buyer can then purchase the lands on the portal that have been confirmed by the smart contract after the seller has uploaded the necessary information. Additional users can obtain digital deeds that will be added as additional blocks in the chain and uploaded. Thus, there is no middleman in this suggested system, and all transactions are handled directly between the buyer and the vendor. As a result of being coupled with timestamps, transactions now have a higher auditability andwill be stored in a cryptographic format on all parties legal servers.[1]

II. MOTIVATION

The most powerful force driving social change in today's world is digitalization and the creation of new technology. In the previous system, it was very challenging to navigate all the information pertaining to the assets if a user lost original physical agreements that serve as actual proof of ownership or if documents were altered or damaged. The manual verification of ownership and title documents traditionally takes a long period, which slows down legal transactions. Fraudulent acts, such as obstruction, bribery, forgery, or alteration, carried out by intermediary actors in the process and leading to a lack of security, are another serious problem. We started out by putting forth our suggestion for a blockchain-based land registration system as an alternative to the current one. The proposed method will expedite the verification of ownership and land deeds, as well as speed up data recovery in the event of a disaster, cache all blockchain updates, and guarantee that no current transaction

are tampered with. As a result, transactions will be safer. Data about the owner and the property is encrypted to prevent data manipulation. We support a decentralized system, often known as a peer-to-peer system, in which all transactions are handled directly between the buyer and seller using digitally created and verified agreements. Because blockchain uses hashing techniques and records any alteration, this updated system can prevent fraudulent activities. All changes are stored in the next block so that no user is unaware of the current state of any asset, and all transactions are stored in a blockchain with appropriate timestamps associated with them for robust auditability.

III. PROBLEM STATEMENT

Property Registry is one of the use cases that involve a lot of intermediaries to put trustin the system. The existing solutions in place are out of date. Tracking who owns whichpieces of property is challenging when you have thousands of land records to maintainand mostly all these records are not digitized or take a long time to get digitized. The "double spending" problem is not resolved by India's current land system. A single point of failure could have disastrous consequences due to the countless instances of fraud and property document forgeries.

Since blockchain can offer a decentralized platform for secure preservation of these papers, it can be the most effective, long-term solution. The existing method has security issues because all of the documents are kept in a single, potentially susceptible government database. In addition, there have been several instances of corruption where unauthorized individuals tampered with official records, which can be detrimental.

IV. OBJECTIVES

The main objective of the project was to build a solution which consisted of a decentralizedapplication. The complete setup should serve the following purpose:

- Provide a interface for the user to buy/sell their properties.

Provide a interface for the land inspector to verify the transactions involved in property dealing and transfer the land ownership.

User should be able to carry out the deals easily and in transparent manner.

Solution should be able to handle multiple users.

Generate a digitally verified ownership transfer document

V. LITERATURE SURVEY

Many of the guidelines for good governance in land administration could or must be adhered to while using blockchain technology. Along with the history of transactions (chain of title), transparency and efficiency are also present. Additionally, it is possible to store unique identifiers like parcel numbers and (legal and natural) person identity numbers. The implementation of transaction rules will allow for the validation of transactions. In the present, efficient Land Registry systems, this is primarily carried out manually by carefully reviewing the deed.[1]

The techniques and issues with the ancient land written account system were examined in this essay. The standard approach is susceptible to various types of interference at every stage, which indirectly affects cost accounting in terms of paper resources, the need for extensive record keeping, and security issues with those records. Because it requires significantly fewer and more dependable human resources, the intended system is highly inexpensive. Additionally, this study proposed a formula for a pre-agreement contract between a customer and a merchandiser.[2]

This study makes the following recommendations: An initial, planned model should be implemented into the ILMIS infrastructure in order to strengthen security and shield land title records from both internal and external threats. Digital currency has been the technology's diode, and it continues to permeate other socioeconomic sectors including agriculture, medicine, and electricity. People will misuse this technology, even though it is not the right regulation.[3]

Storing sensitive information like property papers needs a secure and steady database. Existing centralized systems has numerous drawbacks like performance bottleneck and single point of failure.

Hence, a decentralized system with high security is needed. To cater this need, in this paper, we propose blockchain based system for secure storage of property papers. In our system, when a land is bought by a person, the government authority will provide the person with the hard copy of property papers and our system will store the documents into the Inter Planetary File System (IPFS), a decentralized database. The IPFS network will generate the hash of document. This hash will be securely stored into the Ethereum blockchain after satisfying the conditions of the smart contracts. The smart contracts will validate and verify the documents from the government authorities. This will create a decentralized, tamper-proof ledger from which we can retrieve the stored data easily.[4]

Blockchain is an immutable and decentralized digital ledger that is managed by a network of computers, not owned by a single entity. No third party is required to initiate the transaction.The

records in the Blockchain database are transparent and the data is accessible to anyone on the internet. Every active peer on the internet keeps a copy of the original records in the Blockchain and no update is possible without agreement among them. The peers can verify transactions in the blockchain using encoded 'hash' that has to match with the Blockchain's history.[5]

VI PROPOSED SYSTEM

Even though the data is in digital form and held on many platforms, there are now several issues with transparency, trust, and efficiency in the commercial real estate industry and land registration systems. With relation to the state of Maharashtra, it is intended to implement a minor module of the land registration process.

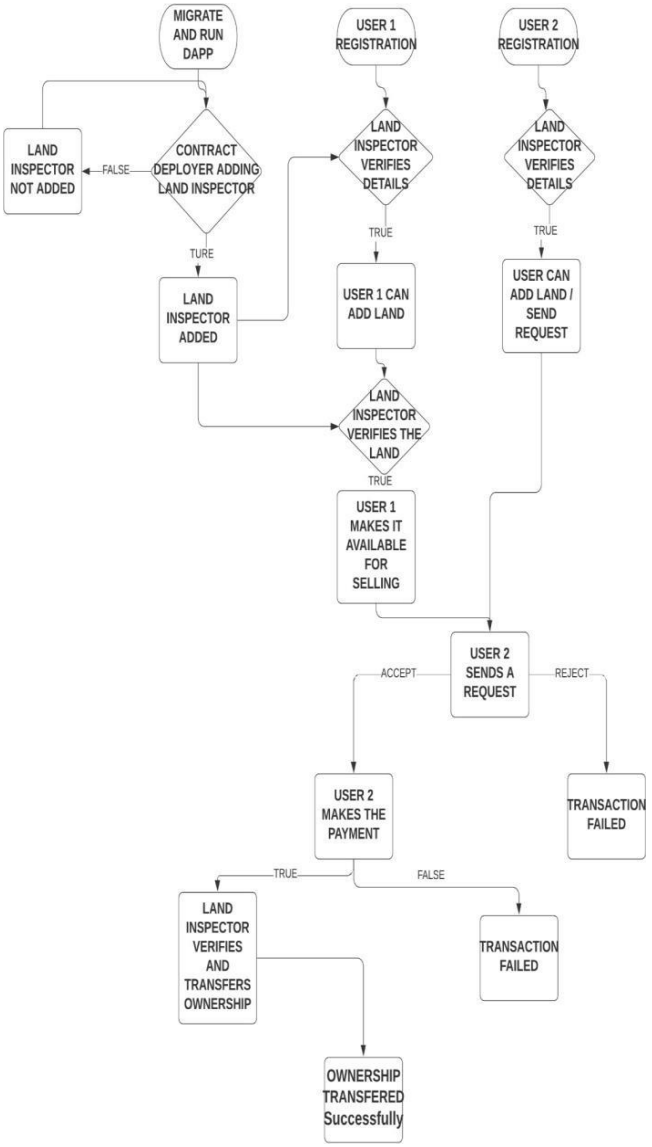

Fig 1 : Proposed methodology

To overcome the previously described challenges, we suggest a private and permissioned blockchain system that limits the participants who can contribute to the consensus process. Our blockchain technology uses distributed consensus methods for ledger consistency and asymmetric cryptography for user security. Decentralization, persistence, anonymity, and auditability are the four main characteristics of blockchain technology, and their combination leads in lower costs and increased effectiveness and dependability.

Blockchain enables anybody to check the accuracy of the system's state, in contrast to centralized traditional systems where different observers may have different views of the system and are required to trust the central authority for verification and authentication. Each state transition in this configuration is verified by verifiers, who may be limited to a group of peers as well.

The user can register themselves and send the specifications first, after which the pre agreement algorithmic rule is carried out. The vendor and the client sign a pre-agreement title contract that includes their signatures, seller IDs, buyer IDs, sell IDs, the amount of transfer, and payment status. After then, a sell request is sent with the pre-agreement title contract. Blockchain can be used to establish confidence within the system for a land written account and eliminate the problem of duplicate outlay by allowing the system to LOCK the specific land title and prevent other group actions on the same Sell ID until the system has received approval or disapproval. Additionally, associated possession and debt verification and validation are completed, along with a report on the property's location and debt.

VII. METHODOLOGY

The two primary building elements of the system are the blockchain network and the smart contract engine. The smart contract engine has a storage for holding good contracts or deeds. It is linked to a user module, and the user interfaces have two categories of users: clients UN agencies looking to buy land, and vendors UN agencies looking to sell their land. User information, including name, address, phone number, and email, is also saved in a reliable contract engine. The user will register under an exploit username. Blockchain verifies the transactional paperwork and provides the system with security. Additionally, the blockchain provides a public interface for accessing data.

Flutter - We have made frontend of our project using Flutter. Flutter is open source and created by Google. It is a cross platform SDK. Using single codebase we can create application for Android ,IOS and Web application. Currently with newer version of Flutter we can also create apps for Windows, Linux and Mac os. On the front screen, one can login as a user, land inspector, or contract owner. The contract owner can add a land inspector and see all the added land inspectors. The land inspector's dashboard consists of the functionality to verify user, verify land and transfer ownership. If we login as the user, we have the options of adding lands,

Fig 2 : Login Page

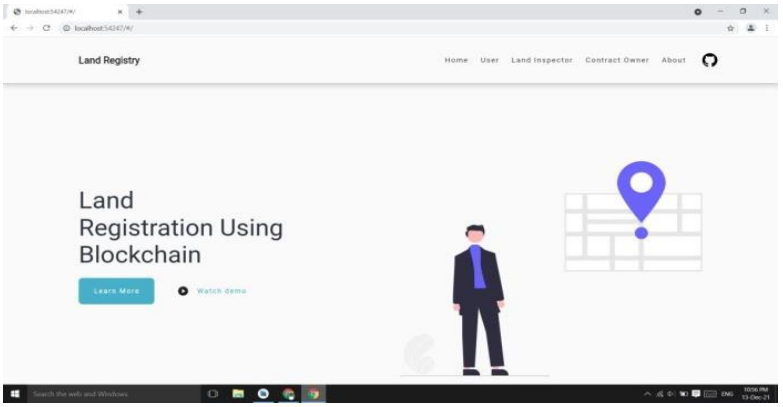

Fig 2 : Login Page

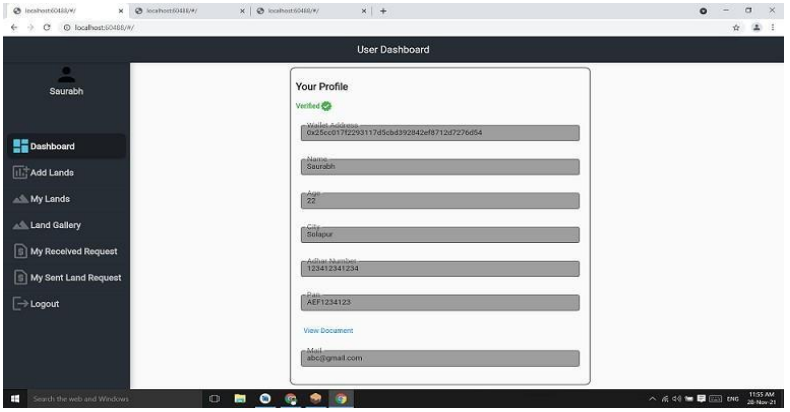
Fig 3 : User Details



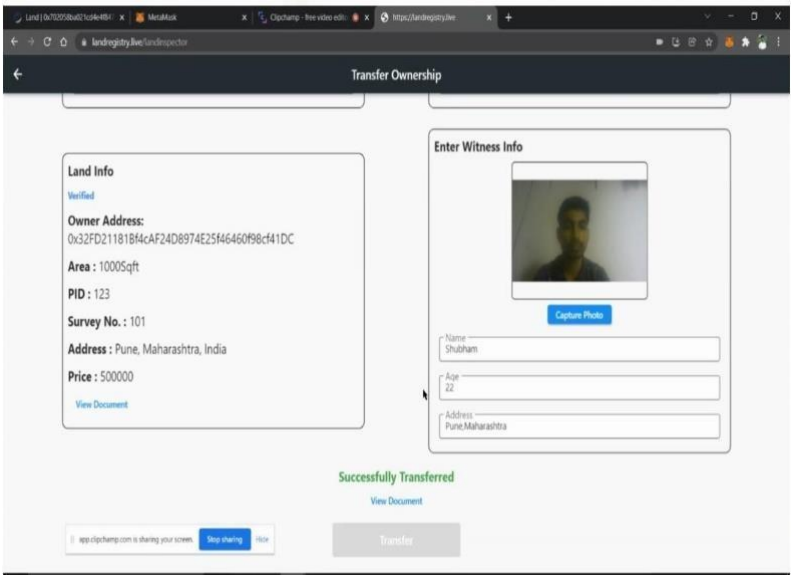


Fig 4 : Witness Information

land details, seeing all lands, sending and receiving land requests. We have used truffle IDE to set up the DAPP.

Smart Contract - Blockchain is to bitcoin, what the internet is to email. A big electronicsystem, on top of which you can build applications. Currency is just one. Bitcoin supportsan optional and special feature called scripts for conditional transfer of values. Ethereum blockchain extended the scripting feature into a full blown code execution framework called smart contract. A smart contract provided the very powerful capability of code execution for embedding business logic on the blockchain. With addition of code execution comes serious consideration about public access to the blockchain hence, the classification of public, private and permissioned blockchain based on access limits. In this project we have implemented a smart contract as the backend which consists of all the terms and conditions for a smooth and secure transfer of property registration.

Truffle - Truffle is a world-class development environment, testing framework and assetpipeline for blockchains using the Ethereum Virtual Machine (EVM), aiming to make life as a developer easier. Truffle is widely considered the most popular tool for blockchain application development with over 1.5 million lifetime downloads.

Metamask - MetaMask is a software cryptocurrency wallet used to interact with the Ethereum blockchain. It allows users to access their Ethereum wallet through a browserextension or mobile app, which can then be used to interact with decentralized applications.

web3.js - Web3.js talks to The Ethereum Blockchain with JSON RPC, which stands for"Remote Procedure Call" protocol. Ethereum is a peer-to-peer network of nodes that stores a copy of all the data and code on the blockchain. Web3.js allows us to make requests to an individual Ethereum node with JSON RPC in order to read and write data to the network. It's kind of like using jQuery with a JSON API to read and write data witha web server.

VIII. RESULTS

Login Page - On the front screen, one can login as a user, land inspector, or contract owner. The contract owner can add a land inspector and see all the added land inspectors. The land inspector's dashboard consists of the functionality to verify user, verify land and transfer ownership. If we login as the user, we have the options of adding lands, land details, seeing all lands, sending and receiving land requests.

Working - First user adds his land details which are verified by the land inspector. Tobuy or sell land, user must send a request to land inspector. After the request has been accepted by land inspector the users can make the transactions. The transaction is verified by the land inspector. After the transaction is verified, the ownership is transferred

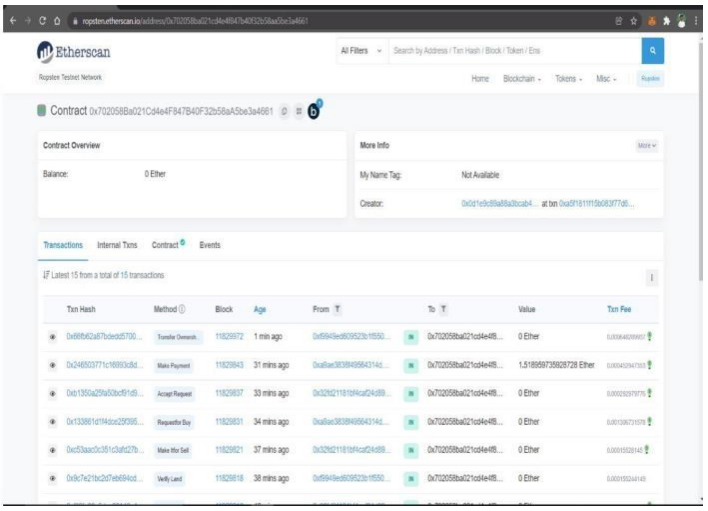

Fig 5 : Contract Information

IX. FUTURE SCOPE

In the future, our scope could be enlarged by integrating our system with government APIs because our established system is currently subject to deployment of transactions where we directly use all the papers that have already been personally validated by the authority. By doing this, we can easily and automatically validate the users and their actions. Users who speak their native languages can also incorporate a language translation feature. Finally, we can add other aspects to our system, making it more dependable and user-friendly, and maintain track of a piece of land's complete history.

X. CONCLUSION

The current system is vulnerable to many sorts of manipulation at every stage and indirectly affects costs through the use of paper resources, the need for extensive record keeping, and record security concerns. Blockchain has the ability to address every problem. A framework for a safe and trustworthy land registry system has been put out in this project to address the major problems of tampering, double spending, and providing nearly real-time updating of land records. The proposed method is particularly cost-effective since it requires fewer and more reliable human resources. We have also offered a pre- agreement contract algorithm for use by the buyer and seller.

At the moment, our main priority is getting rid of intermediaries. However, in order to use the blockchain successfully, we might also identify the land by using geographical factors like geolocation, latitude, and longitude. This would further improve the accuracy of transactions and ensure that no unlawful ones were executed. One of the future goals would be to put this into practice on a wide scale.

IX. ACKNOWLEDGEMENT

Motivation and guidance are the keys towards success. I would like to extend my thanks toall the sources of motivation. We would like to grab this opportunity to thank Dr. P.R. Rodge, Principal forencouragement and support he has given for our project. We express our deep gratitude to Dr. Uttara Gogate, Head of the Department who has beenthe constant driving force behind the completion of this project. We wish to express our heartfelt appreciation and deep sense of gratitude to our project

guideProf. Shweta Patil for his/her encouragement, invaluable support, timely help, lucid suggestions and excellent guidance which helped us to understand and achieve the project goal. Her concrete directions and critical views have greatly helped us in successful completion of this work. We extend our sincere appreciation to all Professors for their valuable inside and tip during the designing of the project. Their contributions have been valuable in so many ways that wefind it difficult

to acknowledge of them individually. We are also thankful to all those who helped us directly or indirectly in completion of this work.

Department Of Computer Engineering, Shivajirao Jondhale College of Engineering
Dombivli, India
pendurkarrohit@gmail.com | mrugeshrasal385@gmail.com | singhsumit313@yahoo.com

Abstract— **Websites that compare product reviews have emerged as an essential informational resource for customers trying to make informed judgments about their purchases. Through these platforms, customers may browse user reviews and ratings, search and compare products, and base their decisions on the expertise and experiences of other shoppers. Due to the significance of user-generated material in the purchasing process, there is an increasing need for sophisticated and user-friendly product review comparison websites. With technologies like artificial intelligence, social integration, and better verification procedures, a proposed system aims to improve the user experience in order to meet this demand. As a result, users will experience a platform that is more personalized, entertaining, and outfitted with cutting-edge technologies to deliver reliable information to customers. Product review comparison websites have the ability to play an even more significant part in the decision-making process by staying on the cutting edge of technical developments and consistently enhancing the user experience. This study presents an overview of websites that compare product reviews, the suggested system, and their influence on the choice to buy.**

Keywords—Artificial Intelligence, Data analytics, Product Review, Recommendation system, Recommendation engine

I. INTRODUCTION

Websites that compare product reviews have grown in importance as a tool for consumers trying to make educated judgments about their purchases. Users of these websites have access to a platform where they can look up and compare products, read user reviews and ratings, and base their judgments on the collective wisdom and experiences of other users. As consumers rely on the experiences and opinions of others to inform their own decisions, user-generated information offered by these websites has emerged as a crucial component in the purchasing decision process.

The demand for more sophisticated and advanced platforms has grown as the use of product review comparison websites continues to soar. The suggested system incorporates social, augmented reality, and artificial intelligence aspects to improve the user experience. It also uses better verification procedures to guarantee that the data provided is reliable and correct. As a result, consumers trying to make wise purchasing decisions will have access to a tool that is more valuable, personalized, and entertaining. Product review comparison websites have the ability to influence consumers' purchasing decisions even more in the future by utilizing the most recent technical developments. [1]

II. LITERATURE REVIEW

Websites that provide information and analysis on various products, including their features, costs, and user evaluations, are referred to as "product review comparison websites." They are a resource that helps customers compare various items based on many factors in order to make educated purchasing decisions.

Overview of Websites Comparing Product Reviews: Websites that compare product reviews have been increasingly popular in recent years as a result of the expansion of e-commerce and the ease of online shopping. They offer a variety of product-related details, such as specs, features, costs, and customer reviews, which are compiled from numerous sources. Websites that compare product reviews include some well-known ones like Amazon, Best Buy, and Consumer Reports.

Benefits and Drawbacks of Product Review Comparison Websites: There are several benefits to using a product review comparison website, such as the simplicity of comparing products, easy access to a wealth of knowledge, and the chance to read user reviews and ratings. Additionally, they can offer consumers up-to-date data on prices and product availability in real-time. Websites that compare product reviews can have certain drawbacks, though, such as the possibility of biased or fraudulent reviews, the limitations of user reviews in capturing the genuine value of a product, and the possibility of out-of-date information.

Prior research and conclusions on websites that compare product reviews:
Websites that compare product reviews can significantly influence consumers' purchasing decisions, according to prior study. According to several research, these websites help consumers feel more confident while making purchases, which results in more informed and satisfying purchases. Other studies have demonstrated that the use of product review comparison websites can harm brand loyalty and undermine consumer confidence in conventional brick and mortar retailers.In conclusion, in the digital age, websites that compare product reviews have become an invaluable resource for customers. They offer a wide variety of details on numerous products, making it simpler for customers to compare and decide what to buy. To make the best purchasing decisions, it is crucial to be aware of the limitations of these websites and to critically assess the information provided. To fully comprehend the effects of product review comparison websites on customer behaviour and the market as a whole, more research is required.

Table 1: Literature review

Reference	Focus	Key Findings
[1]	Product Recommendation Systems a Comprehensive Review	The recommender system will take the information and formulate the decision in one of the following two ways either by the use of collaborative filtering or by the use of content filtering.
[2]	Product Recommendation using Machine Learning Algorithm - A Better Approach	The k-mean is a method for grouping which is not parametric. According to their similarity, it distributes the objects into k clusters. In this article, using the Euclidean distance this similarity is calculated.
[3]	Product Based Recommendation System On Amazon Data	This system is not quite consumer friendly as it doesn't compare prices of the product from different websites.
[4]	Result Review Analysis of Product Recommendation System in Domain Sensitive manner.	This system focuses a lot on user data and user history and also on the search pattern.
[5]	Comparing consumer produced product reviews across multiple website with sentiment classification	This system encourages consumers to post reviews of their purchased products, so that new consumers can evaluate these reviews for same product across different websites to help them make purchasing decisions.

From this table we can conclude that Consumers are often faced with the challenge of making informed purchasing decisions when shopping online. There are countless products available, each with its own unique features, benefits, and drawbacks. In addition, user reviews and ratings can vary widely, making it difficult to determine the quality and suitability of a product. This can lead to poor purchasing decisions, resulting in wasted time and money.

III. PROBLEM STATEMENT

The problem today we face is the availability of vast amount of information available online, as well as the numerous websites and marketplaces that offer products for sale. Navigating this maze of information can be overwhelming, especially for consumers who are new to online shopping.
The goal of the product review comparison website is to address this problem by providing consumers with a centralized resource for gathering information on products, user reviews, and ratings. The website aims to make the process of shopping online more intuitive, efficient, and reliable, by providing users with a clear and concise source of information on the products they are interested in. This will enable consumers to make informed purchasing decisions with confidence, ensuring that they get the best value for their money.

IV. ALGORITHM

Step 1: Start

Step 2: User visits the site's landing page

Step 3: Login or registration

Step 4: Home page

Step 5: Search product for Reviews and comparisons

Step 6: Search product by categories or by using search box

Step 7: Get Results/Desired product

Step 8: If found then fetch product details

Step 9: If not found then repeat step 5

Step 10: Comparison page

Step 11: Choose from multiple online stores

Step 12: Stop

IV. PROPOSED SYSTEM

Among the most well-known e-commerce sites worldwide are Snapdeal, Amazon, and Flipkart. Web scraping is a technique used to collect data from these websites. In the process of web scraping, data is automatically extracted from websites and stored in an organized way, like a database. This enables the rapid gathering of enormous volumes of data from numerous websites.

A database, which acts as a central repository for the information, houses the data gathered from various websites. Large volumes of data can be structured and managed effectively in the database. This makes it possible for the website to swiftly obtain the needed information and provide it to the user in an organized and understandable manner.

The creation of the actual website is the process's last phase. The website is made to give consumers a platform where they can look for products, evaluate various possibilities, read user reviews and ratings, and decide which products to buy. The website makes advantage of the database's data to offer users the most recent details on a variety of products. The website offers a comprehensive and user-friendly platform for customers wishing to make informed purchasing decisions by utilizing the data acquired from Amazon, Flipkart, and Snapdeal.

Searching for and comparing products is one of the website's primary functions. To discover what they need, users can browse categories or conduct specialized product searches. After a product is chosen, the website offers comprehensive information about it, including characteristics, customer reviews, and ratings. Users may easily comprehend the advantages and disadvantages of a product since this information is presented in a clear and straightforward manner.

A general overview of the working of a web application related to product review comparison:

User Login: Users would first need to create an account on the product review comparison website or sign in using their existing social media accounts.

Product Search: Users can search for products using keywords, filters for product features, prices, and user ratings.

Product Comparison: Users can compare different products based on various criteria, such as specifications, features, prices, and user ratings and reviews.

User Reviews and Ratings: Users can provide reviews and ratings for products they have used, and view reviews and ratings from other users.

Recommendation Engine: The recommendation engine would use machine learning algorithms and data analysis techniques to recommend products to users based on their search history, preferences, and purchasing behavior.

Product Purchasing: Users can purchase products directly from the product review comparison website or through a linked e-commerce platform.

Social Sharing: Users can share their reviews and recommendations with friends and family on social media, and view reviews and recommendations from their social network.

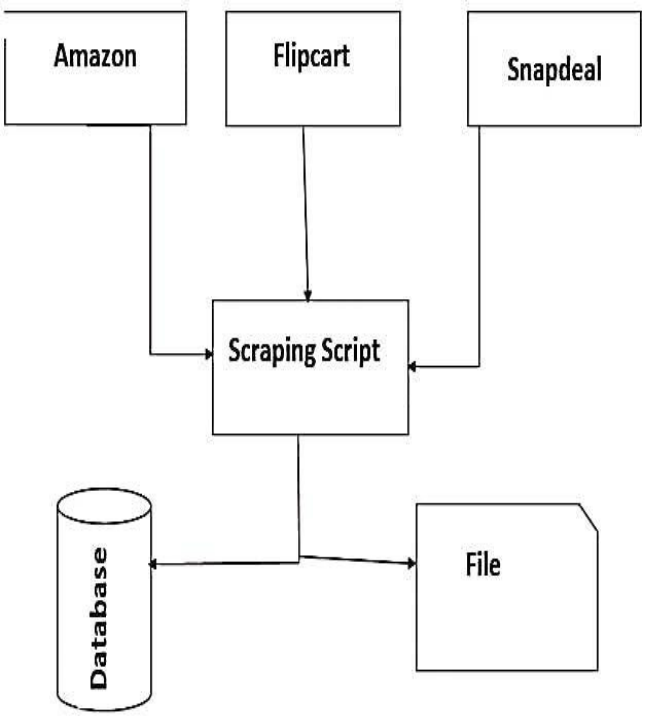

Figure 1: - Block diagram of the proposed system

The suggested system has the potential to completely alter how people find and buy things, making it a useful resource for years to come.

V. METHODOLOGY

The methodology for developing the product review comparison website involves several key steps. These steps are designed to ensure the accuracy, reliability, and relevance of the information provided on the website.

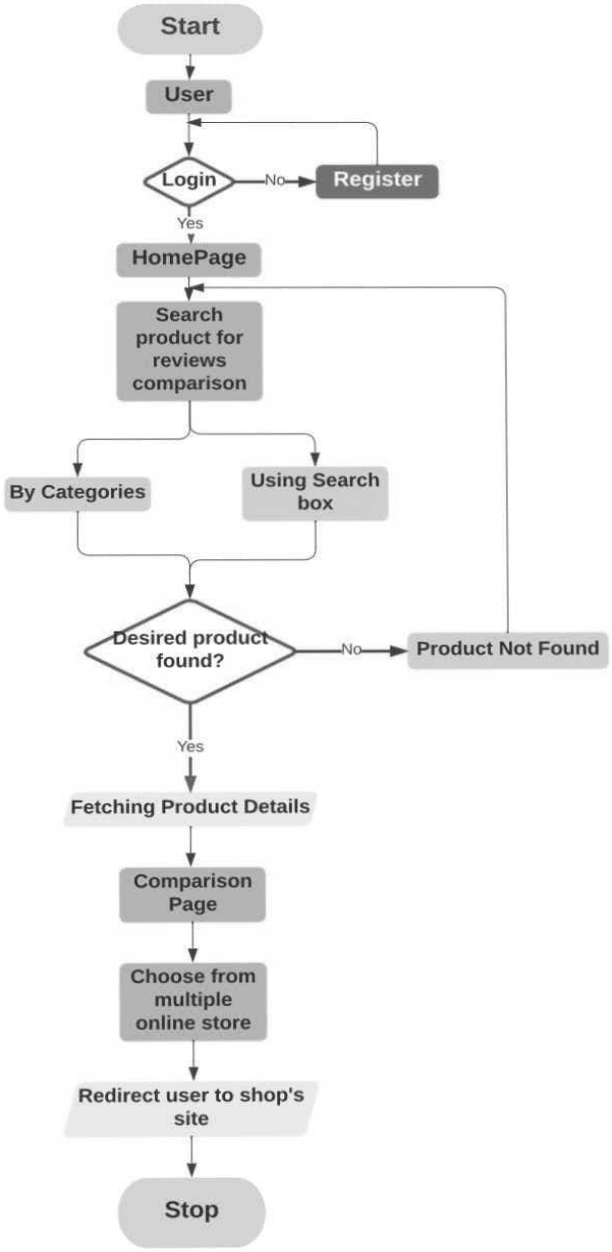

Figure 2:- Flow of the proposed system

The first step in the methodology is data collection. This involves utilizing web scraping techniques to gather information from Amazon, Flipkart, and Snapdeal. The data collected includes product information, user reviews, and ratings. The data is stored in a database, which serves as the centralized repository for all information. This step is critical to the success of the website, as it provides the foundation for all other steps.

The next step in the methodology is data cleaning and preprocessing. This involves the removal of any irrelevant or duplicate information, as well as the correction of any errors in the data. The data is then organized and structured in a format that is easy to use and understand. This step is important to ensure the accuracy and reliability of the information provided on the website.

Methodology for "Product Reviews Comparison Website" can be divided into the following steps:

Web Scraping: The first step involves collecting product reviews from popular e-commerce websites such as Amazon, Flipkart, and Snapdeal. This can be done using web scraping techniques that allow data to be extracted from websites automatically.
Database Creation: The next step involves storing the collected product reviews in a database. This database will serve as the source of data for the product reviews comparison website.

Product Reviews Comparison Website Development: The final step involves developing the product reviews comparison website. This website will allow users to compare product reviews from different e-commerce websites and make informed purchasing decisions.

In the development of the product reviews comparison website, the following technologies can be used:

Front-end development: HTML, CSS, JavaScript, and front-end frameworks such as React or Angular can be used to create the user interface.

Back-end development: A back-end technology such as Node.js or Ruby on Rails can be used to create the server-side logic.

Database management: A database management system such as MySQL or MongoDB can be used to manage the database.

Web scraping library: A web scraping library such as BeautifulSoup or Selenium can be used to extract data from the e-commerce websites.

The entire process of collecting product reviews from e-commerce websites, storing them in a database, and developing the product reviews comparison website requires a good understanding of web development, databases, and web scraping techniques.

The third step in the methodology is the development of the website itself. This involves the use of advanced web development technologies to create a platform that is user-friendly, intuitive, and provides users with the information they need to make informed purchasing decisions. The website is designed to be easily navigable, with clear and concise information on products, user reviews, and ratings. These technologies are used to provide a more personalized and engaging experience for users, as well as improve the accuracy and reliability of the information provided. The use of these technologies ensures that the website remains relevant and up-to-date, providing users with a valuable resource for years to come.

VI. ADVANTAGES

1. Improved user engagement: Customers will quickly take their money elsewhere if they don't get what they're looking for quickly. Pretty sure you don't want the same to happen to your store. Personalized recommendations help engage your site visitors more. That leads to more extended stays and, eventually, lower bounce rates.

2. Improved time and cost efficiency: With an AI-powered personalization tool, you can save time and money. It automatically undertakes product suggestions alongside cross and upselling approaches. Hence, it enhances efficiency gains that can save your operational costs in the long run.

3. Improved customer loyalty: Successful personalization systems can achieve 20% improvement in customer satisfaction. Satisfied customers are more likely to stick with your brand and even get more referrals. You can also use data insights from a product recommendation system to tailor your customer loyalty programs. It makes it easy to offer personalized rewards based on customers' wants and preferences. Hence, the rewards, whether discounts, coupons, free or subsidized shipping, etc., can resonate with each customer.

VII. RESULTS

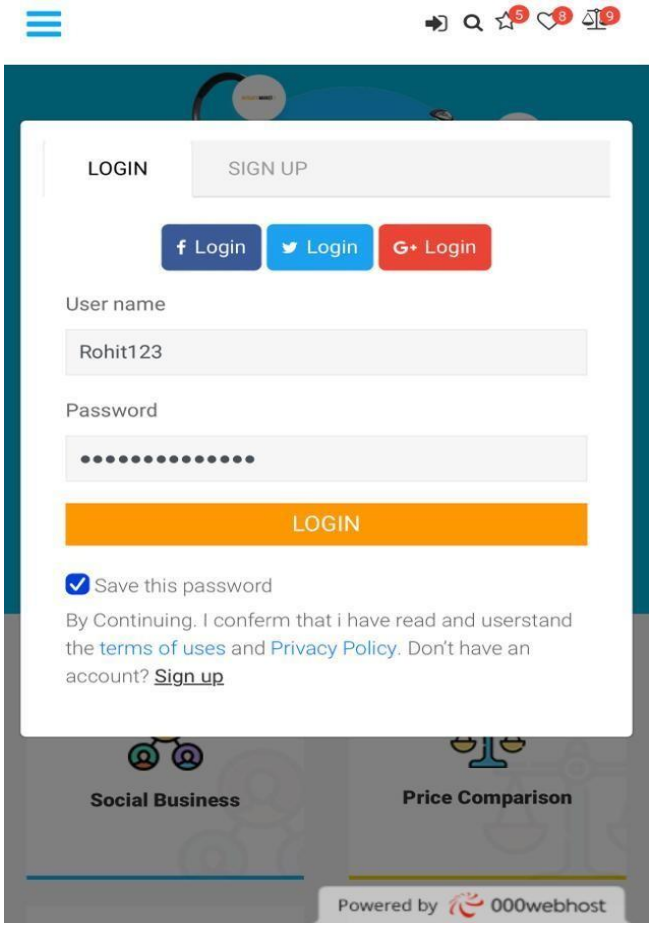

Figure 3:- Login page

This is where users can login into the website

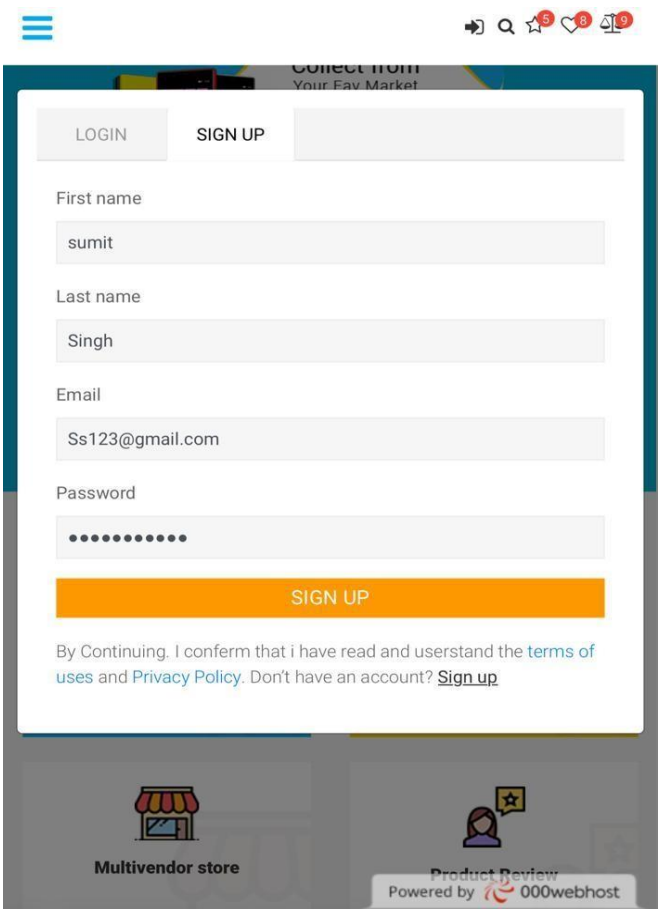

Figure 4:- Signup page

This is where users can create a new account on the website.

Figure 5: - Home Page

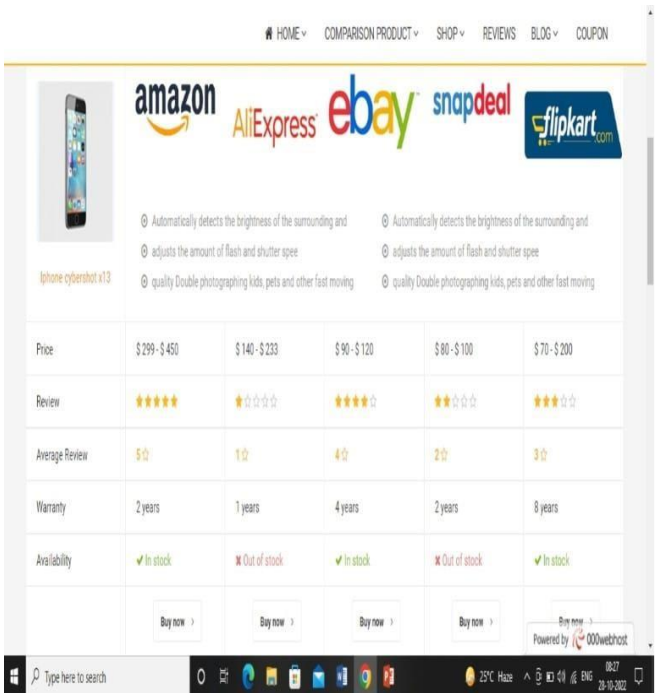

Figure 6: - Comparison Page

This is where all the prices and ratings of the product can be compared.

VIII. CONCLUSION AND FUTURE SCOPE

Websites that allow users to search and compare products, read user reviews and ratings, and make informed judgments about which products to buy have become increasingly popular. This website have become a crucial resource for customers as the role of user reviews and ratings in the purchasing process increases. Through greater personalization, social features, and enhanced verification, the proposed system intends to improve user experience and give even more relevant and accurate information. Websites that compare product reviews have the potential to be even more important in the decision-making process if they continue to be at the forefront of technical development and continually enhance the user experience. This website has a promising future ahead of it as it continue to assist customers in finding the products that best suit their requirements and tastes and assist them in making wise purchases.

Here are some probable directions in which the proposed system could go in the future:

Integration with AI-powered shopping assistants: Product review comparison websites may interface with AI-powered shopping assistants to offer consumers real-time assistance and direction while they browse and compare products.

Future advancements could improve the user experience and offer even more precise and relevant information to support consumers in making wise shopping decisions. By adding opinions of trending influencers and YouTube recommendations.

Big Data Characteristics and Applications

Harshit Mundra , Vijay M. Rakhade , Lawlesh N. Yadav , Neehal.B. Jiwane , Ashish. B. Deharkar
Asst.Prof, Computer Science & Engineering, Shri Sai College of Engineering & Technology, Bhadrawati, India

Abstract **: In the past, data or let's say traditional data was limited because there were not many platforms to share data such as Social media, Online Deals, E Commerce,etc. and it was easy to store, process and cover the data due to its small volume and structured format, but day by day technology evolved following the world and new services got introduced due to which data generation increased which leads to the development of numerous ways that can be used to store and reuse this quantum of data. These technologies with their capability to prize information from large data sets for better decision-making process have created ways to maintain data, process data and new growth openings. But if data isn't well defended from pitfalls like phishing, etc, all these processing becomes futile, if these data falls in wrong hands, it could be misused. There are numerous ways to maintain data security and integrity of data but still it could be violated if not carried out properly. So while dealing with data, Security and sequestration becomes high concern in order to cover it from attacks. Our purpose in this paper is to know about the characteristics, challenges faced while maintaining big data and applications of Big Data.**

Keywords**: Big Data, Big Data Types, Characteristics**

INTRODUCTION

As we all Know, we deal with data every day, like when we make videos to post on social media, or when we send the messages throw texting applications, or when we receive something through mails, and many other cases. This data keeps on increasing and keep on increasing as the time goes by. Now a days we also see many new platforms where either user sends or receive data that come every day. Also now that internet era is going on, even if user make slight clicks here and there, new data is generated for that click. Like that for everything there is new data about that.

Big Data helps medium sized to large sized companies to store, manage and manipulate the large amount of data that is of large volume, and comes in wide variety and with high velocity.

Types of Big Data

Primarily there are three types of Big Data: Structured, Unstructured and Semi-Structured.

Structured Data is the data that is in fixed format like the traditional data.This type of data is organized and you can easily access and store this type of data in traditional databases. The example you can take is data stored in tables and spreadsheets.

Unstructured data is the data that is with an not formatted or unknown structure. You can see this type of data everywhere such as videos, images, text, and other formats.

Semi-structured data is the data that is kind of unstructured but has a particular structure to it. For example e-mail.

Characteristics of Big Data

Volume:

The amount of data you have. The volume of data will keep on increasing as the time goes by. You can also observe this

Velocity:

Velocity is nothing but the speed of data processing Big data processes requires high velocity as the data is in large amount. It consists of the rate of change, activity bursts, and the linking of incoming data sets.

Variety:

Variety is nothing but the different types of big data. It is among the biggest issues faced by the big data industry as it affects performance. It's vital to manage the variety of your data properly by organizing it. Variety is the various types of data that you gather from different kinds of sources.

Veracity:

Veracity refers to the accuracy of your data. It is among the most important Big Data characteristics as low veracity can greatly damage the accuracy of your results

Value:

Value refers to the benefits that your organization derives from the collected data.

Validity:

It is nothing but how valid and relevant is the data to be used for the intended purpose.

Volatility:

Big data is constantly changing. The data you gathered from a source a day ago might be different from what you found today. This is called variability of data, and it affects your data homogenization.

Visualization:

It refers to showing your big data-generated insights through visual representations such as charts and graphs. It has become prevalent recently as big data professionals regularly share their insights with non-technical audiences.

Big Data Applications

As Big Data is used everywhere there are many applications lets view some:

Government:

As the government collect a large amount of data, so they use big data analytic to manage this huge amount of data

Hospitals:

They deal with large amount of data related to patients, so they use big data.

Schools and Colleges:

They keep records of large amount of Data related to students and staff and also related to events.

They use big data to manage this large amount of data.

Social Media analyzers:

They study trends and behaviour of social media users. So they use big data to keep this large amount data in check.

Banking:

Banks also deal with huge amount of customer data, so they use big data to keep this large amount of data in check.

There are many more applications of big data that are not listed here but you can observe the in your day to day life.

Conclusion

From above mentioned details, we can figure out that we see that big data is very important part of our day to day life. We can also observe it used everywhere. Big data also play important role for many organizations or companies. We can also expect to see the importance of big data increase even more as the time goes by. As the data will keep on increasing as the time goes by.

Abstract—**This paper presents a methodology for developing a face and voice recognition proctoring system for online interviews and applies it on an online hiring platform. The results show that the project can detect faces and recognize them based on the database. The project help users to ensure safety and conduct smooth online interviews without any malpractices. The AI-based voice and face recognition proctoring system is a technological solution designed to enhance the security and integrity of online exams and assessments. The system utilizes advanced machine learning algorithms to verify the identity of test-takers and monitor their behavior during the exam. The system consists of two main components: voice recognition and face recognition. The voice recognition module analyzes the unique vocal characteristics of the test-taker and matches them with pre-registered data to confirm their identity. The face recognition module captures images of the test-taker and analyzes their facial features to verify their identity. During the exam, the system continuously monitors the test-taker's behavior to detect any signs of cheating or misconduct. It uses real-time video analysis to detect unusual behaviors such as looking away from the screen, talking to someone else, or attempting to access unauthorized resources. The system also uses natural language processing to monitor the test-taker's speech patterns and detect any suspicious language or indications of cheating. If the system detects any suspicious behavior, it immediately flags the incident and sends an alert to the exam proctor. The proctor can then review the footage and take appropriate action to maintain the integrity of the exam. The AI-based voice and face recognition proctoring system is a powerful tool for ensuring the security of online exams and assessments. By leveraging advanced machine learning algorithms and real-time monitoring, it provides a robust defense against cheating and other forms of academic misconduct.**

Keywords—Face recognition , Face detection, CNN, Neural Network, voice recognition

I. INTRODUCTION

An AI-based face and voice recognition proctoring system is a technology-driven solution designed to ensure the integrity of online exams. As online learning becomes more popular, institutions are facing new challenges in verifying that students are not cheating during online exams. Traditional methods of proctoring, such as using a human proctor to monitor the exam, can be expensive and may not be practical for large online classes. An AI-based face and voice recognition proctoring system addresses these challenges by using advanced algorithms to analyse a student's facial and vocal features to verify their identity. The system captures several images and recordings of the student's face and voice before the exam and uses them to create a reference dataset. During the exam, the system compares the live video and audio captured from the student's webcam and microphone to the reference dataset to ensure that the student is the one taking the exam. The system uses advanced AI-based techniques such as eye-tracking and keystroke analysis to detect any suspicious behaviour or anomalies that may indicate cheating. If the system detects any discrepancies or anomalies, it alerts the proctor to review the footage and take appropriate action.

The use of an AI-based face and voice recognition proctoring system can help ensure academic integrity during online exams, while reducing the need for human proctors and minimizing costs. However, it is important to ensure that the system does not violate the privacy of students and that it does not unfairly penalize students who may have technical issues with their webcam or microphone. Therefore, proper implementation and transparent communication with students are essential to ensuring the success of such a system.

Security Companies: The truth that machines can nowadays correctly apprehend individuals, affords a slew of possibilities for the safety sector, leader amongst them the capacity to discover unauthorized get entry to the places wherein non-legal humans should not be. This is mainly beneficial if protection forces are attractive or dealing with intrusions in a place that won`t be included through constant CCTV cameras.

Immigration checkpoints: Chief among these is the ability to detect and prevent border crossings by known criminals or persons of interest through facial recognition. Border controls are now synchronized with information databases such as INTERPOL's "face identification" method to identify individuals based on a measure of accuracy. By processing facial information via the cloud, predictive algorithms can be run on footage to not only improve typical image quality, but also factors such as aging, plastic surgery, cosmetics and even the effects of narcotics. be able to consider.

Ride-sharing transport: Passengers in the ride sharing industry can also benefit from facial recognition. For the sharing economy, facial recognition provides an additional layer of travel verification and security. Cars may be equipped with native face scanning his technology that allows for additional security benefits without the need for additional devices. Vehicles can be unlocked by recognizing faces, ensuring that only passengers who have booked a ride can board. This is the best security available today. Security that users are unaware of because it is seamlessly integrated into their behaviour.

Cars: In-car voice technology has made it safer and easier to navigate – and to listen to exactly what you want, whenever you want. Most new cars can connect to Bluetooth devices, such as smartphones, which effectively makes your car voice enabled; just talk to your phone to start navigating or listening to a playlist. However, some newer cars have their own speech recognition to remove your phone from the equation and let you navigate or listen to music without ever looking at a screen.

Accessibility: Speech recognition can be very helpful if you cannot type freely or are visually impaired. We will be able to navigate and communicate online and on the phone with just our voice, making computers and smartphones more accessible to some.

Security: Speech recognition technology has advanced to the point of being able to uniquely identify speech. This has powerful implications for personal security and identity. One of the developments for personal security is voice authentication with what is called biometrics. This basically uses your voice to unlock your device. This means that something only you have access to (your vote) could be your password.

II. LITERATURE SURVEY

Face and voice recognition proctoring systems are becoming increasingly popular in online education and testing environments. These systems use advanced technology to verify the identity of the test taker and ensure that the person taking the test is the same person who is supposed to be taking it.

The paper provides a comprehensive survey of face recognition techniques, including the history, current state of the art, and future directions of the field[1].

This paper provides a comprehensive survey of voice recognition techniques for authentication, including the history, current state of the art, and future directions of the field[2].

This paper presents a proctoring system that uses computer vision and machine learning to monitor students during online exams. Thesystem uses facial recognition to verify the identity of the test taker and monitors the test environment to prevent cheating[3].

This paper presents a voice biometric system for online proctoring in higher education. The system uses voice recognition to verify the identity of the test taker and monitors the test environment to prevent cheating[4].

This paper presents a face and voice recognition based online examination system that verifies the identity of the test taker and monitors the test environment to prevent cheating. The system uses a combination of facial recognition and voice recognition to ensure the authenticity of the test taker[5].

This paper presents a robust face and speech recognition system for online exam proctoring. The system uses a combination of facial recognition and speech recognition to verify the identity of the test taker and monitor the test environment to prevent cheating[6].

This paper presents a face recognition and tracking system for online exam proctoring. The system uses facial recognition to verify the identity of the test taker and tracks the face throughout the exam to prevent cheating[7].

Overall, these papers demonstrate the importance of face and voice recognition proctoring systems in ensuring the integrity of online education and testing environments. While there are still challenges to be addressed in terms of accuracy and privacy concerns, these systems represent an important step towards ensuring fair and equitable assessments in online settings.

III. PROPOSED SYSTEM

An AI-based face and voice recognition proctoring system is a software system that uses artificial intelligence technology to monitor online exams and ensure that

students are not cheating. This system uses advanced algorithms to analyze a student's facial and vocal features, and determine whether they match the features of the student who is supposed to be taking the exam.

For this project, we have decided to work with following technology:

a. Flask: API
b. NodeJS: Backend Process
c. MongoDB: Database Design

Before the exam, the students must register their face and voice in the system. The system would capture several images of the student's face and voice, and use them to create a reference dataset. During the exam, the system would use the student's webcam and microphone to capture live video and audio. The system would then compare the live video and audio to the reference dataset to determine if the student is the one taking the exam.

If the system detects any discrepancies or anomalies, such as a different face or voice, it will alert the proctor. The proctor can then review the footage and take appropriate action, such as stopping the exam or flagging the student for further review. The system would also use additional AI-based techniques, such as gaze-tracking, video split, web scraping and keystroke analysis, to detect any suspicious behavior or anomalies that may indicate cheating.

Overall, an AI-based face and voice recognition proctoring system has the potential to improve the security and fairness of online exams, by using advanced technology to prevent cheating and maintain academic integrity. However, it is important to ensure that the system does not violate the privacy of students or unfairly penalize students who may have technical issues with their webcam or microphone.

The below architectural diagram Fig 1 shows the process of face recognition:

- First, images or frames from the video stream are sent to the face recognition module, which recognizes faces in the input images.
- Sends the bounding box coordinates of the detected faces as output. Face preprocessing is done in the cue detection block to identify the locations of facial reference points (also known as datum cues) such as the eyes, nose, lips, chin, and chin.
- Before submitting the aligned face to the facial recognition module, check the face for spoofing to ensure that the face is from a live image or video feed and has not been spoofed to gain unauthorized access.
- The image is then sent to the next block, the face recognition block. This block performs a series of processing tasks before face recognition is successfully completed.
- This is an important step because we don`t want the facial recognition engine to be distracted by variations in different poses, facial expressions, lighting changes, etc. in the input facial image.
- After the within-class variation of the input surface has been resolved, the next important processing step is feature extraction.
- Here, a comparison is made between the feature vector obtained in the last step and the face vector registered in the database.

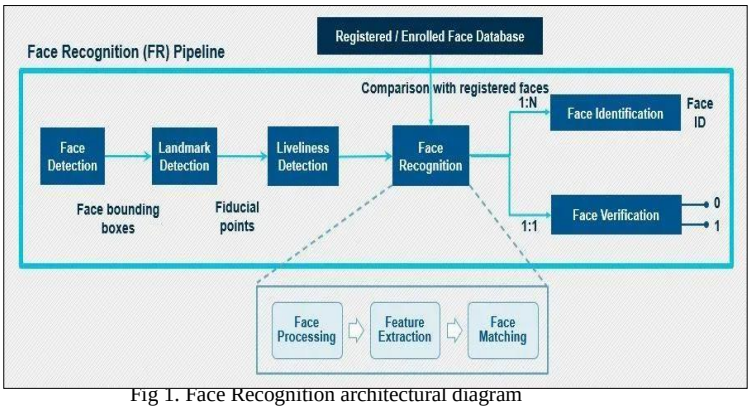

Fig 1. Face Recognition architectural diagram

An architectural diagram of a typical speech and speaker recognition system is shown in Fig 2.The system is trained to recognize the voice of individual speakers, each of whom delivers a specific set of utterances via a microphone jack or telephone.

- The captured analog speech waveform consists of her three components: Speech segments, silent segments, and background noise signals.
- To extract the relevant audio signal, the audio waveform is digitized and signal processing is performed to remove noise signals and silent or unvoiced components.
- Relevant information ignored during this process is considered completely lost, and conversely, irrelevant information such as the fundamental frequency of the speaker or the characteristics of the passed microphone is treated as useful, and the performance of speech feature classification is improved. affect.
- The extracted speech signal is then converted into a stream of pattern feature vectors of speech patterns for classification and training.
- If irrelevant information is allowed, the speech features that can be generated from the distorted speech signal may not resemble the class distributions learned from the training data.
- The system recognizes individual speaker voices by comparing the audio features of the extracted utterances with the respective template features invoked by the training system.

- The GMM Recognizer computes a score that is used to match the speaker's most characteristic speech features. The speaker's speech recognition decision criteria was based on the correlation analysis of the speaker's speech features from the ANN and the GMM.

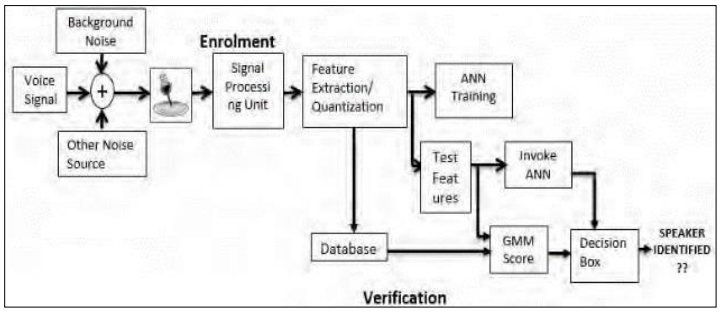

Fig 2. Voice Recognition architectural diagram

IV. RESULT AND DISCUSSIONS

For a smooth conduct without any cheating, a combination of various techniques along with face and voice recognition is used on secure browser. This requires the supervisor to complete some actions which is basic necessity. There are other ways to trick such as a person sitting behind person and having conversation, or even interactable AI devices, such issues are solved with voice recognition. External gear such as spectacle camera which covers the whole field of view of test taker and applying computer vision to feed. It is necessary to avoid fraud. So, AI used in face and voice recognition helps to proctor multiple students simultaneously.

A camera is used at user's end to capture frames for authentication of user. These frames are captured to monitor the user. The frames are taken at taken at regular intervals and it's face is identified. If the user is unidentified, it is been removed from the meeting.

The system also uses microphone of user to record it's voice at beginning, to confirm identity and enter the meeting. Also proctoring is done in whole session with voice recognition. When the user is speaking, the voice is taken as samples from instances and identification is done each time. This eliminates the possibility of another person which is not in view of proctor to have conversation with user.

V. CONCLUSION

An AI-based face and voice recognition proctoring system is a technology that can automatically verify the identity of a person through their facial features and voice. This system is increasingly being used for online proctoring in education, certification, and recruitment settings.

While the system can offer a range of benefits, such as enhancing security and reducing cheating, there are also concerns about its potential drawbacks. For example, there are concerns about the accuracy of the technology and the potential for bias in its implementation. Additionally, there are privacy concerns related to the collection and storage of biometric data, as well as the potential for misuse or unauthorized access to such data.

In conclusion, while AI-based face and voice recognition proctoring systems can offer benefits in certain settings, careful consideration should be given to their implementation to ensure that they are used ethically and responsibly, and that privacy concerns are addressed.

Review On Study Of The Platform For Secure Mobile Application

Laxmi M. There, Neehal .B. Jiwane, Ashish.B. Deharkar, Vijay M. Rakhade
CSE, Shri Sai College of Engineering and Technology,
Bhadrawati, India

Abstract: **These days, smartphones and other mobile gadgets play a huge role in all facets of our lives. due to the fact that they essentially gave the same capabilities as desktop workstations and became powerful in terms of CPU (central processing unit), storage, and installing a wide variety of software. Security is therefore seen as a crucial component of wireless communication technologies, notably in wireless ad hoc networks and mobile operating systems. Additionally, as the number of mobile applications grows across a range of platforms, security is seen as one of the most important and significant topics of discussion in terms of problems, trustees, dependability, and accuracy.Security this article intends to give a comprehensive report on thriving security on mobile application platforms and to inform users and businesses about critical dangers. Additionally, several methodologies and methods for security measurements, analysis, and prioritizing at the pinnacle of mobile platforms will be described in this article. Increased knowledge and awareness of security on mobile application platforms are also beneficial for avoiding discovery, forensics, and countermeasures employed by the operating systems. Last but not least, this study also covers security add-ons for well-known mobile platforms and analysis for a poll inside a recent platform security investigation, awareness, sensitive data, and vulnerability.**

Keywords: Threats, cyber strategy, mobile platforms, application security, mobile malware.

I. INTRODUCTION

At this time, smartphones and other mobile gadgets are quite significant to individuals all over the world. Because they supplied the same features and services as desktop workstations, the security issue is still a significant challenge. Attackers and harmful software have grown more prevalent in recent years. 2015 will be a turning point for threats to mobile devices, according to a report on threats, as the total number of mobile malware samples exceeded 5 million in Q3 2014. Therefore, numerous studies and researches now focus on the security requirements and problems associated with diverse mobile platforms. The choice of appropriate mobile platforms is therefore one of the most crucial choices while using a smartphone. In general, the three main categories of the security aims and objectives of information in an organization are confidentiality, integrity, and availability. To put it another way, confidentiality, integrity, authentication, and authorization can all be used to gauge security issues, the security incident became more powerful on mobile platforms and phone devices because of the amazing increase in memory, data transfer, and processing. The methods for analyzing and ranking security requirements in mobile application platforms will be the main focus of this study. In terms of theory, rather than using technical facts. Additionally, the analysis and assessment of the research and approaches now in use will be discussed. This study introduces the "threat model" of mobile platforms inside two well-known key platforms, IOS and Android, as well as general model security architectures.Last but not least, we'll talk about privacy and security concerns with mobile platforms. It is important to note that in this article, security on mobile platforms has been examined from several angles, revealing how both the Ionic and Android platforms have developed security models to counter threats, specific justification for securing mobile application platforms, and security threat assessments[15].

II. THE CRITICAL VALUE OF THE STUDY

Currently, the most accessible targets for hackers and dangerous software are now smartphones and mobile devices. Mobile malware samples total more than 5 million in Q3 2014, according to McAfee Labs' threat prediction

report. Additionally, in the past year, 110 million Americans, or almost 50% of US adults had some type of personal information exposed.Therefore, it is clear that having the most recent information on the security mechanisms offered by mobile platforms is crucial. People will therefore have the proper information to select the best platform to utilize on a regular basis. Finally, based on the results of this study, platform providers will use this survey to strengthen their security measures.

III. MOBILE APPLICATION SECURITY PLATFORMS

Mobile application development in various platforms is based on functionaland non-functional requirements. Currently, various types of platforms exist to deploy mobile applications with different privacy policies. Therefore, this research focuses on the most priceless and popular mobile application platforms in the world. Furthermore, it discusses how the security within each platform is different from each other for instance, Motion BlackBerry OS, Apple IOS, Google Android, and Microsoft Windows Phone. There are some imperative security issues to be major impacts on mobile devices. In addition to these, controlling thirdparty applications is a difficult task within each mobile app store, which they have a huge impact on increasing the security issues within mobile platforms. Dimensional Research institution stated that security risks were the major cause of the mobile security platforms. The number of IT professionals saying Android was the riskiest increased and was by far the most frequent platform indicated (64%). Moreover, Apple/IOS followed Android (16%) Windows Mobile (16%), and Blackberry (4%). Perception of Android security problems continued to grow theatrically as the platform was perceived to have the greatest security risk (up from 49% in 2013 and 30% in 2012). Mobile platform security is an increasingly important area of research as more people rely on their mobile devices for their day-to-day activities. As the number of mobile device users continues to grow, so does the potential for malicious attacks. Mobile platforms are especially vulnerable to attack due to their portability, the small form factor, the multiple applications and services, and the lack of security measures in place. There are a number of challenges associated with securing mobile platforms, including the complexity of hardware and software, the diversity of devices, and the potential for data leakage. This study seeks to understand the current state of mobile platform security and to identify potential avenues for improvement. It will examine the various threats to mobile devices, the security measures currently in place, and the effectiveness of those measures. The study will also look at the challenges associated with developing and deploying secure mobile applications and will identify best practices for ensuring the security of mobile platforms.

IV. LITERATURE SURVEY

“Becher, M., Freiling, F., Hoffmann, J., Holz, T., Uellenbeck, S.and Wolf, C. (2011) Mobile Security Catching Up? Revealingthe Nutsand Boltsofthe Security of Mobile Devices. 2011 IEEE Symposium on Security and Privacy.P 96-111”, describes the one may argue that the year 2000 marked the start of the smartphone era. Since then, other additional "smart" devices have entered the market, including BlackBerries, iPhones, and most recently, Androidbased phones. The risk of mobile attacks would increase significantly by the end of 2007, according to research on smartphone security and the potential for malicious software. These include a decrease in operating system heterogeneity, increased smartphone adoption, and increased interoperability of executables on mobile devices. The anticipated abundance of attackers has not yet materialized. “Bhattacharya, P., Yang,L,Guo M, Qian K, and Yang M.(2014), Learning Mobile Security with Lab ware, IEEE Security & Privacy”, describes Security is therefore seen as a crucial component of wireless communication technologies, notably in wireless ad hoc networks and mobile operating systems. Additionally, as the number of mobile applications grows across a range of platforms, security is seen as one of the most important and significant topics of discussion in terms of problems, trustees, dependability, and accuracy. This article intends to give a comprehensive report on thriving security on mobile application platforms and to inform users and businesses about critical dangers. Additionally, this article will show several strategies and methods for security measurements, analysis, and prioritizing at the pinnacle of mobile platforms. Additionally, to avoid detection, forensics, and countermeasures used by the government, raises understanding and awareness of security on mobile application platforms. “Braun, P., and Rossak, W. (2005) Mobile agents. Basic”, describes a few potential uses for social mobile applications are the creation of communities or groups around common interests or objectives, the sharing of information like personal profiles, news, exclusive deals, or any kind of recommendations, and the preselecting of potential social network communication partners. We offer strategies for information representation using semantically

rich languages based on existing standards and outline the decentralized peer-to-peer architecture. We explain how mobile agents are made possible in mobile ad hoc networks to serve as user representatives and intelligent information carriers, and we offer the first version of a social mobile application. “Burkle, A., Hertel, A., Müller, W. and Wieser, M. (2008)”,describesthat we propose an agent-based middleware that has been created as a component of an ongoing linkage project for social-mobile applications. The idea of the MobiSoft project is to use electronic personal assistants in face-to-face interactions to facilitate, enhance, and promote human social interaction. A few potential uses for social mobile applications are the creation of communities or groups around common interests or objectives, the sharing of information like personal profiles, news, exclusive deals, or any kind of recommendations, and the preselecting of potential social network communication partners. We offer strategies for information representation using semantically rich languages based on existing standards and outline the decentralized peer-to-peer architecture. We explain the advantages of using mobile agents as user representatives and intelligent information carriers in mobile. “G. Delac, M. Sillic, and J. krolo Emerging security threats for mobile platform ’,in proceeding of the 34th international convention MPRO, pp.1468-1473, IEEE, Opatija, Croatia, May 2011”describes the It's important to remember that while mobile security risks and best practices are rather universal, security policy administration is largely local and, as a result, is tailored to particular business scenarios and application settings [105]. Therefore, at the outset of our research, we made the assumption that we would only be able to identify and examine general knowledge that is relevant to the study's issue. As a result, explicit knowledge signifies an awareness of the generative processes that make up the field of mobile security. “D. He, S. Chan, and M. Guizani, “Mobile application security: malware threats and defenses,” IEEE Wireless Communications, vol. 22, no. 1, pp. 138–144, 2015”, describes the, however, there are several drawbacks to this study, as well as some potential areas for future research and improvement. First, including more factual data and experimental outcomes would make the findings more convincing. Second, through an open dialogue with specialists in the field of mobile security, cognitive biases, such as the individual view of the research problem, should be reduced. Third, we ignored sparse topics and individual case studies in favor of retrieving general artifacts, which reduced the analysis's granularity.

V. CONCLUSION

The introduction and examination of numerous mobile device and mobile application security challenges by presenting a wider range of mobile threat tactics concludes. In comparison to PCs, the main dangers and hazards that confronted smartphones have been underlined. In addition, future risks to data security and communication will be harder to handle because hackers are constantly seeking new ways to compromise smart device platforms, according to studies from the literature. This can be accomplished through additional security measures, access point manufacturers, and application programming interfaces, or APIs. Mobile applications are a result.Simplify how applications can be utilized for business, social networking, commerce, travel, education, banking, and network utility while addressing every part of our lives. Additionally, one of the potential and difficult tasks that must be taken into account throughout the planning stages is security. More importantly, developers need to think about how secure their applications are on several widely used platforms, like IOS and Android. It is clear that there are an increasing number of mobile end consumers that download programmers. As a result, when an application is signed, better security measures should be implemented. In conclusion, more user education regarding mobile safety has been determined to be essential for reducing the number of data losses, attacks, and threats.

Survey Paper on Detection & Analysis of Alzheimer's Disease

Deepali Joshi, Harshali Patil Computer Department
TCET
Mumbai, India

Abstract:-**Alzheimer's disease (AD) is brain related disorder and should be detected at early stage to reduce further complications. The diagnosis of Alzheimer's disease (AD) is essential for treating the patients and should be done at earliest stage to reduce future risks as there can be occurrence of irreversible brain damage. The methods used for detection of AD is Magnetic resonance imaging (MRI), Positron Emission Tomography (PET), computed tomography (CT). Out of the mentioned methods Magnetic resonance imaging (MRI) provides critical insights. Along with MRI for detection convolutional neural networks can be used. Categorization is done in various stages such as mild cognitive impairment (MCI), normal control (NC), Alzeimers Diesease (AD).**

Keywords: Alzheimer's disease, Convolutional neural networks, detection, diagnosis, prediction, Magnetic Resonance Imaging.

I. INTRODUCTION

Alzheimer's disease (AD) is a neurodegenerative illness, an disease related to brain. This disease gradually affects the memory of an individual and leads to various issues that creates hurdles in day to day life activities. The difficulties faced by patients are they are unable to perform the daily routine work such as walking, speaking, writing and also face serious problems such as identifying the persons, family members. At the early stage of AD the cognitive skills starts to decline. Various symptoms[2] are observed during the AD period and they change over a period. The symptoms cause the nerve cells to be frequently damaged. There are various stages of AD such as mild cognitive impairment (MCI), normal control (NC) and AD . One of the stage is mild cognitive impairment (MCI) and is the intermediate stage of AD where people can do daily routine task independently but in some cases, assistance is required to manage daily routines of life. Recent studies show that the MCI stage lies between normal control (NC) and AD. If more symptoms are observed in that stage then it is called a late mild cognitive impairment (LMCI) or
progressive MCI, if symptoms remain stable then it is called stable mild cognitive impairment (sMCI). It is very essential to observe the stages and the transition between them. The doctors have to be cautious about a situation when symptoms converted from one stage to another. It is very difficult for researchers to determine the transformation of the accurate symptom from one stage to another. Different types of medical images play an important role in identification and to find the transformation of symptoms. Various scanning mechanisms can be considered such as Positron Emission Tomography (PET), Magnetic Resonance Imaging (MRI) and computed tomography (CT). MRI is one of the most used imaging modalities to diagnose various diseases. It helps to detect the diseases at early stage and are highly sensitive. The MRI images are prominently used as compare to other modalities for AD classification. In classification various features are extracted from MRI images which are used for prediction or diagnosis. The features are gray and white matter intensities[1], cortical thickness, and cerebral spinal fluid (CSF) used for predicting the stage at which the disease is.

In AD classification problems, traditional machine learning-based approaches produce better results in terms of classification. In machine learning, the support vector machine is famous that is commonly used in several studies. However, machine learning-based approaches require highly trained labor to process the data samples. Furthermore, different modalities, especially MRI and PET

images produced different regions belonging to AD.

In recent research studies, deep learning, convolutional neural networks (CNN) achieves competitive results in pattern recognition and classification. The neural network-based approaches are utilized in computer vision, video classification, medical image analysis. It is a type of artificial neural network inspired by the hierarchical model of the visual cortex. The CNNs is a multilayered structure which includes convolutional layers, pooling layers, activation functions and fully connected layers. In case of classification problem several intermediate layers extract the low-level features and then are used to build high-level features. It is a hierarchical structure that increases the depth, breadth of the network. The CNN's key block is the convolutional layer, which has more importance in extracting the input data feature. During training, it uses learnable filters that will extract the small part of the images.

II. BRAIN ANATOMY

The brain is protected by a bone structure that is covering it called as the cranium and popularly known as skull. The cranium will protect the brain from damage or injury. Between the skull and brain is the meninges, which consist of three layers of tissue that cover and protect the brain and spinal cord. The brain is a complex organ that is responsible for controling thoughts, memorys, emotions, touch, motor skills, vision, breathing, temperature, hunger and other processes. It is made up of more than 100 billion nerves that communicate. The brain consists of 3 main structural divisions: the cerebrum, the brainstem, and the cerebellum. The brain is divided in three basic units: the forebrain, the midbrain, and the hindbrain. The hindbrain includes the upper part of the spinal cord, the brain stem, and a wrinkled ball of tissue called the cerebellum. The hindbrain is responsible for controling the body's vital functions such as respiration, heart rate.

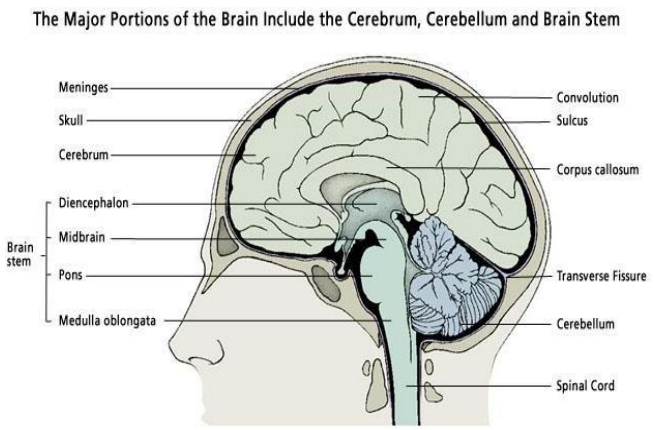

Fig 1: Portions of Brain

The brain consists of Gray and white matter are two different regions of the central nervous system. In the brain, gray matter refers to the darker, outer portion, while white matter describes the lighter, inner section underneath. In the spinal cord, this order is reversed: The white matter is on the outside, and the gray matter sits within.

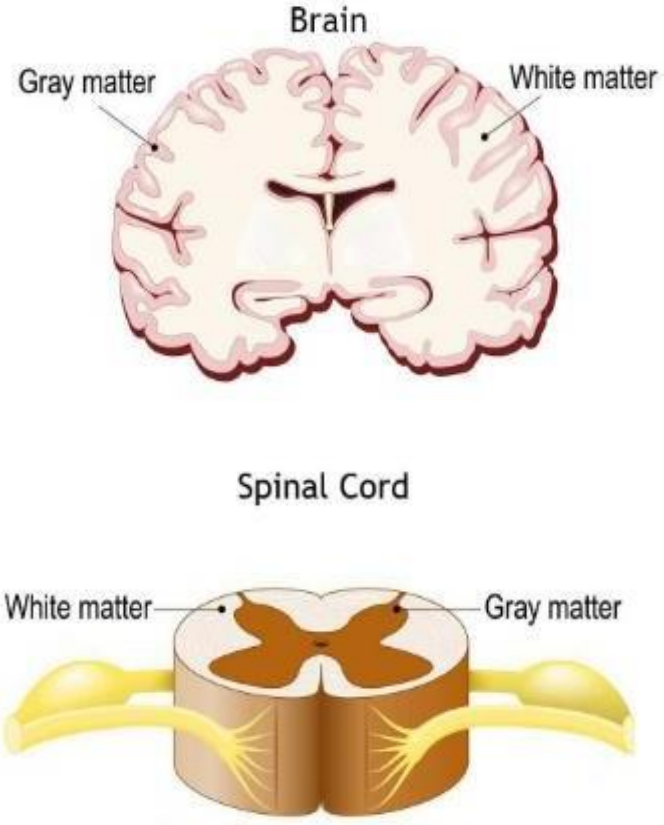

Fig 2: Portions of Brain

III. CONVOLUTIONAL NEURAL NETWORKS

A Convolutional Neural Network (CNN) is basically used for image classification and recognition. It is made up of multiple layers such as Convolutional layers, Pooling layers, fully connected layers. The layer called as Convolutional layer will apply filter to the input image in order to extract features, the Pooling layer will downsample the image to reduce computation, and the fully connected layer will make the final prediction. The network will learn to the optimal filter through backpropagation and gradient descent methods.

The Artificial Neural Network algorithm performs really well. They are are used in various classification tasks such as image, audio, words. Neural Networks are used for various purposes, examples are for predicting the sequence of words the Recurrent Neural Networks more precisely an LSTM, similarly for image classification Convolution Neural networks can be used. The Neural Network is made up of three types of layers:

1. ***Input Layers:*** The input to the model is provided by this layer. The number of neurons in this layer are equal to the total number of features in the data.

2. ***Hidden Layer:*** The output from the Input layer is then feed to hidden layer. There can be many hidden layers depending upon the model and data size. Each hidden layer can have different numbers of neurons which are generally greater than the number of features. The output from each layer is computed by matrix multiplication of output of the previous layer with learnable weights of that layer and then by the addition of learnable biases followed by activation function which makes the network nonlinear.

3. ***Output Layer:*** The output from hidden layer is given as input to logistic function like sigmoid or softmax which will convert the output of each class into the probability score of each class.

The data is then fed into the model and output from each layer is obtained this step is called feedforward, after this the error is calculated using error function. Few of the common error functions are cross-entropy, square loss error, etc. After this, we backpropagate into the model by calculating the derivatives. This step is known as Backpropagation which basically is used to minimize the loss.

IV. DISCUSSION & ANALYSIS

Researchers have used machine learning and deep learning-based techniques to diagnose AD at an early stage. Researchers have developed systems that will help for diagnosis of AD. The approaches are more helpful in computer vision, image classification, and artificial intelligence systems. In deep learning, CNN-based techniques can manipulate the input data samples where manual experts for the feature extraction is not required. The authors have proposed systems based on CNN-1 and CNN-2. The parameters considered are accuracy, sensitivity and specificity. For diagnosis of AD, the neuroimaging plays an important role in for the early detection. The important one is the MRI. There are various stages for detection such as mild cognitive impairment (MCI), normal control (NC) and Alzheimer's Disease (AD). For the research work, author has classified the NC,MCI and AD patients with two approaches based on CNN. In both the approaches, author used the GM images extracted after the segmentation of MRI subjects. After completing the experimental process, the proposed models average performance on NC vs. AD is 95.33% and 89.87%, which showed the efficiency of CNN-1 and CNN-2 models.

V. CONCLUSION

The brain is one of the part of the body and is the essential one since it helps to control thoughts, memory, emotions, touch, motor skills, vision, breathing, temperature, hunger etc. Just like other body parts may suffer from problems or diseases in the same way the brain can face problems and may get affected by disease. Early detection of brain issues is crucial because at later stages many complications can be developed. Therefore it is essential to detect the disease at early stage. Alzheimer's disease (AD) is an illness that is related to brain. Due to this disease the memory of an individual is affected and creates various issues that creates problems to carry out day to day life activities such as the patients are unable to perform the daily routine work.

Neuroimaging is very essential technique to detect the onset of the Alzheimer's disease (AD). Neuroimaging basically produces images of brain structure, brain activity, nervous system. Various techniques are available such as MRI, PET Scan, CT Scan. Once the Alzheimer's disease (AD) is detected at early stage it becomes easy to start with treatment. Convolutional Neural Network (CNN) can be used along with Neuroimaging for detection of Alzheimer's disease (AD).

Smart Cards: The Future Technology

Khushi Chitaliya ,Mrs Swati Mude
Artificial Intelligence and Data Science Thakur College of Engineering and Technology
Mumbai, India
tcet@thakureducation.org, khush3502@gmail.com

***Abstract*— Smart Cards are one of the rearmost operations of Information Technology. This composition covers all information about it as history, origin, advantages, disadvantages, and forthcoming trends in smart card technology. The government wanted to replace everything which we carry in the portmanteau will be replaced by a smart card. As smart cards and other chip-grounded cards advanced, people set up new ways to use them, including charge cards for credit purchases. numerous diligence has enforced the power of smart cards into their products similar to GSM digital cellular phones to television- satellite decoders.**

Keywords— GSM digital cellular phones (*keywords****)***

I. INTRODUCTION

A Smart card, chip chard, or integrated circuit card(ICC), is any portmanteau-sized card with bedded intertwined circuits which can reuse data. This implies that it can admit input that is reused by way of the ICC operation and delivered as an affair. A smart card, a type of chip card, is a plastic card bedded with a computer chip that stores and transacts data between druggies. The smart card may be effective with reference to attendance but it can also be applied in the same expressway in other seminaries other colorful places can also be acquainted and improve there-existing norms. New functions may carry utilizing smart cards to pierce indoor facilities, parking parcels, and cafeterias. By introducing this system, we can ameliorate the security levels of parking parcels, easier to identify the person who, for illustration, bloodied the futsal court by penetrating the entry history of the smart card, and scholars may now store plutocrat in smart card precisely like the Touch N ' Go card for cafeteria operation and mostly improves the luxury of smart card druggies [2] As experimenters and manufacturers struggle to develop and distribute products in step with the rearmost technological advances, confusion over the language of new bias arises. For purposes of discussion, this document will use the following description of a smart card a credit-card-sized device containing one or further intertwined circuit chips, which perform the functions of a microprocessor, memory, and an input/ affair interface. The bias which aren't of standard credit card size(i.e., plastic keys and dog tags, or cards that are thicker than the standard credit card), but which else conforms to this description, will be appertained to in this document as" smart commemoratives."[1]

II. LITERATURE REVIEW

Now if we talk about the history of mileposts in the development of smart card technology.1970 —Dr. Kunitaka Arimura of Japan filed the first and only patent on the smart card conception. These are times were further invention takes place for smart cards Roland Moreno patented the memory card in 1974. By 1977, three commercial manufacturers Bull CP8, SGS Thomson, and Schlumberger, started developing smart card products. In March 1979, Michel Hugon from Bull CP8 was the first to design and develop a microprocessor-grounded card combining a processor and original memory. He constructed the motorized smart card.1979 early developments for the banking sector.1995 first public eID card(Finland ID).1999 first smart cards for transport.2001 the department of defense first issued military cac credentials for physical access control and secured logical authentication.2003Micro-SIM launched 2005 first ICAO- biddable electronic passport(Norway passport) 2012 Nano- SIM introduced 2018 first biometric contactless payment card, eSIM, launched(consistency is< 1 mm or0.039 in) 2019 First 5G SIM available.

III. SMART CARD ARCHITECTURE

The architecture of a smart card included three elementsLike the following elements are

- I/O SYSTEM:
- CPU or Central Processing Unit
- Memory

Smart cards must have certain units to perform I/O functions. Normally, a smart card has some logic circuit that, in conjunction with the microprocessor, controls the timing and flow of data transferred into and out of the smart card's memories. To exchange data smart card must have a physical structure through which it can interface with a reader/writer device to connect to other computers. There is generally two types of physical interface takes place for smart cards

1- contact type

2- non-contact type(contactless)

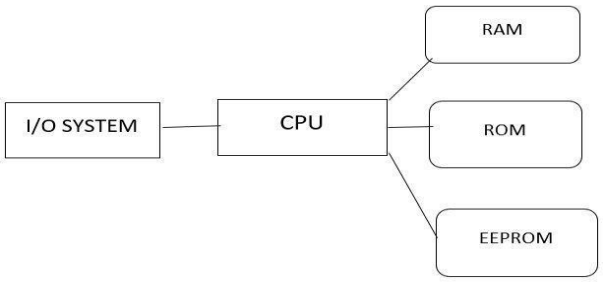

Fig no-01 Architecture

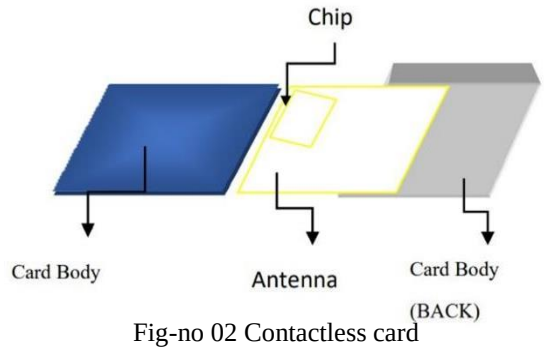

Fig-no 02 Contactless card

The discrepancy, a smart card with an anon-contact type interface can transmit information to and admit information from an anthology/ pen device without a physical connection. anon-contact type interface may be enforced using capacitive plates placed inside or on the face of the card. When placed within a short distance from an anthology/ pen device containing corresponding capacitive plates, information can be changed. With the anon-contact interface, problems similar to electrostatic discharge and impurity of physical connections(dirt, grease, etc.) may be avoided. (RSKI 87,p. 16) still, a smart card with a non-contact interface may bear fresh factors which may increase the card's vulnerability to internal breakage. ISO isn't presently working on homogenizing any non-contact ICC interfaces.[1]

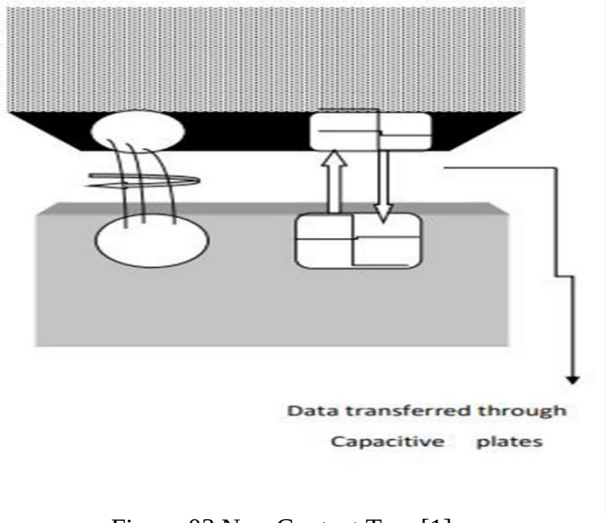

Fig no-03 Non-Contact Type[1]

A contact smart card must be fitted into a smart card anthology with a direct connection to a conductive contact plate on the face of the card(generally gold-plated). Transmission of commands, data, and card status takes place over these physical contact points, this interface consists of an 8- contact connector, which looks like a small gold circle or series of places on the shells of the card. Memory for storing the data & nearly all the recollections presently used in smart-card microcomputers are manufactured from the semiconductors accouterments. Semiconductor recollections correspond of matrices of cells formed by transistors to store information. By varying the composition and cell configurations of semiconductor accoutrements, recollections with different characteristics can be produced.

Four types of semiconductor memory used in smart cards are bandied below. Random Access Memory(RAM)-Smart card RAM is generally manufactured from essence oxide-semiconductor silicon. RAM is nonpersistent memory, it's used as a temporary working space for storing and modifying data. Smart card RAM is generally unpredictable in nature(That, it'll lose its stored information incontinently if power to the memory is removed). RAM, the fastest type of memory, is frequently used as a " scrape pad ", buffer, or another type of temporary storehouse. Smart card ROM is a semiconductor memory that is non-volatile (i.e., its stored information is retained indefinitely without a nonstop power force to the memory), it's used for storing the fixed program of the card(.eg., operating system, endless data). Erasable Programmable Read-only memory(EPROM)-Smart card EPROM is a Non-unpredictable semiconductor memory that can be originally programmed at the stoner's installation rather than at the ROM manufacturer's factory. Data and programs can be loaded into the smart card EPROM via a smart card anthology/ pen device; the transfer of the information is controlled by the smart card's microprocessor. When it's used in other types of computers, EPROM can be canceled (by exposure to ultraviolet light) and reprogrammed. EPROM may be used in other types of computers, EPROM can be canceled (by exposure to ultraviolet light) and reprogrammed. EPROM may be used in a smart card to permanently store an inspection trail, and a complete history of the operation of the card. Then in EPROM only we can tack the data not to cancel the data from smart card EPROM, it may ultimately come full, and therefore, the smart card will expire ". Electrically Erasable Programmable Read ONLY Memory(EEPROM)-Smart card EEPROM is anon-volatile semiconductor memory that can be electrically canceled and reprogrammed via an anthology/ pen device at the stoner's installation. We can save data content when power is turned off. Reading from EEPROM is as fast as reading from RAM, but writing to EEPROM is 1000 times slower than writing to RAM. Reliably accept at least 100000 write cycles, and retain data 10 times. Then's a selection of parameters from some of the smart cards on the request moment. Smart cards like these are programmed is assembly language and don't important in the way of coffers. To keep down costs, they don't get resources.[3]

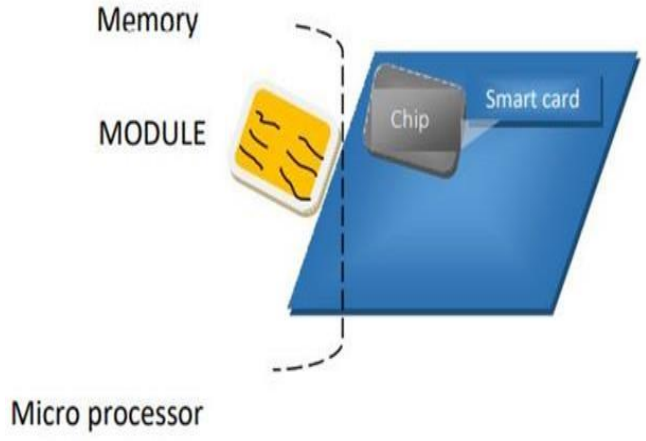

Fig no-04 Contact type [3]

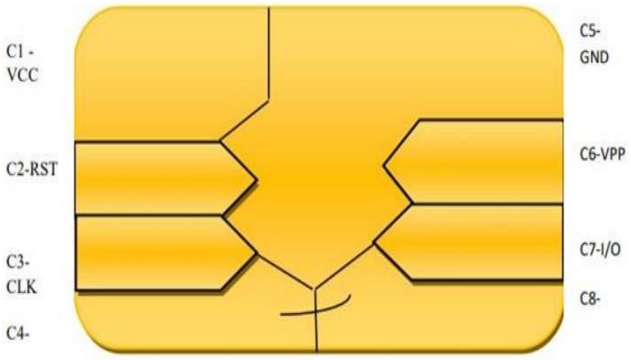

Fig no -05 Pinout micro module[3]

Smart card	Word size	ROM	EEPROM	RAM	VOLTAGE	CLK	Writer/erase cycle	Transmission Rate
InfineonSLE44C10S	8-bit	9k	1K	256GB	2.7-5.5V	5MHZ	500000	9600BAUD
Orga ICC4	8-bit	6K	3K	128B	4.7-5.3V		10000	
Gem Combi	8-bit		1K		4.5-5.5V	13.6MHZ	100000	106kbaud
DNP Resonant	8-bit		1K		5V	13.6MHZ		9600baud
Ama Tech Contactless	8-bit		1K		5V	13.6MHZ	100000

Table -01 Selection Parameter for smart card[1]

IV. CENTRAL PROCESSING UNIT

The CPU or the microprocessor is the unit component that distinguishes the smart cards from other cards which are designed to simply store data. The microprocessor in association with the operating system enables the smart card to "make its own decision " concerning where the data is stored in its memories and under what circumstances it should transfer information through its input/output interface. The microprocessor consists of three majors components:

- Arithmetic logic unit: The ALU provides the basic logic and arithmetic functions for the microcomputer.
- Control unit: The control unit assures that the timing of events in the various parts of the bus provides a link between the smart card and the computer.

Bus: The configurations for the bus, which may be comprised of several segments of the microcomputer are coordinated.

V. SMART CARD AND IDENTITY MANAGEMENT

A Smart card can be used to securely hold user information, and to provide two-factor or three factor authentication. Smart card technology enables distributed and federated applications in lieu of a central database of all user identity and other personal information. The use of smart cards and federated data with standard based protocols would allow academic institutions, medical practitioners, the police , telecommunication and other government agencies to have access to data across multiple data stores with an assurance that: The smart card user identity is authenticated ;

The records of the user retrieved will be analysed for approval if it matches with the data in the chip or rejected if there is mismatch. Only the agencies registered under the government and have need of the data have access to the central data base.[1]

In the case of user data access, proper security controls and restrictions must also be implemented around the application, database, and environments that house the electronic data. Smart cards can be effective in supporting numerous organizational programs in the country such as SIM card registration, voters card registration, healthcare applications and many more , with or without a unique identifier[1]

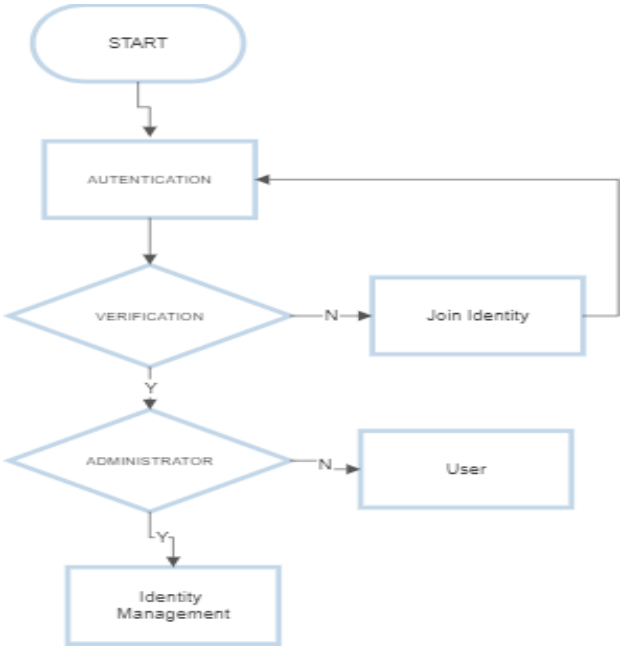

Fig no -06 Identity authentication for smart card[4]

VI. SMART CARD HELP TO PROTECT THE PRIVACY

Smart cards offer a number of features that can be used to give or enhance sequestration protection in the system. Smart cards give mechanisms for authenticating others who want to gain access to the card. These features can be employed by a system to cover sequestration by, for illustration, icing that a banking operation has been authenticated as having the applicable access rights before penetrating fiscal data serve on the card.

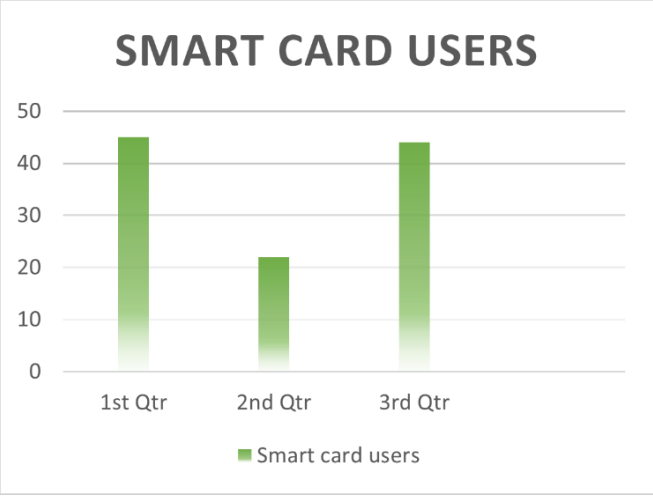
Secure data storehouse. Smart cards give a means of securely storing data on the card. This data can only be penetrated through the smart card operating system by those with proper access rights. This point can be employed by a system to enhance sequestration by, for illustration, storing particular stoner data on the card rather than in a central database. Smart cards give a robust set of encryption capabilities including crucial generation, secure crucial storehouse, mincing, and digital signing. This protects the

dispatch communication from latterly being tampered with and provides the dispatch philanthropist with an assurance of where it began. The fact that the signing key began from a smart card adds credibility to the origin and intent of the signer. Secure dispatches. Smart cards give a means of secure dispatches between the card and card compendiums. analogous in conception to security protocols used in numerous networks, this point allows smart cards to shoot and admit data in a secure and private manner. This capability can be used by a system to enhance sequestration by icing that data transferred to and from the card isn't interdicted or tapped into. [1]

Biometrics. Smart cards give mechanisms to securely store biometric templates and perform biometric matching functions. For illustration, storing point templates on a smart card rather than in a central database can be an effective way of adding sequestration in a single sign-on system that uses point biometrics as the single sign-on credentials. .particular device. [2]

Personal device A smart card is, of course, a particular movable device associated with a particular cardholder. The smart card plastic is frequently substantiated, furnishing an indeed stronger list to the cardholder. For illustration, a healthcare operation might handpick to store medicine radiation information on the card rather than in paper form to ameliorate the delicacy and sequestration of a case's conventions., and instruments. numerous of moment's smart cards have been certified they misbehave with assiduity and government security norms. They gain these instruments only after completing rigorous testing and evaluation criteria by independent instrument installations. These instruments help systems cover sequestration by icing that the security and sequestration features and functions of the smart card tackle and software operate as specified and intended.[1]

VII. CONSUMERS PRIMED TO USE SMART CARD



45 percent of consumers are favorably disposed to using smart cards

25 percent of households would actually obtain these smart cards

44 percent of consumers are likely to use identification-type smart cards (telephone cards, gas cards, automated teller machine [ATM] cards, etc.)[5]

Attribute	Details
Report coverage	Revenue forecast, company ranking, competitive landscape, growth factors, and trends
Actual estimates/Historical data	2014 - 2015
Forecast period	2016-2025
Country scope	U.S., Canada, U.K., Germany, Russia, India, Japan, China, Brazil, and Mexico
Market representation	Revenue in USD Million & CAGR from 2016 to 2025

Table no-02 Survey on Smart card[4][5]

VIII. APPLICATION

A smart card is in use in daily life applications are discussed below:

The most commonly used smart cards for domestic purposes are DTH cards. These cards provide authorized access to information received from satellites. The information received by these cards gets encrypted and decrypted within it.

Government purpose:

The government of India issues identity cards to all citizens. An example of such cards is " AADHAR cards", or "Pan cards" provided to all citizens.

Health care purpose:

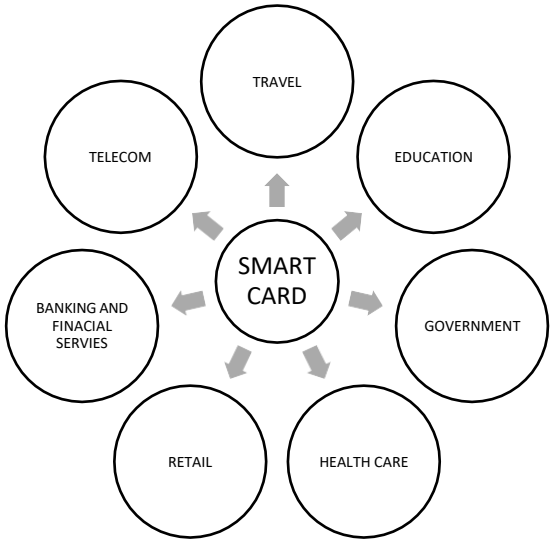
The advent of smart cards in health care sectors has allowed hospitals to securely store patients' medical reports safely and reliably. It helps authorities to access information quickly, can update if required, and immediate insurance processing, and refund.

Financial Transactions:

Smart cards are very handy as a tool for financial transactions both in traditional and web-based applications. A cash value can be stored in smart cards to use it as credit cards. Its potential to support both consumers and businesses against lower rates of transactions widens its applicability in marketing targeted programs in financial services.

Telecom sector :

Providing secure cellular communication is assisted by smart cards. New apps and functions are providing real-time download capabilities by smart cards. A SIM card is given by cellular operators to their subscribers and its use of multimedia



IX. CONCLUSION

Smart cards can add convenience and safety to any traction of value and data; In this paper, we also discussed the background and the architecture of the smart card. Now if we talk about the future aspects of data in the smart card by the use of biometrics. Smart card readers can be built into future computers on peripherals which will enable the users to pay for goods purchased on the internet. The smart card is not only a data store but also programmable, and portable tamper resistant.

X. ACKNOWLEDGMENT

I am humbled to acknowledge the priceless guidance offered by Mrs Swati Mude(Assistant Professor) Thakur College of Engineering and Technology for this research paper.

Abstract—**The rapid development of the internet has enabled job recruitment websites to become a popular means of connecting employers and job seekers. Online job recruitment websites have been developed to facilitate the hiring process and reduce the costs associated with traditional offline recruitment methods. This paper explores the current state of online job recruitment websites and their impact on the recruitment process. The literature review examines the advantages of online job recruitment websites, such as increased reach and efficiency, and their limitations, such as privacy concerns and the difficulty of verifying job postings. The paper then presents an overview of the types of job recruitment websites and the features they provide. Finally, the paper discusses the future of online job recruitment websites and their potential to revolutionize the recruitment process.**

This project is aimed at developing a web-based and central recruitment Process system for the HR Group for a company. Some features of this system will be creating vacancies, storing application data, and Interview process initiation, scheduling interviews, storing Interview results for the applicant and finally Hiring of the applicant. Reports may be required to be generated for the use of the HR group. This project 'Job Board App' is an online website in which jobseekers can register themselves and then attend the exam. Based on the outcome of the exam the jobseekers will be short listed. For freshers, the exam will be conducted at some venue after a short listing of the preliminary Aptitude Test. The details of the examination, venue & Date of the examination will be made available to them through the website.

Keywords—Ai recruiter, Jobseekers, Administrator, Company, Preliminary aptitude test.

I. INTRODUCTION

The internet has revolutionized the way we find and apply for jobs. Online job recruitment websites have become an important tool for employers and job seekers in the 21st century. Online job recruitment websites provide employers with an efficient and cost-effective way to find qualified job applicants and for job seekers to find suitable job

opportunities. This paper explores the current state of online job recruitment websites, their advantages and disadvantages, and their potential for revolutionizing the recruitment process.This project Job Board App is an online website in which jobseekers can register themselves online and apply for jobs and attend the exam. Job Board App provides online help to the users all over the world. Using web recruitment systems like recruitment websites or job sites

also play a role in simplifying the recruitment process.

Such websites have facilities where prospective candidates can upload their CV and apply for jobs suited to them. Such sites also make it possible for recruiters and companies to post their staffing requirements and view profiles of interested candidates. Earlier recruitment was done manually, and it was all at a time-consuming work. Now it is all possible in a fraction of second. It is all done online without much time consuming.[1]

.

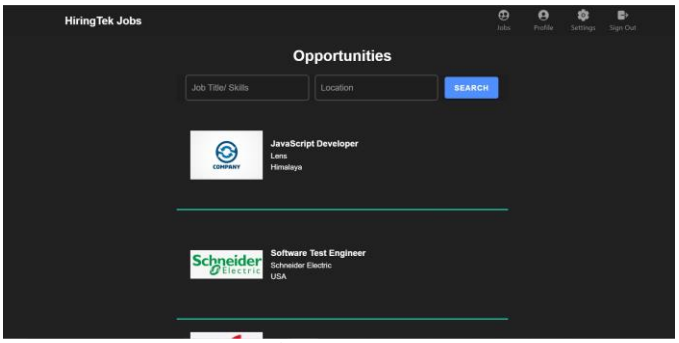

Fig 1: Overview of Job board Application

Job Board App enables the users to have the typical examination facilities and features at their disposal. It resolves typical issues of manual examination processes and activities into a controlled and closely monitored workflow in the architecture of the application.

This multi-platform solution brings in by default, the basic intelligence, and immense possibilities for further extension of the application as required by the user. The system makes it friendly to distribute, share and manage the examination entities with higher efficiency and easiness.Using web recruitment systems like recruitment websites or job sites also play a role in simplifying the recruitment process. Such websites have facilities where prospective candidates can upload their CV and apply for jobs suited to them.

A quick look at the overall trends in Online recruiting shows the rise in the importance of marketing the web site, online training, dawn of video interviews and emergence of professional Internet Recruiters. Online recruiting and online recruiting systems,[2]

II. LITERATURE SURVEY

System Analysis is the detailed study of the various operations performed by the system and their relationships within and outside the system. Analysis is the process of breaking something into its parts so that the whole may be understood. System analysis is concerned with becoming aware of the problem, identifying the relevant and most decisional variables, analyzing, and synthesizing the various factors and determining an optional or at least a satisfactory solution. During this a problem is identified, alternate system solutions are studied, and recommendations are made about committing the resources used to the system.[3]

DESCRIPTION OF PRESENT SYSTEM

Presently recruitment is done manually. That is if a company or organization needs employees they make an announcement through the newspaper. People who are eligible send applications to the organization or company. From these applications they are called for interviews or tests. After tests the company has to do short listing manually. From these shortlisted candidates, they are called for interviews. After the interview short listed candidates are employed. So it's all a time consuming procedure.

LIMITATIONS OF PRESENT SYSTEM

Recruitment is done manually. These tasks are time consuming. It may take one month or longer. People around the world cannot apply. The Job Board App is very convenient because in the manual system there are a lot of difficulties in conducting and managing a recruitment exam, short listing, maintaining staff etc.

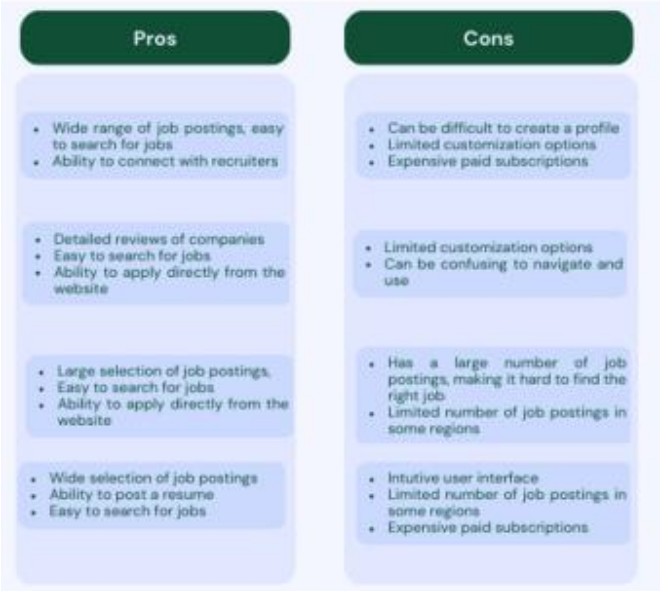
PROPOSED SYSTEM

The Job Board is aimed at developing a web-based and central recruitment Process system for the HR Group for a company. Some features of this system will be creating vacancies, storing application data, and Interview process initiation, Scheduling Interviews, Storing Interview results for the applicant and finally hiring of the applicant. This

project Job Board App is an online website in which jobseekers can register themselves and then attend the exam. Based on the outcome of the exam the jobseekers will be shortlisted. The details of the examination & Date of the examination will be made available to them through the website. People all around the world can apply and register. It has made all the process easy.[4]

ADVANTAGES

Job Board App enables the users to have the typical examination facilities and features at their disposal. It resolves typical issues of manual examination processes and activities into a controlled and closely monitored workflow in the architecture of the application.



This multi-platform solution brings in by default, the basic intelligence, and immense possibilities for further extension of the application as required by the user. The system makes it friendly to distribute, share and manage the examination entities with higher efficiency and easiness. It is a comprehensive resource for finding a job online.

III. PROBLEM STATEMENT

The role of online job recruitment websites on employers' hiring and recruitment processes is an important yet under-researched topic. This research paper will explore the potential benefits and drawbacks of online job recruitment websites for employers, as well as analyze the impact of these websites on the overall recruitment process. The paper will also examine how employers can best utilize online job recruitment websites to efficiently and effectively find suitable candidates for their open positions. Finally, the paper will provide recommendations on how employers can maximize their use of online job recruitment websites to achieve the best outcomes for their hiring and recruitment needs.

Hiring Tek provides a recruitment platform as a service and also builds a jobs board public app to list out jobs posting. Implementation Requirements:

1. Enhance the UI(user interface) to provide the facility to subscribe the notification system with different keywords and implement the backend RESTful API associated with the UI.

2. Build an RESTful API to scan the uploaded candidate profile and resume and show all the jobs which match the skills set and experience in the ranking order.
.
3. Enhance UI to provide ability to search with keywords and various predefined filters to match the jobs postings and implement the backend RESTful API associated with UI.

4. Build the automated unit and functional tests to validate the functionality to avoid the product regression and to make it stable with bug free.

5. Design the backend schema layout in the mongo DB to persist all the settings and user data.

It will be accessed from all mobile platforms and desktop devices. The requirement is to enhance the Jobs board app to include a subscription system to match the candidates' requirements and notification system. Also, require adding the search functionality, user interface and backend API to search the job posts as per user requirements.

IV. PROPOSED SYSTEM

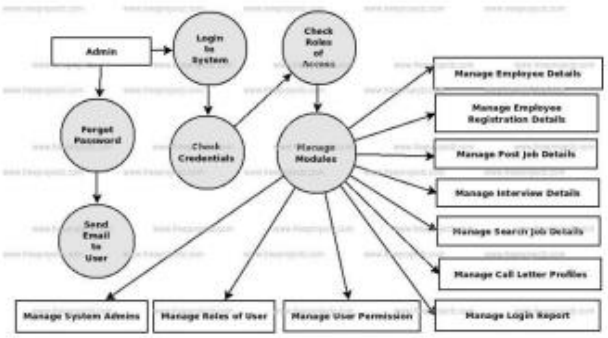


Fig 2: Architecture Diagram for the proposed model

The Architecture for the Job Board Application

E-recruiting systems have evolved through numerous technological developments since their introduction in the mid-1990s. At the early stage of corporate e-recruiting, the purpose of the career Web site was to simply post job openings on the static Web page for job seekers' information. As the e-business technologies advance and recruiters gain more e-recruiting experience, the front-end
e-recruiting systems add new features and functions, target job seekers better, and integrate with a back-end human resource management system.

An advanced e-recruiting system of large companies has been powered by an enterprise wide system and incorporated best-practice recruiting methodologies to achieve strategic advantage.[5]

While sound architecture is critical to the successful development of complex systems and seamless integration with other systems, it has not yet been well established for the holistic e-recruiting system because of its infancy. The architecture helps recruiters and system developers understand how various components of the e-recruiting system work together to achieve recruiting goals. Here, a high-level architecture of the holistic e-recruiting system for a corporate career Website is presented. Since the architecture is a roadmap to the development of the e-recruiting system that supports the recruiting process, understanding the e-recruiting process is required in order to better identify architectural components.

The architecture of the holistic e-recruiting system consists of eight distinct yet interrelated subsystems: applicant tracking management subsystem; job requisition management subsystem; job agent management subsystem; prescreening/self-assessment management subsystem; e-recruiting performance analysis subsystem; candidate relationship management subsystem; workflow management subsystem; and database management subsystem. The accompanying figure shows the relationships between e-recruiting processes and the eight components of the holistic e-recruiting system.

Applicant tracking management subsystem. Finding the right candidates for a particular job is a difficult and costly task for recruiters and hiring managers.[7] The functions of an applicant tracking management subsystem include gathering job applications, storing candidate profile resumes, checking the status of each candidate in the recruiting process, generating requested information for decision makers, and disseminating the information to other human resource management systems. The fundamental technology for applicant tracking is a Web-based search engine that scans through the applicant database based on keywords, phrases, or natural languages.

Job requisition management subsystem. The primary function of this subsystem is to streamline job requisitions and online postings. Users of the job requisition management system are recruiters and hiring managers. Job requisition and approval submissions can be processed without a manual data entry into a job database when integrated with a human resource management system. This subsystem is a single automated job posting point to

multiple recruiting sites such as an internal career Website,[6] external job boards, and industry consortia. During the recruiting process, the job requisition management subsystem allows managers to regularly monitor current job postings and close job postings as they are filled or canceled.

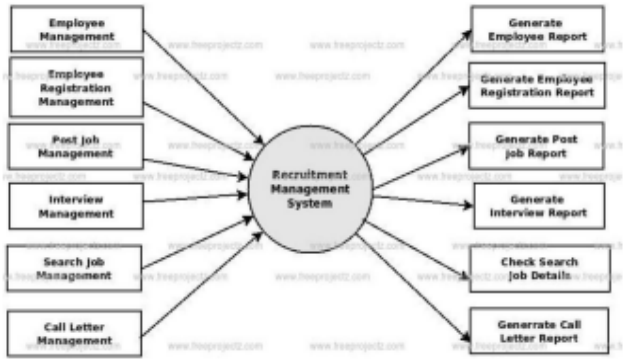

Fig 2: Workflow

Job agent management subsystem. The purpose of this subsystem is to promote information exchange between e-recruiting users and the e-recruiting system by using a personalized search agent. Creation of the personalized job agent is interactive, leading to the creation of a unique profile. For job seekers, a job agent can perform a particular search based on job search and communication parameters such as job locations, job categories, and the frequency of job search. Based on the job agent's notification, job seekers may apply for jobs online or ignore them. Recruiters specify to the personalized job agent the duration of the job postings, frequency of the candidate search, and mode of notification.

Prescreening/self-assessment management subsystem. The purpose of this subsystem is to assess the degree of match between applicants' qualifications and job requirements at the time of online job applications. To improve the overall quality of job applicants, the prescreening/self-assessment management system minimizes the submission of job applications from job seekers who do not meet basic job requirements. For certain job categories, pre screening helps recruiters sort through a pool of resumes and rank them based on a predefined scoring system. The choice of the questionnaire item is crucial to the success of this subsystem. Commonly used question items include levels of technical skills, personalities, interpersonal skills, work ethics, and aptitude. The process of the prescreening/self-assessment tests is interactive and has an option of "exit any time without completion."[8]

E-recruiting performance analysis subsystem. This subsystem analyzes the strategic, financial, and operational performances of an e-recruiting system in order to improve the overall efficiency and effectiveness of the career Web site. Table 2 summarizes major metrics

used at leading companies. Performance reports are generated based on predefined report format and real-time data. As each user has unique reporting requirements, this subsystem should provide recruiters with an easy-to-use report generator equipped with a variety of reporting options. The performance analysis subsystem should be able to alert managers of an exceptional situation when certain performance measures do not meet thresholds defined by managers.

Candidate relationship management subsystem. This subsystem provides recruiters with long-term relationship management programs and tools needed to effectively manage applicants. One of the disadvantages of the e-recruiting method is a lack of the human touch such as a face-to-face meeting or conference call. The candidate relationship management is designed to provide applicants with a feeling they have an ongoing relationship with the company through a "virtual human touch." Delivering a maximum level of virtual human touch will increase the chance of job acceptance by candidates by implicitly indicating the attractiveness of a company's job opportunities.

The rationale behind the use of a candidate relationship management subsystem is that maintaining the best pool of job applicants at all times is faster and more cost-effective than looking for new job applicants when jobs become available. Given the widespread adoption of the various e-recruiting technologies in the job market, only companies with a positive long-term relationship with job applicants will gain a competitive edge.

Workflow management subsystem. While each of the previously mentioned subsystems supports the e-recruiting process partially, the workflow management system integrates these subsystems to support the entire spectrum of e-recruiting activities.

This subsystem enables interrelated subsystems to collaborate around the e-recruiting activities and to integrate with other human resource management systems. For example, once job applicants have entered their resume and profiles in response to a job opening,

The workflow management system triggers the applicant tracking subsystem for candidate screening, and a job agent sends a list of candidates meeting the desired requirements to hiring managers for further actions. The potential value of this system is currently regarded as the driving force behind the standardization of e-recruiting processes.

Database management subsystem. The holistic e-recruiting system stores all the data on jobs and applicants at a centralized database. During the traditional batch-mode recruiting process, once recruiting is complete, paper-based applications and resumes are kept in the file cabinet for a predefined period of time and thrown away. Later, when a new job is available, another recruiting cycle begins with a new collection of job applications. E-recruiting has changed the recruiting practice from batch-mode to ongoing recruiting. Many companies encourage job seekers to submit applications and resumes online regardless of the current job availability, store the applications and resumes at the

centralized database for a considerable period of time, and evaluate a pool of job applicants stored in the database as soon as a new job is available.

III. MODEL EVALUATION AND RESULT

The last and most crucial phase comprises model evaluation and discovering really considerable results.

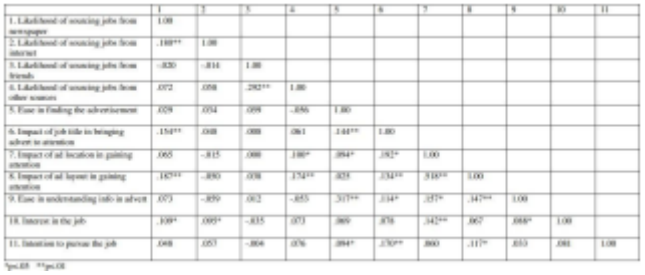

Fig 4: Intercorrelation between variables

The data obtained indicates that the number of vacancies advertised remained fairly constant. The number of applications had a significant increase in 2001, the year that electronic recruitment was introduced, from 7,071 to 12,219, increasing the average number of applications per job significantly from 17.5 to 28.62 and providing initial support for the hypothesis that the use of the internet as a recruitment source increases the number of applications received by the organization. These numbers remained high until 2004 when the numbers of applications per job decreased to similar averages that were received prior to the introduction of e-recruitment, down to 16.24 applications per job.

This decrease coincides with a change to the organization's e-recruitment strategy which ceased utilizing two major Australian
recruitment job boards

To better understand the employment trends of the organization a report was generated which placed the number of applications and jobs per year against the two key employment groups within the organization, professional staff and academic staff. The results of this report are depicted in Figure 3.
The results indicate that the increase in applications in 2001 is attributed primarily to the professional employment group, with only a gradual increase in academic applications. In contrast, the number of academic applications continued to increase after 2002,
whilst the number of applications for professional vacancies declined significantly from 11,821 in 2002 to 9,198 in 2003, with another significant decrease to 6,517 in 2004.
The number of applications received by the organization. These numbers remained high until 2004 when the numbers of applications per job decreased to similar averages that were received prior to the introduction of e-recruitment, down to 16.24 applications per job.

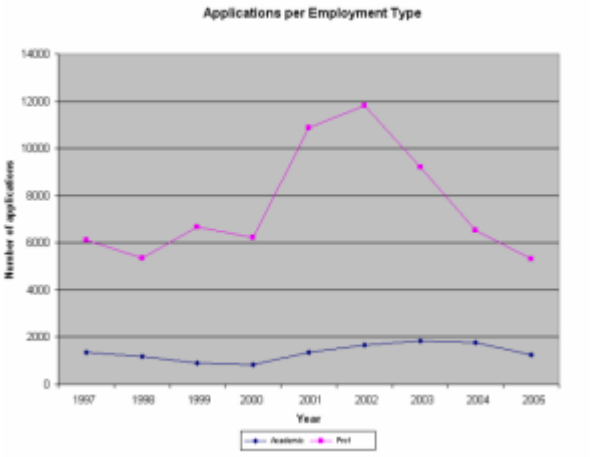

Fig 5: number of applications per year based on Employment group

Research Question 1: How does e-recruitment impact on the quality of applications
received?
Research Question One explored the quality of applications sourced through the internet as compared to the proposed overall increase in the volume of applications received for positions, demonstrated by the component of the study model below:

Fig 6: process flow of recruitment system

Fig 6: process flow of recruitment system

In order to explore the first research question, a number of reports were generated from the organization's human resource information system based on data captured by the organization.

The first report detailed the number of applications received by the organization each year and the number of applicants shortlisted each year. [10]
The data is presented in Table

	Year								
	1997	1998	1999	2000	2001	2002	2003	2004	2005
Number of applications	7,466	6,528	7,575	7,071	12,219	13,481	11,033	8,297	6,589
Number of shortlisted applicants	1,235	1,232	1,224	1,088	1,137	1,340	1,377	1,432	1,444
% of applicants shortlisted	**16.54**	**18.87**	**16.16**	**15.39**	**9.31**	**9.94**	**12.48**	**17.26**	**21.92**

Fig 7: Percentage of applicant getting placed

overall, the results from Tables demonstrate that there is no discernible increase in the quality of applicants that used the internet as a recruitment source as opposed to applicants that

use newspaper or other recruitment sources, despite the increase in the quantity of applications that are associated with the use of e-recruitment

IV. ACKNOWLEDGMENT

I gratefully acknowledge the support, guidance and encouragement of my Dissertation Guide Associate Professor Dr. Megharani Patil ma'am for this novel work.

Abstract— **Security of cloud computing is a firm hand of cyber security devoted to securing cloud computing systems. Security of cloud computing or directly cloud security touch on to a board set of policies, technologies, applications, andcontrols utilized to protect virtualized IP, data, application, services, and the associated infrastructure of security of cloudcomputing.**
.

Key Words -***Security, Cloud Computing***

I. INTRODUCTION

The security of cloud computing is a collection of technology designed to address internal and external threats. Security of cloud computing or more clearly cloud security touch on to a board set of policie , technologies , applications ,and controls make use of to protect virtualized IP , data , application , services , and The related infrastructure of cloud computing .Cloud computing Industry is growing .According to Gartner, World Wilde cloud services revenue is on pace to surpass $56.3 billion in 2009, a 21.3% increase from 2008 revenue of 46 .4 billion, according to Gartner , Inc. The market is expected to reach $150.1 billion in 2013. Business are increasing cloud adaption. We expect a great deal of migration towards cloud computing within the federal government in addition to the already robust private sector growth. The growth of the cloud should not protect the data that goes into it.

II. ARCHITECTURE

Security in cloud computing is a major concern. Proxy and brokerage servies should be employed to restrict a client from accessing the shared data directly. Data in the cloud should be stored in encrypted form.

SECURITY OF CLOUD COMPUTING

Security is protection from, or resilence against, potential harm caused by other,by restraing the freedom of others to act. Security of cloud computing is a collection of security measures designed to protect cloud-based infrastructure, application and data.

These security measures are configured to protect cloud data, support regulatory compliance and protect costomerrs privacy as well as setting authentication rules for indivial user and devices. From authencating access to filtering traffic , cloud security can be configured to the exact need of the business .and because these rules can be configured and managed in one place ,administration overheads area reduced and IT tearms emprovered to foucs on other area of the business.

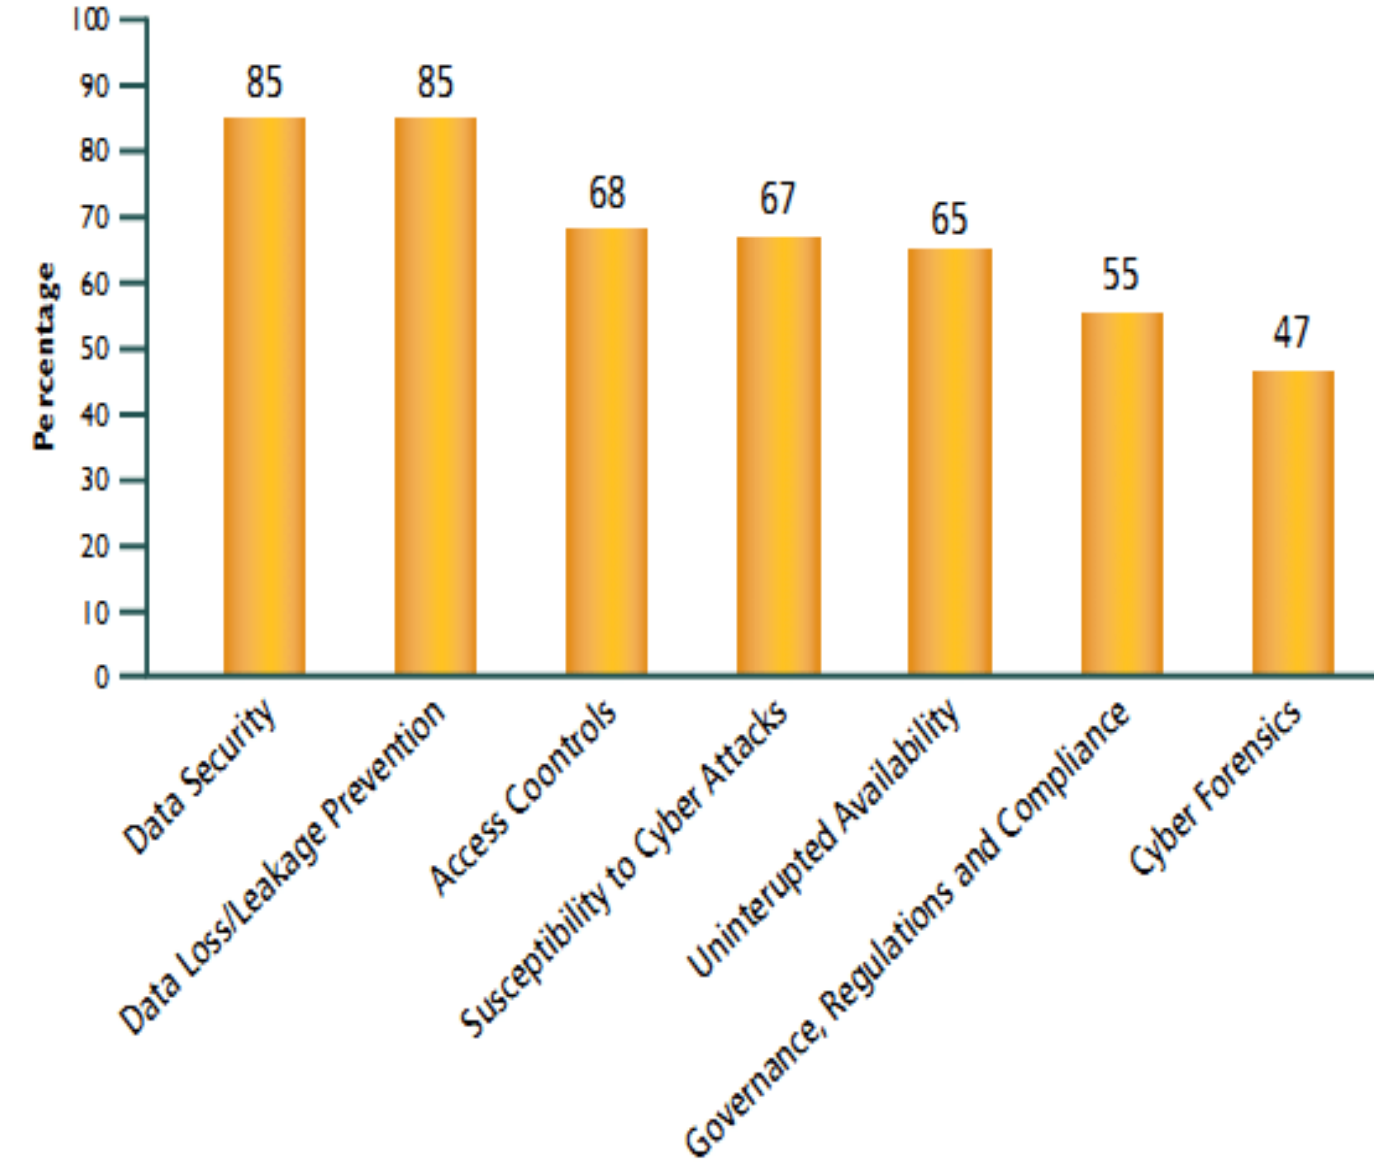

Fig1.cloud security

Cloud computing is based on five attributes: multitenancy, massive scalability, elasticity, pay as you go, and self-provisioning of resources.

Multitenancy:

Unlike previous computing models, which assumed dedicated resources (i.e., computing facilities dedicated to a single user or owner), cloud computing is based ona business model in which resources are shared (i.e., multiple users use the same resource) at the network level, host level, and application level.

Massive scalability:

Although organizations might have hundreds or thousands of systems, cloud computing provides the ability to scale to tens of thousands of systems, as well as the ability to massively scale bandwidth and storage space.

Elasticity:

Users can rapidly increase and decrease their computing resources as needed, as well as release resources for other uses when they are no longer required.

Pay as you go:

Users pay for only the resources they actually use and for only the time they require them. Self- provisioning of resources:

User self – provision resources, such as additional system (processing capability, software, storage) and network resources.

CLOUD SECURITY DESING PRINCIPLES

The security design principle are the key pillars for implementation of cloud security to project system, application and platform security architecture.

Below are the key desing principles which needs to be considered for cloud technology adoption.

1.

1) Security at all layers: Ensure robust security is applied to all layers [physical, network, data, application,etc. of their architecture with multiple security controls. This will ensure end to end protecting of application/ data hosted by departments on cloud platform.

2) Safeguard data while at rest and in transit: Identify and Classify the dada in terms of critically / sensitivity and define their levels. This can be prevented via using the available security controls like access control, tokenization, encryption, etc.

3) Monitoring and auditing: Ensure monitoring, auditing and alerting is configured to capture the changes in the department's system in real time. Further, log integration and metric collection can automatically investigate, act and respond.

4) Access management and Controls: Ensure implementation of principle of selective privileges and impose segregation of duties with appropriate access and authorization. Centralized identity and access management can eliminate any unauthorized access and information loss/ theft

5) Readiness for security events: Department/CSP need to prepare system for any unusual security event. Regular vulnerability and security tests need to be conducts to identify the security gaps and issues. Drill can be conducted to record the response of the cloud systems at different layers.

6) Automate security best e practices: Automating software/hardware/application, based security system via AI/ML/Bots to improve the ability to secure environment which can perform regular checks and implement the controls needed to restrict the attack and enhance cloud security.

7) Cloud Vendor Lock-in: Department to ensure that there is no vendor lock-in by Cloud services provider while hosting the application/data, as there is no standard guidelines between different cloud providers for data migration and exports, so it becomes difficult to migrate data from one cloud provider to another or migration to on-premise Dara centre.

BENEFITS OF SECURITY OF CLOUD COMPUTING

. High Availability – Ensuring continuity is one of the primary reasons behind businesses looking for reliable cloud security solutions. The right cloud computing security solutions. The right cloud-computing security solution should incorporate real-time support,24*7*365 live monitoring of business assets and have redundancies built-in so your website and applications remain online and functional even in the case of an attack.

With cloud service providers, such as Active Co 's cloud Services vancouver, you can rest assured that your core business assets, such as website and applications will always remain functional globally[3].

. cloud DDoS protection – Traditional network infrastructure work on the basic of origin and backup serves that can be easily disabled DDoS attacks that are capable of generating up to 20Gbps of traffic. These attacks can take anywhere from hours to mitigate during which your services may be completely or partially affected and your business sustains severe financial and reputation loss. To ensure continuity of service, you need managed hosting providers and/or content delivery networks with DDoS absorption capabilities as well as real- time scanning to identify and prevent/mitigate DDoS attacks. This is done through the CDN`s capability of making use of a global network of PoPs that can manage spikes in legitimate traffic and divert synthetic spikes from a attack on the network. This enables CDN`s to both bring downtime down to zero as well as enables security controls that feel intuitive.

Flexibility- the right cloud computing solution for your business ensures irrespective of capacity. whether you`re experiencing a surge in legitimate traffic or in the case of an attack, the solution should be able to provide you enough flexibility to avoid server crashes and avoid unnecessary costs during lean hours through up or downscaling.

Data Security- Ensuring the privacy and security of your business` sensitive information and transactions is a top priority for your cloud computing security solutions. It should be able to prevent third parties for eavesdropping or tampering with your data through the right security protocols, such as, transport layer security [TLS]- the replacement to secure sockets layer [SSL] Ecommerce sites are particularly vulnerable to data breaches and should take care to implement a CDN with PCI compliance and other relevant digital rights management layers.

Regulatory compliance- Ecommerce businesses and financial institutions also face a greater degree of both industrial and governmental compliance and regulations checks. With the right CDN, you will be able to build a highly compliant

infrastructure that is capable of always protecting your consumers` data.

. Round The Clock Support- cloud Services Vancouver Have a host of companies offering cloud security solutions. The right cloud security solutions for your business, however, should be able to render downtimes to near zeros. It should be able to provide you with effective and time-sensitive customer support 24*7*365 any time of the day or night with live monitoring.

SECURITY OF CLOUD COMPUTING ADAVATAGES

1) Shifting public data to a external cloud reduces the exposure of the internal sensitive data
2) Cloud homogeneity makes security auditing / testing simpler
3) Clouds enable automated security management
4) Redundancy / disaster recovery

IV. CONCLUSION

The cloud computing has the potential to be a disruptive force by affecting the deployment and use of technology. The cloud be the next evolution in the history of computing, following in the footsteps of mainframes, minicomputers, PCs, servers, smart phones, and so on, and radically changing the way enterprise manage IT. Cloud computing provides advanced computing resources available on – demand, that scale as needed, with regular updates and without the need to buy and maintain an on - premise infrastructure. With cloud computing, teams to marked as they can rapidly acquire, scale services, without the considerable effort that requires managing a traditional on – premise infrastructure.

Abstract— **Live talking avatar presents an approach for creating an interactive model. It presents a real-time talking avatar. The live talking avatar has many potential applications in video phones, virtual conferences, entertainment, etc. In this project, we have designed the model as to communicate via the internet for various uses. In this paper, we propose and implement a real-time talking avatar, where we can communicate with each other by synchronizing live human voice and motion from ours while keeping anonymity by using a voice conversion technique. We improve the accuracy of the human- to-character/avatar conversion by specializing to the character's visuals. Finally, we conduct subjective experiments and show the possibility of a new style of visualization and animation on the internet.**

Keywords—Real-time, interactive model ,AI model , Avatar, Animation , Visualization.

I. INTRODUCTION

Human-computer interaction plays an increasingly important role in today's computer system. The use of virtual animated characters in the current digital support system can greatly benefit user experience and interaction. These virtual characters or simply avatars can be applied to a wide range of applications for entertainment, personal communications, commerce, or education. Along with the development of the new web standards and technologies, today it is possible to deploy standard computer graphics applications on internet environments, keeping a good balance between visual quality and latency. The solution we present in this work is primarily the system for avatar creation and animation, which can be deployed on web platforms. Although, there are several approaches concerning model presentation and model deformation, this work presents a new approach for avatar creation which is achieved only with a live human face. In this paper we present an approach for creating interactive and speaking avatar models, based on standard face images. We have started from a 2D live human face model that can be adjusted to a particular face. a process based on Procrustes analysis is applied in order to find the best match for input key points, obtaining the rotation, translation and scale needed to best fit the model to the photo.

II. CHALLENGES

Research in this area has focused on improving the quality of character animations and reducing the computational resources required to create them. One of the key challenges in this field is to create animations that are indistinguishable from real videos. Other challenges faced is that the dataset will be very large and complex. Also, User Interface should be simple and easy to use. Decreasing the time required to predict the results is also necessary.

Achieving a high level of accuracy is very important in the field of Avatar character Animation and face detection.

Also, there are many challenges faced while using the live talking avatar. Some are as follows: -

1) Emotion detection: - Avatar also must be able to detect the micro-expressions on the face to help with emotion detection.
2) Personalization: - Avatars must be customized and personalized according to the requirement.

III. PROBLEM DEFINITION

A computer can efficiently and effortlessly interpret a lot of faces where it is difficult for the other websites and machines to interpret such a high amount of data. The most prevalent technology which is being used for the prediction is machine learning and deep learning. Our proposed system is successfully animating the real time movements into a animated avatar with help of machine learning. Our system has achieved a good efficiency in generating the resultant and accurate avatar movements. We have also reduced the overall time needed for execution. The purpose of live talking avatar technology involves machine learning algorithms to replicate the face movements and mimic realistic-looking videos in the form of Avatar.

IV. EXISTING SYSTEM

There are existing system that use live talking avatar. That systems does not involves awidespread plan to test the special features and general functionality of platform. The process used was strictly quality and had limited personalization.

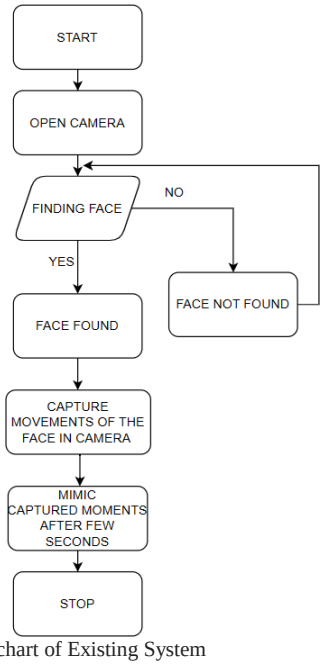

Fig 1.Flowchart of Existing System

1. The first step was to catch the input video into frames. The video capture function provided by using Html element “video” was used for this purpose. Since the method explored in this project was based on using a single face as input, multi- frame information was not needed. Besides, the similarity between two adjacent frames is too high hence putting them all into a training set will not only reduce the training efficiency but also potentially give rise to issues such as overfitting.
The videos chose for this work were all at a frame rate of 30 frames per second. After testing it was identified that selection of multiple face was not a reliable approach.

2. After finding the face, The second step was to use the color property RGB() to detect the area which hold the most blue colored value on the face and point them. The problem faced by the system was due to atmosphere and other environmental issues the camera was not able to mark blue colored point marks on the face. To overcome this problem at the time of testing we applied external blue colored sheet pieces on our faces for easy detection of the face. After detecting all the blue marked points on the face the avatar will move according to the movements of the face in the camera frame. All this animation will be carried out with the help of animate property which is supported by html element canvas. The canvas is responsible for creation of our avatar and its working in real time.
3. To make our Avatar more realistic live human we added new feature "the movement of hairs" by using the property of JavaScript "Pendulum" which allows us to create movements by applying a specific range.
As the avatar moves from right to left the hair also moves in the opposite direction for some instance and then come back to the original position.
This step is a iterative step as the avatar moves the hair will move continuously according to the user hair in the camera frame.
Co-operation

V. PROPOSED SYSTEM

A live talking avatar is a proposed system that utilizes artificial intelligence and computer-generated imagery to create a virtual representation of a human that can mimic their facial expressions, voice, and body movements. This technology has a wide range of potential applications, including customer service, virtual assistants, and online education. However, its development is still in progress, and further research is needed to improve the realism and interactivity of these avatars

The proposed system has the ability to mimic the user’s movements in real-time. It also includes the movement of hair as well as lips. The camera frame registers the user’s movements and the avatar moves according to it.

The application recognizes ‘blue’ for mimicking the movements of the user. So, the user has to use blue tape or a blue paper chit and place it over a part of the face for the system to recognize the face points.

The system first finds and renders the avatar and then searches for a face in front of the camera. If the system cannot find your face, it will search for a face again. Once a face is found, the system will follow the user’s movements in real-time.

The system still cannot imitate the user’s speech or talk and does not have voice recognition. It can only display the user’s lip movements. Another limitation is that the user has to use a blue element to read the user’s facial movements.

To make our Avatar more realistic live human we added new feature "the movement of hairs" by using the property of JavaScript "Pendulum" which allows us to create movements by applying a specific range.
As the avatar moves from right to left the hair also moves in the opposite direction for some instance and then come back to the original position.
This step is a iterative step as the avatar moves the hair will move continuously according to the user hair in the camera frame.

The proposed system still has ways to go with respect to the development sector, albeit it has come a long way from the existing system.

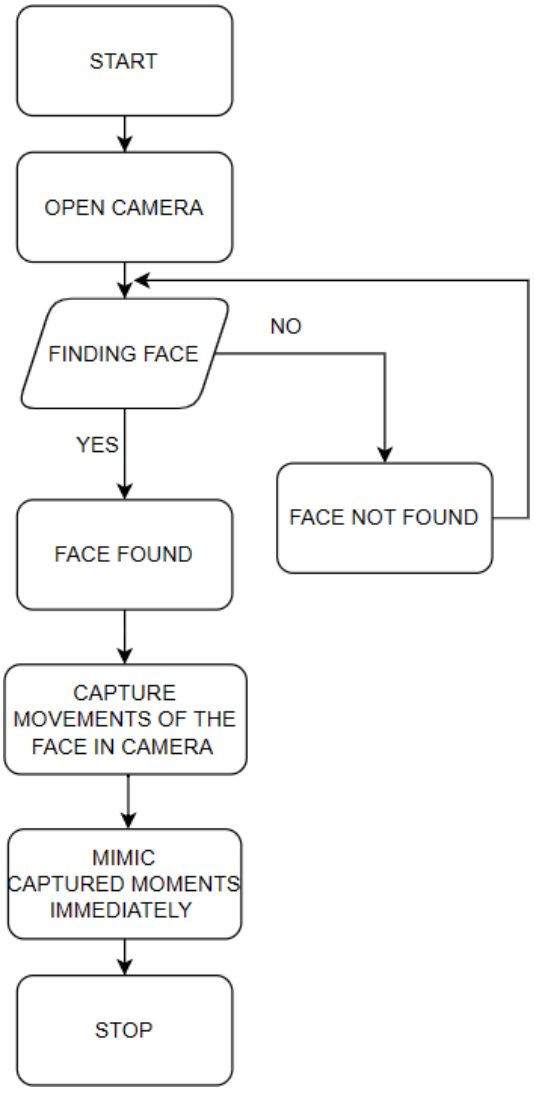

Fig 2. Flowchart of Existing System

VI. METHODOLOGY

➢ Creation of Avatar

Firstly, for the creation of our Avatar We used Canvas Element of HTML Which Allows to create different Graphics on Web page. The importance of Canvas lies on JavaScript which is actually responsible For drawing graphics. Canvas has several methods for drawing paths, boxes, circles, text etc. Which can be written in in JavaScript.

- We used Many Methods From these to draw Our Avatar. Like For Drawing Face First We divided our Window into 4 equal parts and then used the drawing methods like quadraticCurveTo().
- By applying Co-ordinate points of screen, we successively drew half-side of face.
- By using Method of Canvas Translate() We drew the other half of face by applying opposite co-ordinate points from first.

❖ For the creation of Beard and Hair we used lineTo(), quadraticCurveTo() methods which allows drawing of straight and curve lines.

❖ For the creation of Eyes, Ears And other Body We used methods like circleTo(), bezierCurveTo().

❖ For filling the color we used canvas.fill(); method which fills the color in drawing.

❖ For animation of Canvas on web-page the animate() method is required. we used animate() method for animation of canvas which is repeated for each frame in every second. Also after every change (like translate, movements etc.) on different parts of avatar like hair,face,neck,eyes the restore() method is required. We use it for every one of them.

❖ For applying movement to our Avatar manually, we provided slider and applied the mathematical function linear interpolation which provides the movements to face horizontally and vertically within applied range.

❖ For the movement of lips, we provided another slider with linear inter-polation with a small range. As value of slider increases the lips move vertically and as the value decreases the lips move horizontally.

❖ For the movement of hair, we provided the inbuild method pendulum () which uses range the as the head moves right hair moves opposite in direction and after few seconds they reset to their initial position.

❖ To make our Avatar more Realistic we used the properties like scaling and offsets which were very helpful for targeting movements at specific area.

❖ By using DOM(document-object-model) we provided every element's id and assign them to camera. By applying many methods with specific ranges we successfully achieved the movement of avatar in real time.

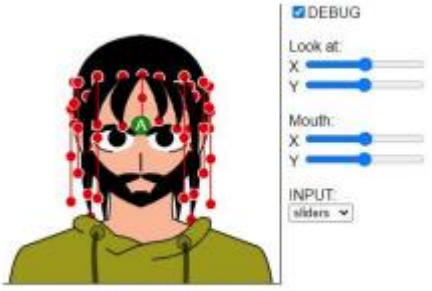

Fig 3. Movement by using Slider

VII LITERATURE SURVEY

SR.NO	LITERATURE	AUTHOR	WORKING	LIMITATIONS
1)	Creation of symmetric diagram of avatar by using a picture of face as model.	Java script design patterns- Addy Osmani.	Applied basic geometry for symmetric diagram.	Cant use z-axis as avatar is in 2D .
2)	Applied basic mathematical functions.	Margin Haverbeke	Applied functions like linear inter-polation .	For rendering , sliders are required .
3)	For realistic representation of the avatar we used scaling property .	Rado Istadori	Scaling methods of x axis and y axis. (x off-set and y off-set).	Still advanced scaling methods are needed.
4)	For hair movement, we provided in-build concept pendulum.	Rado Istadori	Movement of hair (like pendulum)	Requires long hair to work perfectly
5)	For scanning face DOM (document object model) is applied .	Margin Haverbeke	Scanning face successfully.	Requires high level specification s.

VIII.CONCLUSION

Our Proposed system is using various deep learning and machine learning algorithms in order to mimic the movements of the user and the system is achieving the maximum accuracy of the user's movements. A live talking avatar can be a very useful tool for a variety of applications, including animations, virtual events, and entertainment, etc. a poorly executed system cannot be useful and also annoying for the users to use . therefore , it is very important to create a useful and high quality technology .

IX.RESULT AND DISCUSSIONS

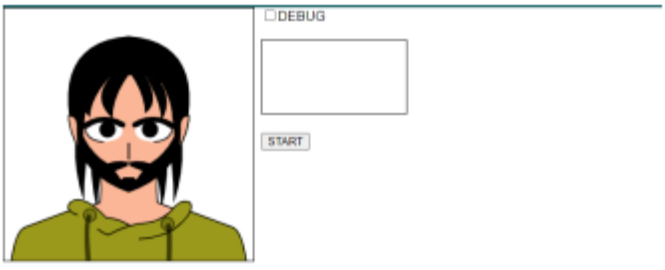

Fig 4. Static Models In figure 4, you can see that the avatar character is ready to express the same expression as of the camera.

Fig 5. Motion Model

In this figure 5, we can see that the avatar and camera person trying to mimic with same expressions.

Predictive Text Generation

Gurleen Pannu, Palak Jain, Shrinjay Kaushik, Computer Department
TCET
Mumbai, India
gkpannu20@gmail.com, palakj2987@gmail.com, shrinjaykaushik99@gmail.com

Abstract:- **With the improvement in the field of machine learning and the ability of computers to make sense of written language, the prospects of the field have exploded. Nowadays, a predictive text generator has become the need of the hour, whoever may be the user. Current systems for word prediction and text messaging – predict words based on the frequency, however, the words used in a sentence sometimes depend on the context used. Multiple words are mapped on a keypad to generate the next word in the sequence. We offer a Context-Based Word Prediction system for summarizing Earning Scripts of corporate organizations, thereby minimizing the amount of time required to analyze such documents and adapt to the changes in the industry and maximize profits. Using Machine Learning, a word prediction model can be developed such that words are predicted keeping in mind the context. The model will be using RNNs and LSTMs for the generation of words / long sequences.**

Keywords-RNNs, LSTM, Text Summarization, Earning Scripts, Prediction Model, NLP

I. INTRODUCTION

It may take days, if not weeks, for typical humans to methodically look through a 50- page technical paper, filter out unnecessary material, and write a detailed summary of that text while without risking its correctness. Even if you put your best effort into text summary, you can't rule out the possibility of data redundancy or, worse, missing anything critical. But what if you could have a nonhuman substitute do it for you? This option will never tire of reading, organizing, and analyzing, its brain will not become overworked, and it will be as close to flawless as you can get. Natural language processing (NLP) is one of the oldest and most investigated areas of artificial intelligence (AI).

Text summarization is a technique for condensing extensive passages of text. The goal is to develop a cohesive and fluent summary that only includes the document's major ideas. In machine learning and natural language processing (NLP),

automatic text summarization is a common challenge. Data is to this century what oil was to the previous one, propelled by current technical breakthroughs. Today's world is propelled by the collection and transmission of massive volumes of data. With so much data moving in the digital world, machine learning algorithms that can automatically condense lengthy texts and offer accurate summaries that can effectively communicate the intended messages are necessary.

II. LITERATURE REVIEW

In one of the past papers, a new algorithmic framework called the LeakGAN for the generation of long text via adversarial training was proposed. By leaking the feature extracted by the discriminator as the step-by-step guiding signal to guide the generator better generate long text, LeakGAN addresses the non-informativeness and sparsity problems of the scalar reward signal in previous GAN solutions. However, we found that long Text Generation with the system did not yield satisfactory results due to many factors such as LSTM - RNN's failure to capture long-term dependency, discriminator's failure to give those "good but tiny" sequences appropriate penalty, as well as the capacity of the discriminator to check the global consistency of the whole sentence, is localized and thus requires further work.

Through one of the other papers, it was seen that the paper proposed a context-based word prediction system for the prediction of the most appropriate word in a given context. This system also extended to informal words. The algorithms used include Hidden Markov Model and Support Vector Machine. It was noticed that in the current system, if there are 20,000 words, SVM needs to learn classification for these many classes which can be very large considering: No. ofdigits in code = No. of letters in word. Hence, the usage of SVM limits the number of codes. In the system the Average percentage error for Informal word based on Context based word prediction system is still quite high.

III. PROBLEM STATEMENT

To develop a Text Summarizer to reduce the work and effort and that can accurately summarize the Earning Scripts of corporate organizations. Use innovative technologies and technical insights to differentiate the proposed model of text summarizer from the existing models. Analyze results and optimize the model to achieve acceptable results.

IV. DATA COLLECTION

For data, we have worked on the Earning Script of a company for the year 2022-23. Using Earning Script as a dataset allows the model to work with the numerals and symbols associated with such documents and helps in the ideal training of the same.

V. PROPOSED SYSTEM

Before we embarked upon the actual implementation, the **5W1H** questions were decided to be as follows:

1. Why do we need a text generator?
2. When are they helpful to people?
3. Who benefits from these text generators?
4. Where can the text generators be used?
5. What is the main idea behind automated text generators?
6. How is it done?

We further performed survey analysis by creating a Google form with a set questionnaire pertaining to Predictive Text Generation. The results observed can be inferred from the below graphs.

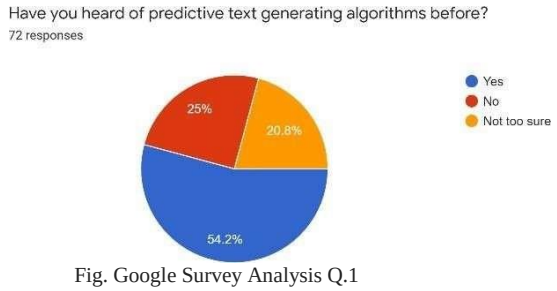

Fig. Google Survey Analysis Q.1

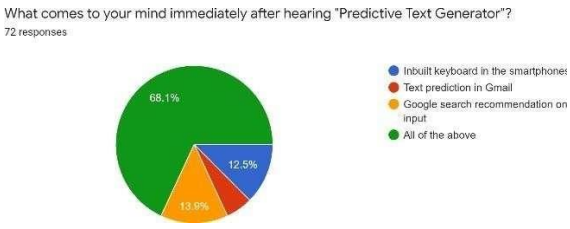

Fig. Google Survey Analysis Q.2

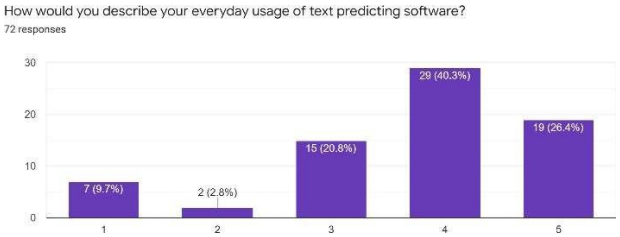

Fig. Google Survey Analysis Q.3

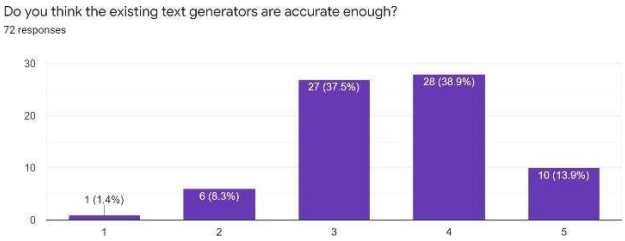

Fig. Google Survey Analysis Q.4

The entire working flow of the project is as follows:

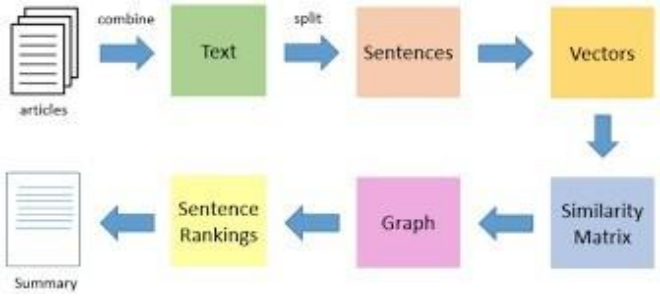

Fig. Workflow of the project

Predictive text generation using Recurrent Neural Networks (RNNs) is a popular technique used in Natural Language Processing (NLP) tasks. RNNs are a type of neural network that is well-suited to modeling sequential data, making them an ideal choice for text-generation tasks.

The basic idea behind predictive text generation using RNNs is to train a model on a large corpus of text and use it to generate new text. The model is trained to predict the next word in a sentence given the previous words in the sentence. This is done by feeding the model a sequence of words, one at a time, and updating its internal state after each word. The internal state of the model serves as a memory that can capture information about the context of the text.

Once the model is trained, it can be used to generate new text by feeding it a seed sentence and asking it to predict the next word. This process can be repeated iteratively to generate longer pieces of text.

One common approach to improve the quality of the generated text is to use a technique called "sampling". Sampling involves randomly selecting the next word from the probability distribution produced by the model, rather than always selecting the word with the highest probability. This allows for more diverse and interesting text to be generated.

Overall, predictive text generation using RNNs is a powerful technique that can be used for a variety of applications, including chatbots, language translation, and text completion. In this project, we work on a model that can shorten the earning scripts issued at the end of the fiscal year to produce a shortened version of the script for the corporate officials to understand and incorporate the necessary changes with ease and with the surety that the shortened document includes the important contextual nuances of the earning script.

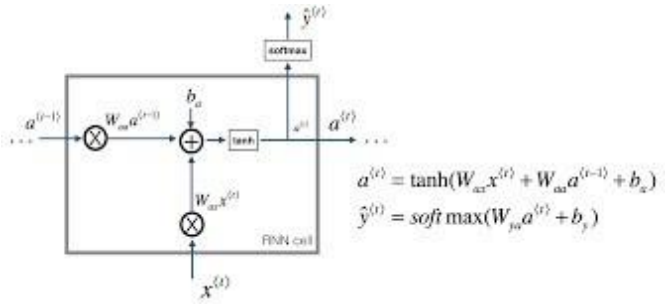

Fig. Recuurent Neural Networks

We have also employed Long short term memory models to incorporate longer text because of the model's ability to store a greater amount of information.

$$
\begin{aligned}
f_t &= \sigma_g(W_f x_t + U_f h_{t-1} + b_f) \\
i_t &= \sigma_g(W_i x_t + U_i h_{t-1} + b_i) \\
o_t &= \sigma_g(W_o x_t + U_o h_{t-1} + b_o) \\
c_t &= f_t \circ c_{t-1} + i_t \circ \sigma_c(W_c x_t + U_c h_{t-1} + b_c) \\
h_t &= o_t \circ \sigma_h(c_t)
\end{aligned}
$$

Fig. Long Short Term Memory

VI. RESULT AND DISCUSSION

From the implemented model we can conclude that the text summarizer is able to accurately summarize the earning script based on the context of the characters in the script. The accuracy of the earning script can be further improved by training on various texts – fictional, mathematical, legal, and educational. The summary of the text does not accommodate the introduction of new laws affecting the corporate industry and hence, the model can be trained on the same. The trained model can also be used to summarize fictional content, for instance – novels, technical papers, blogs, and other creative and legal content.

VII. CONCLUSION

As a result, we can conclude that Recurrent Neural Networks (RNNs) and Long Short Term Memory (LSTMs) can be used to summarize long texts while also keeping in mind the context. We can go even further by creating an entire paragraph suggester. Based on the findings, we may conclude that the technologies employed yielded positive outcomes. Because the RNNs and the LSTM were trained on documents containing alpha-numeric values and mathematical symbols, the trained model is capable of making sense of corporate and legal documents along with technical papers as well. This summarizer serves the purpose of saving invaluable time for corporate individuals and reduces human errors like overlooking critical information and neglect as a result of lethargy.

VIII. FUTURE SCOPE

We'd like to look into methods for generating numerous sentences with diverse content in the future. Furthermore, we would like to build an application that would act as a workable prototype available for all sorts of applications including mobile devices, PCs, etc. We'd further need a larger dataset to enhance the accuracy and prediction of the model.

IX. ACKNOWLEDGEMENT

We gratefully acknowledge the support, guidance, and encouragement of our Guide Professor Mrs. Ashwini Patil Ma'am, and our industry mentor Mr. Abhinav Garole for guiding us in building this model.

Deep Learning Based Intrusion Detection Model for Network Security

Dr. Sagar Dhanraj Pande, Govinda Rajulu, Lanke,Mukesh Soni, Dr. Mukund Anant Kulkarni, Renato R. Maaliw III, Dr. Pavitar Parkash Singh

sagarpande30@gmail.com,govinda.lanke@gmail.com,mukesh.research24@gmail.com,my_mukund@yahoo.com,rmaaliw@slsu.edu.p h, pavitar.19476@lpu.co.in

Abstract Abstract: Since it serves as a potent means of network security defence, intrusion detection technology is an essential component of the network security system.As the Internet has grown quickly, so too have network data volumes and threats, which are now more sophisticated and diversified. Modern intrusion detection equipment cannot reliably recognize different types of attacks. A CBL_DDQN intrusion detection model based on an upgraded double deep Q network is suggested based on deep reinforcement learning to address the imbalance of regular traffic and attack traffic data in the actual network environment as well as the low detection rate of attack traffic. This model integrates the feedback learning and policy generating methods of deep reinforcement learning with a one-dimensional convolutional neural network and a bidirectional long-term, short-term memory network to train agents to attack different types of samples.Classification, to some extent, lessens the reliance on data labels during model training. The Borderline SMOTE algorithm reduces data imbalance, thereby improving the detection rate of rare attacks. The NSL KDD and UNSW NB15 data sets are used to assess the model's efficacy.The findings demonstrate that the model has performed well with respect to the three indices of accuracy, precision, and recall, and the detection effect is significantly superior to Adam BNDNN, KNN, SVM, etc. The detection method is an efficient network intrusion detection model

Keywords: Keywords: Deep Learning, Intrusion detection, Classification, LSTM, CNN, SMOTE

INTRODUCTION

Nowadays, everyone has a smartphone, and UPI has just "Network intrusion detection system (network intrusion detection systems, NIDS)", as a proactive defense technology, is the primary means to discover potential network threats in time and formulate reasonable defense strategies and is an integral part of the network security technology system [1-4]. It can detect attacks in time and reduce network security threats by collecting and analyzing relevant network data.

Signature-based NIDS relies on an attack signature database for detection. It has a high detection rate for existing data in the database but cannot detect new attacks [5-8], and the database needs to be updated frequently. Anomaly-based NIDS identifies hidden attacks in computers by analyzing unusual traffic distributions and can be used to detect new types of attacks. The system uses configuration files to store all normal behaviors of users, hosts, network connections, and applications. This approach compares current activity to the configuration file and flags any significant deviations as anomalies [9-12]. This data sensitivity effectively prevents various malicious behaviors. However, this sensitivity advantage can lead to high false favorable rates, leading to unnecessary panic and overreaction [13-15].

Machine learning algorithms, such as Bayesian networks [16], support vector machines [17], etc., are widely employed in anomaly-based NIDS. Small-scale traffic data detection challenges have been successfully tackled by these methods. Performance of classic intrusion detection methods, however, is facing considerable hurdles in dealing with huge high-dimensional data due to the ongoing advance of network technology and the ongoing expansion of network scale.

Representing representation learning, deep learning can automatically learn high-level data features directly from complex original features, doing away with the requirement for specialized knowledge in the manual feature extraction procedure. As a result, the deep Model architecture is the basis for the vast majority of modern intrusion detection systems. Among the most popular deep models are the autoencoder [18], the convolutional neural network (CNN) [19-20], the recurrent neural network (RNN) [21], etc. Literature [22] proposes to use CNN for network intrusion detection and uses CNN to select features to classify traffic. Compared with traditional algorithms, it has a good effect but ignores the connection in the time sequence of traffic data; Literature [23] proposes to use LSTM (extended short-term memory network) is used in intrusion detection and has achieved good classification results, but without considering the spatial characteristics of the data, there is still room for improvement in classifier performance. To fully extract the

features of network traffic data, literature [24] proposes to use CNN and LSTM in combination, use CNN to learn the parts of network packets, and then use LSTM to learn the details of network traffic, compare with using LSTM, CNN or LSTM alone. The upgraded model is more efficient and produces more accurate results when classifying traffic data. These models rely on large amounts of labelled data samples, even though the neural network model is capable of powerful feature extraction. Still, there is a lot of data that needs labelling, and doing it manually is a costly and time-consuming process.

Reinforcement learning (RL) is an active solution to the aforementioned issues. Traditional RL is based on the Markov decision process (MDP) to create algorithms;however, it can only examine small-scale problems. Moreover, the natural environment is often complex and changeable. Therefore, it is problematic for traditional RL methods to obtain effective solutions when solving practical problems. Literature [25] combines reinforcement learning with deep learning. It proposes deep reinforcement learning (DRL), which approximates the complex data space and mapping relationship in reinforcement learning with neural networks,

significantly expanding the application range of reinforcement learning. This is because coupled with its unique feedback mechanism; reinforcement learning also has aextensive range of applications in classification problems application. Literature [26], for the first time, equates the classification problem to the continuous decision-making process of the agent (agent) and proposes a classification task solution based on reinforcement learning, with an accuracy rate of 87.4% in the eight UCI data sets. Literature [27] proposed an AE-DQN model based on adversarial multi-agents for the problem of network intrusion detection and achieved good detection results. Although the above-mentioned deep reinforcement learning model shows unique advantages in solving the classification problem with imperfect labels, the selection of the deep learning network model cannot Whether the selection of the deep learning model is mainly appropriate determines the classifier's performance. Therefore, the focus of the above models is only on the generation of agent strategies[28-29].

Uneven data is another common issue. The classifier can obtain higher overall classification accuracy, but the recognition rate of smaller class data is meagre, and misclassification of minority classes will bring huge costs. At the algorithm level, by changing the classifier, the existing classifier can strengthen the learning of the minority class[30].

In order to boost the system's detection rate for different types of traffic, this study presents a network intrusion detection model based on the enhanced double Q network. The model incorporates the hybrid network model of CNN and BiLSTM into the learning framework of the deep Q network, simulating the intrusion detection process as the sequential decision-making process of the agent. Improve the classifier's ability to identify different forms of attack flows. Concurrently, an unbalanced processing strategy is offered to improve the detection rate of rare attacks while taking data imbalance into account.

2. CBL_DDQN model based on improved double deep Q network

This paper introduces the mixed CBL model of CNN and BiLSTM into the dual deep Q network framework. To better utilise the CBL network to fit the Q function and the feedback mechanism in the dual deep Q network, a new model for intrusion detection called CBL DDQN is developed. and optimization strategy to optimize the CBL network, and finally, realize the correct classification of traffic.

Network traffic data is a sequence with a time step, which has both spatial and temporal characteristics [13-16]. Because both CNN and BiLSTM are very good at extracting features from input, we create a CNN-BiLSTM hybrid model, the CBL model, by fusing a one-dimensional convolutional network with a bidirectional long-term, short-term memory network (see Figure 1).

The parameters are discretized in the highest pooling layer to shorten training time and prevent overfitting; middle-layer parameters are normalised with batch normalisation to speed up training; and the BiLSTM layer is used to learn onward and rearward time series data. One way to improve understanding is to utilise two BiLSTM layers that each learn at a different granularity. One-dimensional convolutional neural network with long-term time-dependent feature correlation; network layer between BiLSTM layers to extract features efficiently and speed up training; Dropout layer to prevent model overfitting; and Softmax function for probability matrix output.

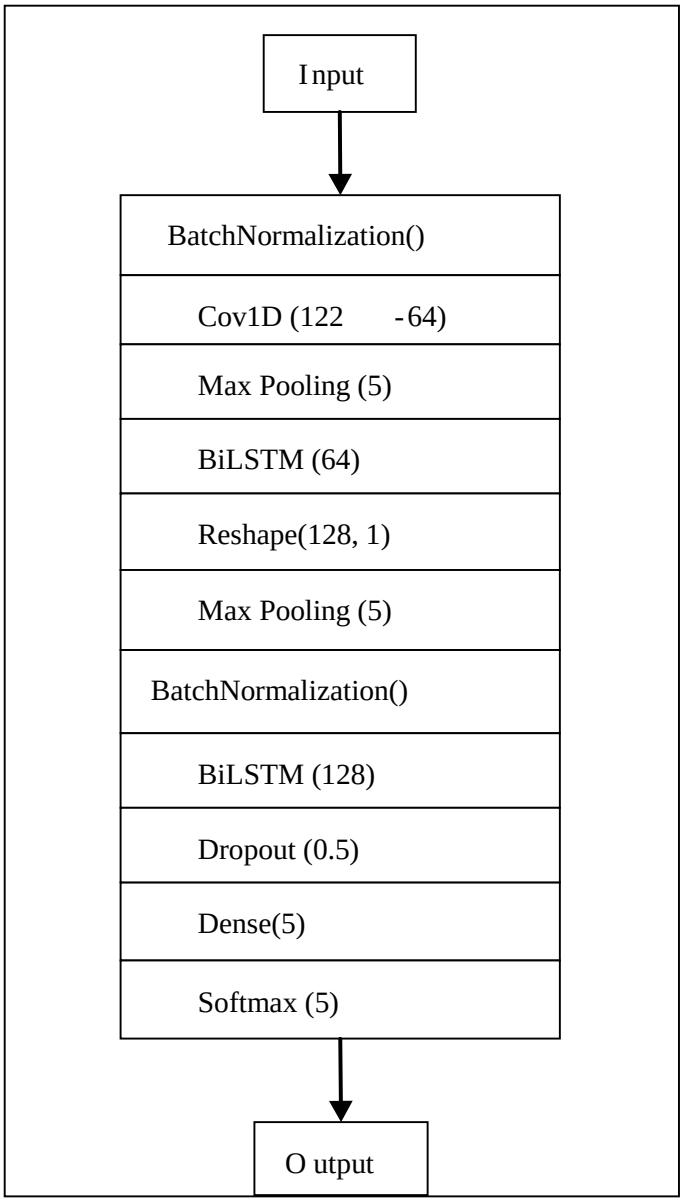

Figure 1 CBL model framework

3. Selection and processing of data sets

4.1 Dataset selection and preprocessing

In this study, the CBL DDQN model is validated using simulation tests on two public intrusion detection datasets NSL KDD and UNSW NB15. Table 1 and Table 2 detail the two datasets, respectively.

Table 1 Attack category information of NSL_KDD dataset

Attack Category	**Quantity**	**Convert Tag**
Normal	077054	0
Dos	053385	1
Probing	014077	2
R2L	003749	3
U2R	000252	4

Table 2 Attack category information of UNSW_NB15 dataset

Attack Category	**Quantity**	**Convert Tag**
Normal	93000	0
Generic	2677	1
Exploit	2329	2
Fuzzers	16353	3
Dos	44525	4
Reconaissance	24246	5
Analysis	58871	6
Backdoor	13987	7
Shellcode	1511	8
Worms	174	9

Data preprocessing mainly includes the following three parts: character feature medicalization, one-hot encoding and numerical normalization.

(1) Numericalization of character features

The category features of standard records and different attack records are converted from character type to digital label, and the label distribution after conversion is shown in Table 1 and Table 2.

(2) One-hot encoding

With one-hot encoding, the distance calculation between components can be more realistic.

(3) Numerical normalization

After one-hot encoding, to reduce the impact of the value of each dimension attribute feature on the subsequent network, each dimension attribute feature is normalized according to formula (18), and the normalized interval is [0,1] :

$$\dot{x} = (x - x\min)/(x\max - x\min) \quad (18)$$

4.2 Experimental results and analysis

In this paper, two network traffic data sets, NSL_KDD and UNSW_NB15, are used for experiments. The details of the dataset are described in Section 3.1. In the experiment, set all the data of the entire training set as one epoch, set the maximum epoch to 30, make statistics on the classification results of the model every five ages of training, and use the control experiment to test the system before and after using the Borderline-SMOTE algorithm. The recognition rate of the data. The classification results after statistical training for 30 epochs is shown in Figure 2 and Figure 3.

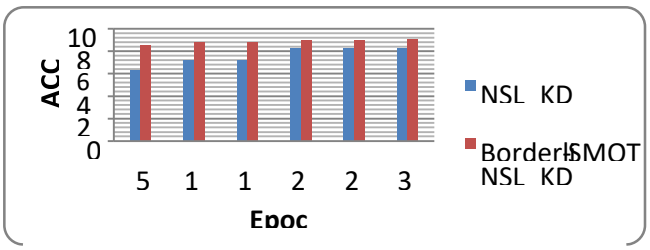

Figure 2 The recognition rate of the model for NSL_KDD

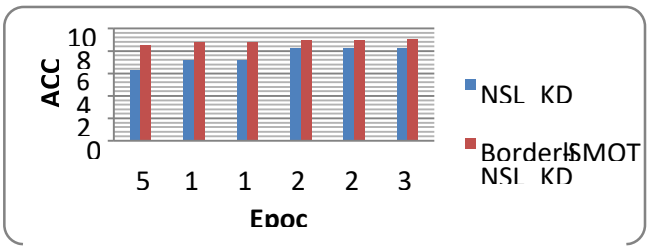

Figure 3 The recognition rate of the model for UNSW_NB15

Figure 2 and Figure 3 show that the classifiers' performances are steadily rising as the training process progresses. If you compare the model introduced with the Borderline-SMOTE algorithm to the same training, you'll see that the latter has a greater classification accuracy. Within a certain threshold of repetitions, the accuracy of the original data set can be directly.

It can be seen visually that the introduction of the imbalance processing algorithm has a more significant role in promoting the convergence of the model.

Accuracy, recall, and precision of six approaches were evaluated to further validate the model described in this research. Table 9 and Table 10 display the statistical outcomes of Adam-BNDNN[18][29], DQN[19][30], RF[19], SVM[19], MLP[19], and Adaboost[20], where the data in bold is the optimal value of this performance index.

For intuition, the data drawn in a bar graph, and the result is shown in Figure 4.

Figure 4 Classification performance of each model for NSL_KDD

Figure 5 Classification performance of each model for UNSW_NB15

With the help of Figure 4, it is clear that the CBL DDQN model suggested in this paper has a substantial detection effect on the NSL KDD dataset. All performance parameters are higher than prior similar studies, with precision at 99.96%, recall at 99.97%, and precision at 99.79%.

Similarly, for the sake of intuition, the data drawn in bar charts, and the results are shown in Figure 5.

Taken together, Table 4 and Figure 5 show that the UNSW NB15 detection results using this paper's model have an overall identification accuracy rate of 90.12%, recall of 95.20%, and precision of 89.93%. On the downside, it does not perform as well as its counterparts. After cautiously considering a number of performance factors, the model suggested in this research is able to produce a good intrusion detection impact.

The above two sets of experimental results demonstrate that the upgraded dual deep Q network model suggested in this paper may effectively address the intrusion detection problem.

4. Conclusion

The purpose of this paper is to present the CBL DDQN network intrusion detection model, which incorporates the hybrid network CBL network of CNN and BiLSTM into the DDQN framework to enhance the model's performance. In comparison to more standard deep learning algorithms, this one reduces or eliminates the need for labelled data. In this way, it outperforms deep learning algorithms in terms of classification accuracy. Moreover, the Borderline-SMOTE technique is used to increase the number of unusual attack samples because of the fact that the disparity between the data makes it hard for the classifier to understand the data features properly. Based on these findings, it appears that the imbalanced processing technique helps the model become more accurate in classifying data.

In conclusion, the suggested model in this paper has good results in the imbalanced data classification challenge. Its overall performance is higher than that of the enhanced DQN network and other deep learning networks, suggesting a novel approach to deep reinforcement learning.

Abstract: During the execution control of their initiatives, organizations use a variety of devices to aid independent direction. Regardless, they are still insufficient in the face of skewed statistics and shifting management approaches. The absence of frameworks for controlling the execution of enterprises has an impact on the nature of their categorization in terms of supporting independent direction. The presentation of soft registering methods, which provide heartiness, effectiveness, and flexibility at apparatuses, is an optional arrangement. This research provides a technique for project execution control based on SoftComputing and ML, which contributes to the executives' ability to further improve the project. The proposed method allows for AI and the replacement of fuzzy inference frameworks in project evaluation. The results are derived from seven calculations involving space apportioning, neural architecture, gradient descent, and genetic algorithms. Adoption of the proposed framework, which has been included in this paper for project personnel, signifies a change in the nature of venture evaluation. The obtained result ensures that the apparatuses are in perfect working order to assist the independent direction in projecting the executive associations.

Keywords: Soft Computing, ML, Project Execution,

I. INTRODUCTION

For project-oriented associations, the proper use of information, processes, procedures, abilities, and equipment is critical to the success of the organisation. Estimating and tracking the development of an effort is made possible in large part by the monitoring and control process [1]. This makes it possible to distinguish between different types of management plans, so that corrective steps can be made as necessary to meet the project's goals. In the context of a company's management team, reconciliation involves coming to daily decisions about where to place the company's assets and efforts, anticipating possible problems so that they can be addressed before they become critical. Developia group of executives that work together as a team with the leader's role as a pioneer and a keen eye for detail is critical to the success of the project. All of the

following should be documented: scope, cost, timeliness, and quality; coordination of activities; and human resources (HR) [2]. An individual who is in charge of overseeing improvement initiatives must have the ability to understand the challenges at hand, differentiate between solutions and take autonomous action, all with the goal of supporting the primary goals of the organisation [3]. PC instruments can be used to assist individuals during the execution and control phases of a project. In this way, it's possible to explain what's going on and propose particular solutions to the problem. It is now possible for project managers to know exactly what action they need to take to solve a specific problem at any given time [4]. As a result of PCs that facilitate autonomous management, which rely on clear and quantitative records, this situation has arisen. Various tools for project managers have been developed during the last many years. Despite this, the majority of these tools don't take into account the treatment of vulnerability, nor the ability to adapt to the needs of different projects [5]. It is possible to complete an execution plan and illustrate the progress of the project through the administration records supported by integrated Project Management. This enables them to discover the root causes of problems so that they may make decisions based on a freshly established set of demands [6]. Multitudinous financial calamities with a large negative impact on relationships are caused by Integrated Project Management errors and deficiencies [7]. Disappointment is common in this field because of the following factors:

- There is a lack of knowledge about good project management procedures.
- Involvement in the management and observation of projects is minimal.
- Problems in dealing with information that is both ambiguous and vulnerable.
- Information gathered by individuals may be out of date if certain members of the project group are no longer in attendance.
- Instrumental flaws in the automated evaluation of projects.
- Instruments of assessment and control that are past their expiration dates in relation to shifting management styles as a result of progress made throughout their continuous improvement [8].

ML can be used as an alternative solution to the previously described concerns. Measurements, rationales, calculations, brain organisation, hypothetical data, man-made consciousness and soft registration are all intertwined in this interdisciplinary field of study [9].

Some of these challenges can be addressed by utilising a project execution control technique that takes into account the sensitivity of registration and artificial intelligence (AI) [10]. As a means of assisting project-based groups in their own self-governance, the suggested structure is projected to provide several benefits. Investigative zeal and down-to-earth dedication are centred on the following perspectives:

- The use of AI in project execution control, increasing the heartiness, variety, and harmony between the force of expectation and the understanding of project management tools.
- Free ware that includes a few soft AI registering methodologies and trial and error of frameworks for the evaluation of project performance will be used to further develop the Analysis. Pro.SC.PMC library [11].

II. LITERATURE REVIEW

A. *Project Management Best Practices:*

Schools or institutions dedicated to the formalisation of association approaches develop Project Management as a discipline. The PMBOK criteria [9], the ware Engineering Institute (SEI) with the Capability Maturity Model Integration (CMMI) [5], the International Project Management Association (IPMA) [12], and criticism, identify ambiguous or unsettled circumstances, and encourage continuous improvement. It suggests that records related to the information categories of Scope, Cost, Time, and Quality be used for this. It oversees the treatment of vulnerability in project

the International Organization for Standardization (ISO) with its guidelines 10006 and 21500 [13] are among these organisations.

The PMBOK recommends monitoring project execution throughout its life cycle in order to provide constructive

gambles, as well as future usage investigation for cost estimation and undertaking plan executives [14].

The importance of PC apparatuses as a support for decision-making in the undertaking improvement group was discovered by CMMI. It oversees process streamlining inside the organisation at level 5, with a focus on continuous improvement in the presentation of cycles through innovative and incremental modifications. It suggests that businesses should periodically renew the meaning of their cycles in order to include the most recent changes made by the organisation into standard cycles when they benefit [15]. The ISO 10006:2003 and 21500:2013 recommendations provide instructions for project directors to supervise quality during project improvement. They are in charge of the estimation and investigation processes, as well as the ongoing development of the project's execution. They advocate for the management of risk associated with spending as well as the control of the project plan. In [16] it is stated that the association's project management processes and techniques should be enhanced based on previous experience, rather than recommending radical changes. It ensures that during the project, the executives provide excellent independent direction at all levels of the organisation [17].

B. Records used to assess the project:

This investigation makes use of a number of project management documents that have been determined in accordance with [18]. These records reflect the project's execution in terms of the PMBOK guidelines and CMMI's basic information regions (see Table.1).

TABLE.I: RECORDS ESSENTIAL TO PROJECT PLANNING

Records	**The executives' information regions of the undertaking**
IEP: Index of Execution Performance	Executives' authority and responsibility
IPP: Index of Plan Performance	Making the most of your time
ICE:Index of Cost-Effectiveness	Expense management
VPI: Viability Performance Index	Extension and administration of high grade
HRPI: HR Performance Index	Executives in Human Resources
PIC: Performance Index Calculated	An administration that is calculated
IIQ: Index of Information Quality	Consistency of data

C. In Project Management, Soft Computing and Machine Learning Applications

With the ultimate goal of achieving appropriate administration, heartiness, and greater proclivity with reality, soft registering strategies monitors resistance to the dubiousness, vulnerability, and imperfect reality of realities [19]. Soft registering entails a variety of computing philosophies, including fluffy logic, brain network hypothesis, probabilistic thinking, and transformational calculation, to name a few [20].

Using information and collected understanding, soft registering strategies provide PC apparatuses with a way to interact with human thinking. Furthermore, they enable independent direction by increasing efficacy, adaptability, and an acceptable balance between force of expectation and understanding. These tactics are effective in situations where there are numerous information sources and there is a high level of resistance to information imprecision; they allow for minimal cost setups and a higher demonstrating limit. A few studies have suggested possible arrangements for project executives based on AI, information mining, computerised reasoning, and soft registering. However, when compared to other application areas, explicit utilizations of these tactics in project directors are somewhat low. A few related works are listed below. In [21], a method based on soft registering is given for categorising projects into three categories: simple, medium, and difficult. In [17], a record structure is built to evaluate the project leaders' presentation in terms of quality, cost, time, and risks. In [22], a fluffy derivation framework is presented to determine the record that analyses the undertaking execution by combining two information sources obtained by the research of substantial worth: expense execution and arranging execution. A model based on ANFIS [23] is presented in [14] to assess product exertion. [24] introduces a framework based on brain networks for utilising the authoritative undertaking the executives development model. [25] proposes a fuzzy derivation framework for evaluating the success of programming project administration. Some of the researches are using machine learning techniques[26,27] for classification and predictions for many applications.

In general, the following characteristics are not included in the profiles of experts investigated:

- The application of artificial intelligence (AI) techniques.
- A shift in the assessment framework, as evidenced by the association's continued improvement.
- The model must be reconciled with the project's executive apparatuses.
- Free programming is used to run the model.
- The recommended solution will be used to evaluate the project's implementation.

A technique is presented as a solution to the concerns that have recently been raised. It employs a number of computational methodologies to assist organizations with task execution control and decision-making.

III. EXECUTION CONTROL TECHNIQUE FOR PROJECTS

An administered learning methodology is used in the suggested strategy to change the bounds of the fluffy derivation frameworks. Learning is based on a number of accomplished initiatives, the mathematical advantages of which are understood via essential administration records and the assessment offered by association specialists. A set of preparing cases and a set of approval cases are derived from this basis of activities [28]. Extricate the informative gathering from the completed undertakings data set; apply multiple AI procedures; and use comprehensive quantifiable measurements to determine the framework that best assessments the activities execution in the association, as shown in Figure 1. The suggested technique uses a set of records as input and produces a fluffy derivation framework for project evaluation as a result. This instrument is more than likely to be finished when top management determines that stated evaluation framework has to be updated as a result of the association's consistent improvement in management styles.

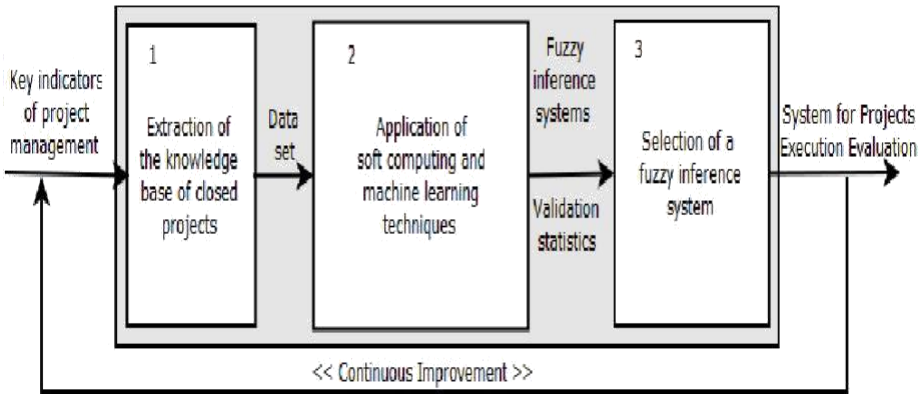

FIGURE.I: PARTS OF THE PROJECT EXECUTION CONTROL APPROACH.

Part 1) Entries to this square are compared to the project executives' records, which are then decided and stored in the association data base. It goes without saying that the use of the records mentioned in Table 1 is recommended. The finished project information base is advised, getting the pre-determined records and the master assessment to the undertakings, which will operate as case preparation. As a foundation for the age and streamlining of fluffy guidelines using AI, this wellspring of data capabilities. To get the preparation and approval sets, the foundation of pre-characterized undertakings is haphazardly divided into numerous allotments. These allotments are then utilised to execute cross-approval between each procedure's studies.

Part 2) Experiments are carried out to register and AI processes for delicate it. The delicate it is made sense of to record tactics in the following section. The following information is saved in the data set for each investigation: fluffy derivation frameworks established, name of the technique used, learning bounds, a measure of rules created, and the aftereffects of elements for measuring the nature of evaluation [29]. Correct Classifications, False Positives, False Negatives, Mean Square Error (MSE), Root Mean Square Error (RMSE), and Symmetric Mean Absolute Percentage Error (SMAPE) are the approval metrics, as shown in Equations 1, 2, and 3.

$$= \frac{1}{} \quad (\quad -)^2 \ldots\ldots\ldots(1)$$

$$=1$$

$$= \quad \overline{\quad} \ldots\ldots\ldots(2)$$

$$1 \quad -$$

$$=100* \overline{\quad} \quad \overline{\quad} \quad (3)$$

$$+$$

$$=1 \quad 2$$

Where m is the count of instances, is the average result value, and is the framework-determined result.

Part 3) Statistical tests are carried out and the best fluffy derivation framework is selected. For this, the effects of delicate registration methods are considered in terms of the type of evaluations, using measures obtained in part 2, which allow obtaining the accuracy of calculations done. These estimates are subjected to Friedman and Wilcoxon tests

of completed projects to ensure constant improvement of the proposed framework. This update may be issued when administrators believe it is necessary for the organization's continued growth [31].

A. The Proposed Method Makes Use of Delicate Computing Techniques

For the transformation and AI of the framework that examines the undertaking execution, a few calculations were used as the technique. The following is a collection of sensitive registering techniques that have been used in practice.

W.M. (Wang and Mendel). This method generates a slew of new fluffy principles and refines them using a space segment methodology [32]. The five stages of the educational experience are as follows.

i) Separate the passage and leave voids of mathematical knowledge, which is

vi) .

base
supplied in fluffy districts, referring to the etymology phrase for time intervals.

ii) Create fluffy principles based on the preparatory instances, determine the degrees of having a location with fluffy sets for each case, and choose the etymological word with the highest degree in each variable.

iii) Assign a degree of importance to each standard developed, with the goal of resolving conflicts between created regulations.

iv) Construct a consolidated rule basis based on the guidelines and etymological concepts presented.

v) After discarding the repetitious and those with the lowest grades, create a final rule foundation

...	…	…	…	..	..	…	…	...
212	24	24	94	1	2	1	3	2

An informative collection with the content is used for learning: 68 projects rated as Fine (32%), 97 projects rated as Standard (46%), and 47 projects rated as Poor (22%); it does not include invalid or out of reach values to follow the distribution. The informative gathering is hastily divided into 22 discrete allotments. Each section is responsible for preparing 76 percent of the 212 cases and approving the remaining 25%. The cross-approval approach uses these allotments to undertake 22 executions of each soft computing operation. The results obtained from each procedure in each of the 22 information allotments allow for consideration of the presentation of calculations, taking into account the following factors: percent of correct characterizations, number of misleading up-sides, number of bogus negatives, MSE, RMSE, and SMAPE. The following , and pleasing manner, increasing the character of client life, thanks to the offered approach [28].

is a summary of the effects of the different kinds of approvals used in this investigation. Figures.3 and 4 depict the behaviour of seven computations related to % of correct characterizations and SMAPE. It's easy to observe that ANFIS produces the greatest results [17].Finally, using the Wilcoxon test, it was possible to confirm that the ANFIS approach delivers much better results than the rest of the computations and provides the optimum framework for evaluating projects [18]. An assortment of 6 organisations and 15 programming advancement centres profit from the reconciliation of the suggested method at the GESPRO stage, where around 312 projects are supervised every year. The instrument has an average of 6500 users, all with different levels of expertise and professions. Decision-making with the help of GESPRO is finished in a necessary, light-footed

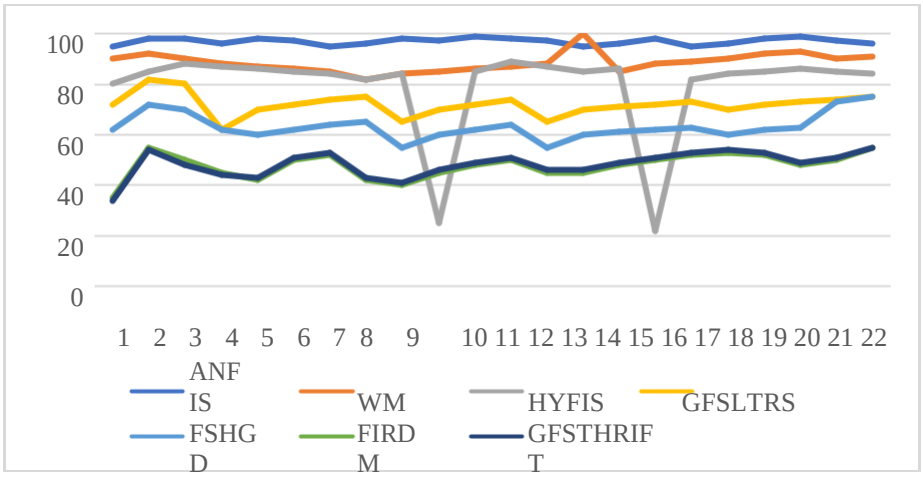

FIGURE.III: PERCENTAGE OF CORRECT CLASSIFICATIONS OBTAINED FOR EACH PROCESS ON THE 22 TEST INFORMATIONAL COLLECTION ALLOTMENTS.

Another advantage of the suggested method is the use of free programming as a need for achieving inventive power, which ensures authoritative progress in a broad and sustainable manner [27]. This legislationis advanced and mirrored by the computational climate and capabilities built on open-source programming developments. This implies the following advantages for the executive instrument: complete control of functionality, timely detection and correction of errors, and constant improvement in light of cooperative occurrences [3].

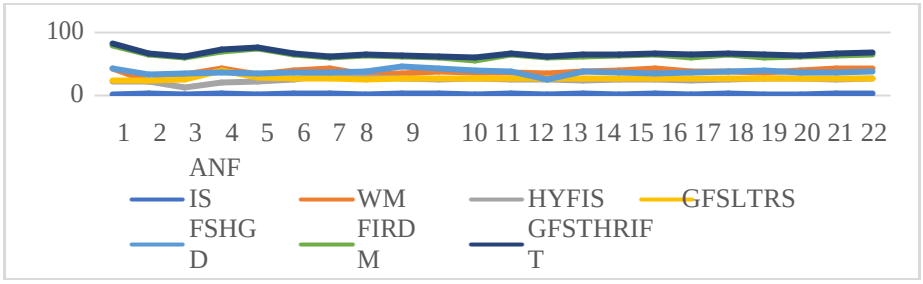

FIGURE.IVEVERY METHOD ON THE 22 ALLOTMENTS OF THE TEST INFORMATIVE GATHERING YIELDED A SYMMETRIC MEAN ABSOLUTE PERCENTAGE ERROR.

Finally, the influence of the proposal, from a financial standpoint, is dependent on investment money, which proposes making better decisions based on data provided by the suggested approach to regulate the undertaking execution [31]. In addition to preserving assets, sending forth labour and goods that are beneficial to the progress of society as a whole.

CONCLUSION

Project execution control is a perplexing position that involves scepticism in concepts and fragility in data, a situation in which the use of careful registration processes yields excellent results. The suggested technique employs these processes in project evaluation, increasing the heartiness, adaptability, and harmony between the executive apparatuses' force of expectation and comprehension. It also makes it possible to secure information about experts in organisations and to accomplish a good project execution control. The use of artificial intelligence (AI) for project evaluation increases a company's ability to adapt to changing management styles as a result of its growth and continuous improvement. With the development of the AnalysisPro.SC.PMC library based on free programming and including important records for project executives, a commitment has been made to the enhancement of current choice aid instruments used by projects.

Abstract – **with its great explosion and the advancement of related technology and services, such as the World-Wide-Web (WWW), the Internet has provided a rich environment for building Internet-based electronic commerce (e-Commerce) applications. The growth of e-commerce has been phenomenal and it is radically transforming the way companies are doing business in all sectors-ECommerce has become an increasingly important source of competitive advantage for B2B companies. It enables them not only to decrease transactional costs and offer wide range of additional services, but also to enhance efficiency in collaboration with their customers and suppliers. Thus, the objective of this paper is to explore how industrial companies use B2B E-Commerce, how it enables their services and what are the main advantages. In the context of continuous increase of the services role in B2B markets and rapid development of information technologies, the paper turns high practical and theoretical importance for business environment. The paper can also support companies in decision making on E-Commerce investments strategy.**

Keywords- B2B E-Commerce, B2B E-Commerce strategy, services in B2B market, types of B2B E-Commerce, international perspectives of B2B E-Commerce, IT technologies, E-Services, Services.

I. INTRODUCTION

Since the last decades e-commerce has become an increasingly important source of competitive advantages. The opportunities of e-commerce enforce managers to redesign business processes and even to rethink the existing business models and the relationships with their business partners. Many different empirical findings demonstrate that ECommerce enables companies not only to decrease transactional costs and to offer additional services, but also to gain efficiency in supply chains and enhance collaboration with their customers and suppliers. Especially, business-to-business (B2B) e-commerce may support services broadly offered by companies in B2B markets.

In the context of globalization of economy, continuous increase of the role of services in B2B markets and rapid development of information technologies this topic is considered to be of high practical and theoretical importance for business environment. Though nowadays in business literature the number of publications and research papers, devoted separately to e-commerce and B2B markets of goods and services is rather high, The role of e-commerce in the review on how such companies use e-commerce may summarize the knowledge in both fields. It provides a structured knowledge on B2B e-commerce based on the existing literature and can be interesting as a starting point for young researchers. B2B e- commerce is analysed not isolated, but the paper establishes the links and emphasises interdependences to the related fields of management science and hence can generate a broad understanding of the topic. Furthermore, the article may also have an impact on business practice. For the executives, who expect to implement e-commerce in their companies, this research represents a useful reference to getthe first insights and broad theoretical background on this topic and provides different illustrative examples.

Hence, the main objective of this paper was to explore how industrial companies use B2B e- commerce, how it enables their services and what are the main advantages for their businesses. In order to achieve this goal the following tasks were defined:

to build an understanding of B2B markets

to distinguish the opportunities from using e-commerce

to provide a way to evaluate e-commerce opportunitiesfor existing business strategies.

Based on the main objective and the tasks, the paper was divided into four sections. At first, the theoretical background on B2B markets is reviewed. It research represents a useful reference to getthe first insights and broad theoretical background on this topic and provides different illustrative examples.

Hence, the main objective of this paper was to explore how industrial companies use B2B e- commerce, how it enables their services and what are the main advantages for their businesses. In order to achieve this goal the following tasks were defined:

- to build an understanding of B2B markets
- to distinguish the opportunities from using e-commerce
- to provide a way to evaluate e-commerce opportunitiesfor existing business strategies.

Based on the main objective and the tasks, the paper was divided into four sections. At first, the theoretical background on B2B markets is reviewed. It includes the characteristics of B2B markets, procurement process and relationship marketing as the basis for further investigations. After that, a review on B2B e-commerce, main types, trends and opportunities are provided in detail

II. B2B MARKETS: THEORETICAL FRAMEWORK

In general terms B2B can be defined as firm's interaction with other firms, comprising suppliers, distributors, agencies and customers [1]. More concretely, B2B markets are about buying goods and services in order to use them in development, creation and delivery of own products and services or to resell to others [2]. Though, business-to consumer (B2C) markets in business literature and at universities are predominantly discussed

In the proposed model by Morgan and Hunt, the relationship is based on trust and commitment. They define commitment as enduring desire to maintain valued relationship and believe in relationship. It is necessary that both parties believe that the relations are important and want to endure relations indefinitely. Morgan and Hunt define trust as the status, where one party has confidence in the reliability and integrity of the other partners and vice versa. They posit, that can be reached if companies or networks provide "resources, opportunities and benefits that are superior to the offering of alternative partners; maintaining high standards of corporate values and allying oneself

Private industrial networks are owned by a single, often a leading company in industry. It sets the rules, establishes control mechanisms and invites firms to participate in its network. Private industrial networks focus on strategic direct goods and services and are interested in long-term relations. They can be defined as "extendedenterprises", as this webenabled network oftrans- organizational processes is closely tied to the existing ERP System of industrial company [19]. Private industrialnetwork makes sense when there is an opportunity forcompetitive advantages and there is no public or industrysponsored marketplaces or they are with exchange partners having similar values and communicate valuable information, including expectations, market intelligence and evaluation of the partners performance and avoiding malevolently taking advantage of their exchange partners" [Morgan and Hunt, (1994), p.34].

Another interesting model was proposed by Möller and Hallinen (2000). The authors propose to divide marketing relationships into two levels: relationship based on markets (for example, can be used for indirect goods) and relationships based on networks (for example, can be used for direct goods). Figure 2 illustrates this idea.inefficient [17]. Manyglobal players, market-leaders are operating privateindustrial networks, such as GE, Nike, Wal-Mart, etc. Today private industrial networks form the largest part of B2B E-Commerce. For example, some years agoVolkswagen Group introduced the Group BusinessPlatform as a tool for communication and cooperation with its suppliers in order to optimize processes and improve thequality level. The goal of the company was not just to findpartners, but also to integrate their suppliers into all business processes, such a procurement, logistics, quality, technical development, and sustainability [20].

and analyzed, there is a number of characteristics and special features that differ B2B from B2C [3]:

- business customers will purchase just the products they really need and which can increase the value of their own products;
- the relationship is more complex and long-term oriented;
- marketing communication is professional and deep;
- purchasing processes are multistage.

Based on these special characteristics, it reveals, that it is crucial to examine B2B markets separately. The main topics to be discussed are supply chain management (SCM), especially buying process and relationship marketing.

A. Characteristics of B2B markets: B2B vs. B2C

Traditionally, two generic types of markets may be distinguished: consumer markets and business markets, whereas the latter include industrial markets or B2B, business-to-government (B2G) and non-profit organization markets. In general terms B2B can be defined as firm's interaction with other firms, comprising suppliers, distributors, agencies and customers (Vagro and Lusch, 2011). B2B markets are networked organizations operating in a complex environment (Kotler et al., 2009). The management target of the companies is to understand the business buying processes and to build profitable relationships with business consumers by creating additional value (Kotler and Armstrong, 2010). More concretely, B2B markets are about buying goods and services in order to use them in development, creation and delivery of own products and services or to resell to others (Kotler and Armstrong, 2010).The knowledge and understanding of B2B can be really important from different perspectives. Taking for example the ranking of 'Fortune 500', the number of consumer (B2C) and industrial companies (B2B) presented in this list is almost equal. In German The role of e-commerce in B2B markets of goods and services 45 speaking countries especially industrial companies play an important role for the whole economy of the region (Fauska, 2012). And finally, the market volume of B2B is much higher than the one of consumer markets (Kotler and Armstrong, 2010). Hence, before analysing B2B e-commerce it is important to understand the main characteristics of business markets. They can be summarised in three blocks:

- market structure and demand
- nature of buying customers
- decision process.

In comparison to consumer goods markets, business buying process in B2B markets is very complex. It involves large sums of money, technical and economic considerations of all stakeholders, including their own interests, at different levels of organization. In B2B markets buyers and sellers are more interdependent and

work closely together during all the stages of buying process. Moreover, the buying process could create additional value for the partners (Kotler and Armstrong, 2010). According to these features the main differences to B2C, which should be taken into account while analyzing B2B, are the following

- business customers will purchase just the products they really need and which can increase the value of their own products
- the relationship is more complex and long-term-oriented
- marketing communication is professional and deep
- purchasing processes are multistage
- procurement manager buys goods not just for the company, but also in order to present himself, his promotion or bonus can depend on his decision and negotiation skills..

Based on special characteristics of B2B markets, it reveals, that the main topics to be discussed on B2B are supply chain management (SCM), especially buying process and relationship marketing. These two concepts must be reviewed before analysing the opportunities of B2B e- commerce.

B. Procurement Process in B2B Markets

Procurement process as part of SCM can be described as the way firms purchase goods or services they need to produce their own products, which will be sold to

end-customers. As illustrated in Figure 1, business buying process consists of several complex steps that involve not only sellers, buyers and intermediaries, but also different organisational levels and departments in a series of connected and interdependent transactions. That is obvious, that during each phase of the purchasing process the transactional costs occur. The first four steps concentrate on decision where to buy and what to pay for a product. The next steps involve carrying out the purchase formalities. At the end the analysis of the process may be done. This process is described for a one-to-one relationship between buyers and sellers. In B2B market there are many of such relationships and sets of connected processes. The set of firms, which are linked through a series of transactions refer to the supply chain (Laudon and Traver, 2011).logistics, IT, and procurement. That could ensure long-term relationships between the companies.

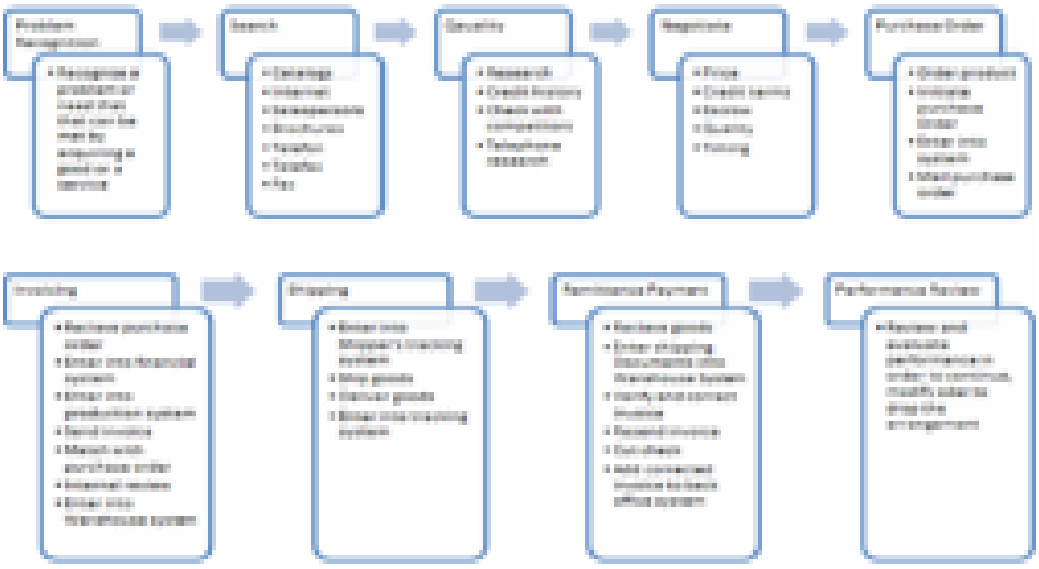

Figure 1 Procurement process in B2B markets (see online version for colours)

C. Relationship Marketing in B2B Markets

During the analysis of B2B markets attention should be paid to relationship marketing. During the last decades a number of essential changes took place in B2B markets, which reinforced the importance of strong relations between business partners. The importance of services has increased dramatically. Quality management has become a topic of high priority, so companies need to involve suppliers as well as customers into their quality management programmes to maintain competitiveness in the market. The development of information technologies facilitates closer interactions between companies. The interactions are getting more complex and even the borders of a company may be blurred (Koutsch, 2003).

As defined by Morgan and Hunt (1994, p.34), "Relationship marketing … refers to all marketing activities directed toward establishing, developing, and maintaining successful relational exchanges,…, involving suppliers, lateral organizations, customers, or one's own employees or business units". Relationships with customers appear to be one of the most important competitive advantages of industrial companies. That is caused by the specific characteristics of B2B markets, such as limited number of partners, constant interchanges between companies, closer collaboration in order to find the best solution for existing problem. Based on these features of B2B markets, it is essential to build strong relationships with partners in order to succeed. As stated by Anderson and Narus, companies cooperate with each other in order to achieve common goals. The outcome from collaboration may exceed the results, which companies could achieve if they were operating isolated (Anderson and Narus, 1990). Morgan and Hunt (1994, p.34) also mention that, "effective competitor in today's global marketplace requires one to be an effective cooperator in some network of organizations". Already in year 1991, Drucker (1991) named the economy of the future as 'network society'. Moreover, according to Prahalad and Ramaswamy (2000), nowadays the focus is shifted from key competences of one company to key competences of a network.

Strong long-term relationships may help companies to support each other in three directions (Koutsch and Smirnova, 2004):

- economical (by cooperating in making investments, cost reduction programmes)
- strategic (developing key competences, knowledge and other intangible assets)
- behavioural (sharing common values, culture and goals, using social networks of each other).

In the proposed model by Morgan and Hunt, the relationship is based on trust and commitment. They define commitment as enduring desire to maintain valued relationship and believe in relationship. It is necessary that both parties believe that the relations are important and want to endure relations indefinitely. Morgan and Hunt define trust as the status, where one party has confidence in the reliability and integrity of the other partners and vice versa. They posit, that can be reached if companies or networks provide "resources, opportunities and benefits that are superior to the offering of alternative partners; maintaining high standards of corporate values and allying oneself with exchange partners having similar values and communicate valuable information, including expectations, market intelligence and evaluation of the partners performance and avoiding malevolently taking advantage of their exchange partners" [Morgan and Hunt, (1994), p.34].

Another interesting model was proposed by Möller and Hallinen (2000). The authors propose to divide marketing relationships into two levels: relationship based on markets (for example, can be used for indirect goods) and relationships based on networks (for example, can be used for direct goods). Figure 2 illustrates this idea.

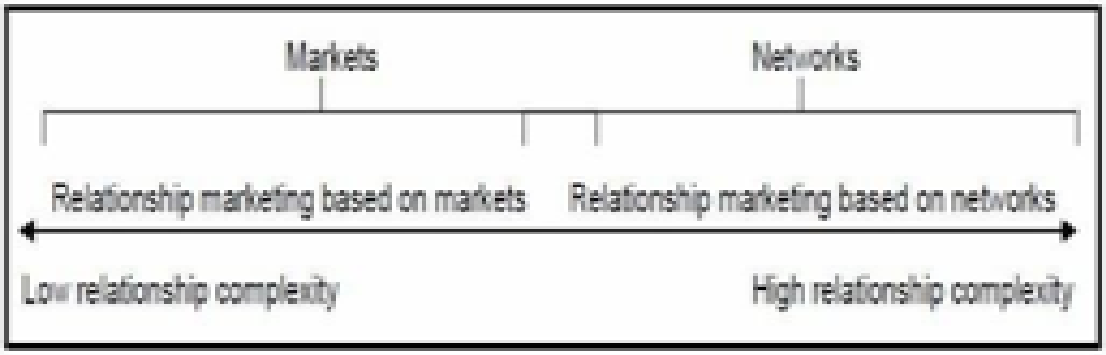

Figure 2 Two main forms of relationship marketing

The main characteristics of marketing relations based on markets are described as (Möller and Hallinen, 2000):

- focus on individual customer relations
- huge number of consumers
- low level of interdependences
- product or services can be easily replaced or substituted
- sellers are ore active than buyers
- focus on a number of interactions and less on the long-term relations
- emphasis on managerial, economic and psychological aspects of exchange.

III. B2B E-COMMERCE: THEORETICAL BACKGROUND AND MAJOR TRENDS

In business practice and among academics there are still some discussions concerning the definition of e-commerce. So it will be important to set a working definition for this paper. Within this article e-commerce will be defined as the use of the internet to transact business, digitally enabled commercial transactions between and among organisations and individuals (Laudon and Traver, 2011).

As nowadays e-commerce is still developing, new variants of existing types of e-commerce may appear. For example, B2G e-commerce can be defined as a part of B2B cooperating with government. Additionally, there are two more fast growing types of e-commerce based on technological distinction:

- peer-to-peer (P2P) e-commerce enables the internet users to share files and other information directly without any intermediary (Laudon and Traver, 2011)
- mobile commerce (M-commerce) is based on use of wireless digital devices, such as netbook, smartphones to transact on the web (Becker et al., 2012).

As working definition of B2B e-commerce for this research, B2B e-commerce will be defined as B2B commerce, which is enabled by the internet (Laudon and Traver, 2011). More concretely, "B2B e-commerce refers to substitution of computer data processing and internet communications for labor services in the production of economic transaction" (Luckey-Reiley and Spulber, 2001).

A. Evolution of e-technology in B2B e-commerce

In order to understand B2B e-commerce mechanisms better, the evolution of e-technology will be introduced in this part of the article. B2B e-commerce has gone through several technology driven stages, which are illustrated in Figure 3.

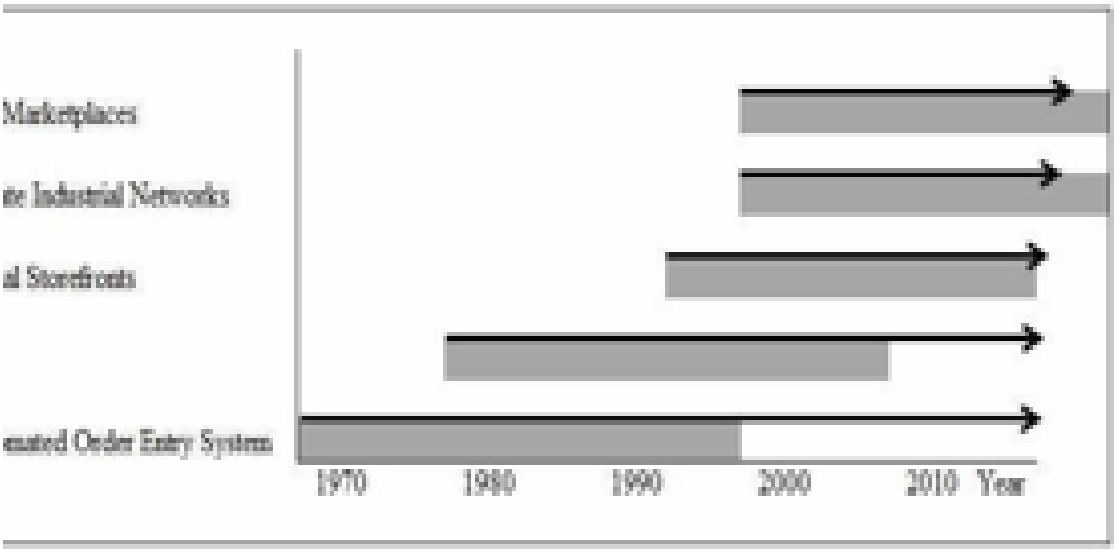

Figure 3 Evolution of the use of technology platforms in B2B e-commerce

In the late 1990s net marketplaces and private industrial networks emerged. They enabled to overcome the limitations of the previous e-technologies. Net marketplaces bring together a huge number of suppliers and purchasing firms together into a single digital marketplace operated over the internet (Zhang and Bhattacharyya, 2010). They can be defined as networked information systems that serve as infrastructure for information exchange and other transactions connected with buying or selling processes (Varadarajan and Jadaw, 2002). Net marketplaces are transaction-based and support many-to-many relationships. B2B net marketplaces boomed dramatically at the end of 1990 and beginning of 2000. Though that was a peak time for Net marketplaces, many of them still exist nowadays (Zhang and Bhattacharya, 2010).

In contrast, private industrial networks are the internet-based communication environment that enables business partner not just to buy or sell goods and services, but also to collaborate with each other, they are relationship-based. They encompass collaboration in products development and manufacturing, marketing activities, inventory management, and etc. Private industrial networks are owned by buyers. Nowadays this form of B2B e-commerce is the most prevalent (Laudon and Traver, 2011).

B. Types of B2B E-Commerce: Net Marketplaces and Private Industrial Networks

In literature on B2B E-Commerce there are different classifications of B2B E-Commerce. Nevertheless, the most often used criteria for classification is a number of agents (buyers and sellers involved into transactions), the characteristics of markets where company operates (vertical or horizontal) and the nature of buyer and seller relationships (either long-term orientated or transaction-based). Different authors name the types of B2B E-Commerce in a slightly different way, though the main idea is mostly the same (based on the criteria mentioned above). In this paper, the classification, proposed by Laudon and Traver [4] in their textbook on E-Commerce, will be reviewed and analyzed. Following this classification B2B E-Commerce can be generally classified into two types: net marketplaces and private industrial networks. The both types and subtypes of B2B E-Commerce will be discussed subsequently.

Net marketplaces bring together a huge number of suppliers and purchasing firms together into a single digital marketplace operated over the Internet [11]. As it is demonstrated in Fig.3, net marketplaces can be classified based on two parameters, “what businesses buy” (manufacturing/direct goods or operating/indirect goods) and “how businesses buy” (focus on spot purchasing or longterm relations) and reflects horizontal markets or vertical markets.

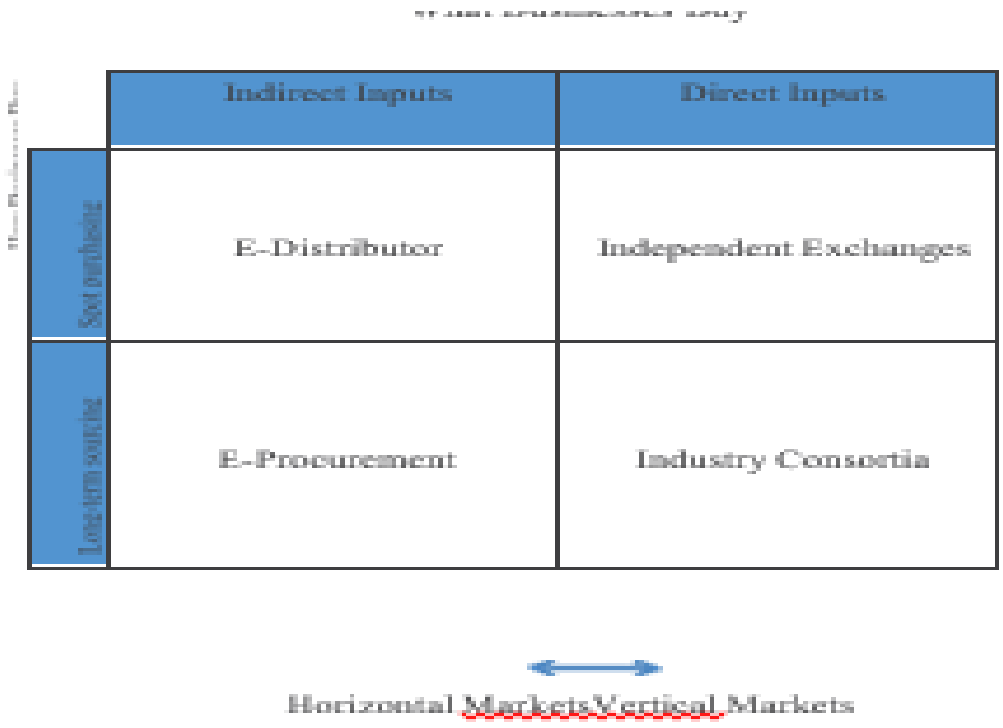

Figure 4. Four main types of net marketplaces [4].

Net marketplaces can be divided into four main types: Edistributors, E-procurement, independent exchanges and industry consortia [4]. Sequentially, these four subtypes of ECommerce will be described and illustrated with examples.

E-Distributors represent the most common and the easiest form of net marketplaces. They simply link suppliers and buyers together, playing a role of traditional intermediary [12]. Often E-Distributors represent the existing "brick-and-mortal" companies, which trade via catalogue and now shift a part of their business online [10]. American company Grainger.com represents an illustrative example for E-Distributor. Grainger is a leading distributor for MRO in the U.S.A. It works with more than 3,000 suppliers and has access to about 2 million customers in

157 countries. Though Grainger was founded as a "catalogue sales business", it recognized the opportunities of technological changes rather early. In 1996 Graiger.com provided the first transaction capable web site in the industry. On the web site of Grainger customers can easily search and compare products, create personal lists, review orders. All these features allow customer to reduce paper work and consequently administrative costs [13].

E-Procurement net marketplace is an independent intermediary which links many sellers and a huge amount of buyers together. This type of marketplaces is usually used for purchasing indirect goods on long-term basis. The value of goods sold by E-Distributor is relative low, whereas the transaction costs concerning these products are relative high due to purchasing frequency. So E-Distributors may add value to buyers by increasing efficiency in procurement [14]. For instance, Ariba.com is operating in this way. Ariba offers not only a network for buyers and sellers, but also a great number of specific customized services, such as management information and communication tools within the system. They may include reporting, automated messaging, and web meetings. As described in this example, E-Procurement net marketplaces add value for both parties, which are involved in the process [15].

Independent exchanges connect many buyers and sellers searching/selling direct goods on spot term in real time environment. They serve vertical market within single industry. The main advantage for buyers is lower prices due to strong competition in independent exchanges. Sellers benefit by receiving an easy access to potential customers [4]. Smarterwork.com can be named here as a very interesting example. Smarterwork illustrates this kind of net marketplaces, which offers mostly services. Smarterwork specializes on linking companies and qualified service providers together. They provide staff for a concrete project and their own facilities, like PC, software and office space. As soon as the project is over the contract between employee and the company will be also ended. It means that the company can save fix costs on personnel dramatically [16].

Industry consortiums are owned by groups of industrial companies. They serve vertical markets and bring together a great number of suppliers with a small number of very large buyers. They are used to form long-term relations for purchasing direct goods. The main goal of

industry consortium is to unify supply chains within the whole industry, across many tires through common data definition, network standards and common platforms [17]. GHX.com represents an illustrative example for industry consortia. It is a consortium for medical services suppliers. They bring companies from healthcare industry together to create new efficient processes and reduce errors in the healthcare supply chain. GHX customers can save money by connecting to GHX and using complementary software solutions to automate procurement processes [18].

Private industrial networks are owned by a single, often a leading company in industry. It sets the rules, establishes control mechanisms and invites firms to participate in its network. Private industrial networks focus on strategic direct goods and services and are interested in long-term relations. They can be defined as "extended enterprises", as this webenabled network of trans-organizational processes is closely tied to the existing ERP System of industrial company [19]. Private industrial network makes sense when there is an opportunity for competitive advantages and there is no public or industry sponsored marketplaces or they are inefficient [17]. Many global players, market-leaders are operating private industrial networks, such as GE, Nike, Wal-Mart, etc.

Today private industrial networks form the largest part of B2B E-Commerce. For example, some years ago Volkswagen Group introduced the Group Business Platform as a tool for communication and cooperation with its suppliers in order to optimize processes and improve the quality level. The goal of the company was not just to find partners, but also to integrate their suppliers into all business processes, such a procurement, logistics, quality, technical development, and sustainability [20].

B. Opportunities of E-Commerce in B2B Markets

After the main characteristics of B2B markets were analyzed, it is obvious that the main opportunities, which companies may expect from of E-Commerce, are the efficiency in SCM processes and enhancement of relations with their business partners. E-Commerce enables the cost reduction during every stage of the buying process, namely, before, during and after the purchase [10]. It was discovered that there are new methods which can be used and certain business activities can be completely restructured [21]. In summary, the following conclusions concerning cost efficiency as a consequence of using E-Commerce can be done:

- both demand and supply sites can improve productivity by using E-Commerce;
- increase the transparence of information, goods and financial flows;
- efficient reach of potential sellers and buyers and

as a result the improvement of matching the buyers and sellers; • reduction of the transaction costs at each stage of procurement processes;

- time and personnel reduction for procurement or selling processes.

Additionally, B2B E-Commerce is able to form and intensify collaboration between business partners. It acts as a dialogue simulator, facilitates interactivity and real time information exchange. By increasing collaboration between buyers and sellers, E-Commerce may improve the customization of offers, quality of products based on analysis on sales history and forecasts. It enables seamless information exchange that makes the collaboration easy and effective and leads in the future to the competitive advantages [14]. B2B E-Commerce technologies can be used to build up and sustain competitive advantages for companies [22].

C. Market Development of B2B E-Commerce

During the last decades B2B E-Commerce has been promptly growing all over the world. According to the study of the economies of thirteen countries (G8, Brazil, China, India, South Korea and Sweden, which contribute more than 70 percent of global gross domestic product) the Internet is now used in every country, in each sector and by most of the companies and counts for about 3.4 percent of GDP. If the Internet were a sector, it would be bigger than energy or agriculture industries and its contribution to GDP would be bigger than those of Spain or Canada Over the last 15 years the Internet accounted for about 10 percent of GPD growth within the studied countries. As well it has a great impact on the development of small and medium- sized enterprises (SME). SME with high Web presence grew two times quicker as those that had low level of presence [23].

Moreover, the main IT trends, like the increase of the Internet security and comfort level of online payments, cloud computing and software-as-a-service (SaaS), integration of enterprise resource planning systems (ERP) [4], demonstrate that the implementation and the utilization of B2B ECommerce is getting less costly, provides more security and enables the "ease of use" for the end-users. All these technical innovations and advances secure the future development of B2B E-Commerce.

Nevertheless, the implementation and realization of B2B E-commerce significantly differs from country to country. According to Berthon et al. B2B marketers have to consider "hard" terms such as infrastructure as well as "soft" terms, like values before building E-Commerce relationships in other countries [24]. If a customer trusts online supplier he is even more committed to open communication and share of information [25]. There are three drivers, which could help companies to decide whether to use B2B E-Commerce while entering new geographical markets [24]. These key drivers are the following [24]:

- E-readiness. It determines the ease with which a business relationship can be conducted.
- Country's values. They need to be understood as a fundamental facet of culture.
- Corruption. It engenders the loss of social integrity and promotes mistrust between social actors.

The authors mention that technical infrastructure is an important, but not a sufficient condition for development of B2B E-Commerce. Mostly the economic and social development, as well as the level of corruption may corrode E-Commerce [24]. Here it will be interesting to provide some examples. North America and Western Europe present the best conditions for developing E-Commerce relations. Asia Pacific can be the second best choice to invest in ECommerce. Central and Eastern Europe are still challenging a high level of corruption, which hampers the development of B2B E-Commerce. Africa, Middle East and Latin America are currently struggling with building the physical, economic and political infrastructure to provide a platform for E-Commerce [24]. The Economist Intelligence Unit publishes yearly "Digital Economy Ranking" Report, which provides an interesting benchmarking of the countries [26].

IV. EVALUATION OF E-COMMERCE OPPORTUNITIES

Though many different benefits of E-Commerce

for B2B companies were discussed, nevertheless it is crucial to keep in mind, that it is still not a universal medium for decreasing transactional costs and enhancing relationships with partners. It is very important to consider the existing company's strategy and analyze how E- Commerce can match it. In this context an interesting and practical approach was proposed by Feeny, which can help managers to start this strategic analysis [3].

During the first step Feeny proposes to construct a coherent map of e-opportunity, based on three dimensions: E-Operations, E-Marketing and E-Services [27]. The basic information on these three domains is summarized in Table 1. It is recommended for a manager to go through all these three domains and analyze the existing processes and strategy to check if there is a possibility to introduce ECommerce or to replace the current processes by E-Solutions [27]:

- Will E-Commerce strategically change the way a business manages itself and its supply chain?
- Can a company achieve strategic changes in downstream activities?
- Can E-Commerce give companies a new way to address an identified set of customer needs?

Table I. Three E-Opportunities Domains And Their Components [27]

buying processes and to build profitable relationships with business partners, these two issues were firstly described in detail. It demonstrated that the procurement process of industrial company is a highly complex process

Domain	Components
E-Operations (Web-based initiatives that improve the creation of existing products)	- Automation of administrative processes - Supply chain reconfiguration and integration - Re-engineering of primary infrastructure - Intensified competitive procurement - Increased parenting value
E-Marketing (Web-based initiatives that improve the marketing of existing products)	- Enhanced selling process - Enhanced customer usage experience - Enhanced customer buying experience
E-Services (Web-based initiatives that provide customer affiliated services)	- Understanding of customer needs - Provision of customer services - Knowledge of all relevant provides - Negotiation of customer requirements - Construction of customer options

involving many stakeholders. It consists of nine steps, from problem recognition to evaluation of the process

As soon as the first analysis is done, manager has to answer the question, if these developments can change the cost structure and positively influence the relationship with the existing customers and improve customer platform and penetration, considering the investment costs and time horizons. This evaluation can be used as a starting point for analyzing the use of E- Commerce as a competitive advantage [3].

V. CONCLUSION

The objective of this article was to explore how industrial companies use B2B e-commerce and to analyse the role of e-commerce for their businesses. This objective was reached by an analysis of the desk research and the paper represents a review of some theoretical approaches on the topic.

The objective and the chosen methods of the research defined the structure of the article. As the management target of B2B companies is to understand the business

performance. That means that during each stage of the process transactional costs occur. As it was shown, the use of e-commerce can significantly decrease these costs for information, communication and decision and thus contribute to profitability of a business. It reduces not only costs for locating an appropriate seller or buyer, obtaining price and product information, it also may affect the entire industry structure. E-commerce trends to raise bargaining power over suppliers, leading to less asymmetry between supply and demand sides. The internet provides new effective channel to reach end users directly and gives an opportunity for all companies to get an equal access to buyers and suppliers. That means that ECommerce can also facilitate building up and maintaining the relations with business partners, which appear to be one of the crucial assets. As it was demonstrated on different practical examples, e-commerce also supports the use of different kinds of additional services provided by industrial companies, which may increase the value of products and services and could be also considered as

competitive advantage of a company.

In practice industrial companies can use e-commerce in

form of net marketplaces or private industrial networks. Depending on what and how companies buy or sell, as well on the industry, e-distributor, independent exchanges, e- procurement or industry consortia models can be chosen as a form of net marketplace. Different examples of companies selling either goods or services, being 'brick- and-mortal' or virtual demonstrate successful use of such e-commerce types to collaborate with their business partners.

Despite of the recent economic recession B2B e-commerce continues to grow. Moreover, the internet technology provides new inexpensive opportunities for implementation of e-commerce. Though in general terms B2B e-commerce is growing rapidly all over the world, there are still differences in the extend of e-commerce use. Implementation of B2B e-commerce strongly differs from country to country, depending on such key drivers like e-readiness, country's values and level of corruption.

Moreover, it is crucial to emphasise that the use of e-commerce and its advantages still depend on a company and its business strategy. Though many different scholars and empirical evidences indicated, that e-commerce may play a critical role for facilitating efficiency and profitability of industrial companies, it appears to be crucial to examine whether it prevails also within different business strategies and may be considered as universal method, applicable in many companies to decrease costs and build closer partner relations. This question opens a number of interesting and challenging paths for future research.

The results of the study might have both theoretical and practical impact. As it represents a review and summarises a broad theoretical background on the topic, it could be chosen as a basis for further research on different strategies in B2B markets and analysis of the role of B2B e- commerce for them. for example, this research was recently used as the first step within a research paper devoted to the topic "business strategies and B2B e- commerce opportunities of global narrow specialized companies" (Fauska, 2012).

The paper also provides guidance for managers and gives them an outlook on how e-commerce can be used by their companies. Hence, it may support managers in decision making on e-commerce investments, during definition, implementation and execution of e-commerce strategy.

Paying guest finder

Dr. K.K.Tripathi,Patil Lakshmikant, Mhatre Gunaksha, Gole Sandip
Department Of Computer Engineering, Shivajirao Jondhale College of Engineering Dombivli (E)
patillakshmikant10@gmail.com | gunaksha2601@gmail.com | Sandipgole671@gmail.com.

Abstract— **The software "PAYING GUEST FINDER" was created to manage numerous actions in the PG, as the name implies. The system will compare the user's request with the database's details, and once a match is made, the user is provided with the necessary information. From the system's admin page, he can enter information about the rooms. This will lessen the time new and returning students must spend looking for rooms and other essential items. A computerized system that is more user-friendly and more GUI focused is designed in response to the shortcomings of the existing system in order to be compatible with it.**

Keyword- Paying Guest, Graphical User Interface, Advertisement, Location, Accommodations, House

I. INTRODUCTION

Despite the many inherent benefits of traditional websites, mobile apps and mobile websites are becoming very popular. This is because majority of the consumers now basically browse the Internet using their mobile phones or tablets. PG finder is a website that seamlessly connects and interacts with everyone globally. PG finder is a valuable tool for the modern business. Any news, information, advertisements, displayed on this website reaches millions of potential customers. A mobile application, sometimes known as a mobile app, is a type of software created specifically for smartphones and tablet computers.

Frequently, websites that run in mobile web browsers rather than directly on mobile devices and desktop applications that run on desktop computers are contrasted with mobile apps. Moving away from the integrated software systems often seen on PCs are mobile applications. Instead, each app offers a few discrete and constrained functions, like a game, a calculator, or mobile Web browsing. Due to the early mobile devices' constrained hardware capabilities, websites may have avoided multitasking; yet, because they let users choose what their devices can do, their specialization is now part of what makes them desirable. A good and authorized PG can be located with the aid of the website PG finder.

II. LITERATURE REVIEW

1	International Research Journal of Engineering and Technology (IRJET)	This system enables the user to make their own online reservations for paying guests' rental homes, dining establishments, as well as stationary or school-related items..
2	Online Accommodation Submitted By: ROHIT JHA ABHISHEK ANAND SOUMYA SHRIVASTAVA	User can take a look on different aspects of the Information provided like location map, food, price, transportation facility and even security measuresand select a best PG oftheir choice.
3	"PG LOCATOR APP" Mr .Nawale Rohit Ramhari , Mr. Mouriya Narayan Dilip , Mr.Saindane Sumit Madhukar, Mr.Wagh Prasad Sunil	In the present system a customer can get only little information like address, contact number and food. Due to lack of information like price, exact location, security measures, the customer is unable to find the best PG of their choice.
4	PG Locator Akshatha.M1 , Bhavya .B. M2 Student1 , Assistant professor	Technology refers to the collection of tools that make it easier to use, create, manage and exchange information. In the earlier times, the use of tools by human beings was for the process of discovery and evolution..
5	Online Application for Booking Paying Guest and Explore Mess in Nearby Location	Idea behind project is to solve problem of people which they are facing when they shift to different city.

A literature review is primarily conducted to analyse the context of the current project, which aids in identifying weaknesses in the system in place and provides direction for how to address unresolved issues.Therefore, the following themes not only present the background but also expose the issues and shortcomings that prompted the development of this project. Numerous studies have been conducted on how people learn to behave in groups. The section that follows examines many sources that cover a range of subjects connected to group behaviour.

With the help of this method, users can book themselves independently online. The system can perform a variety of tasks, including: providing a query for arrival date and length of stay; providing the number of on rooms; viewing all available rooms and allowing the user to select one or more of them; recording the type of guests and how many will be in each room; providing the cost of booking; and asking the users if they were satisfied with their accommodations.Some figures with explanations are offered to help with system understanding.

The link between the web server and the end user is depicted in the first picture, along with a step-by-step breakdown of how users interact with statistics and the application. The interaction between the user and the screen is depicted in the second figure. When a user interacts with the interface, several processes are carried out, and the screen displays additional pages. The third graphic, however, demonstrates how each page is connected to the others.The first is when the user navigates through the pages in order after entering their information. The user has the option to navigate to the previous pages or the login page using the second method of navigation. The page will preserve the most recent page if one user's insert is rejected as the final one.

III. PROBLEM STATEMENT

Everyone is aware of how important patience is and should possess a sufficient amount of it. You will undoubtedly find it among those who reside as paying guests. As a paying visitor, you will need to learn to be very patient because every step will require you to adjust. Here are seven potential problems that you could run across as a student looking for dorms, apartments, or PGs.

Advertisements for PG Finder, apartments, and hostels will often claim that the rooms are large and airy, but in practise, things tend to be different.You will discover when you check out the PG that the rooms are not even roomy, which proves that you should never believe anything you read in an advertisement.
So, it is better to check everything by yourself.

IV. EXISTING SYSTEM

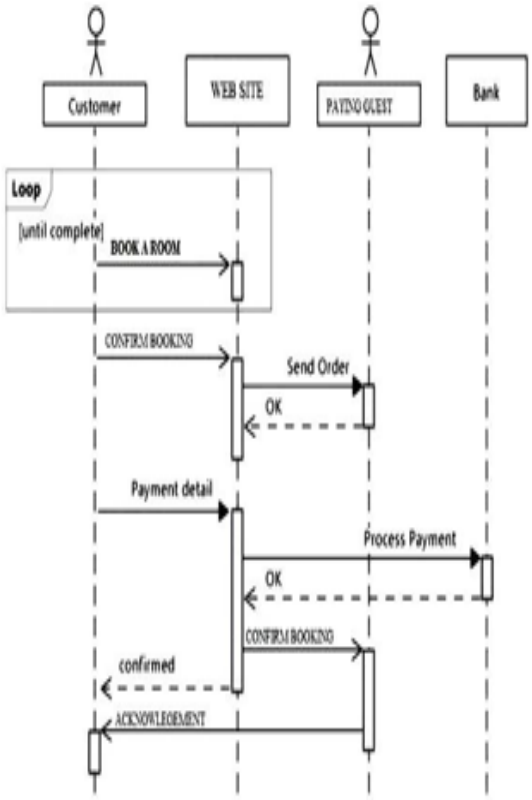

Figure -1: Sequence diagram

The goal of what we are attempting to illustrate in this research is partially satisfied by a variety of discrete applications in the Existing System. Due to their separate nature, each will collect its data in a unique way. As a result, there is a significant use of time and data. To own a paying rental guest and eat in a food zone, the user needs launch a different application. As a result, the system's integration with this application is inadequate. A person who uses NESTAWAY to book a room in a paying guest based on his location would not be able to reach a suitable dining zone because NESTAWAY only offers information on the infrastructure of the accommodation. Because of this, even though the current system resolves the issue, it does so in a busy, sluggish, and time-consuming manner, which provides us a suggestion to create an application based on the algorithm of merging various platforms.

Booking options for apartments and hotel rooms are offered, including OYO & NESTAWAY. Applications like ZOMATO are available to find, review, and visit eateries. There are currently no solutions for finding

stationery stores close by.
In the present system a customer can get only little information like address, contact number and food. Due to lack of information like price, exact location, security measures, the customer is unable to find the best PG of their choice. Often the customer may be misguided.

Disadvantages of Existing System
They are meant for hotel and flat services only. None offer a service for paying visitors. Lack of restaurant services at a reasonable price in the application. insufficient integration high consumption of data. takes a lot of time. many platforms for various jobs.

V. PROPOSED SYSTEM

General model of online accommodation is shown in fig in which administrator and staff at remote Server can send request to client system to capture their desktop.

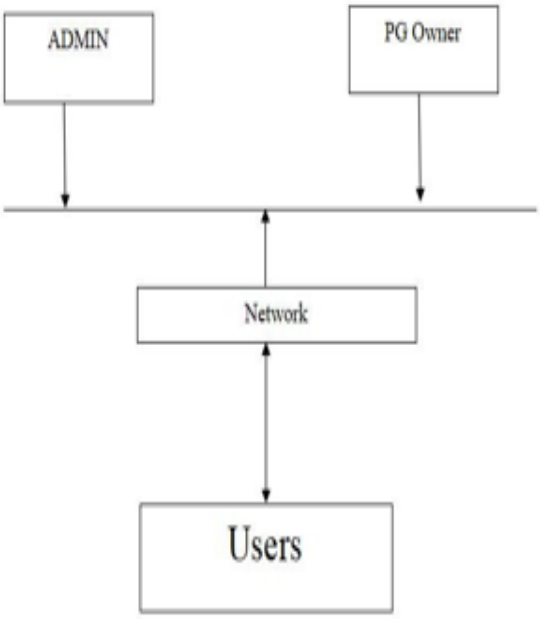

Figure 2:- General Model

The system is divided into various modules ,each module are further divided into sub-module. The connection of the main modules is shown with the help of DFDs.DFDs are made of the following representation

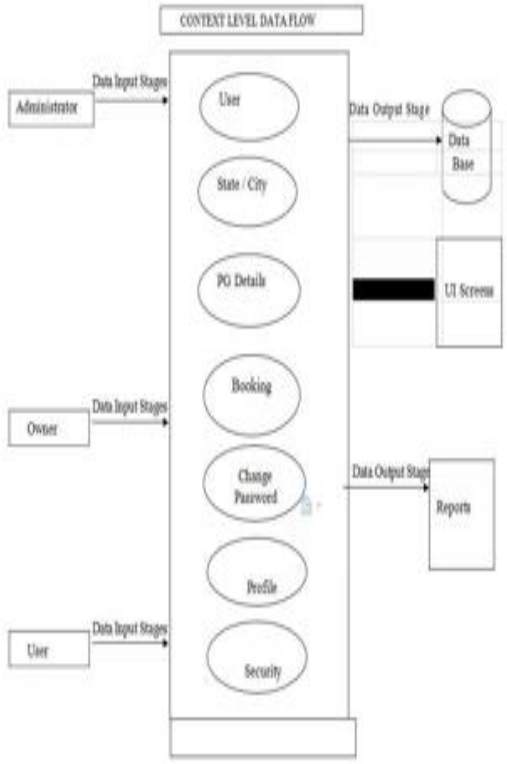

Figure -3: Data Flow Diagram for Context Level

This Data Flow Diagram For Context Level Shows Data Flow Of The System.

We offer a project that is a web application used to reserve paying guest lodging, a dining establishment or restaurant, as well as a store selling school supplies or other stationary close to the user's location. It is a platform-integrated programme that includes all three elements. They were discrete and random before in the current system, but it has been combined into one distinct application currently. This includes not only making things easier for the customers but also assisting different individuals in hosting their lodging on the website. A person that visits our website enters his or her location (or taken up manually). There will be several cloud storing features on our website.
The user will be able to locate every paying visitor in the area using these cloud services. The consumer can then get in touch with the specific host of the rental service to inquire about booking and room availability. The host can update the availability features by utilizing our application to access the cloud storage. The user will be able to explore our application using real-time tracking and locate food zones based on the position of paying customers. As a result, the paying customer won't have to worry about getting to the restaurant.

VI. ADVANTAGES OF PROPOSED SYSTEM

1. used to reserve lodging for paying visitors, a dining establishment, as well as stationary or school-related items.

2. Previously, they were discrete and random in the current system; today, they have been combined into one different website.
3. used to reserve lodging for paying visitors, a dining establishment, as well as stationary or school-related items.
4. Previously, they were separate and random in the current system; today, they have been combined into one unique application.

VII. RESULTS

Figure 4:- Home page
This is How The website Will Look Like When You First Open It

Figure 4:- Sign up page
This is where users can create a new account on the website.

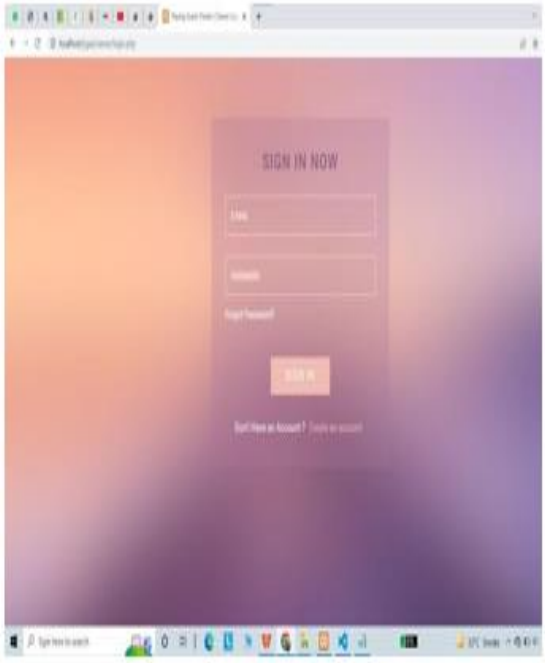

Figure 5: - Login Page

Figure 6: - Admin Dashboard Page

VIII. CONCLUSION AND FUTURE SCOPE

This integrates basic amenities for the users especially the students in one platform. It also adds the capability of promoting the hosts' lodging options through the internet application. Overall, this application will be a blessing for all students because it gives them access to a portable all-in- one application. In the current system, none of the programme enable a user-friendly environment where all three elements are combined into a single integrated platform. The website contains a number of conclusive elements that imply further development and the creation of a business perspective using different hosting platforms is possible. Cloud services are included, which makes it even more amazing. The proof that the website makes use of the positioning system might be a tool that helps the website in its design. Future website development will result from the website's adaptable and simple design. This website compiles all the everyday concerns that can be used as inspiration for business perception.This website has the potential to be a long-term business augmentation. Data transparency may result from the open and subjunctive nature of the communication between the client and the host. This application not only addresses problems, but also considers the preferences or choices of the users when they are in a different location."Time is money," as the saying goes from a managerial perspective, is true. Finally, the paper offers a suggestion to help people manage their time and data better, which is a benefit to everyone.

A Survey of Methodologies used in Explainable Recommendation Systems

Drashti Shrimal , Dr. Harshali Patil
Computer Engineering department,Thakur College of Engineering & Technology, Mumbai, India
drashti.shrimal@tcetmumbai.in, harshali.patil@tcetmumbai.in.

Abstract— **Explanations in recommender systems help users better understand why a recommendation (or a list of recommendations) is generated. The increase in sophistication and complexityof recommendation algorithms has turned them into black boxes where the algorithmic reasoning behind the predictions is hard to understand by users. Explaining recommendations has become an important requirement for enhancing users' trust and satisfaction. However, explanation methods vary across different recommender models, increasing engineering costs. As recommender systems become ever more inscrutable, directly explaining recommender systems sometimes becomes impossible. This paper aims at exploring the concept of using SHAP (SHapley Additive exPlanations) values to provide counterfactual explanations for recommendations. By analyzing the impact of different features on the recommendation outcome, SHAP values can help to identify areas of improvement for the recommendation system. The paper also discusses the use of interpretable machine learning techniques for generating product feature recommendations that are easily understood by users. Finally, the article proposes the use of local surrogate models to explain individual recommendations, by using a simplified model that is easier to interpret than the original recommendation algorithm. Overall, the article provides insights into the challenges of explaining recommendations and offers potential solutions for creating more transparent and user-friendly recommendation systems.**

Keyword -Explanations, Recommendation systems, Shap-enhanced, Interpretable Machine Learning.

I. INTRODUCTION

Recommendation systems have been a fundamental component of various digital platforms such as e-commerce, social media, and entertainment services. These systems are designed to predict users' preferences and suggest relevant items, such as products, movies, or music. However, traditional recommendation systems often lack transparency and interpretability, which can lead to distrust and dissatisfaction among users. Explainable recommendation systems (XRS) aim to address this issue by providing clear and understandable explanations of how recommendations are generated, helping users to make informed decisions and build trust in the system.

As recommendation systems become more prevalent in our daily lives, it is increasingly important to ensure that these systems are transparent and understandable to their users. Explainable recommendation systems are designed to provide users with insight into why certain recommendations are being made, thereby increasing transparency and user trust. These systems not only enhance the user experience but also provide businesses with opportunities to optimize their recommendation strategies. In this article, we will explore the concept of explainable recommendation systems and their importance in promoting user understanding and trust. We will also discuss the importance & challenges associated with developing these systems.

II. IMPORTANCE OF XRS

Explainable recommendation systems are important because they help to improve the transparency and accountability of the recommendation process. By providing clear and understandable reasons for why certain recommendations are being made, users can have more trust in the system and feel more confident in the recommendations they receive. Additionally, explainable recommendation systems can help to reduce bias and discrimination in the recommendation process. By identifying and explaining the factors that are being used to make recommendations, it becomes easier to identify and address any potential biases or discriminatory practices. Moreover, explainable recommendation systems can be used to provide educational or informative recommendations that help users learn more about a particular topic or product. This approach can encourage users to explore new areas of interest and promote lifelong learning. Finally, explainable recommendation systems can help to improve user satisfaction and engagement. By providing clear and meaningful explanations for recommendations, users are more likely to understand and appreciate the value of the system, and are more likely to continue using it over time. In summary, explainable recommendation systems provide transparency, trust, and accountability in recommendation systems. They can also help identify biases and inaccuracies and provide educational or informative recommendations.

III. CHALLENGES FACED BY XRS

Let's review a set of common challenges faced by Explainable Recommendation systems:

1. Lack of standardized interpretability metrics: There is a lack of standardized metrics to measure the interpretability of recommendation systems. This makes it challenging to compare the interpretability of different

systems.

2. Difficulty in balancing accuracy and interpretability: Explainable recommendation systems often struggle to balance accuracy and interpretability. More complex models may provide higher accuracy, but may be difficult to interpret. Simpler models may be more interpretable, but may not provide as high accuracy.
3. Difficulty in understanding complex models: Complex models such as deep learning models can be difficult to understand and interpret. This makes it challenging to explain the recommendations generated by these models.
4. Limited availability of labeled data: Explainable recommendation systems require labeled data to train interpretable models. However, labeled data is often limited, making it challenging to train these models.
5. Privacy concerns: Explainable recommendation systems may collect and use sensitive user data to generate recommendations. This can raise privacy concerns and may limit the adoption of these systems.
6. User trust: Users may not trust the recommendations generated by explainable recommendation systems if they do not understand how the system works. This can limit the adoption and effectiveness of these systems.
7. Difficulty in handling context: Explainable recommendation systems may struggle to handle context-dependent recommendations. For example, recommending a winter coat may be appropriate in one context, but not in another.

IV. LITERATURE SURVEY

A. Shap-enhanced counterfactual explanations for recommendations

In this paper, a method for explaining recommendations in a recommendation system is presented. The method uses SHAP (SHapley Additive exPlanations) to calculate the contribution of each feature in making a recommendation. Instead of using the SHAP outputs directly, the method uses them to select possible candidates for counterfactual explanations, which are easier to understand and more faithful. The explanation method can be applied at two levels: list-level explanations that consider the recommendation list as a whole and instance-level explanation that only explain a single instance in the list. Experiments showed that SHAP can reduce the time needed for searching counterfactual explanations under certain conditions. The authors plan to evaluate the explanation method through a user study, to extend the approach to large-scale data and other recommendation systems that do not involve features, and to incorporate contextual information and other side information into the explanations.

The authors of this paper present a case study to explain recommendations made by a context-aware recommendation system (CARS) that was proposed in a previous paper. The dataset used is LDOS-CoMoDa, a dataset for context-aware movie recommendation that includes 121 users, 1197 movies, and 12 context factors. The authors chose to focus on the three most impacting context factors: "social", "mood", and "physical". The goal of the recommendation system is to generate recommendations for a user given their contextual situation, which is composed of several contextual conditions. To apply Algorithms to the CARS, the authors compute counterfactual explanations for the recommendations. In this case, the contextual factors are all categorical and the values of the contextual factors are changed randomly to identify counterfactual explanations. The authors present an example where the user's mood is positive and is identified as the most impacting factor. Changing the user's mood from positive to negative results in a change in the recommended movie list. The authors explain the recommendations at the instance level (Top-1), meaning they explain the reasoning behind a single recommendation.

Let’s have an overview on the contributions of the paper. The paper "Shap-enhanced counterfactual explanations for recommendations" is significant and contributes to the field of machine learning in several ways:

- Explanation: The paper provides a way to explain the recommendations made by machine learning models, which is important for building trust and improving transparency in the AI field.
- Counterfactual explanations: The paper introduces the concept of counterfactual explanations for recommendations, which allows for a better understanding of how a particular recommendation was made. The approach helps users to understand the impact of changing certain features on the recommendation and how it would have affected the outcome.
- Model-agnostic approach: The approach is modelagnostic, meaning it can be applied to any machine learning model, regardless of the underlying algorithm. This makes the method more widely applicable and accessible.
- Empirical evaluation: The paper provides empirical evidence of the effectiveness of the approach through experiments on real-world dataset. Let’s have a glance on the strengths and weaknesses of the approach:

a) Strengths

- The paper presents a novel approach to provide counterfactual explanations for recommendation systems, by incorporating the SHAP values.
- The results demonstrate that the SHAP-enhanced explanations provide better explanations compared to traditional methods, as they are able to capture non-linear relationships between features and model predictions.
- The approach is flexible and can be applied to various recommendation systems, including both

collaborative filtering and matrix factorization models.

- The paper provides a comprehensive evaluation of the proposed approach, including both qualitative and quantitative analysis.

b) Weaknesses:

- The study only focuses on a small dataset, and it may not be generalizable to other recommendation systems or datasets.
- The evaluation metrics used in the paper are limited, and it would be beneficial to consider other metrics to evaluate the quality of explanations.
- The paper does not provide a thorough discussion on the limitations of the proposed approach and its potential drawbacks.
- The study does not consider the scalability of the approach, and it may not be suitable for large-scale recommendation systems.
- Overall, the paper presents a promising approach to provide counterfactual explanations for recommendation systems, but further research is needed to validate its effectiveness and generalizability. [1]

B. Acronyms Online Product Feature Recommendations with Interpretable Machine Learning

The paper deals with the problem of helping customers purchase the best product among alternative products. The authors propose an interpretable machine learning approach to determine the key features of a product that best explain the price and help customers differentiate the most suitable product. The problem is formulated as a supervised machine learning problem based on price and evaluated using linear and tree models with Shapley Values. The results of offline evaluation show that the proposed method outperforms the baseline and is comparable in conversion rate to the baseline in online A/B tests. The authors also involve human experts to evaluate the relevance of the recommendations.

The authors focus on building a product feature recommendation system for online customers. The aim of this system is to help customers differentiate specific products from a set of similar products based on recommended features. The paper uses interpretable machine learning techniques to explain how the machine learning models work and to facilitate human understanding of the final model. The authors select SHAP (SHapley Additive exPlanations), a model-agnostic method, as the tool to interpret the machine learning models and understand the feature importance. The paper describes the process of processing the raw data, extracting features, and building regression models using Linear Regression, LightGBM and CatBoost. The authors use these regression models to learn the feature importance and understand what features contribute more to the product's price. The authors also use the feature direction to understand if a feature positively or negatively contributes to the product price. The final feature ranking list is computed by averaging the Shapley Values for each feature from all three regression models. The authors evaluate the proposed method against a baseline algorithm Left Nav Algorithm and find that it scores higher on offline evaluation metrics and is comparable with the baseline algorithm in online A/B tests.

Let’s have an overview on the contributions of the paper.

The paper "Online Product Feature Recommendations with Interpretable Machine Learning" is significant because it addresses the need for interpretable product feature recommendations for customers in e-commerce settings.

It contributes to the field by introducing a new approach to product feature recommendations that utilizes interpretable machine learning to generate feature recommendations. The use of the price as the training label and the study of the Shapley Values provide a unique and effective solution to the problem of product feature recommendations. The results of the offline evaluation and online A/B tests demonstrate the effectiveness of the proposed approach, making it a significant contribution to the field of ecommerce product recommendations.

Let’s have a glance on the strengths and weaknesses of the approach:

a) Strengths:

- The use of the model-agnostic method, Shapley Values, allows for interpretation of the contribution of features to the model predictions based on data visualizations.
- The approach has been evaluated against a strong baseline and has achieved higher scores in offline evaluations on metrics such as NDCG, precision, recall and coverage.

b) Weaknesses:

- The approach is limited to the use of the product price as the training label and may not be suitable for other types of training labels.
- The use of human experts to label the top features may introduce bias and subjectivity into the evaluation process.
- The online A/B tests on conversion rate were only comparable with the baseline and may not have a significant improvement over existing approaches. [2]

C. Towards Explaining Recommendations Through Local Surrogate Models

The paper aims to provide an explanation for recommendations generated by machine learning models. The authors address the issue of limited interpretability in existing recommendation systems and present a new approach to enhance their explainability. The paper proposes the use of local surrogate models, which are simple and interpretable models that are trained to approximate the behavior of the complex recommendation model in a local region around a specific instance. The authors argue that these local

surrogate models can provide a better explanation of the recommendation compared to global models that attempt to explain the behavior of the recommendation model for the entire data set. The authors evaluate the performance of the proposed approach on a movie recommendation task, using a matrix factorization model as the recommendation model. The results show that the local surrogate models can effectively explain the recommendations generated by the complex model, by highlighting the features that contribute most to the prediction. The paper concludes that the use of local surrogate models can provide a simple and interpretable explanation for recommendations generated by complex machine learning models, helping users to understand the reasoning behind the recommendations. This can increase the transparency and trust of the recommendation system, leading to a more positive user experience.

Let's have an overview on the contributions of the paper. Overall, the paper contributes to the field by presenting a novel approach to enhance the interpretability of recommendation systems, which can benefit both users and practitioners of machine learning-based recommendation systems.

Let's have a glance on the strengths and weaknesses of the approach:

a) Strengths:

- Local interpretability: The method proposed in the paper provides local interpretability of recommendation systems, which means that the reasons for a particular recommendation can be explained at the individual user level. This is useful for building trust with users and for identifying potential biases or inaccuracies in the system.
- Scalability: The method is scalable and can be applied to large datasets and complex recommendation algorithms. This is important for real-world applications where recommendation systems may have millions of users and items.
- Flexibility: The proposed method is flexible and can be applied to a wide range of recommendation algorithms, including collaborative filtering and content-based approaches. This means that it can be adapted to different domains and applications.
- Accuracy: The paper reports that the proposed method is able to achieve high accuracy in predicting user preferences and explaining recommendations. This is important for building trust with users and for improving the overall performance of recommendation systems.
- Novelty: The proposed method is a novel approach to explaining recommendation systems, which means that it offers a new perspective on this important problem. This can lead to new insights and improvements in recommendation systems.

b) Weaknesses:

- Limited interpretability: Local surrogate models are designed to be simpler and more interpretable than the original machine learning model, but they can still be difficult to interpret in some cases. The interpretation of these models is limited to the specific features used by the surrogate model and does not necessarily provide a complete understanding of the original model.
- Data dependency: The effectiveness of local surrogate models is highly dependent on the data used to train them. If the data is not representative or if there are biases in the data, the explanations provided by the surrogate model may not be accurate or trustworthy.
- Scalability: Local surrogate models require the computation of a new model for each prediction, which can be computationally expensive and timeconsuming. This can limit the scalability of the technique, particularly in real-time applications where speed is important.
- Lack of generality: Local surrogate models only explain the predictions for a single instance and do not provide a global understanding of the model. This can limit the usefulness of the technique for understanding the behavior of the model as a whole.
- Interpretation bias: The interpretation of local surrogate models may be biased towards the assumptions and choices made by the modeler. This can limit the ability of the technique to

provide unbiased and objective explanations. [3]

V. CONCLUSION

In recent years, there has been a growing interest in developing interpretable machine learning models for making recommendations in e-commerce and other domains. One approach to achieving interpretability is through the use of Shapley values to generate counterfactual explanations for recommendations. These explanations can help users understand why certain products or features are recommended to them and can increase their trust in the system.

The paper "Shap-enhanced counterfactual explanations for recommendations" proposes a novel method for generating counterfactual explanations that combines Shapley values with causal inference techniques. The method is evaluated on a real-world e-commerce dataset and is shown to outperform existing methods in terms of both the quality of the explanations and the accuracy of the recommendations. Another paper, "Online Product Feature Recommendations with Interpretable Machine Learning", proposes a framework for making feature recommendations in an online setting using interpretable machine learning models. The framework uses a combination of collaborative filtering and decision trees to generate recommendations and provides interpretable explanations for the recommendations using Shapley values. [4] Finally, the paper "Towards Explaining Recommendations through Local Surrogate Models" proposes a method for generating local surrogate models that can provide explanations for individual

recommendations. The method is evaluated on a movie recommendation dataset and is shown to provide accurate and interpretable explanations for the recommendations. [5]

In conclusion, these papers demonstrate the potential of interpretable machine learning models and Shapley values for generating accurate and interpretable recommendations and explanations in e-commerce and other domains. The proposed methods can help increase user trust and satisfaction with recommendation systems and can provide valuable insights into how these systems make recommendations.

Edge Computing & Emerging Applications

Tarunima Mukherjee, Dr. Harshali Patil
Thakur College of Engineering & Technology , Kandivali East – Mumbai, India
tarunima.mukherjee@tcetmumbai.in, harshali.patil@thakureducation.

Abstract— **In last few years, the Edge computing paradigm has**

gained traction in both research field and industrial applications. With the proliferation in the area of Internet of Things (IoT), the number of smart devices getting connected to the Internet is increasing at a rapid pace thereby resulting in generation of large-scale data, which in turn has led to an increase in issues such as high bandwidth load, privacy issues, lesser response speeds, and security concerns in traditional cloud computing models. Cloud computing is no longer sufficient to support the diverse needs of today's intelligent society for data processing, resulting in emergence of edge computing technologies. In this paper, we look at the concept of edge computing and its architecture, how machine learning is leveraged for resource management of Edge devices followed by Real world applications of EC. We also review the various performance metrices of EC, vis-à-vis ML algorithm performance under different application scenarios. Finally, we discuss the remaining challenges and promising areas for future research in the area of Edge computing.

Keyword– Edge Computing, Cloud Computing, IoT, Resource Management, Latency

I. EVOLUTION LEADING TO IOT AND COMPUTING

When the computers were launched, they were huge, heavy in built with complex architecture and could only be accessed by directly being present at the computer location. However, with the invention of personal computers, the paradigm changed and now the computing can happen in a much more distributed fashion. During this era, personal computing was the prevalent computing model. The applications were executed, and the data was stored locally on a user's device, or sometimes within an on-premises data center. In a conventional setting, the data is generated on the user's computer or any given client application. It is then moved to the server through various mediums like intranet, LAN, etc., where the data is stored and worked upon. This methodology is a classic and proven approach to client-server computing.

With the aggressive growth in the volume of data being produced and the huge number of devices getting connected to the internet, it is increasing becoming difficult for traditional data center setups to accommodate the desired speed of computations. As per Gartner's study, 75 percent of enterprise data generation will happen at outside of centralized data centers by 2025. This huge amount of data puts unusual burden on the internet, which then results in congestion and disruption to end users.

Current advancements in computing, algorithms, connectivity and deep learning are reforming human-machine interface. By implementing these innovations to consumer products can deliver a more robust and enhanced user experience like in case of mobile devices. Similarly, in case of transportation, vehicles can include smart features that make them more efficient, reliable and safer. In industrial applications, developers can attain higher levels of efficiency, scalability of manufacturing processes and precision. Consumers also can reap the benefits of the Internet of things (IoT) and smart home automation and live a stress-free life. With the evolution of IoT technology and sensors in recent times, managing and utilizing the data which is continuously generated by millions of connected devices is not easy. To deliver the potential benefits of artificial intelligence (AI), there is a need of large amounts of sensor data for virtually instantaneous decision making. These new demands are driving the industry toward Cloud computing, Edge computing, Fog Computing etc. If you use a computer or mobile device at home or at work, you almost certainly use some form of cloud computing every day, whether it's a cloud application like Gmail or be it a streaming media like Spotify, or cloud file storage like OneDrive. One of the most renowned industry analyst, Gartner has predicted that by 2023 the across the globe the end-user public cloud spending will touch nearly USD 600 billion. Cloud computing is on-demand access, via the internet, to computing resources—applications, servers (physical servers and virtual servers), data storage, development tools, networking capabilities, and more—hosted at a remote data center managed by a cloud services provider. Cloud services are centralized in a "cloud" or a set of data centers which can be accessed from any device over the Internet.

Transmittance of the entire data to the cloud requires an ultrahigh network bandwidth thereby cloud computing can introduce latency because of the distance between users and the data centers where cloud services are hosted. Restricted capacities, resource-limited devices, continual services with sporadic connectivity, security etc. are few other challenges with cloud computing paradigm. To address the above issues the emerging paradigm of computing is Edge computing. With this computing in place we move computing closer to end users to minimize the distance that data must travel, while still retaining the centralized nature of cloud computing. This paper attempts to explain the various facets of Edge Computing In order to better understand AI/ML for edge computing, in this paper we attempt to do a comprehensive overview of this field. In order to plan the review procedure there is a need of Research

Questions (RQ). Table 1 displays the research questions, the rationale behind them, and the relationships between various parts and subsections of this paper where we are addressing these RQs.

Table 1 Research Questions being addressed in the paper

S. No	Research Question	Motivation	Section Mapping
RQ 2	In edge computing, what resource management methods are available that are based on ML?	The purpose of this question is to delve into the numerous methods employed in either the simulation or realtime application of AI/ML-based edge computing	III
RQ 3	Where is ML-based edge Computing frameworks stand right now?	This question is useful for determining the nature of research that has been conducted utilising ML-based edge computing.	IV
RQ 4	Which kind of architecture is used the area of edge computing.	This inquiry probes the Multiple Architecture used for ML-driven edge computing	V
RQ 5	What are the most common applications of IoT-enabled Edge?	Use cases for IoTenabled Edge AI are discovered and discussed in the paper.	VI

Now we will address these research questions in the sections described going forward in the paper

II. INTRODUCTION TO EDGE COMPUTING

Edge computing has become one of the most effective solutions to the network problems related with moving large volumes of data generated in today's scenario. The concept of edge computing is simple - instead of, the data center is brought close to the data.

The idea of edge computing is to bring the data center close to the data instead of moving the data close to the data center. The storage and computing resources of the data center are positioned nearby or at the same location where the data is generated.

The core idea is to make computing closer to the source of the data. This brings the service and utilities of cloud computing closer to the end user and is characterized by fast processing and quick application response time.

Researchers have different definitions of edge computing. Shi et al. [1] introduced the emergence of the concept of edge computing: ''Edge computing is a new computing mode of network edge execution. The

downlink data of edge computing represents cloud service, the uplink data represents the Internet of

Everything, and the edge of edge computing refers to the arbitrary computing and network resources between the data source and the path of cloud computing center.''

Zha et al. [2] proposed the definitions as - ''Edge computing is a new computing model that unifies resources that are close to the user in geographical distance or network distance to provide computing, storage, and network for applications service.''

The recently developed IoT enabled applications such as ARVR, surveillance and real time traffic monitoring needs quick processing and faster response time. User run these applications on their resource-constrained mobile devices and the core service and processing are performed on cloud servers. Leveraging services of cloud by mobile devices result in high latency and mobility-related issues Edge computing fulfills the above-mentioned application requirements by bringing the processing to the edge of the network. Edge computing is defined as a paradigm enabling the technologies to allow computing at the network edge, on downstream and upstream data on cloud and IoT services behalf, respectively. This model relies on a novel concept and regarding some similarity in nature, "edge computing" in literature could imply other architectures like Mobile Edge Computing (MEC), cloudlet computing, or fog computing (FC). Edge computing is recognized as a link which bridges the IoTs to the nearby physical edge devices for enabling the users to run the newly emerged IoT applications in their device such as mobile devices, tablets etc. Below figure depicts edge computing approach [3]–

Figure 1 Edge computing approach by IoT and edge device

The data flow diagram for edge computing is depicted as below

Figure 2 Edge computing approach by IoT and edge device

From the above two figures it is clear that the objective of Edge computing is to migrate the cloud's network, computing, storage capabilities and resources to the edge of the network and provide intelligent services at the edge to meet the critical needs of the IT industry in agile, real-time business scenarios and meets the requirements of low latency and high bandwidth on the network.

III. RESOURCE MANAGEMENT FOR EDGE COMPUTING

The development of Edge computing is seen as a solution to problems of network traffic, latency, power consumption etc. for Cloud-based IoT systems. Edge nodes are located close to the IoT device as contrary to the cloud data centers. As a result the execution time and bandwidth issues can be resolved however, we should remember that edge nodes are not designed to deliver high degrees of processing power or huge storage ability which is prevalent in cloud data centers [4].

Therefore, one of the difficulties that need to be solved in edge computing is resource management, which consists of resource provisioning, task offloading and resource scheduling.

Resource provisioning- Resource provisioning is defined as selection, implementation and run time management of hardware and software resources for effective performance of the applications. There are fluctuations in IoT devices' workload that leads to the issue of over and under provisioning. In the case of overprovisioning, a larger number of resources is assigned as compared with the desired IoT workload, which results in customers paying more for the services which they have used [5]. In case of under provisioning, lesser number of resources are allotted for the IoT services, as per the necessity of the IoT workload and it increases the chances violation of the of Service level agreements [6]. Hence, an efficient mechanism is desired to overcome the explained challenges and provide adequate resources based on the service demands.

Task offloading – The designed architecture of edge networks is such that with limited resource it becomes tricky to assign optimal resource (cloud or edge) for computation-intensive tasks in applications such as that of ARVR, multimedia delivery and vehicular networks [4]. As a result, the offloading decision becomes of paramount importance which is dependent on several factors like types of workloads, priority, communication link, deadlines, capacity of edge nodes etc.

Resource scheduling and allocation – In order to process the IoT requests during the runtime of an application, the number of edge nodes which are available to process the requests is fixed and hence we require an effective scheduling technique that will allocate optimum resources for the upcoming workload and execute it within the timeframe [7].

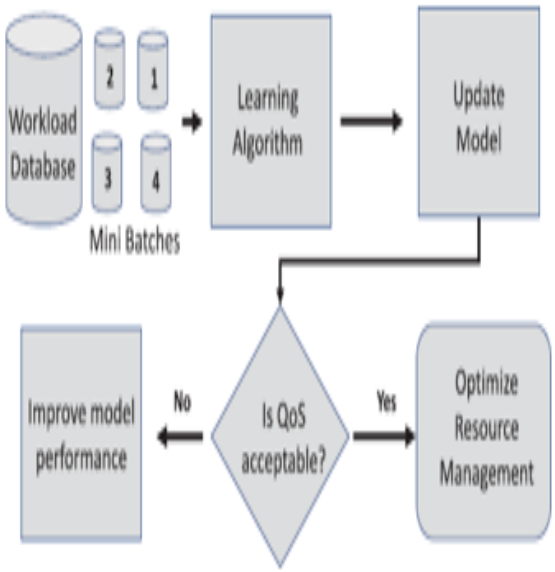
The methodologies for ensuring Resource management for edge computing as discussed above is addressed using diverse techniques. One of these methods that have been gaining popularity recently to solve resource management problems in Edge computing is by using Machine Learning (ML) and the same is described in the next section of the paper.

IV RESOURCE MANAGEMENT FOR EC USING MACHINE LEARNING

In this section, we examine Online vs Offline ML options for ensuring resource management of edge computing.

Online Machine Learning - One of the design options which is used while developing edge computing is Online ML. In this framework, the algorithm is constantly learning by leveraging new data [8]. As a result, real-time data must be used where Online ML is used for edge computing. A good example for the usage of this technique is models which predicts the stock market [9]. Fig. 3 shows the diagrammatic view of Online ML concept [9]. The algo. keeps learning till new data is fed in the edge device and the process is fast and inexpensive. Online ML is extensively used for scenarios where data flow is frequently changing.

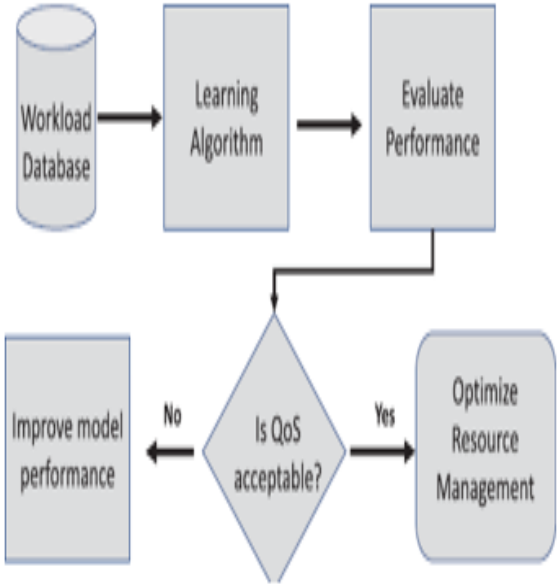
Figure 3 Online ML Scheme for Edge Computing



Offline Machine Learning - In contrast to Online ML, there is no continuous flow of data in case of Offline ML or Batch Learning. The model here is trained using a definite set of data. Once the model is trained, performance of the test set is evaluated and if the test set performance is within acceptable defined limits, the learning phase is terminated.

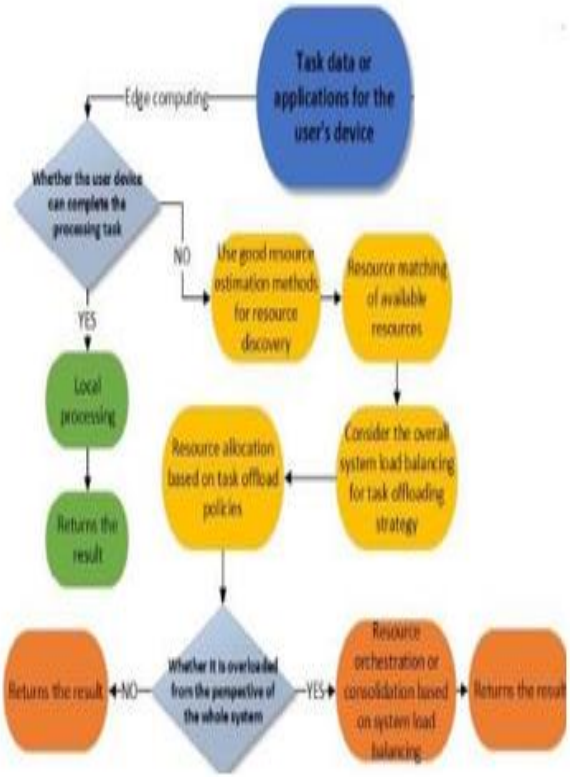
In case the model further needs to be trained using new set of data, then in that case both the old and new data are used together for training purpose. Fig. 4 gives the working schema of Offline ML [9]. As compared to online ML, the amount of data used here to train the model is quite larger. As a result, CPU and RAM requirements will be higher to train the model in Offline ML and additional time is required to train the model as well.

Figure 4 Online ML Scheme for Edge Computing



In the edge computing paradigm, there are various techniques/ methodologies / design options as explained in this section. For ensuring optimal resource optimization either by offloading task data or by placing applications on another device or multiple devices [10], we can sum up the journey of Resource Management through Figure 5.

Figure 5 Flow Chart for Resource Management for Edge



V ARCHITECTURE OF EDGE COMPUTING

With the advancement in IoT era and the development of 5G, edge computing is gaining momentum and is considered as one of the important technologies for the new generation of communications network [11]. Edge computing architecture is a combined network structure which extends cloud services to the edge of the network by introducing edge devices between terminal devices and cloud computing [12][13].

The construct of cloud-edge computing consists of terminal layer, edge layer and cloud computing layer and these are explained as below –

1) Terminal Layer - The terminal layer comprises of various types of devices which are connected to the edge network like mobile terminals and numerous Internet of Things devices such as camera's, sensors, smart cars etc. In the terminal layer, the device performs the dual role of being a data consumer and that of a data provider. In order to reduce the terminal service delay, the perception of the various terminal devices is considered and not the computing power. As a result, the millions of devices which are the part of terminal layer

only collect the raw data and upload it to the upper layer, where it is then stored and calculated.

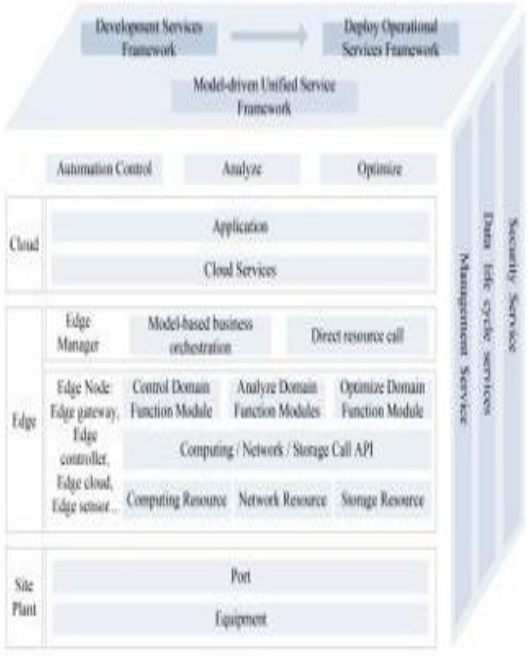
2) Boundary Layer - The boundary layer is the core of the three-tier architecture. The boundary layer is located at the network edge and comprises of edge nodes largely distributed between cloud and terminal devices. This usually includes access points, routers, base stations, gateways, switches etc. The edge layer supports the access of terminal devices downward, and storage along with computation of the data uploaded by terminal devices. The layer connects with the cloud and uploads the processed data to the cloud [14]. As the edge layer is at the proximity to the user, the data transmission to the edge layer is faster for real-time data analysis and intelligent processing.

3) Cloud Layer – Amongst the various services of cloud-edge computing, cloud computing provides the most effective data processing capability. The cloud computing layer consists of several storage devices and high-performance servers. Powerful computing and storage capabilities plays a significant role in areas requiring large amounts of data analysis such as regular maintenance and business decision support. The cloud computing center can store the reported data of the edge computing layer permanently and can complete the analysis tasks that the edge computing layer cannot handle by its own and also enable the processing tasks that needs integration of the global information. Also, the cloud module can dynamically adjust the deployment strategy and algorithm of the edge computing layer according to the requirements.

The edge reference framework has an underlying service layer that binds the entire framework, including data lifecycle services, management services, and security services. The data lifecycle service provides unified management for the preprocessing, analysis, distribution, and execution of machine data, as well as visualization and storage. Management services provide integrated management in terms of monitoring the operation of the architecture and providing info to the management platform. The security service can define the business logic of the entire life cycle of data through the business orchestration layer, flexibly deploy and optimize the data service, and meet the real-time requirements of the business. Security services cover all levels of edge computing architecture adapt to the specific architecture of edge computing and make use of the unified security management and perception system to ensure the safe and reliable operation of the entire architecture.

From the viewpoint of vertical structure, the model-drives unified service framework at the top of the scale to realize the development and deployment of services. In line with general framework of edge computing calculation, it is divided into cloud, field layer and edge layer. Also, the edge layer comprises of two integral parts viz. the edge node and the edge manager. Edge node is simply the hardware, which holds the business of edge computing and the edge manager uses the software capabilities to equally manage all the edge nodes Also, as per the hardware characteristics and service types, edge computing nodes are divided into edge gateways which process and convert network protocols, edge controllers which controls the real- time closed-loop services, edge clouds which process large-scale data, and edges which collect and process low-cost information Sensors, etc. The control, analysis and optimization domain function module is used for information transmission of upper and lower layers and the planning of local edge resources. Edge computing reference architecture provides four service development frameworks from the terminal to the cloud, including real-time computing systems, lightweight computing systems, intelligent gateway systems and intelligent distributed systems. All the layers and the architecture can be represented [15] as below –

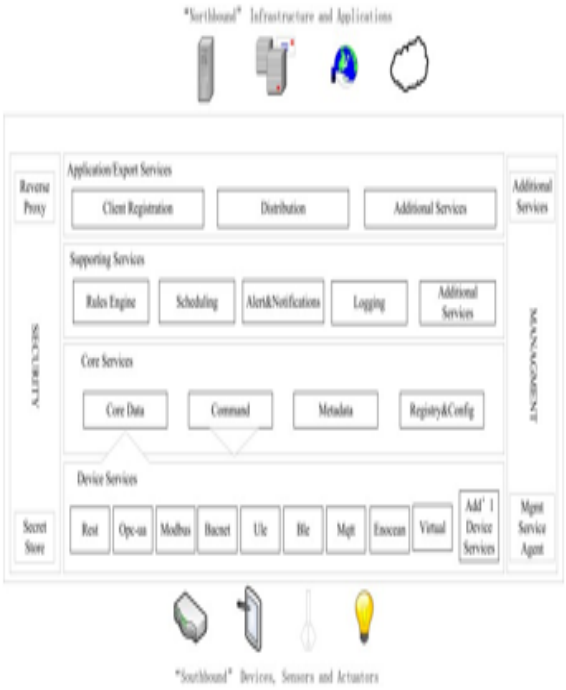
Figure 6 Edge computing architecture



EdgeX Foundry is a neutral open-source project hosted by the Linux foundation and is an universal open framework for computing on the edge of the Internet of Things. This is hosted on a reference software platform which is completely independent of operating systems and hardware. The Edge X framework enables a plug-and- play component ecosystem to integrate the computing open platform at the edge of the Internet of Things and accelerate the deployment of solutions.

The edge x foundry architecture [9] is depicted as below –

Figure 7 Edge X Foundry Architecture



As can be seen from the figure 7, ‘‘Southbound’’ comprises of all IoT application devices which directly communicates with the edge network. Cloud computing center along with the communication network constitutes the ‘‘Northbound’’. The ‘‘Southbound’’ is the source of the data, while the ‘‘Northbound’’ is used to collect the data from the south side and store, integrate and analyze the data.

The EdgeX Foundry is located between the South and Northbound and comprises of a collection of microservices which is divided into four service layers and two underlying enhanced system services. From the vertical viewpoint, Software development kit (SDK) is provided by the device service layer and is used to create the communication channels with the ‘‘Southbound’’. The device service layer converts the data from the device and sends it across to the core service layer. It can also receive commands from other microservices and pass them to devices. The core service layer which is at the center of the architecture is the key layer which helps to realize the edge capabilities. The core service layer comprises of four micro-service components namely the core data, commands, metadata, registry and configuration. The core data service provides management services and storage for the device data. The command service is responsible for defining the operation commands in the device file into a general API, caching and managing commands, and can pass the requirements of the cloud computing center to the device side. Metadata provides pairing of devices and services. Registration and configuration services is leveraged to provide configuration information for other micro-services. The support service layer is used to provide edge analysis and intelligent services, and to provide the framework itself with rules engine, alerting, logging and scheduling services. The application and export service layer can be connected with the cloud computing center to transfer data to the cloud computing center to ensure the independent operation of EdgeX Foundry. In the export service layer, the client registration service records the relevant information of the back-end registered system, and the distribution service exports the corresponding data to the specified client. Thus, we see that Edge X provides a scalable and an open-source platform, in which we can run all the micro-services on several operating systems in the form of containers and support dynamic addition or reduction of functions.

VI Application of Edge Computing

With the increase in the usage of internet-connected devices across the world, it is observed that adoption of edge computing has not only helped the organizations to improve their revenues but has also acted as an enabler for the companies in providing better service delivery for end users. The objective here is to provide access to high computing capabilities without increasing the complexity to the end user devices & without adding to network congestion. Few applications of Edge computing are described as below – Autonomous Vehicles - To ensure safety of the passengers an autonomous vehicle requires to simultaneously collect and process the data about its location, traffic conditions, direction, speed, and many more - all-in real-time scenario. To achieve this sufficient onboard computing capacity is desired and to achieve this every autonomous vehicle, in effect, is its own network edge. These Edge devices collect data from vehicle cameras & sensors, process it on the go & makes the decisions in milliseconds, with almost zero latency. Smart Cities, Clean Energy and Green Technology – With the increase

in Green technology movement across various domains, IoT device usage is also on the rise. Cities and smart grid systems use edge computing devices to monitor public buildings and facilities for achieving higher efficiency in heating, lighting, clean energy etc.

Few examples are given below -

- Intelligent lighting controls use edge computing devices to control individual lights or groups of lights in order to maximize efficiency while ensuring safety in public spaces.
- Solar fields uses embedded edge computing devices to sense changes in weather, adjust positioning & report metrics such as battery usage.
- Wind farms use edge computing to connect to cell towers and route sensor data to substations using cellular routers and switches

Healthcare and Medical Applications - The healthcare and medical industries collect patient related data from sensors, monitors, wearables and other apparatus to provide healthcare professionals with well-timed and correct insights on patients health condition. Edge computing solutions equipped with AI and machine learning capabilities also helps in identifying the outlier data so that medical professionals can respond to health concerns on real time basis with minimum false alarms.

Manufacturing Industries - Industrial IoT has added millions of connected devices in manufacturing plants to gather data on production line performance and the quality of finished products. Due to minimal latency of edge computing devices, the concerned persons on assembly line are able to get an immediate insight to problem which in turn helps to him to drive improvements to achieve the

5G and Mobile Services – Edge computing in telecom, often described as Mobile Edge Computing MEC, offers execution resources (compute and storage) for applications with networking close to the end users. The edge computing nodes enable content delivery, localized data processing and low-latency SaaS platform in end-user applications. MEC also helps in easing out network congestion for embedded applications which uses high bandwidth data streams.

VII PERFORMANCE METRICES FOR EDGE COMPUTING

The merit of any architecture in edge computing paradigm is gauged by using one or multiple performance metrics and as a result these metrics play an important role in the assessment of the architecture [16]. Performance metrics are mostly dependent on the type of layers (Terminal /boundary/ Cloud layer) or the computing model where the architecture is performed. The performance of the layers is measured in multiple terms.

Monitoring related metrics are used for monitoring the performance of the entire architecture. Some of the Monitoring related metrices are given below -

1. Resource Utilization: This parameter lets us know the percentage of the resource utilized for completing a specific inbound workload.
2. Throughput: This is ratio of the number of tasks arrived at to the number of tasks completed for a given period of time.
3. Resource Load: This parameter is the ratio of the number of tasks waiting in the queue to be executed to the number of tasks running at the same point in time.
4. Latency: This is the measure of the time gap which is observed between the actual response time and preferred response time.
5. Maximum Running Resource: This metric measures the highest number of resources used.
6. Virtual Machine Runtime: This parameter lets us know the borrowed time of the VM.
7. SLA Violation: This parameter measures the number of tasks which has been delayed more than the provided desired time.
8. Fault tolerance: This metric provides us with the ratio of the number of detected faults to the number of faults which exists.

Statistical Analysis related metrics-

This is a process to statistically gauge the performance of ML based algorithm for a given time series data [17]. Summary of various studies done in this regard is encapsulated below –

Work	Application	Method/ Algorithm	Parameter	Result
18	Resource allocation edge computing network for multiple user	Deep Q-Learning	Data packet size, Channel quality, and waiting time	Deep Q-learning surpasses random and equal scheduling
19	Intelligent offloading systemfor vehicular networks	Mobility-Aware Double DQN (MADD), Dynamic Matching Algorithm	Task scheduling & resource allocation (Quality of Experience)	MADD algorithm performanceis 20% which is 12% higher than greedy algorithm
20	Computation offloading in Virtual Edge computing systems (Sliced Radio Access Networks)	Integrated Double Deep Q-Network with Q - Function decomposition technique	Maximizing Long term utility performance	Outperforms over three baseline schemes, namely, mobile execution, server execution, and greedy execution
21	Resource allocation in IoT network	E-greedy Q-learning	Long term weighted sum cost (task execution latency and power consumption)	Better trade-off is achieved between edge & local computing Modes
22	Intelligent Resource Allocation Framework (iRAF) for Edge paradigm	Deep Neural Network for prediction and Monte Carlo Tree Search approach for generating training data	Network states & task characteristicslike utilization of edge network resources, the channel quality, latency requirement of services.	iRAF achieves 51.71% and 59.27% performance over deep learning and greedy search methods respectively

Work	Application	Method/ Algorithm	Parameter	Result
18	Resource allocation edge computing network for multiple user	Deep Q-Learning	Data packet size, Channel quality, and waiting time	Deep Q-learning surpasses random and equal scheduling

Planning related metrics: -

The Planning metrices helps in making decision regarding optimization. Few planning metrices are explained as below –

1. Decision Number: This metric gives us the total number of decisions made during the Edge Computing process.
2. Contradictory Decision: This gives us a measure of the number of instances wherein an already taken decision is reversed, because of some incorrect decision in the process.
3. Completion Ratio: This is defined as the ratio in which the sources compete for the various resources.

4. Cache Hit Ratio: This ratio gives us a measure of the success of the service caching system in reducing the losses encountered during data transmission within the network.

VIII Advantages of Edge Computing

From the above applications it is evident that Edge computing has emerged as one of the most effective solutions to network problems associated with transferring huge volumes of data generated in today's scenario. Below are few key benefits which is realized through edge computing: -

Elimination of Latency-

Latency measures the time required to transfer data between two points in a given network. Significant distances between the two points combined with some network congestion can result in transmission delays. As edge computing brings both the points to each other's proximity, latency issues are almost reduced to zero.

Saving the Bandwidth –

Bandwidth indicates the speed at which a given amount of data is transferred through the network. All the networks works on a defined amount of bandwidth which in turn restricts the volume of data which can be transferred between the devices By installing the data server near the points wherein the data is being generated i.e. edge computing enables several devices to run over a relatively smaller and much more efficient bandwidth.

Reducing the Congestion-

High levels of congestion is experienced on the networks due to large volume of data being generated by billions of devices every day. With the implementation of edge computing, the essential analysis is carried out at the local storage and local servers which in turns prevents congestion

IX Challenges of Edge Computing

Edge computing is still in its early years and faces some drawbacks. The major challenges in Edge Computing are described as below:

Implementation Costs - The costs associated with implementation of an edge infrastructure for a company involves both complexity and higher cost implications. The implementation requires carving out clear scope and purpose before implementation.

Incomplete Data – With the limited computational capabilities in Edge computing, the EC infrastructure setup process partial sets of information. As a result, organization may lose important data, information and time.

Security- Due to the Distributed nature of Edge Computing architecture, ensuring adequate security measures is one of the key challenges [23]. Below are the various types of security threats which EC architecture is prone to: -

- Phishing – This is a technique to obtain sensitive or confidential information from the end user who is connected to the cloud by using an IoT equipment. Cybercriminals circulate electronic content to a wide range of users / victims which encourages them to take specific actions, such as clicking on a link or replying to email etc. When the users do so, they unknowingly provide personal sensitive information like their username, password, financial details etc. The various phishing methods include email, online advertising, SMS etc.
- Malware - This is specially designed to harm an edge device, system, or data. There are different types of malwares which tries to breach the security of edge devices.

- Rootkit – This is a specific type of Malware which secretly starts accessing various parts of an edge device, software, or system. This modifies the hardware and the Operating system in such a way that it remains unknown to the edge user.
- Trojan – This is a form of malware which is non-replicating in nature however contains a hidden functionality. The Trojan usually does not try to propagate or inject itself into other files but does its assigned job for which it was made.
- Backdoor – This is a type of Malware which targets remote accessing capability into a edge device, or software, by bypassing traditional security measures installed in the devices.

Partition and Offloading tasks (resource allocation) - Workload allocation is not a simple task. Distributed computing like that of Edge computing, should also consider the location as an added aspect of computation. Resource mobility defines how to dynamically discover the resources in the network and manage all the required available resources, including long term and short-term resources. Also, in certain situations, when the edge devices are damaged, then the most important aspect is to ensure that the system resumes as fast as possible, with

the best replacements [24].

X Future Scope in Edge Computing

Constant evolution in the field of computer science, its corresponding technologies and faster development life cycles leads to unresolved issues like scalability, mobility, security and privacy, device heterogeneity, reliability, resource management, computation offloading, etc. The area of Edge Computing also continues to pose the above challenges and, in the days, to come by, we need to address these issues. Some of the most persistent issues which needs to be taken care of in future are discussed below –

Mobility – With the increase in the number of mobile devices getting connected to the edge network at a rapid pace. it is bringing forward critical challenges which needs to be addressed. With the increase in Mobility the instances of disconnections between edge devices and the edge network are also increasing thereby lowering the global quality of the services and its related parameters of such as losses, bandwidth and delay.

Security & Privacy – For any given heterogeneous edge networks, security requirements vary from device to device depending upon the applications used. While few devices can operate with lower processing capabilities demand lightweight security and on other hand delay-sensitive networks, such as vehicular networks, demand highly efficient security mechanisms to address their applications.

Heterogeneity – With the increasing number and variety of connected devices like mobile, along with the upgradation of various network access technologies like 3G, 4G, Wi-Fi, WiMAX, and the upcoming 5G, the edge eco system envisages the integration of current devices with the IoT which in turn contributes to a highly heterogeneous environment. This heterogeneity not only demands an additional effort to be made to ensure seamless handover between different network technologies but also it needs to manage several requirements from devices with requires distinctive resources from the network, like storage and computational speed. A combination of network and device management which ensures the desired computational timings and optimizes the communications along with efficient usage of devices will be the prerequisite for the success of the EC paradigm.

XI. Conclusion

Edge computing provides data storage and computing at the edge of the network, and provides Internet intelligent services nearby, providing support for the digital transformation of various industries, and meeting the requirements of different industries for data diversification. In the future, with the continuous development of the

Internet and human society, edge computing will play a more important role and effectively promote the development of various industries

Abstract— **The most prevalent cancer among women worldwide is cervical cancer. In any country, preventative interventions are more cost-effective than curative ones. Early diagnosis of an illness yields better treatment outcomes than late diagnosis. The two major risk factors that might lead to cervical cancer include the use of hormonal preventives and age issues. Carry out cervical cancer screening tests to improve survival and decrease mortality at the earliest possible stage. This research aims to apply the different machine-learning models to find cervical cancer risk factors. Those models include the UCI voting method and ceasefires Decision tree, logistic regression, and random forest techniques. To handle unbalanced datasets, use the principal component analysis (PCA) and synthetic minority oversampling method (SMOTE). In data collection processes, datasets are validated, and the validation process is continued ten times to avoid any overfit data. This final validated dataset contains four variables with 32 different risk factors. The variables include Biopsy, Hinselmann, Cytology and Schiller. The accuracy, sensitivity, and area under the receiver operating characteristic curve (ROC AUC) of the predictive models developed for each of the four target variables were found to increase at more excellent rates with the use of the voting classifier, PCA, and SMOTE approaches. All target variables' accuracy, sensitivity, and PPA ratios increased in the SMOTE-voting model, respectively. The principal component analysis technique sped up model performance while decreasing the time it took to handle computational data. Finally, we compared our models' performance to that of numerous other research and found that, by specific criteria, our models were better able to detect cervical cancer.**

.

I. INTRODUCTION

Approximately 6,000 Indian women and almost 355,000 women globally succumb to cervical cancer yearly [1]. Early detection and diagnosis utilising machine learning and artificial intelligence may significantly reduce mortality rates from cervical cancer. Researchers are using artificial intelligence and portable video imaging to build diagnostic tools to identify cervical cancer signs in women with limited access to healthcare. Countries with widespread screening programs for aberrant cells and the papillomavirus have seen a steep decline in cervical cancer occurrences. This, along with the fact that many countries with lower incomes lack access to diagnostic services and HPV vaccinations, means that the projected number of cases globally will increase by the next 10 years. There is a raise for gynecological examinations in women throughout the globe, making it all the more important to develop innovative analytic procedures that account for regional variations.

Applied Machine learning (ML) and deep learning (DL) to a wide variety of fields, including but not limited to cancer diagnosis (including but not limited to a brain tumour, cervical cancer, breast cancer, COPD), activity recognition (including but not limited to activity, exercise, and temperature detection), and cognitive health assessment (including but not limited to a review of dementia patients) (1–3, 3–10). Because of technological advancements, current medical diagnosis is more accurate than ever before (11–14). Global cancer statistics (15) says that each year there are 493,000 new cases of cervical malignancy, of which 15,000 are female malignancy cases. The fatality rate from this illness is very high (83%), mainly because it is only prevalent in 16 underdeveloped nations and also in 17 African countries. For example, in Uganda, where 65% of cervical cancer cases are proven (18).

II. PROPOSED METHODOLOGY:

2.1. Logistic regression process (LR):

Over the last two decades, medical researchers have widely used the statistical method of LR. Use method when a dataset's dependent variables take on a binary form. LR may be used as a predictive model which connects a single binary dependent variable and any number of independent variables. The correlation between the dependent and independent variables is related using linear regression. LR will help to get the output as an accurately predicted value by supporting the linear regression. Logistic regression creates a curve between 0 and 1 in the slope. There are many parallels between linear regression and this kind of regression. The natural logarithm of the probability for the target variables may be substituted for the possibilities when drawing the regression curve. There is also no need for

predictors to have normal distributions or consistent variances.

A. Decision tree (DT):

Among the many machine learning methods, DT sees widespread use. Apply the DT to do regression or classification of a dataset. As a result of answering a series of questions, segregate the data in this process. The virtual node, or root of the tree, contains all samples and is the starting point. Each primary node is subdivided into many subsidiary nodes or split in two ways. The "divide and conquer" technique is used for the tree's creation. This method ensures that all training samples are labelled consistently. Differently labelled training samples are stored in their subtree [9], [18]. A DT's numerous benefits include its versatility in dealing with data, it's capacity to recover lost values, its high potential for initial correctness, and its straightforward installation [16].

B. Random forest(RF):

The RF algorithm is a machine learning (ML) algorithm. It combines many decision trees into a single robust learner and uses them for unsupervised and supervised classification and ensemble learning. RF uses classification and regression tree (CART) technology based on bootstrap aggregation techniques to improve a non-correlated mix of many decision trees. The goal is to correctly categorise data and understand the connection between y-values and their respective independent factors (x) [10], [14]. Random subsets using train data generate decision trees, and then those trees are analysed separately using methods like information gain and the GINI index (DT). More excellent trees equal more accuracy. Each DT does not influence the creation of the features, make up the classification or the creation of the target variable; instead, each DT acts as a vote for a particular class. Then RF takes the average of all the trees if there is a regression issue or the classification with the most votes if there is a classification difficulty [9], [21].

C. Ensemble Learning (EL):

In recent years, EL's effectiveness as a method has led to its widespread use. Incorporating numerous independent machine learning algorithms, it boosts classification accuracy beyond that of typical machine learning algorithms. This method reduces the risk of overfitting the training data by integrating and averaging many classification models, which is especially helpful when working with a limited sample size. It improves the training dataset's efficiency, which is crucial for many biological applications with little data. The goals of EL approaches are improved categorization of the training data and enhanced generalization to novel data [22], [23]. Techniques like boosting, bagging, and voting are a few well-known ensemble approaches.

2.2. Imbalance issue in dataset:

The dataset may be unbalanced if there is a large discrepancy in the number of instances between the classes. Unbalance datasets are one of the issues in predicting the output, so the need to maintain the unbalanced datasets should not be more than 10% in overall datasets. For the vast majority of students, on the other hand, this accuracy nears a perfect 100 [20]. If you want to fix the issue of an imbalanced dataset, one of the finest things you can do is use a sampling technique. Numerous research has shown the superior performance of classifiers when using a balanced dataset instead of an unbalanced one. Adjusting the initial dataset by increasing the minority class (known as the oversampling method) or reducing the majority class (also known as the undersampling approach) is one use the sampling technique to produce a nearly equal representation of types (known as the under-sampling strategy) [21].

2.3. Feature selection process:

May improve a model's efficiency with the use of feature selection algorithms. In addition to strengthening the model, these methods may reduce noise in the dataset, clarify the classification techniques used by the model, and streamline their application.
(PCA) to reduce the size of a dataset while still retaining the most important details may be used to extract new, tiny, independent features. The associated characteristics may be merged as main components when using the statistical dimensionality reduction method [22]. Eigenvector advantage is used in the mathematical procedure of principal component analysis (PCA) to describe the feature orientation. In this case, transform the x-dimensional feature space into the y-dimensional main component space, where y x. They use a covariance matrix to determine eigenvectors and eigenvalues. When analysing the cervical cancer dataset, the main component is the eigenvector, with the largest eigenvalue since it best characterises the most important associations between characteristics [11].

2.4. Validation process:

Validation process is a resampling procedure for a small data sample used for testing and verifying ML models. The dataset Using cross-validation k-fold methodology, arbitrarily split into k (the number of folds) identical portions. After that, we use the remaining k-1 pieces as training data while keeping one piece as validation data for testing the model. Next, k iterations of the CV procedure are performed, with a new set of folds serving

as the test subject each time. After doing k-folds, results are combined by averaging the values [26], [11]. Unlike k-fold, Stratified K- Fold is useful when dealing with data that is not evenly distributed. Firstly, stratified k-fold performs a single shuffle before dividing and preserves row labels. In the next step, information is divided into k equal pieces. The goal is to have a uniform various models for predicting cervical cancer and to acquire insights into clinical diagnoses.

III. IMPLEMENTATION WITH RESULTS:

During the modelling phase, we put four different prediction models for each target variable in place, compared their findings, and picked the one with the highest sensitivity for spotting cervical cancer. The Jupyter Notebook, a freely distributable environment for the development and execution of Python 3.3 programmes, was used to build these prediction models. These construct the models using several Python packages, including Scikit-learn, matplotlib, NumPy, and pandas.

As a part of preprocessing, data is cleaned and organized, principal component analysis (PCA) with 11 main distribution of class percentages across folds [17].

2.5. Evaluation process:

Obtaining a correct cancer diagnosis for a patient is crucial for their well-being. Thus this is one example of how may use total accuracy to evaluate the model in biological data. Therefore, multiple metrics, including overall accuracy, are utilised to evaluate and contrast components was employed as a feature reduction approach and the time period needed to analyze them. The dataset was then partitioned into test and training sets. For this reason, use SMOTE technology in the training set to help achieve balance to the minority class's most excellent accuracy and prevent classification misleading caused by the imbalanced dataset.

As illustrated in Fig. 1, the voting classifier selects highly predicted classes as test sample class variables by combining three classifier prediction outputs. Logistic regression, random forest, and decision tree classifiers. Used The stratified 10-fold validation approach to avoid overfitting. Then, they assess the model's accuracy, sensitivity, specificity, precision (PPA), null predictive accuracy (NPA), f1-score, and receiver operating characteristic area under the curve (ROC AUC).

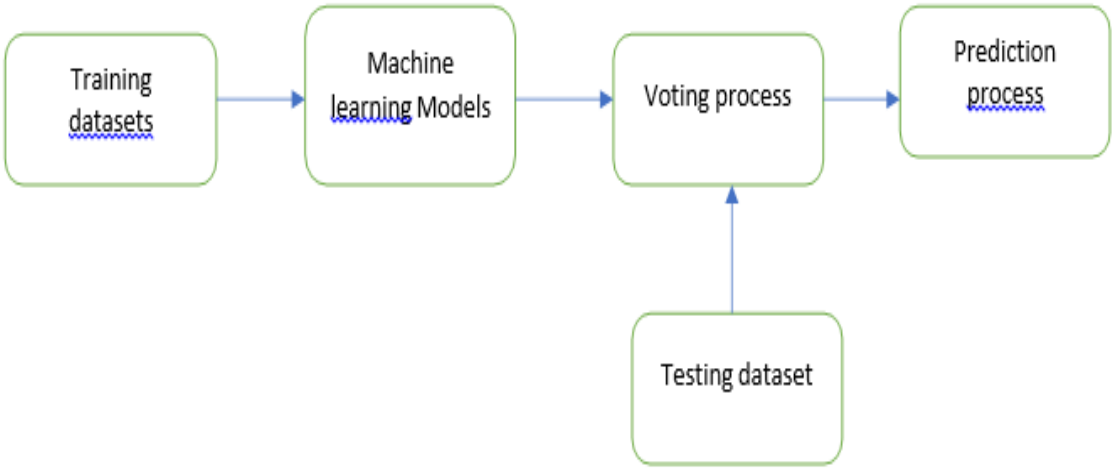

Figure 1: The voting classifier.

3.1. Hinselmann test result:

Collected a total of 1401 standard samples and 149 malignant ones. The voting model's overall accuracy jumped from 96.69 to 97.82% compared to its performance before SMOTE was included. The usage of SMOTE resulted in a 0.94% increase in accuracy, a 0.95% increase in sensitivity, and a 97.82% increase in the ROC AUC metric rate, as shown in Table-1.

Matrices %	Prior to SMOTE		Later SMOTE	
	Voting	Voting for PCA	Voting	Voting for PCA
Accuracy	96.69	97.93	97.82	98.92
Sensitivity	51	51	97.88	96.52
Specificity	99	99	98.79	98.79
PPA	49.2	49.2	78	79.9
NPA	96.3	96.3	99.5	97.7
F-score	51.1	51.1	97.23	97.83
ROC	66.72	66.72	98.32	99.1

Table 1: Hinselmann test – prediction result

Eleven main components are optimal for SMOTE-voting-PCA. This example has a negative prediction accuracy of 98.56%, measured by the ROC AUC scale; SMOTE-voting-PCA improved sensitivity by 47.48% and accuracy by 32.92% compared to voting before SMOTE. Moreover, SMOTE voting-PCA had an overall accuracy of about 98%. Thus, the voting classifier's function may be realised using the SMOTE and PCA techniques.

3.2. Schiller test result:

The voting classifier used before SMOTE achieved an overall accuracy of 91.19 per cent, based on a dataset that included 123 patients and 1125 control samples. Compared to the previous voting model, SMOTE-Voting improves accuracy by 96.32 percentage points, sensitivity by 41.23 percentage points, positive predictive accuracy by 24.2 percentage points, negative predictive accuracy by 6.2 percentage points, and ROC by 32.1 percentage points.

To put it another way, when comparing the voting model to the voting PCA with 11 significant components, the sensitivity, NPA, and f1-score all dropped by 3%, 0.43 percentage points, and 5%, respectively. Table 2 shows the best balance of accuracy, sensitivity, PPA, NPA, and f1-score by achieving the 11-component SMOTE voting PCA model for the Schiller test.

Matrices %	Prior to SMOTE		Later SMOTE	
	Voting	Voting for PCA	Voting	Voting for PCA
Accuracy	91.19	91.32	96.32	98.52
Sensitivity	56	54	95.72	98.72
Specificity	97.23	99.23	98.2	98.99
PPA	63	64	85.52	96.13
NPA	93.32	92.31	98.1	99.52
F-score	58.0	54	96.23	98.82
ROC	69.23	62.74	92.23	99.89

3.3. Cytology Test result:

Matrices %	Prior to SMOTE		Later SMOTE	
	Voting	Voting for PCA	Voting	Voting for PCA
Accuracy	95.32	95.62	92.72	92.88
Sensitivity	53.2	53.2	92.22	93.14
Specificity	99.22	99.88	96.22	95.62
PPA	61.00	74	63	70.12
NPA	96.23	96.32	96.32	98.32
F-score	54	55	92.32	94.23
ROC	61.42	49.22	73.22	94.32

With 132 malignant and 923 benign samples, the previous voting model obtained a total accuracy of 94.29% before SMOTE was included. Although the accuracy dropped to 92.72% after SMOTE, the sensitivity and ROC AUC rate improved, making this a improved result than the voting model later SMOTE.

Table V demonstrates that compared to the other models, the NPA, f1-score, ROC AUC, and sensitivity were all higher in the SMOTE-voting-PCA model with 11 main components.

Table 3: Cytology test- results prediction

3.4. Biopsy test result:

With 74 malignant and 1125 benign samples, the voting model attained an accuracy of 94.22% without using SMOTE. Table 4 demonstrates that, across the board, the voting and voting-PCA pre-SMOTE models performed similarly.

Accuracy, sensitivity, PPA, NPA, and ROC AUC were all higher in the SMOTE-voting-PCA model than in the SMOTE-voting model after SMOTE, by 4.11%, 2.55%, 7.82%, 0.89%, and 6.62%, respectively. As a consequence, Table 4 shows the findings of the examination.

Matrices %	Prior to SMOTE		Later SMOTE	
	Voting	Voting for PCA	Voting	Voting for PCA
Accuracy	94.22	94.26	96.32	98.52
Sensitivity	52	53	96.82	98.82
Specificity	99.32	99.6	97.32	99.1
PPA	60	65	84.23	90.1
NPA	94.73	94.72	98.72	99.01
F-score	53	54	96.22	98.32
ROC	66.22	53.54	95.62	99.6

IV. CONCLUSION:

Early diagnosis of cervical cancer increases the

effectiveness of treatment. If caught early enough, cervical cancer has one of the best survival rates of any illness. This study addresses these issues and develops a model for detecting cervical cancer using machine-learning techniques that is sensitive and accurate. It also produces a strategy for handling imbalanced datasets, which reduces prediction efficiency and increases false categorization. In this research, using one of the ensemble approaches (the voting method), we integrated the three models of machine learning algorithms for predicting cervical cancer. Four target variables are considered from different datasets, and PCA and SMOTE techniques are applied to improve model accuracy and maintain the balance of the dataset, respectively. From the results, it is evident that the voting approach, along with SMOTE and PCA technology to develop a prediction model, the Schiller target variable obtained an accuracy, sensitivity, and ROC AUC of 99.52%, 99.23%, and 99.89%, respectively.

Abstract— **The Internet of things (IoTs) carries the secure transmission and storage of a large amount of sensitive information. This paper uses the anti-tampering and anti-cloning features of the hardware physical unclonable function (PUF) to generate a shared key, combined with security primitives such as MASK algorithm and Hash function and proposes a lightweight Anonymous key sharing security authentication protocol. Through the security analysis and verification of Ban logic and the proper tool ProVerif. It is proved that the protocol can defend against man-in-the-middle attacks, desynchronization attacks, impersonation attacks, modeling attacks, etc. By comparing other protocols, it is verified that the protocol has the advantages of low computing cost, small communication overhead and storage capacity, and high-security performance; it is suitable for secure communication transmission of resource- constrained devices.**

Keyword- Lightweight Authentication, Internet of Things, Authentication protocol, desynchronization attacks, anti-tampering

I. INTRODUCTION

With the rapid development of sensing, automation and communication technologies, the massive data generated by the IoTs (IoT) has dramatically threatened the effective and safe transmission, storage and protection between devices [1]. Traditional network Security protocols will use complex security primitives such as encryption algorithms [2], digital signatures, Hash functions [3], and message verification codes to ensure the confidentiality, integrity, and non-repudiation of information transmission [4]. , However, usually small size, strong resource constraints and low hardware processing capability, so the security primitives with slow transmission rate and high communication overhead are not suitable for the authentication of lightweight devices [5].

The secure communication of the IoTs assumes that hardware devices and systems are safe. Still, malicious attackers can destroy confidential device information using chip cloning and dissection [6]. Information encryption is an effective way to protect information security certification. Still, encryption the algorithm's key is usually stored in non-volatile memory (NVM), and the attacker can successfully read the private information in the memory through a side channel and physical attacks [7]. Physically unclonable function (PUF) is an emerging The hardware security primitives of the chip use the random process deviation that cannot be controlled in the manufacturing process of the chip to generate the unique digital signature of the device [8]. It is susceptible to physical tampering, does not need to be stored, has low hardware overhead, can solve the security problems faced by traditional keys, and is suitable for lightweight IoTs device security authentication protocols [9-11].

Key-sharing authentication protocols are usually completed using public key algorithms and digital signatures at the software layer. Still, these encryption primitives run slowly and have high communication overhead, and new quantum computing methods can effectively crack public key algorithms. To solve the problem of IoTs devices In terms of security issues in channel transmission and critical storage, this paper uses reconfigurable CROPUF anti-tampering and anti-cloning features to generate shared keys, replacing asymmetric encryption algorithms and digital signatures with high communication overhead, combined with MASK algorithm and Hash function A lightweight anonymous key sharing security authentication protocol is proposed for encryption methods such as. The protocol ensures security properties such as anonymity, availability, integrity, and forward/backward secrecy. Some authors are also proposing lightweight authentication schemes [12-14] to maintain secure communication over the IoT devices.

II. MATHEMATICAL THEORETICAL KNOWLEDGE AND RELATED WORK

1.1. PUF-based key-sharing mechanism

Author [15] used CRO PUF to generate the same shared key for devices, which is suitable for one- to-many security authentication protocols. This mechanism obtains shared keys between devices through two stages.

Phase 1: Generate a reliable response to the shared key. Obtain the high-precision delay matrix S of the CRO PUF through modeling; calculate the delay difference between all paths and sort them in descending order of absolute value. Consider the influence of different temperatures to determine threshold U. When the total value of the delay difference between the two paths is greater than the threshold, the output response is stable.

Phase 2: Generate incentives for the shared key. Store all

the paths of the delay matrix S in the set E, and enumerate all the bits of the shared key L. Randomly select two shared key L. One bit Li, if Li is equal to 1 and the delay difference is more significant than U, it means that a configuration stimulus Di that can produce a stable response of 1 has been found; if Li is equal to 0 and the delay difference is less than -U, it means that a

configuration that can generate a stable response of 0 has been found Incentive Di; otherwise, reselect the shared key L.

1.2. MASK and UNMASK algorithms

The MASK algorithm proposed by author [16] contains three parameters: the input vector s = [s1, s2, s3, ..., sl] with a length of l bits, and a set of l positive integers L = { l1, l2, l3, ..., ll|li ∈ A+ } and generate l-bit output vector sm = [sm1, sm2, sm3,..., sml]. MASK algorithm uses positive integer set L as auxiliary data and inputs vector r with length l-bit to generate an Output function sm of equal length. A set of positive integers L generates $L \rightarrow$ PRNGi(x) through a pseudo-random number generator, where y is an input vector of length n bits, and y = [y1, y2, y3, ..., yn]. Similarly, the reversible transformation UNMASK function of the MASK function uses the positive integer set L to convert the output function sm into a restored output function r.

1) Integer set generation: The vector y is used as the seed of the pseudo-random number generator PRNG circuit to generate a set of positive integers l { l1, l2, l3, ..., ll|li ∈ A+ }. The integer set L contains l n-bit positive Integer; the maximum value of any positive integer is 2n - 1.

2) Function range transformation: define a range function Range() as a linear mapping transformation, given an l-digit integer { k|k ∈ K }, whose value range is [0, 2l - 1], generate an m- digit The new set R= { r|r ∈ Z+ } with integers in the Range [0, 2m - 1], where m ≤ l. The following equation governs the linear range mapping:

$(M\text{old} - M\text{oldamin}) \times (M\text{neemax} - M\text{neemin})$

different ways from the set E for each of the

$M\text{new} = [$

$(M\text{oldmax}$

$]$

$- M\text{oldanin})$

Mold ∈ L is the input of the Range () function, Moldamin and Moldmax are the minimum and maximum values in the Range [0, 2l - 1], Nnewmin and Nnewmax are the minimum values in the new Range [0, 2m - 1] with the maximum value.

3) Bit obfuscation: The MASK function finally completes the bit obfuscation of the sequence based on the Fisher-Yates Shuffler shuffling algorithm, and a finite series of n different elements generates an n! a random permutation algorithm.

The MASK algorithm has two advantages: 1) It effectively hides the relationship between device PUF excitation and response; 2) It verifies the device's input. The PUF will not be activated without verifying the input stream, so the device will not generate any response, effectively preventing the device from any brute force attack.

III. PROTOCOL DESIGN AND ANALYSIS

This paper proposes a lightweight key-sharing authentication protocol based on the IoT device embedded with PUF, including the protocol registration phase, two-way authentication and firmware update phase. The related symbols of the protocol are shown in Table 1.

Table 1 Description of protocol-related symbols

Symbol	Meaning
CRO PUF	Reconfigurable Ring Oscillator PUF
Delay Matrix M_A/M_B	Delay Matrix M_A or M_B
(C,R)	Stimulus C and response R generated by PUF
timestamp()	Timestamp function
(n_{i1}, n_{i2})	pseudo random number
Hash(·)	one-way hash function
Fisher - Shuffler()	Shuffle Confusion Algorithm
PRNG()/TRNG()	Pseudo/True Random Number Generator

IV. FORMAL SECURITY PROOF

4.1 Formal Security Analysis

This protocol ensures the channel transmission security of IoT devices and can also defend against physical attacks on PUF by attackers. The specific security analysis is as follows.

1) Modeling attack. The machine learning modeling attack is aimed at a strong PUF with a publicly accessible CRP interface. The attacker collects many CRPs, trains, learns, and optimizes an accurate model to predict response.

2) However, the reconfigurable CRO PUF is a weak PUF used for key generation. There is no access interface to read the key generated inside the chip, and the key will not be exposed to attackers. At the same time, due to the protection of the protocol mechanism, it is protected by the MASK algorithm (DA , DB) value. The Fisher-Shuffler confusion algorithm divides the response value into two parts (sA1, sA2) and (sB1, sB2) and uses the Hash algorithm and random number generator to protect part of the response value sA1in the device. Since the Hash function is one-way, the attacker cannot obtain the real CRP value by eavesdropping on the content eA, so it is difficult for the attacker to carry out machine-learning modeling attacks on PUF.

3) Untraceability. In the IoT device identity authentication process, if the attacker cannot effectively associate the request and response information of the two authentications, the input and output results cannot be mapped, and the device is considered untraceable. The attacker passes When eavesdropping to obtain messages EA and EB because the incentives DA and DB are encrypted and protected by the MASK function; the attacker cannot infer the value of the incentive DA and DB. After the attacker eavesdrops on the messages eA and eB, that is, eA ←HashA(sA1, PRNG(nB2)), eB←Hash(sA2, PRNG(nA2)). Due to the uniqueness of the hash function, it cannot obtain the values of the shared keys SA and SB. Therefore, this protocol can prevent location tracking, as shown in figure 1.

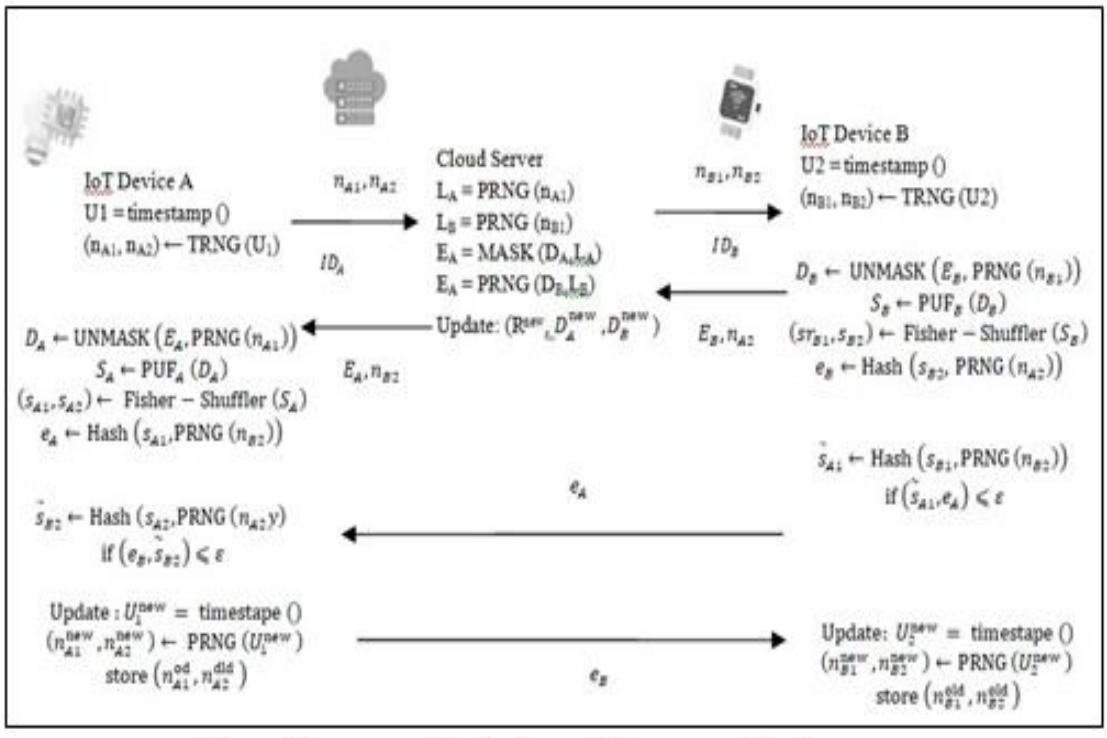

Figure 1 Two-way authentication and firmware update phase

4) Desynchronization attack. In the update phase of the protocol, the device generates new random numbers (*n*new, *n*new) and (*n*new, *n*new) and also stores the random numbers (*n*old, *n*old)and

(*n*old, *n*old). When device B is attacked by desynchronization, the random number of device A will *B*1 *B*2
be updated typically, but the random number of device B will not be updated. When the next authentication round is performed, the server will return the value EA, *n*old, given to device A, and
the value EB, *n*new, is returned to devise B. Since the verification value *e*old returned by device A
*A*2 *A*
is consistent with the previous authentication round, the dnew B returned by device B is different from the last round. Therefore it is possible to detect that the devices are not synchronized.

5) Replay attack. The protocol mechanism uses timestamps and updated random numbers (nA1, nA2) and (nB1, nB2) to defend against replay attacks. Taking the authentication of device A as an
example, assuming that the i-th and i+1 random numbers are (*n*i , *n*i) and (*n*i+1, *n*i+1),, when

the attacker obtains the i-th session message *E*i+1, *e*i+1, and performs the i+1th authentication,
A *B*
device A receives The session message of has been updated to *E*i+1, *e*i+1. Therefore, the attacker

authentication will fail, and the replay attack will be detected.

6) Counterfeit attack.

When the attacker pretends to be a legitimate device, it must send valid messages eA and eB. Using device A as an example, because the generation of information eA requires valid sA1, the input of the PUF is protected by the MASK function to stimulate CA. At the same time, the response SA is protected by the obfuscation algorithm. Due to the uniqueness of the Hash function, effective information sA1cannot be obtained even if the information eA is obtained. Therefore, in this protocol mechanism, the attacker cannot pretend to be a legitimate device and authenticate with the server. Similarly, when the attacker Masquerades as a server, the value of incentive DA and DB cannot be obtained, so mutual authentication with the device cannot be accepted.

7) Man-in-the-middle attack. This protocol can perform a man-in-the-middle attack in defense, the attacker cannot obtain valid information by eavesdropping the messages EA, nB2, EB, nA2, eA and eB. Because the eavesdropped messages are all encrypted information, if the attacker replaces the new message, the devices will not be able to identify each other causing authentication failure. Furthermore, suppose the attacker wants to parse the encrypted information. In that case, it can be known from the above impersonation attack that the attacker cannot obtain the CRP pair (DA, SA) of the PUF, so the authentication between devices will fail.

4.2 Protocol Proof

This section uses BAN logic to prove the security of the shared key generated by PUF. BAN logic is a formal analysis method for authentication protocols, which can prompt some defects that are difficult to find by non-formal methods. The logic symbols commonly used in BAN logic are shown in Table 2. Table 3 shows the logic rules widely used in BAN logic related to this section.

Symbol	Meaning	Symbol	Meaning
P |≡ X	P believes that X is true	P |⇒ X	Entity P has jurisdiction over X
P |~ X	P used to send message X	#(X)	X is fresh
P ◁ X	Entity P receives message X	(X,Y)	X or Y is part of (X, Y)
$\{X\}_K$	Use key K to message X perform cryptographic operations	$P \overset{K}{\leftrightarrow} Q$	K is between P and Q shared key

Table 3 Logic rules widely used in BAN logic

Rules	Logical Expression
Rule 1: Message Meaning Rules	$\frac{P \mid \equiv P \overset{K}{\leftrightarrow} Q, P \triangleleft \{X\}_K}{P \mid \equiv Q \mid \sim X}$
Rule 2: The Freshness Rule	$\frac{P \mid \equiv \#(X)}{P \mid \equiv \#(X,Y)}$
Rule 3: Temporary Value Validation Rules	$\frac{P \mid \equiv \#(X), P \mid \equiv Q \mid \sim X}{P \mid \equiv Q \mid \equiv X}$
Rule 4: Trust Rules	$\frac{P \mid \equiv Q \mid \equiv (X,Y)}{P \mid \equiv Q \mid \equiv X}$

For the convenience of analysis, devices A and B are denoted as E1 and E2, and the server is designated as S. After idealizing the protocol, the message-sending rules are adjusted as follows:

N1: $E1 \rightarrow T$: $nA1$, $nA2$; N2: $E2 \rightarrow T$: $nB1$, $nB2$

N3: $T \rightarrow E1$: $\{dA, nA1\}A1$, $nB2$; N4: $T \rightarrow E2$: $\{dB, nB1\}nB1$, $nA2$ N5: $E1 \rightarrow E2$: $\{sA1, nB2\}nm$; N6: $E2 \rightarrow E1$: $\{sB1, nA2\}ne$

Protocol initialization assumes the following:

A1: $E1 \mid \Xi \#\{nA1, nA2\}$ A2: $E21 \Xi \#\{nB1, nB2\}$

nn nBj

A3: $E11 \Xi E1 \odot T$; $E11 \Xi E1 \rightarrow T$

nm nm

A4: $E21 \Xi E2 \odot T$; $E21 \Xi E2 \odot T$

nm nm

A5: $E11 \Xi E1 \odot E2$; $E21 \Xi E1 \odot E2$

The target formula is as follows:

G1: $E1 \Xi\Xi$ T $\Xi \{dA\}$; H3: $E2 \mid \Xi E1 \mid \Xi \{sA1\}$; G2: $E2 \mid \Xi T \mid \Xi \{dB\}$; H4: $E1$E $\Xi E2 \mid \Xi \{sB1\}$;

Protocol initialization assumes the following:

If the target formula is established, both the device and the server T negotiate and confirm the secret key with each other, and the private key is bound to the platform integrity report and the communication channel. The following logical reasoning can be made according to the rules in Table 3.

From rule 1 and A3, N3 we know:

Therefore, the target formula G1 can be proved: D1|≡S|≡ { cA }, device A and server S share key cA.

From rule 1 and A4, M4 we know:

$nA1$

$E1 \mid \Xi E1 \odot T$,1a$\{dA,nA1\}nA1$

$E1 \mid \Xi T \mid \sim \{dA,nA1\}$

From rules 2 and A2, we know:

$E1 \mid \Xi \#(nA1)$

$E1 \mid \Xi \#(dA,nA1)$

According to rule 3 and formula (1) and formula (2):

$E1 \mid \Xi \#(dA,nA1)$,$E1 \mid \Xi T \mid \sim \{dA,nA1\}$

$E1 \mid \Xi T \mid \Xi \{dA,nA1\}$

From rule 4 and formula (3), it can be seen that:

$E1 \mid \Xi T \mid \Xi \{dA,nA1\}$

$E1 \mid \Xi T \mid \Xi \{dA\}$

Therefore, it can be proved that the target formula H1: E1|≡T|≡ { dA }, equipment A shares secret key dA with server T.
From rule 1 and A4, N4 we know:

$nm1$
$E2|\Xi E2 \textcircled{1} T,2a\{dB,nB1\}nn1$
$E2|\Xi T|\sim\{dB,nB1\}$
From rule 2 and message A2, we can know:
$E2|\Xi\#(nB1)$
$E2|\Xi\#(dB,nB1)$

Similarly, according to rules 3 and 4, and formula (5) and formula (6), the target formula can be proved: H2: E2| ≡ T| ≡ { dB }.
From rule 1 and A5, N5 we know:

nm
$E2|\Xi E1\textcircled{1}E2,2a\{sA1,nB2\}nm$
$E2|\Xi E1|\sim\{sA1,nB2\}$
From rule 2 and message A2 we know
$E2|\Xi\#\{nB2\}$
$E2|\Xi E1|\Xi\{SA1,nB2\}$

From rule 3 and formula (7) and formula (8), it can be seen that:

$E2|\Xi\#\{sA1,nB2\},E2|\Xi E1|\sim\{sA1,nB2\}$
$E2|\Xi E1|\Xi\{sA1,nB2\}$

From rule 4 and formula (9), it can be seen that:

$E2|\Xi E1|\Xi\{sA1,nB2\}$
$E2|\Xi E1|\Xi\{sA1\}$

Therefore, the target formula G3 can be proved: E2|≡E1|≡{sA1}, device B and device A share key sA1.
From rule 1 and A5, N6 we know:

$nA2$
$E1|\Xi E1 \textcircled{1} E2,1a\{sB1,nA2\}nA2$
$E1|\Xi E2|\sim\{sB1,nA2\}$
From rule 2 and A1 we know:
$E1|\Xi\#\{nA2\}$
$E1|\Xi\#\{sB1,nA2\}$

Similarly, from rules 3 and 4, and formula (11) and formula (12), it can be proved that. Target formula: H4: E1| ≡ E2| ≡ { sB1 }.

V. PROTOCOL PERFORMANCE ANALYSES

This section analyzes and evaluates the authentication protocol in terms of security attributes, storage capacity, and communication costs. The authentication protocol program between the device and the server is written in Python. The network interaction is completed by abstracting the socket connected by the TCP client/server. It makes the server wait for a connection with the device on the specified IP address. Once the device establishes a relationship with the server, the protocol performs a mutual authentication session. The server and the machine run on Windows 10, using an Intel Core i7-9750 CPU with a frequency of 2.60 GHz, Equipped with 8 GB RAM, simulating the proposed authentication scheme.
Regarding security attributes, it is compared with other protocols. In the protocol [17-21] mechanism, the attacker can obtain the CRP pair of PUF through eavesdropping, counterfeiting and physical attack. Therefore, it is impossible to defend against modeling attacks. The protocol [18] can protect against PUF attacks through the d-time locking mechanism. Still, the information in channel transmission is not encrypted, which leads to security threats such as eavesdropping, resynchronization and replay attacks in device authentication. Protocol [22-23] the device stores the old and new identities. The attacker obtains the current identity information by accessing the memory to trace the authentication information of the previous or next round, so the protocol is not irretrievable. However, this protocol uses the shared key generated by PUF. It uses the encryption of the MASK algorithm and Hashes function to ensure the privacy and non-traceability of the device.

Figure 2 and Figure 3 list the comparison with other protocols regarding device storage and communication overhead. Referring to the paper by Literature [11], the pseudo-random identity PIDiD is 128 bits, the word length of the CRP pair (Di, Si) is 128 bits, and the byte length of the key is 96 bits. This protocol only stores 128-bit random numbers (no1ld, no1ld), which is far lower than the storage capacity of other protocols. Furthermore, the protocol only transmits information (nA1, nA2, EA, nB2, eA, eB) and the communication overhead is 640 bits. Compared with other protocols [3, 5, 9-11, 18-19], the communication cost of the proposed protocol is lower than that of different schemes (as shown in figure 3), and it is suitable for lightweight devices—Security authentication scenarios

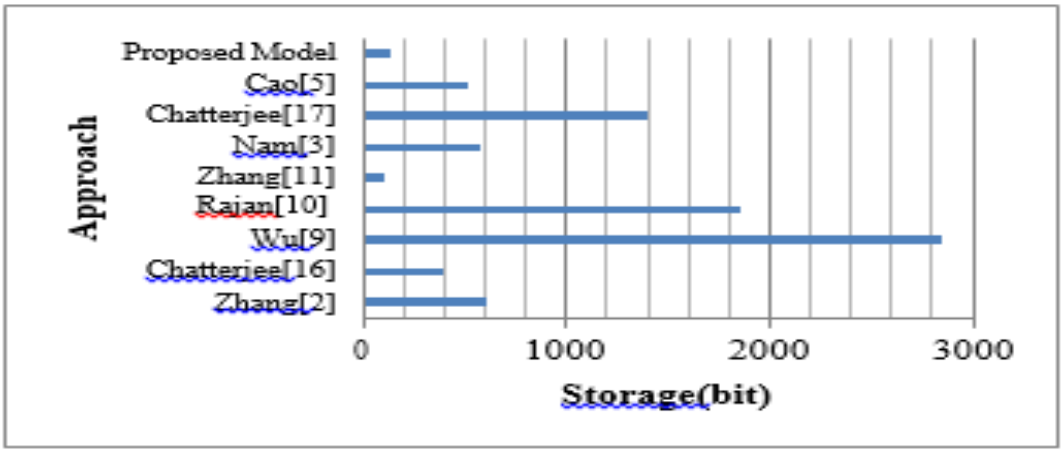

Fig.2: Performance comparison of device storage

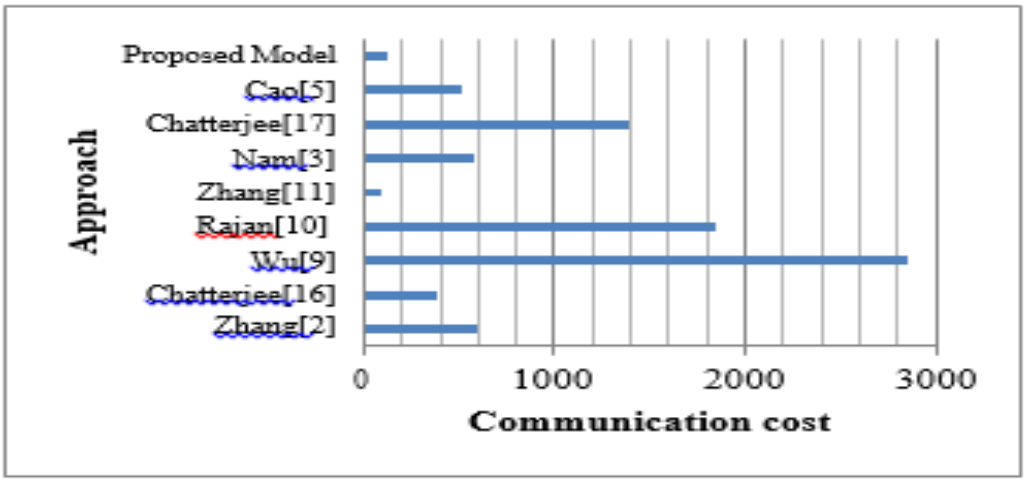

Fig.3: Communication cost in the proposed protocol

VI. CONCLUSION

The massive data generated by the IoTs brings information transmission security threats to resource-constrained terminal devices. At the same time, hardware devices usually face security issues such as chip cloning, device forgery, and key storage. Therefore, the traditional network protocol is not suitable for the security authentication of lightweight IoT devices. This paper proposes a lightweight anonymous key-sharing authentication protocol for IoT devices. This mechanism uses the characteristics of PUF anti-tampering and anti-cloning to generate shared keys on the hardware side combining security primitives such as obfuscation algorithm, MASK algorithm, and Hash function to ensure security attributes such as anonymity, untraceability, non- repudiation, and forward/backward secrecy of information transmission. Through formal verification tools, ProVerif, BAN logic, and informal, the security analysis and verification of the protocol prove the security, reliability and anti-channel attack ability of the protocol operation. Compared with other existing protocols, the proposed protocol has low computing cost, small communication overhead and storage capacity, and high security, suitable for secure communication transmission of lightweight IoT devices.

***Abstract*—A study on the impact of business intelligence and analytics on the modern world economy found that the widespread adoption of these technologies has led to significant improvements in business performance and decision-making. Companies that have implemented BI and analytics systems have seen increased efficiency and productivity, as well as improved customer service and satisfaction. Additionally, the study found that BI and analytics have had a positive impact on the overall economy, with increased competitiveness and innovation among businesses. The study concludes that the continued growth and development of BI and analytics will play a crucial role in shaping the future of the global economy.**

Keywords—Analytics, Business Intelligence(BI), Data, Data Analysis, Decision making, Economy.

I. INTRODUCTION

The modern economy is heavily dependent on datadriven decision-making, and the use of business intelligence (BI) and analytics has become essential for organizations of all sizes. BI and analytics tools allow organizations to collect, process, and analyze large amounts of data, providing valuable insights into their operations and the market. This study aims to investigate the impact of BI and analytics on the modern world economy. The study will focus on how the adoption of BI and analytics technologies has affected the performance of organizations and the overall economy. The study will also examine the future potential of BI and analytics in shaping the global economy. The study will be conducted by analyzing data from various sources such as published studies, articles, reports, and interviews with field experts. The findings of this study will provide valuable insights for organizations and policymakers on how to effectively leverage BI and analytics to drive economic growth and competitiveness.

II. BUSINESS INTELLIGENCE(BI)

Business intelligence (BI) refers to the tools, technologies, and processes that organizations use to collect, analyze, and present data to make informed decisions. BI typically includes a combination of reporting, data visualization, and analytics tools, as well as a data warehouse or other data storage system, to support the gathering and manipulation of data from various sources [1]. The goal of BI is to help organizations make data-driven decisions that improve performance and achieve strategic goals.

III. IMPACT OF BUSINESS INTELLIGENCE ON THE ECONOMY

Business intelligence (BI) can have a significant impact on the economy by helping organizations make better decisions, improve efficiency, and increase profitability [2]. Here are a few ways BI can impact the economy:

- Improved decision-making: By providing organizations with real-time data and analytics, BI can help them make more informed decisions that lead to better outcomes and increased competitiveness.

- Increased efficiency: BI can help organizations streamline their operations by identifying areas where they can reduce costs, improve processes, and increase productivity.

- Greater innovation: By providing organizations with access to large amounts of data, BI can help them identify new opportunities for growth and innovation that would have been difficult to uncover otherwise.

- Enhanced customer service: BI can help organizations understand their customers better, which can lead to improved customer satisfaction and loyalty.

- Increased profitability: By enabling organizations to make better decisions, improve efficiency, and innovate, BI can lead to increased profits and growth.

Overall, the use of Business Intelligence in an economy can lead to better decision-making, increased efficiency and productivity, greater innovation, improved customer service, and increased profitability for organizations, which can ultimately lead to economic growth.

IV. USECASE

One example of a use case for business intelligence (BI) in a business is sales performance analysis. A company might use BI tools to collect and analyze data on their sales, such as the number of products sold, revenue generated, and customer demographics. This information can then be used to identify trends, such as which products are selling well and in which regions, as well as which sales strategies are most effective.

Here's how BI can be used in this scenario:

- Data collection: The company's sales data is collected from various sources, such as its CRM system, financial system, and website analytics.

- Data warehousing: The collected data is then stored in a data warehouse for easy access and analysis.

- Data analysis: The company can use BI tools such as reporting and data visualization to analyze the sales data. They can create reports, charts, and dashboards to track sales performance over time, compare sales by region or product, and identify which sales strategies are most effective.

- Decision-making: The insights gained from the data analysis can be used to inform decisions on sales strategy, product development, and marketing efforts. For example, the company might decide to focus more on the products and regions that have shown the most growth or implement new sales strategies that have been successful in other regions.

- Continuous monitoring: The company can continue to monitor their sales data on an ongoing basis, using BI tools to track progress and make adjustments as needed.

- By using BI to analyze sales data, the company can gain a better understanding of its sales performance, identify areas for improvement, and make more informed decisions that can lead to increased sales and revenue.

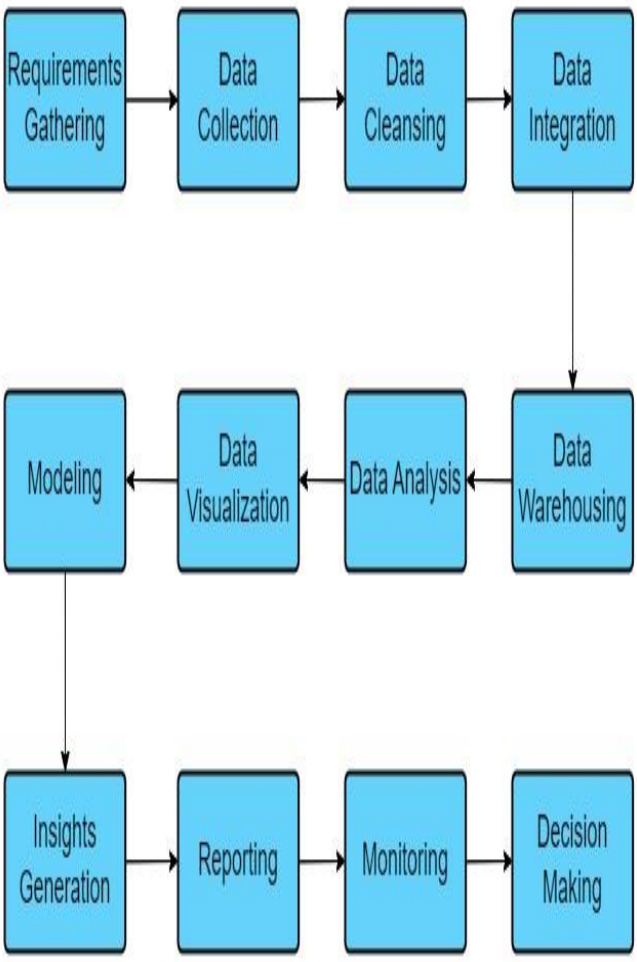

Figure 1: Business Analysis

V. ANALYTICS

Analytics refers to the process of examining data in order to gain insights, identify patterns, and make predictions [3]. Analytics can be applied to various types of data, such as financial, customer, or operational data, and it can be used for a wide range of purposes, such as improving business performance, detecting fraud, or identifying new business opportunities.

There are several types of analytics, including:

- Descriptive analytics: This type of analytics focuses on summarizing data and identifying patterns that have already occurred.
- Diagnostic analytics: This type of analytics focuses on identifying the cause of a particular problem or issue.
- Predictive analytics: This type of analytics uses historical data and statistical models to predict future outcomes or trends.
- Prescriptive analytics: This type of analytics uses data, models, and algorithms to recommend actions or decisions that can be taken to optimize a particular outcome.

Analytics can be performed using a variety of tools, including spreadsheet software, statistical software, and specialized analytics platforms. It often involves the use of data visualization techniques to help make the insights gained from the data more easily understood and actionable.

VI. IMPACT OF ANALYTICS ON THE ECONOMY

Analytics can have a significant impact on the economy by helping organizations make better decisions, improve efficiency, and increase profitability. Here are a few ways analytics can impact the economy [4]

- Improved decision-making: By providing organizations with insights and predictions based on data analysis, analytics can help them make more informed decisions that lead to better outcomes and increased competitiveness.
- Increased efficiency: Analytics can help organizations streamline their operations by identifying areas where they can reduce costs, improve processes, and increase productivity.
- Greater innovation: By providing organizations with access to large amounts of data, analytics can help them identify new opportunities for growth and innovation that would have been difficult to uncover otherwise.
- Enhanced customer service: Analytics can help organizations understand their customers better, which can lead to improved customer satisfaction and loyalty.
- Increased profitability: By enabling organizations to make better decisions, improve efficiency, and innovate, analytics can lead to increased profits and growth.
- Predictive maintenance: In manufacturing and other industries, analytics can be used to predict failures and schedule maintenance, thus reducing downtime and increasing productivity.

Overall, the use of analytics in an economy can lead to better decision-making, increased efficiency and productivity, greater innovation, improved customer service, and increased profitability for organizations, which can ultimately lead to economic growth.

Table 1 USE CASE IN DOMAIN

Table Head		
	DOMAIN	***Use Case***

1	Retail	Customer behavior analysis, Sales trend analysis, Inventory management
2	Healthcare	Patient data analysis, Clinical decision support, Healthcare fraud detection

Table Head

	DOMAIN	***Use Case***
3	Banking	Risk management, Customer segmentation, Loan approval process optimization
4	Manufacturing	Supply chain analysis, Quality control, Predictive maintenance
5	Education	Student performance analysis, Course curriculum optimization, Student retention analysis

VII. USE OF BI & ANALYTICS IN THE MODERN ECONOMY

One real-world example of the use of business intelligence and analytics in the economy is how Walmart, the largest retail company in the world, uses BI and analytics to optimize its operations and improve its bottom line. Walmart has a vast network of stores and a large amount of data on its customers and sales. The company uses BI and analytics tools to analyze this data in order to identify patterns and trends. For example, they use data on customer demographics and purchasing habits to optimize their product offerings and pricing strategies. They also use data on inventory and supply chain operations to improve efficiency and reduce waste. This allows them to make better-informed business decisions and stay ahead of their competition. Overall, the use of BI and analytics has been a key factor in Walmart's success as a company and its ability to compete in the global economy [5].

Here are some of the varied applications of BI:

- Sales and Marketing Analysis: Utilizing BI to analyze customer data, such as demographics and purchasing behavior, to improve sales and marketing strategies.
- Financial Analysis: Utilizing BI to analyze financial data, such as revenue and expenses, to identify trends and make informed financial decisions.
- Supply Chain Analysis: Utilizing BI to analyze data related to suppliers, inventory, and logistics to improve supply chain efficiency and reduce costs.
- Risk Management: Utilizing BI to analyze data related to potential risks, such as fraud or natural disasters, to identify potential threats and develop risk management strategies.
- Human Resources Analysis: Utilizing BI to analyze data related to employee performance, turnover, and benefits to improve human resources management.
- Customer Relationship Management (CRM): Utilizing BI to analyze customer data, such as purchase history and communication preferences, to improve customer relations and retention.
- Operational Analysis: Utilizing BI to analyze data related to operations, such as production and logistics, to improve efficiency and reduce costs.
- Fraud Detection and Prevention: Utilizing BI to analyze data related to financial transactions and identify patterns that may indicate fraud.

- Performance Management: Utilizing BI to analyze data related to organizational performance, such as revenue and employee productivity, to identify areas for improvement and set performance targets.
- Predictive Maintenance: Utilizing BI to analyze data related to equipment and machinery to predict when maintenance is needed and prevent equipment failure.

VIII. ADVANCEMENTS IN BI Recent advancements in Business Intelligence (BI) include the use of machine learning and artificial intelligence to improve data analysis, the integration of big data and real-time data streams, and the use of natural language processing to make BI systems more user-friendly and accessible to a wider range of users. Additionally, the increased use of cloud-based BI platforms has made it easier for organizations to access and share data and collaborate on analysis. Furthermore, the increasing use of mobile devices has also led to the development of mobile BI applications, which allow users to access and analyze data on the go.

Another advancement in BI is the use of augmented analytics, which uses machine learning algorithms to automate data preparation, data discovery, and insight generation. This allows users to quickly and easily gain insights from their data without the need for specialized skills or knowledge. Additionally, the use of data visualization tools, such as dashboards and interactive reports, has made it easier for users to understand and communicate their findings.

BI is also becoming more integrated with other technologies, such as the Internet of Things (IoT) and blockchain, to provide new insights and opportunities for businesses. IoT devices can generate large amounts of data that can be analyzed to gain insights into operations and customer behavior.

Similarly, blockchain technology can be used to secure and validate data, making it useful for supply chain management and other use cases. Finally, advancements in natural language processing (NLP) and natural language generation (NLG) have enabled the development of conversational BI systems, which allow users to interact with the system using natural language commands and receive insights in plain language. Overall, these advancements in BI are helping organizations to make better data-driven decisions, increase efficiency, and gain a competitive advantage.

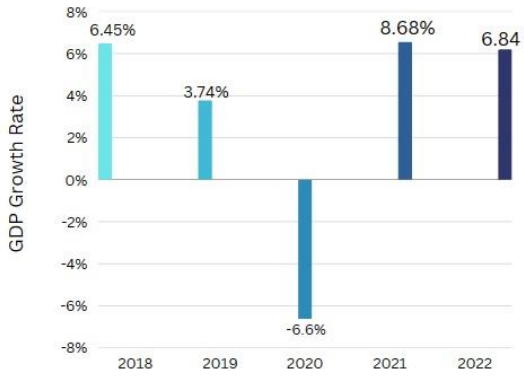

Figure 2: The Bar Graph Explain the past 5 year Economy growth of India from the financial year 2018 to 2019

The Gross Domestic Product (GDP) of India is an important economic indicator that measures the total value of goods and services produced in the country in a given year. It is a measure of the country's economic output and growth. In recent years, India's GDP has been growing at a relatively steady pace, with fluctuations depending on various economic and political factors. For example, in 2020, due to the COVID-19 pandemic, the country's GDP saw a significant contraction and dipped by 7.7% YoY, however, in 2021, it rebounded and grew by 11.0% YoY due to various stimulus measures and vaccine rollouts. It is important to note that the GDP growth rate can be influenced by various factors such as government policies, economic reforms, investment, consumer spending, exports, inflation, and more. In conclusion, the yearly growth of India's GDP has been fluctuating but has shown a positive trend over the years, with an average growth rate of around 7% in the last decade.

IX. CONCLUSION

The effective use of Business Intelligence and Analytics can change the world's perspective towards business and has a huge impact on the modern world economy leading to growth in business through the decision-making process. Also, the technology can be used by very big firms as well as small businesses and can derive business-related decisions to manage their activities. The business can be expanded in the areas of greater interest in the products.

Benefits and Issues of Health Monitoring System Based on the IoT

Muneshwar Gyaniram Neware, Lowlesh N. Yadav,Vijay M. Rakhade, Ashish B.Deharkar, Neehal B. Jiwane
Shri Sai College Of Engineering And Technology, Bhadrawati, Maharashtra, India

Abstract: **A world wherever everything is online and act to alternative things and folks to boost peoples lives like self driving drones and sensors for observation your health is conjointly referred to as the web of things (IoT). IoT devices are very useful in Hospitals. In most of the time using the IoT for Healthcare we replace part of the visit to the physician with an online consultation moreover some medical test can be performed remotely either, right at the patients home. In this paper author focus on Review of issue and benefits of HMS (Human Monitoring System) based on IoT smart devices can track health conditions IoT applications for health care can send a emergency signal if the patient has an asthma attack, heart failure or another medical issue.**

Keywords: **IoT, Sensor, folks, Human Monitoring System, driving drones.**

I. INTRODUCTION

At present Internet has became a part of our daily life. Internet connected devices are becoming more available, it will be harder to imagine that the internet we use today to reach people, find information and assist us in our daily live with innovative services will not be extended toward creating value out of such increased availability of connected objects[1][2]. Internet of Things(IoT) is such when the internet and networks are mashed up. According to infra structure, IoT is the combination of embedded electronics, sensors, software and connectivity and sometimes it is called internet of everything.Heterogeneity of interconnected objects are responsible for exchanging data those are interconnected between pcs, human to human, human to things, things to things[17].

The data will be accessed exploitation the power given from the magnitude of web from anyplace, any time. therefore health information will be remotely accessed with the assistance of IoT. during this sense we've developed a model for aggregation health information from patients as human to things and also the health units accessed the information to supervise the patient's state any time remotely. virtually individuals of all ages square measure exploitation mobile devices like sensible phones and tablets for exploitation numerous applications owing to being advanced mobile technologies. As health is one in all the most important problems within the sensible world therefore remote observation in everything is turning into standard. convenience of web it's currently turning into easier to use mobile technologies for medical applications.

A user can simply connect a health monitor via a mobile device to develop his or her own personal health[3]. There is currently strong need of advance in the field of health information[4].

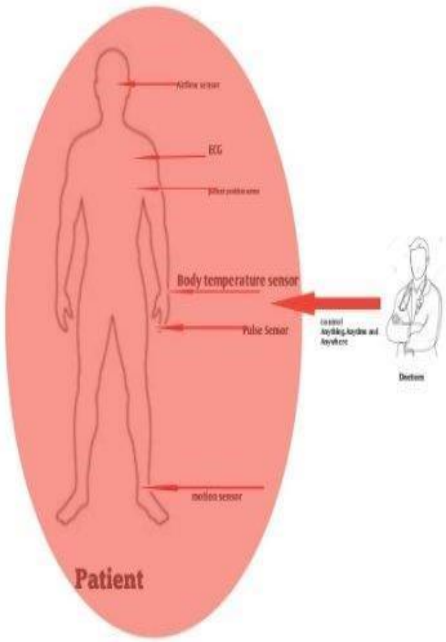

Fig: Human Monitoring System based on IoT Devices

II. SYSTEM EXPLANATION

Basically a hospital management consists of some teams of specialists like doctors, nurses, higher authorities etc. In a busy day the total units have to be compelled to be terribly careful concerning the health condition concerning their patients. however it's abundant robust to take the acceptable action once the patient are several in number. And additionally the value for the medical purpose is high for the large machines like cardiogram machine. every machine will measure every kind of knowledge solely. It takes additionally Brobdingnagian area. The management units store the health knowledge in written. But they can simply use cloud for unlimited storage with low cost. they'll talk to specialist anytime from anyplace they want. Hospital management can't offer patient's health information to their guardians uncomparable. they supply solely visiting hours to the guardians. victimisation this technique they'll easily monitor additional patients and provides correct treatments to the patients. The guardians may get the health data instantly.

A.Phidgets Interface kit

Phidgets Interface kit receives analog input which can measure the continuous quantities like as temperature, humidity, position, pressure, etc. This kit allows extensive variety of sensors which can be connected directly with this kit using cable included with the sensor[16].

1)Accelerometer : The Phidget Accelerometer is a ac- celerometer that measures 3 gravitational(29.4m/s2) change per axis having three axis(x,y,z). This sensor can measures both dynamic acceleration named vibration and static acceleration named gravity or tilt[16]

2) Touch Sensor: A binary result such as Touch Detected or No Touch Detected is the output of the Phidgets touch sensor. Touch is detected when patient is regularly using the sensors or patient is in touch of sensors[16].

3) Light Sensor: Precision light sensor measures human perceptible light level in lux; its measurement range is from
1 lux to 1000 lux of the living environment of the patient. Firing activities are measured by this sensor[16].

4) 4) 4) 4) Humidity and Temperature Sensor: Humidity sensor measures relative humidity from 10% to 95% with a typical error of 2%RH at 55% RH on the contrary temperature sensor measures ambient temperature in the range of -30oC to +80oC with a typical error of 0.75oC in the 0oC to 80oC range. The temperature sensor component is rated at -40oC to +100oC[16].

B. E-Health Sensor Shield kit

The e-Health Sensor Shield approves Arduino and Raspberry Pi users for causation of biometric and medical applications which is used for measuring health condition through using different sensors. All this information can be used to monitor in real time the condition of a patient or to get sensorial data in order to be subsequently analyzed for medical diagnosis. All this biometric information which is gathered by this kit; can be sent through wireless using any of the 6 connectivity options available Wi-Fi, 3G, GPRS, Bluetooth, 802.15.4 and Zigbee[6] depending on the application. This E- Health Sensor Shield kit also ables to make interface with Arduino and Raspberry board for making communication with personal computer[6].

1.E-Health ECG Sensor:

The electrocardiogram is such a diagnostic tool that regularly measures the electricaland muscular functions of the heart. Normally an ECG machine uses 12 electrodes, but this sensor only 3 electrodes for generating patients ECG signal because, this 3 electrode create a triangle around the heart and can receive the information form heart position V1 to V5[6]. Besides this ECG sensor is self-configurable. A user can measure a patients ECG data at any interval he likes. But minimum data interval is one micro-second when this sensor is programmed to make interface with Arduino UNO. But, as comparing with normal sinus rhythm rate[18].

2) E-Health Body Temperature Sensor: Body temperature sensor measures the temperature level of a patient. When a person get sick his body temperature do not remain constant as natural. The reason is that various diseases are accompanied by when characteristic changes in body temperature. Similarly, body temperature allows to monitor of the motion of certain diseases, and a physician can easily evaluate the efficiency of a treatment[6].

C. Arduino UNO: Arduino UNO is a microcontroller which is based on ATmega328. To support as a microcontroller it contains everything it needed. Such that it has 6 analog inputs, 14 digital input/output pins, a 16 MHz ceramic resonator, single USB connection, a power jack and a reset button. Simply the

microcontroller can be connected to a computer with a USB cable or an AC-to-DC adapter or battery to get started[15].

III. ISSUES/ CHALLENGES AND BENEFITS

 The five main benefits of IoT in patient health monitoring system:

1 .Health Monitoring :

Smart devices will track health conditions. IoT applications for aid will send and emergency signal if the patient has a respiratory disease, failure, or another medical issue.

For example, Apple has integrated AN IoT technology in aid to Fall Detection System in Apple Watch. It detects if the user falls And shows an alert. The person has to faucet 'I'm OK' for one minute. In another case, Apple Watch calls emergency services. They conjointly send a message to emergency contacts.

2 .Better Patient expertise:

IoT in hospitals improves the tending system, offers patients an easier thanks to get involved with doctors. It results in up patient expertise and gaining client loyalty. Thus, the ton in tending trade helped the U.S. (Mt. Sinai Medical Center) cut back the waiting time for five hundredth of their emergency patients victimisation AutoBed computer code.

The hospital has around 100 beds, however admits a minimum of 1000 of patients. the first task of AutoBed is matching obtainable beds with new patients. This way, IoT devices in tending assist the hospital within the economical accomplishment of the set goals.

3. Drug Management:

One of the Internet of Things health care edges is best drug management. IoT technology permits dominant the number of taken drugs. Doctors will monitor the dose and track effectiveness of treatment.

Also, the Internet of Things permits causing reminders to patients once they should to take their medication. In some cases, it's doable to inform the friend once the patient hasn't taken drugs on time.

4. Healthcare Automation:

loT devices will facilitate automatize body, manual, and routine tasks. Internet of Things medical applications

will analyze a major quantity of data and make totally different metrics to visualize any changes within the patients' health conditions. Automatic processes of collection knowledge will scale back the amount of errors in creating designation

5. Preventive healthcare:

A lot of individuals die from chronic diseases like heart condition, diabetes, and more. victimisation the analytic capabilities of ton, it's potential to supply patients with a lot of customized sorts of treatment and care.

Smart, Connected or wearable ton devices for health care will monitor condition of older or patients with chronic diseases. Having all that information, doctors are going to be able to provides a higher treatment and see the primary symptoms of the sickness.We've looked solely through the foremost common advantages of the web of Things technology. consistent with them, the role of ton in health care is to boost patients' well-being through trendy technologies likewise as boost physicians' work the loT-equipped medical devices.

 Some issue or challenges of IoT in Health Monitoring System:

1.Data security:-

The main downside of IoT for attention is poor security. information privacy is critical for the medical trade since case history is counselling. Malefactors could try and get access to the company's package and expose sensitive information. However, the good medical package development seller will effectively shield your future loTequipped app from any harmful actions of the third parties.To avoid such problems, it's a necessity to specialise in information security after you create use of heap in attention. Certainly, such a necessity can cause extra prices.

There also are such papers as GDPR and CCPA that shield personal data of patients on heap connected attention applications.

2. Integration of Protocols:

IOMT connects loads of various IoT health devices. to form a versatile scheme, attention needs exploitation the practicality of the many devices with varied protocols. However, there's no single answer concerning communication protocols and standards.

As a result, the combination of IoT within the attention trade is kind of slow and restricted.

Creating medical software system, you must make certain that your app is HIPAA and HITECH compliant. These protocols contain loads of rules and rules connected to process patients' personal data, and so as to facilitate such a compliance, you'll be able to apply to at least one of the attention IoT corporations having the in- depth experience in such Associate in Nursing integration and serving to you with success touch upon the aforesaid issue.

3. Data overload:

An IoT care device collects and processes many more of data. As a result, doctors will face information overload and accuracy problems. the big quantity of data on the internet of Things caring applications will result in difficulties in decision-making throughout treatment.

CONCLUSION

With the development of technology it may be expected that the provision of internet is everyplace. The goal of this system is to mechanically gather information from patients and store the gathered information into cloud for permanent use that may help health professionals to remotely health observance. The hospital management may be ready to monitor additional patients at a time. The system will facilitate guardians of the patients to know the health data. this technique is additionally transportable. So it may be expect that it'll facilitate the health units and guardian of the patients permanently caring and minimizing risk taking required immediate action. In future new health sensors may be additional and analysing the data to produce a satisfactory result supported the measured data to produce live opinion regarding patients state. There may be a telephony or SMS service may be enclosed to tell guardians and health units regarding patient's essential condition.This technique is very useful in day by day.

Abstract— **The cause of this evaluation paper is to discover and study boundlessly about computer-assisted schooling, and its impact on college students and their educational success. laptop-assisted mastering offers lecturers with diverse coaching statistics and multimedia platforms for easy gaining knowledge of of college students. It translates the innovation of computer-assisted education and its fulfillment in today's generation. computer-aided schooling indicates the integrated approach of the laptop and its gadgets. although, it does no longer imply on-line gaining knowledge of will subsequently replace traditional education and teachers, instead instructors the usage of computer-primarily based platforms, and their applications to teaching, like smart training, motion pictures, and web tutoring with stepped forward resources and reduced trainer workloads. by which, students can arrive, grasp, and have interaction themselves at their very own pace in a co-relational environment. furthermore, within the state of affairs of a deadly disease like this, we all are deciding on laptop-assisted education. consequently, with out pc- facilitated training these days, it'd were merely impossible for us to observe, and obtain schooling. the sector has widely opened and regular the brand new era of pc-assisted schooling. This paper is completed to differentiate the success of pc-assisted schooling.**

Keywords— Computer Assisted Education , Computer Facilitated Education , Multimedia platforms

1. Introduction

Training is a vital problem in a single's lifestyles. A correct and smart education is vital for all human beings. it's the technique of reaching accurate information, values, abilties, and useful habits. One of the fundamental important advantages of schooling is that it improves private lives and helps society to run effortlessly. it is the key to trade our non-public increase in an especially giant thank you to the fulfillment and own several opportunities in lifestyles. moreover, an knowledgeable man or woman encompasses a larger chance to range the planet collectively with his facts and ideas rather of accomplice diploma uneducated guy in society. education is the backbone of society. The government has completed and is functioning in empowering training and its regions in numerous little villages in our us of a. earlier, schooling utterly depended on books and magazines, however with the dynamic world; the training system is additionally bit via bit changed. therefore, we tend to vicinity unit currently transferring to computer systems, virtual, and virtual systems for gaining the utmost information, competencies, and statistics. computers have expanded human potentials, practically in every possible area. computers and multimedia generation has drastically reached a stage of refinement that allows lecturers to layout and create applications themselves that permit students to evolve the packages to their man or woman getting to know needs. also, computer systems make certain greater accuracy and make student's lives simpler and extra comfy.

And computer systems play a huge role inside the lives of students in the cutting-edge world. it's far the final results of many consecutive inventions by using several scientists. we can get an idea of how huge of a position this is if we have a look at some things in the contemporary world that we rely on, and primarily take as a right. generation lets in college students to help every other and paintings together for a higher expertise of the cloth. In that sense, they will every so often feature because the (supervised) instructors — and learning through guidance is idea to be noticeably powerful for mastering a topic and fixing problems. laptop-assisted training is one of the main precious gifts of state-of-the-art digital generation. With best one click on, we are in a position to have a compilation of statistics. It refers to gaining schooling thru electronic devices and digital merchandise. Now that we've got got an online learning system no person desires to keep in mind books and schools completely to attain schooling and expertise. There exists no discipline of education in which the technology isn't used, be it medical, civil, or any type of discipline. For example, computer systems assisted education is additionally used for the scientific and scientific field for higher information via visualization of the human physique, which will regularly lead to a better diagnosing pattern and makes health care quicker and more green. you'll gain any affordable understanding of any quiet subject from the utilization of digital devices and intermediate systems. digital learning is changing study room teachings within the majority of the schools, students, and institutes. smart training, video

lessons, on line-offline videos, web classrooms, and lots of extra services are available because of computer systems. laptop-assisted schooling is a simple way of gaining knowledge of and greedy the content material. We are in a position to make appealing and appealing displays to make clear subjects. With laptop-assisted studying, we will analyze every time and also multiple instances. we are able to view the videos, the recorded tutored consultation's infinite instances, and anywhere. laptop education has now not best simplified the system of training but also introduced value thereto. Due to pc-aided schooling, the method of getting to know has end up interesting.

2. What is computer assisted education?

computer-assisted training is frequently mentioned as a systematic use of computers, digital merchandise, multimedia structures, and package deal programs as a relevant function to show ideas or capabilities for the first rate improvement of the pupils. by means of victimization the materials that region unit maintain on in DVDs, cellular phones, and alternative net-primarily based resources, the schooling understanding becomes additional enticing and dynamic, that offers the students quality methods to exhibit their listening and mastering skills. it is accomplice in Nursing integrative generation that describes an academic putting anywhere a computer virus is hired to help the user in gaining knowledge of a precise problem. It refers to companion in Nursing's overall included method of educational approaches. Any use of computer systems to help or support the training or coaching of a personal. At any purpose, computer resource gaining knowledge of gives faster or slower routes through the material for oldsters of assorted aptitudes to healthy their pace and will preserve a revolutionary report for the running shoes. computer-assisted mastering is an associate in nursing most economical manner of speedy data inside the teaching subject. pc-assisted gaining knowledge of is one in every of many terms accustomed express absolutely exclusive packages of computers. therefore, other phrases include pc-aided (or assisted) practise (CAI), pc-primarily based learning (CBL), and pc-managed instruction (CMI).

There are many distinct techniques of laptop-assisted education as an example:

- smart lessons
- Recorded films
- power factor displays
- Zoom instructions
- online publications
- net meetings
- Blogs
- Wikipedia
- Social networking websites
- virtual games
- studying apps like byju's, unacadamy, and so forth.

In a pandemic situation like this maximum of the schools and schools who prefer online platforms. consequently, several pc applications like- Zoom, Microsoft companies, Google meet, and so on place unit helping the faculties, and universities within the tutorial sector. They enabled a platform anyplace teachers will produce a digital room to show, anyplace all of the scholars WHO board completely unique locations will attend the category. They offer numerous options like- screen sharing, whiteboard, hand raising, extra for a much better and charming version of coaching

Pros of computer assisted Education

- It caters to the personal needs of an man or woman.
- college students can select the language and can continually participate in active interactions.
- college students can see their daily development so that they could examine their paintings.
- college students discover it very thrilling and tasty.
- college students can discover complicated topics ruin down into small components.

Cons of computer assisted Education

- From time to time it is able to be expensive for college kids.

- Every so often teachers can discover it is difficult to enforce.

- Occasionally sports of it don't constantly healthy the desires of the trainer.

- Students can every so often habituate to isolation and may face trouble in social interplay.

In the quit, it's up to the faculty to decide whether or not computer Assisted getting to know is useful and right for his or her lessons or now not. as long as the professionals and cons are assessed pretty, the use of computers assisted getting to know inside the lecture room can be a superb manner to take benefit of new technology and build up the language gaining knowledge of studies many of the students.

3. Analysis

It has been analyzed there are numerous approaches of computer-assisted training. by that students will understand and hold close any subject matter at their very own pace, may additionally valuate themselves for their non-public growth and competencies. And it doesn't mean or result at paintings lecturers; it implies teachers exploitation computers and technologies for teaching the pupils. additionally, computers and their applications are wide hospitable in all regions of schooling from science to medicine, arts, and to plenty of diverse fields. The training quarter has been beneath a thriving advancement and is shining with upgrading technology. scholars perceive the significance of non-stop schooling. lecturers will produce virtual school rooms wherever at any time with severa alternatives like display screen sharing, massive area for notes and assignments, files, and posts; additionally numerous different alternatives for study and paintings. And many laptop packages like Zoom, Microsoft agencies, Google meet, and so on have enabled the achievement of pc-assisted education. The quantity of the education zone has raised and that they help academics and create gaining knowledge of interactive, bendy, and fascinating for college students.

4. Result and discussion

The principle goal of this observe become to investigate the effects of the computer-assisted mastering on the achievements and hassle solving competencies on the instructional sciences students. To this stop, This result leads that experiment institution's students with laptop-assisted learning techniques increase their problem solving stage, fulfillment and display a higher performance extra than the manage organization pupil. A good sized difference turned into located on the quit of the application on behalf of the test group between the instructional facts achievements of the manage group who had conventional preparation strategies and the experiment group who had laptop-assisted gaining knowledge of. This study confirmed that, computer-assisted mastering approach turned into more powerful on the students' academic facts achievements than the conventional education strategies.

5. Recommendation

- Children ought to pay constrained time with technology.

- It ought to be worn out green way.

- technology ought to be used until it serves its cause and now not harms.

- technology like this may be created to be had to rural areas

- Upgrading of technology have to be there.

- Simulation and virtualization.

- sensible computer-assisted mastering systems — partner intelligent laptop-assisted mastering machine this is at the some distance aspect the scope of this paper, can have numerous blessings in comparison to wellknown ones.
they're direct outcomes of AI ways.

- There ought to be a correctly disciplined technique of computer-assisted training
-

6. Acknowledgement

I would like to expand gratitude to project guide **Prof. Vijay M. Rakhde** who guided by providing the valuable suggestion in numerous way on this project which gave us the inspiration to improve our self independency. Secondly I would like to express my gratitude toward the project mentor **Prof. Ashish B. Deharkar** who help in finalizing the work done within the limited time period, I would also like to express heartfelt thanks to Head Of Department **Lowlesh Yadav** who has given us a platform where we can work on developing the projects and demonstrate the practical applications.

7. Conclusion

The entire international is counting on the centers supplied with the aid of computers and their assisted packages to educate themselves and work. schooling is boundary-much less, wherein the computer aids in the method of overcoming the difficulties that come at the way. The use of pc-assisted getting to know enhances modern training and presents studying opportunities that can not be taught by using conventional techniques. It gives an interesting opportunity to support conventional strategies and to expand modern methods. In the future, we will see greater advanced software with virtual schooling that can speak and interact with students in a completely realistic way. however, for teachers, the task is no longer only to combine computer-assisted training into the curriculum but additionally to assess its impact on mastering inside the real international. in accordance to these outcomes, there are some hazards except the blessings that the observe unconcealed. For instance, the crew spirit among college students may additionally weaken due to man or woman works. This and similar hazards are waiting for researchers as a subject of every other study. although, in a pandemic scenario like this, simplest because of the centers of laptop- assisted technology, training is accomplishing large heaps. the belief is apparent that the pcassisted education program is the maximum used approach through institutional bodies nowadays to boom the potential of their college students.

Bhadrawati, India

Abstract— **Computer virtual photo generation is a completely crucial department of the pc software discipline, and its software regions consist of measurement, pc-aided design, physics, three-d simulation and different industries. Moreover, with the development of pc hardware performance, photo processing algorithms have progressed the software of virtual photo processing generation. This article makes a speciality of the contemporary virtual photo processing generation and its software status..**

Key Words - ***Digital Image Processing Technology ,Application***

I. INTRODUCTION

Digital photograph processing generation is using laptop generation to cast off the image noise, decorate, segmentation, restoration and so on. The improvement of computer community generation has caused the development of virtual photo processing technology, the increasing stage of mathematics, and the consistent call for for digital photograph processing era from numerous industries in society, which has delivered new possibilities for digital image technology and supplied development. In the Nineteen Twenties, people used digital image processing generation for the primary time. They used cables to switch photos among the United Kingdom and the united states. but, the fine of pictures transmitted changed into not excellent. therefore, photograph satisfactory must be improved and optimized. It changed into now not until the Nineteen Seventies that virtual image processing generation had been updated. The examine of digital pics at this level additionally incorporated a pattern information gadget. As era is continuously up to date and applied to distinct fields, the requirements for virtual image processing generation are becoming higher and better, which additionally hurries up the development of virtual photo processing era.

With the boom of laptop processing power, humans use laptop processing gadgets to slowly shift from characters to photographs. According to statistics, today's records, particularly Internet records, transmits and shops greater than 80% of the records. Compared with the records of the man or woman type, the photograph records is an awful lot greater complex, so it's miles greater complex to manner the characters at the laptop than the photograph processing. Therefore, so one can make using photograph records more secure and greater handy, it's miles mainly essential to perform associated utility studies on photograph virtual media. Digital media photograph processing generation in particular

consists of denoising, encryption, compression, storage, and lots of different aspects. The motive of photograph denoising is to put off the noise of the herbal frequency withinside the photograph to obtain the traits of highlighting the that means of the photograph itself. Because of the photograph acquisition, processing, etc., they may harm the authentic sign of the photograph. Noise is an essential aspect that interferes with the readability of an photograph. This supply of noise is numerous and is in particular derived from the transmission manner and the quantization manner. According to the connection among noise and sign, noise may be divided into additive noise, multiplicative noise, and quantization noise. In photograph noise removal, normally used strategies consist of a median clear out out approach, an adaptive Wiener clear out out approach, an average clear out out, and a wavelet rework approach. For example, the photograph denoising approach achieved via way of means of the community averaging approach used withinside the literature is a median filtering approach that's appropriate for eliminating particle noise in an photograph acquired via way of means of scanning. The community averaging approach strongly suppresses the noise and additionally reasons the paradox because of the averaging. The diploma of ambiguity is proportional to the radius of the field. The Wiener clear out out adjusts the

output of the clear out out primarily based totally at the neighborhood variance of the photograph. The Wiener clear out out has the pleasant filtering impact on photographs with white noise. For example, withinside the literature this approach is used for photograph denoising, and desirable denoising consequences are acquired.

Median filtering is a normally used nonlinear smoothing clear out out this is very powerful in filtering out the salt and pepper noise of an photograph. The median clear out out can each put off noise and guard the rims of the photograph for a high-quality recovery. In the real operation manner, the statistical traits of the photograph aren't needed, which brings a whole lot of convenience. For example, the literature is a a success case of photograph denoising the usage of median filtering. Wavelet evaluation is to denoise the photograph via way of means of the usage of the wavelet's layering coefficient, so the photograph information may be nicely preserved, inclusive of the literature Image encryption is every other essential utility location of virtual photograph processing generation, in particular such as aspects: virtual watermarking and photograph encryption. Digital watermarking generation at once embeds a few identity records (this is, virtual watermark) into virtual carriers (such as multimedia, documents, software, etc.), however does now no longer have an effect on the use cost of the authentic service, and isn't without problems perceived or observed via way of means of a human notion system (inclusive of a visible or auditory system). Through the records hidden withinside the service, it's miles feasible to verify the content material creator, the purchaser, transmit the name of the game records, or decide

whether or not the service has been tampered with. Digital watermarking is an essential studies route of records hiding generation. For example, the literature is the end result of reading the photograph virtual watermarking approach. In phrases of virtual watermarking, a few researchers have attempted to apply wavelet approach to study. For example, AH Paquet and others used wavelet packet to perform virtual watermark non-public authentication in 2003, and efficaciously delivered wavelet principle into virtual watermark studies, which spread out a brand new concept for photograph- primarily based totally virtual watermarking generation. In order to obtain virtual photograph secrecy, in practice, the - dimensional photograph is commonly transformed into one-dimensional data, after which encrypted via way of means of a traditional encryption set of rules. Unlike regular textual content records, photographs and movies are temporal, spatial, visually perceptible, and lossy compression is likewise feasible. These functions make it feasible to layout greater green and stable encryption algorithms for photographs. For example, Z Wen and others use the important thing cost to generate real-cost chaotic sequences, after which use the photograph scrambling approach withinside the area to encrypt the photograph. The experimental consequences display that the generation is powerful and safe. YY Wang et al. proposed a brand new optical photograph encryption approach the usage of binary Fourier rework laptop generated hologram (CGH) and pixel scrambling generation. In this approach, the order of pixel scrambling and the encrypted photograph are used as keys for decrypting the authentic photograph. Zhang X Y et al. mixed the mathematical precept of -dimensional cell automata (CA) with photograph encryption generation and proposed a brand new photograph encryption set of rules. The photograph encryption set of rules is handy to implement, has desirable security, big key amount, desirable avalanche impact, excessive diploma of confusion, diffusion traits, easy operation, low computational complexity, and excessive speed.

2. Overview of Digital Image Processing Technology

Digital image processing, also called pc image processing, consults to the method of converting an image sign into a digital sign and processing it with a pc.This method includes image enhancement, blare reduction, segmentation, restoration, encoding, compression, and extraction of options.The method of digital image processing is displayed in figure 1.Image processing tech cannot be developed without the advancement of computers, the advancement of mathematics, and the development of application provisions . scientifically, and individuals utilized this tech to execute idealized processing of output images.afterwards years of advan cement, the common electronic image processing tech has the after characteristics: greater reproducibility: in comaprison with familiar analog image processing and digital image processing will not be because of storage, copying, or transmissio n in image processing.Causes the replace of image quality; The occupied frequency gang is wider: this is relative to the la nguage details, the image details is many orders of importance bigger than the frequency group of the languageDigital images could be processed from microscopes to astronomical telescopes.elevated adaptability: Electronic images could be utilized nearly as much as they have the ability to be expressed utilizing mathematical formulas and mathematical logic

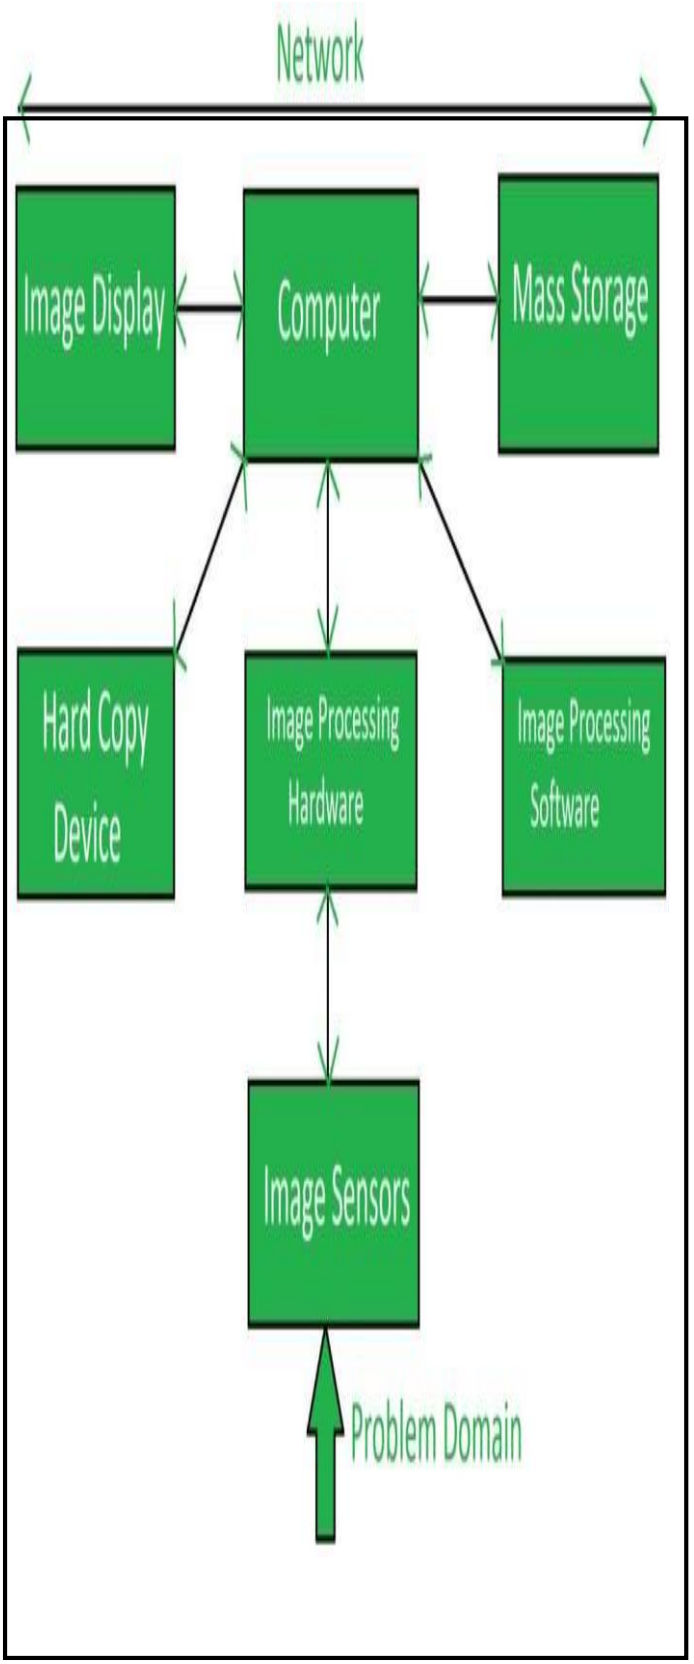

Fig :1 : Process Of Digital Image Processing

as viable. photo recovery is often a difficult and complicated inverse filteringmanner. in particular while the manner of causing picture degradation is extra complex anddifficult to predict, picture healing is more tough to best. irrespective of whether or not the photo ismore desirable or restored, all of the pixels of the complete image need to be calculated. The computationalcomplexity of the photograph pixel is likewise significant.

Photo Compression. some other crucial problem in image processing is the compression of photorecords. mainly after obtaining a big variety of static and dynamic snap shots, the finest difficultyencountered when moving them to the consumer terminal or storing the images for destiny use is thelarge quantity of facts of the snap shots. for instance, a frame of colour image has a facts amount ofabout 768 KB. If no picture compression processing is achieved, it's far tough to save alarge amount of photo data. on the equal time, this trouble also exists within the photograph transmissionsystem, a large number of photo information is tough to speedy transfer, or the transmission of photofirst-rate necessities are very high (inclusive of digital television transmission charge to 100Mb / s), those aredifficult transmission systems suffered. The compression of photo statistics is a crucial problem inthe storage and shipping of photos, or even inside the multimedia technologies referred to later.studies on photo compression coding protracted records. up to now, new technology andtechniques are nonetheless being explored. The image compression coding technique specially removes a massivequantity of data redundancy generated inside the photograph garage process. For better outcomes, excessivedefinition photograph compression coding techniques together with predictive coding, rework coding, andentropy coding can be used.

3. Development Of Digital Image Processing Technology

Since the united states of america started to gain a big quantity of moon photos thru satellite tv for pc and processed it using virtual technology due to the fact 1964, increasingly corresponding technologies have all started to be implemented to photo processing. digital photograph processing additionally occupies an impartial role as a science. The status of disciplines has began for use in clinical studies in various fields. another bounce-ahead development of image era regarded in 1972. The sign was the birth of CT medical generation. below the steering of this technology, an X-ray computed tomography tool was used. consistent with the projection of the human head, the computer processed the information. Reconstructing pass-sectional pics, this photo reconstruction approach changed into later prolonged to a whole-frame CT device and made contributions to human development throughout the instances. eventually, virtual image processing technology turned into utilized in greater fields and evolved into a new discipline of limitless potentialities. Ten years later, virtual photograph processing technology additionally evolved inside the deeper course. people commenced to construct digital human imaginative and prescient structures via computers. This era is referred to as photograph knowledge or laptop vision. many nations have invested a number of research electricity on this area and feature made profound research results. among them, the visual computing theory proposed on the cease of the Nineteen Seventies provided the guiding ideology for the later theoretical development of computer virtual photo generation, however theoretically As such, there are nevertheless many problems in practical operation. China started studies on pc era for the reason that founding of the humans's Republic of China. for the reason that reform and establishing up,

China's improvement in computer virtual photo processing generation has been very massive. Even in some theoretical research, it has caught up with the world's superior stage. With respect to the capability to collect imaging records, China efficaciously acquired a collection of sensors and launches of Earth observation satellites to acquire timely and effective records on wind, sea, sources, and environmental catastrophe reduction, and accomplished effective information. similarly, representatives of virtual image processing generation in a much wider variety of fields are construction, site visitors engineering and biomedical engineering. The application of digital image processing era in these elements can high-quality reflect the current improvement of the era. within the production enterprise, digital picture processing technology can convert the peak, density, and different information which can affect building high-quality and the built environment into the photo of the constructing or group of homes to be constructed, to be able to allow designers to plot more rationally; within the subject of engineering, digital image technology and voice, textual content and different elements constitute the simple content of contemporary multimedia. in the system of shifting images, encoding generation is used to compress the bit quantity of information. The contemporary development content of this era consists of transform coding, and so on. What can also play a function is wavelet remodel picture compression coding, department coding and so on. In biomedical engineering, ebook photograph era can objectively present the mechanism of human sports to researchers in the shape of images, which has an irreplaceable function within the future improvement of medication.

4. Application Of Digital Image Processing Technology

virtual photo processing technology has made super development in all walks of lifestyles. The software fields of digital photograph processing are shown in table 1. In far flung sensing and aerospace, many international locations have dispatched reconnaissance aircraft to take aerial snap shots of goal regions, and then used picture processing

strategies to research pictures. This stored manpower and physics, and may also reap other beneficial information from photographs. because the 1960s, america and different countries have launched useful resource far off sensing satellites. due to the very negative imaging conditions, the great of the picture itself isn't high, and virtual photo processing technology is required, together with scanning with a multi-band scanner. Imaging, image resolution is 30m and these pics are converted to virtual alerts and processed. digital image processing generation has been extensively utilized in various countries, including forest surveys,

catastrophe monitoring, resource exploration and also urban planning.

Field	Application
Physics and Chemistry	Spectrum Analysis
Biology and Medicine	Cell analysis; CT; X-ray analysis
Environment Protection	Research of atmosphere
Agriculture	Estimation of plants
Irrigation Works	Lake, river and dam
Weather	Cloud and weather report
Communication	Fax; TV; phone
Traffic	Robot; products
Economic	IC-card
Military	Missile guidance; training

Table: Application analysis table of digital image processing

The software of digital picture processing era to the aviation discipline can use JPL to better technique the pix lower back with the aid of the Moon and Mars. it is utilized in aircraft far flung sensing and satellite faraway sensing technology, specially thru reconnaissance plane to a certain area of the Earth. In aerial shooting, after the required photographs are processed via the picture, the virtual code can be saved inside the air, and then the satellite tv for pc can pass through the processing center whilst the satellite tv for pc passes over the vicinity with the receiving station. The photograph is analyzed in actual time, and judgment studying can be processed in this technique using a couple of virtual picture processing techniques. digital picture processing generation first came from the medical discipline. consequently, within the field of biomedical engineering, virtual image processing era has additionally performed a huge position.

In addition to the above-referred to CT, there are nevertheless some microscopic image processing technologies, specifically to discover purple blood cells, white blood cells, and chromosome analysis have played an crucial role in clinical diagnosis and remedy of X-ray photo enhancement, electrocardiogram analysis, and ultrasound photo processing strategies. digital photo processing is implemented to the scientific field and is mainly utilized in photograph processing technology along with clinical ultrasound imaging and X-ray angiography. virtual picture processing era plays a completely essential role inside the in addition diagnosis of diseases. The digital photo processing generation is carried out to the real clinical field.

The method is to apply the image overlay technology to perform the non-unfavourable check; the usage of image processing generation to investigate the wise fabric has performed a advantageous role in human exploration of the microscopic homes of the material. In conversation engineering, the primary improvement trend of contemporary communications is incorporated multimedia communications. this is, televisions, computer systems, and phones are mixed and transmitted on virtual communications networks. The maximum complex and difficult areas inside the transmission manner focus on snap shots. In processing, for instance, if the colour tv signal charge is greater than one hundred Mbit/s, the quantity of bits had to compress the facts needs to be transmitted. therefore, the key to the fulfillment of the technology is code compression. At present, new coding strategies that the us of a are vigorously developing, along with wavelet transform photograph compression coding and adaptive photograph network coding, etc. similarly, virtual photograph processing technology is often applied in communications engineering. The application of communique specially specializes in the layout of sound phrases and the analysis of photo facts. it's miles an natural combination of tv, telephone and pc. digital photograph technology is mainly vital on this method. it is code compression. The current coding techniques encompass remodel coding, adaptive community coding, and wavelet

rework photograph compression coding. In business and engineering, the principle packages are centered on the fine of parts in automatic system wiring, pressure evaluation of elastic-mechanical photos, and automated sorting of postal letters, and many others., as well as packages in smart robots.

In navy and public protection, the application of virtual picture processing technology specially specializes in precision steering of missiles, research images, and transmission and display of snap shots. inside the region of public safety, it is specifically used within the identification of human faces, fingerprint identification, and photo recovery. in addition to the utility areas described above, the virtual picture processing generation has additionally been extensively utilized in tv picture enhancing, costume layout, coiffure layout, and restoration of cultural materials.

digital picture processing generation can also be implemented to the military and public security fields, and has performed an lively function in these elements. The application in navy affairs is mainly implemented to the transmission of snap shots, the garage and display of images, and so on., and is maximum usually used within the application of automatic command structures. The software within the public safety field is applied to the general public safety personnel to research and interpret the images despatched back, and has played a terrific effect. The most essential in the public safety device is the reputation of faces and the repair of incomplete images. The biological area is also using digital photo processing era.

3. Acknowledgement

I would like to expand gratitude to project guide Prof. Vijay.M.Rakhde who guided by providing the valuable suggestion in numerous way on this project which gave us the inspiration to improve our self independency. Secondly I would like toexpress my gratitude toward the project mentor Prof. B.Deharkar who help in finalizing the work done within the limitedtime period, I would also like to express heartfelt thanks to Head Of Department Lovelesh Yadav who has given us a platform where we can work on developing the projects and demonstrate the practical applications.

4. Conclusion

To sum up, this paper first analyzes the studies status and most important software fields of virtual picture processing technology, after which research the improvement trend of virtual photo technology. At gift, digital image processing technology has been broadly utilized in life. as an instance, programs in networks, mobile phones, and many others., the development of virtual picture processing technology is carefully related to humans's lives. With the continuous improvement of technology, digital picture processing era will continue to be acquired. progress, these also want greater humans to examine

Abstract— **Existing text classification models based on graph convolutional networks usually update node representations simply by fusing neighborhood information of different orders through adjacency matrices, resulting in an insufficient representation of node semantic information. In addition, models based on conventional attention mechanisms only Word vectors are forward- weighted representations, ignoring the impact of negative words on the final classification. This paper proposes a model based on a bidirectional attention mechanism and a gated graph convolutional network to solve the above problems. The model first uses the gated graph convolutional network selectively fuses the multi-order neighbourhood information of the nodes in the graph, retains the information of the previous order, and enriches the feature representation of the nodes. Secondly, the influence of different words on the classification results is learned through a two-way attention mechanism. While giving positive weights to terms that play a positive role in classification, negative consequences are given to words that have adverse effects of weakening their influence in vector representation, thereby improving the model's ability to discriminate nodes with different properties in documents. Finally, maximum pooling and average pooling are used to fuse the vector representation of the word, and the document representation is obtained for the final classification. Experiments are carried out on four benchmark data sets, and the results show that the method is significantly better than the baseline model.**

I. INTRODUCTION

Text classification has been widely used as the primary task and core technology of natural language processing, including spam detection, sentiment analysis, news classification, etc. Traditional text classification methods based on machine learning include Naive Bayesian [1] and Support Vector Methods. However, these methods require manual
feature extraction, which is labor-intensive and inefficient.

In recent years, with the continuous development of deep learning, convolutional neural networks (CNN) and recurrent neural networks (Recurrent Neural Networks, RNN) have been widely used in text classification. However, most of these models focus on capturing the local information of words. In continuous communication, discontinuous and distant words lack mutual information. Text classification models based on Graphical Convolutional Networks (GCN) [4] can handle tasks with rich structural relationships and solve the relationship between nodes to a certain extent. However, most previous GCN-based models update node representations by fusing neighbourhood information of different orders through an adjacency matrix, which cannot generate word representations well. And based on attention (Attention) [5], the model usually uses the sigmoid function to formulate a positive attention score distributed between 0 and 1 and cannot give negative weights to words that have an adverse effect while ignoring word pairs that have an adverse effect The impact of document representation.

Aiming at the above problems, this paper proposes a text classification method based on a gated graph convolutional network and a bi-directional attention mechanism. The technique first constructs each document as a document graph so that the model can achieve inductive learning. Secondly, the convolutional graph network is improved, using the gate mechanism to selectively fuse the multi-order neighbourhood information of the nodes in the graph, using the previous order information and the updated information to iterate, and the effect achieved is to enrich the node features and generate words. - Better hidden layer representation. Then use two-way attention to improve the traditional attention mechanism to a certain extent. Unlike the conventional attention mechanism, it uses tanh as the activation function to give positive weights to the words that play an active role in the classification. At the same time, negative consequences are assigned to terms that

have the effect of weakening their influence in the document representation so that the model can distinguish words that play different roles in the final classification. Then the assignment adds weighted features to the original part so that the model can enhance the features of words with positive influence and weaken the details of terms with negative impact to obtain a more differentiated feature representation and help the model classify better. Finally, word representations are fused into document representations using max and average pooling for final classification. Overall, the main contributions of this paper are as follows:

(1) Using the gating mechanism to improve the convolutional graph network, a gated chart convolutional network is proposed. The network selectively fuses the multi-order neighbourhood information of the nodes in the graph and retains the neighbourhood information of the previous layer—better-generated word node representations.

(2) The attention has been improved to a certain extent so that the model gives positive weights to the words that play a positive role in the classification and gives negative consequences to the terms that negatively weaken their influence in the document representation. In this way, the ability of the model to discriminate nodes with different properties in the document is improved.

(3) Many experiments have been carried out on four text benchmark datasets, and the results show that the model in this paper is significantly better than the baseline model, which verifies the model's effectiveness in this paper.

II. RELATED WORK

Existing text classification methods using deep learning have made significant progress.Literature. [6] proposed the TextCNN model to extract local and position-invariant features in documents. Literature. [7] used CNN to remove character-level feature representation and achieved good results. Literature. [8] used Bi-LSTM to capture long-distance semantic information in documents using a gating mechanism. Literature. [9] used an optimized multi-channel CNN to extract local features to compensate for the neglect of Bi-RU. Insufficient local features. Literature. [10] used Multi-timescale LSTM to capture context information of different time scales to model long documents. Since CNN and RNN prioritize local information and order information, although these models

can capture local Semantic and syntactic information in word sequences, but ignores the interactive communication of discontinuous and long-distance words. Therefore, attention mechanisms and convolutional graph networks are widely used in text classification to solve these problems and have achieved specific results.

The attention mechanism was first proposed in computer vision [11]. In natural language processing, the attention mechanism was first used in the machine translation task based on the decoder [12] and then extended to other tasks. Literature. [13] combined Attention with Bi-LSTM for relational classification tasks. Literature [14] proposed a hierarchical attention model, using attention structures at the word and sentence levels so that the model can give words and sentences differently. Literature. [15] used attention to calculate the weight value of each concept in the knowledge map, reducing the impact of irrelevant noise concepts on short text classification. However, these attention-based models usually only perform node vectors. Simple positive weighting to obtain document representation cannot well weaken the influence of negatively affecting words on document representation.

Graph convolutional networks have recently received more and more attention. Literature. [16] proposed a graph-based CNN model, which converts documents into graphs for the first time and uses them as the input of graph convolutional networks. Literature. [17] proposed Text-CN, which first uses documents and words as nodes in the chart, then uses sliding windows to generate edge relationships between words, builds a sizeable heterogeneous chart based on the corpus level, and finally uses graph convolution. The network classifies the document nodes. Literature. [18] constructed a document graph for each document, and the weights of the edges between words are randomly initialized and shared globally and are constantly updated during training; A word node uses the Message Passing Mechanism (Message Passing Mechanism MPM) [19], first aggregates the information of its neighbour nodes, and then updates the node representation. Literature. [20] use heterogeneous graphs and topic models to classify short texts. Based on GCN, although text classification models can solve the mutual information problem of non-continuous and long-distance words in documents to a certain extent, these models usually update node representations by simply fusing neighbourhood information of different orders through adjacency matrix and do not make full use of the knowledge of nodes. Multi-order neighbourhood information cannot update the word node representation well.

III. Model based on bidirectional attention and gated graph convolutional network

The model in this paper consists of four essential parts: graph construction layer, gated graph convolutional network layer, bidirectional attention pooling

layer and classification layer. The overall framework of the model based on bidirectional attention and gated chart convolutional network is as follows: It is shown in Figure 1. This section first gives the overall algorithm of the model and then introduces the four parts in detail.

The specific description of the model in this paper is shown in Algorithm 1.

Algorithm 1 Model based on bidirectional attention and gated graph convolutional network

4.3 Experimental Environment And Result Analysis

The operating system is Linux, the memory is 64GB, the CPU is AMDEPYC7302, and the graphics card is 24GB NVIDIA GeForceRTX3090. The model in this paper is implemented using the Pytorch framework.

Table 3 lists this model's GPU memory and time overhead and other models on different datasets (memory and time consumption under the same environment configuration). The data in Table 3 shows that the model in this paper has apparent advantages in terms of memory usage and running time. The reasons are as follows: Text-GCN needs to use training and test documents to build a graph based on the corpus level, which will inevitably generate many edges and consume a certain amount of time. The video memory and time; Text-Level-GNN randomly initializes the weight of the border between words, which belongs to the model parameter. It needs to be updated iteratively during training, so it takes up a part of the time and video memory; the graph constructed in this paper belongs to the document level, and the weight of the edge is in the document construction graph. The time is determined, so it will not consume too much time and video memory.

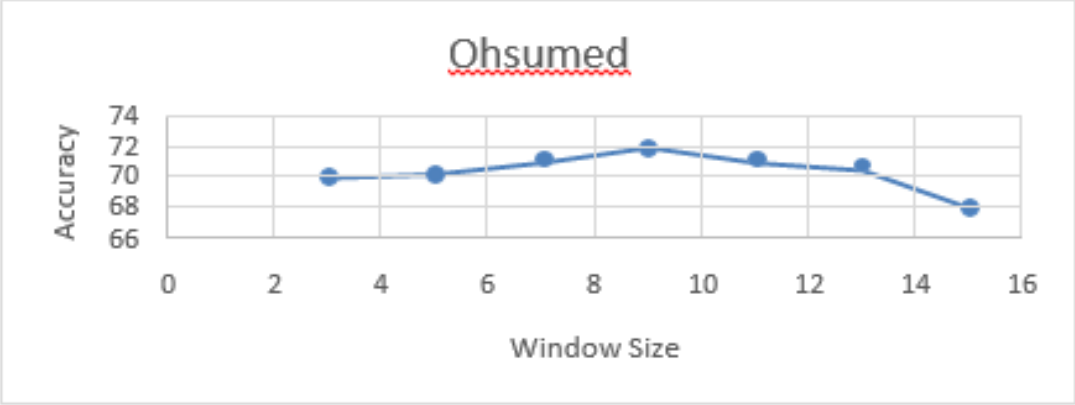
Table 3 GPU memory consumption and running time

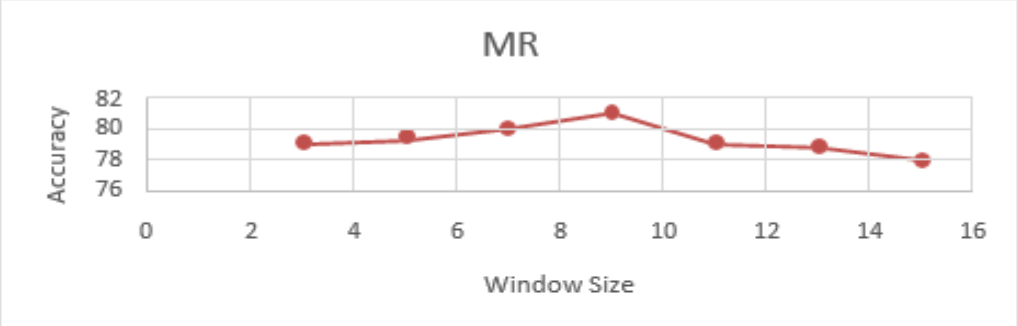
Dataset	Model	Memory/MB	Time/s
Ohsumed	TextLevelGNN	9725	495
	Text-GCN	7195	365
	OurModel	2235	248
R8	TextLevelGNN	8455	585
	Text-GCN	4635	155
	OurModel	1825	125
R52	TextLevelGNN	9175	635
	Text-GCN	5188	195
	OurModel	1865	156

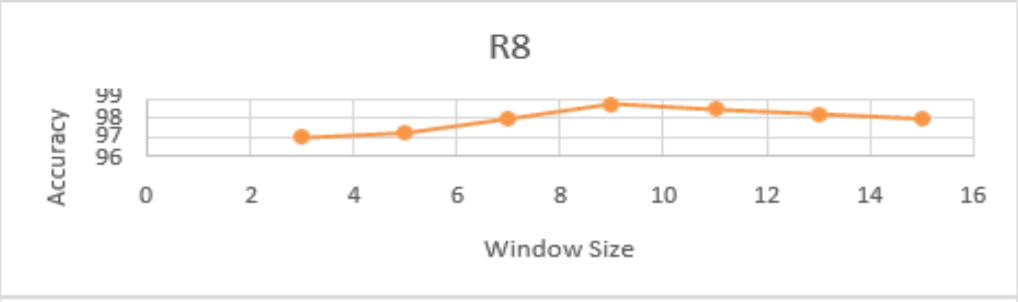
4.7 Parameter Analysis

Figure 5 shows the reflection of sliding window size on accuracy of different datasets. If the window is too large, edges will be added between nodes that are not closely related so that the updated node representation noise information is included in the classification, affecting the classification Effect.

Figure 6 shows the effect of the number of layers of the gated graph convolutional network on classification results on the R52 dataset. Through analysis, the reason may be that as the number of layers grows, the model retains part of the original word information and captures the information of foreign words. By selectively fusing information from two nodes, word representations with richer meaning information are generated. As the number of network layers further deepens, the representation of each node will tend to be the same. Still, due to the gate mechanism, the model retains part of the original word information, which alleviates the excessive problem and smooth the nodes in the graph to a certain extent, so the accuracy will first decrease and then level off.







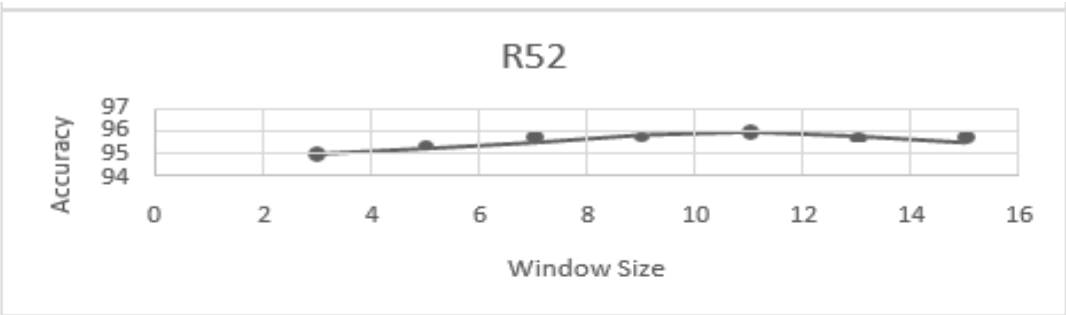


Figure 5. The effect of the sliding window size on the experimental results

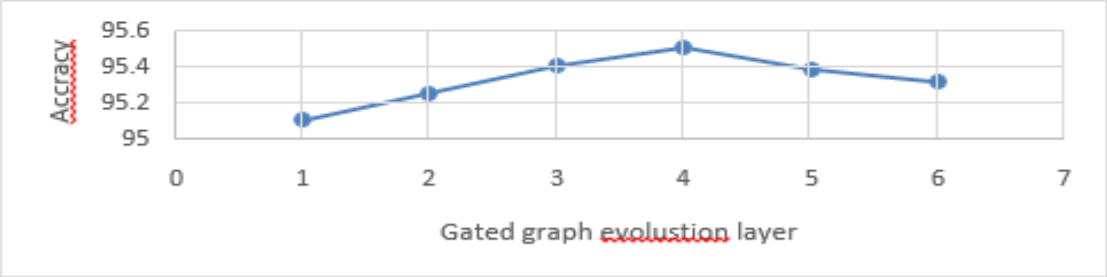

Figure 6. The effect of the number of gated graphs convolutional network layers on the experimental results

CONCLUSION

This paper suggests a text categorization model based on a gated graph convolutional network and a bidirectional attention mechanism. The technique first creates a document as a graph and then uses a gated graph convolutional network to identify multi-order neighbourhood data selectively. After you have feature representations with more noticeable distinctions for final classification, you can employ a two-way attention mechanism to give different weights to words of various types. Many tests on four benchmark datasets reveal that the method in this study is vastly superior to the standard. To improve the model's performance, future work will consider introducing external knowledge, such as some internal statistical characteristics of the corpus. This is

because the graph produced in this paper did not wholly utilize the statistical information of words in the text.

Abstract— **Models for detecting network traffic anomalies based on deep learning usually exhibit weak generalization, confined representative capacity, and low real-world adaption. In light of this, a multi-scale memory residual network-based model for identifying network traffic anomalies is proposed. The distribution analysis of the three-dimensional feature space illustrates the efficiency of the network traffic data preprocessing technique. The deep learning algorithm enhances the model's capacity to represent data by coupling multi-scale 1DCNN-LSTM networks. The realization of the residual network is shown using the residual network notion as a foundation. Deep feature extraction accelerates model convergence to detect network traffic anomalies accurately and effectively while preventing gradient disappearance, explosion, over fitting, and network damage. The experimental findings show how the multi-scale 1DCNN-LSTM network can improve the model's representational competence and generalization ability. Performance indicators for the model in this study are also superior to those for other deep learning models.**

I. INTRODUCTION

With the development of network technology and the expansion of network scale, network traffic is increasing exponentially, and network security threats and risks are becoming more and more prominent. Intrusion Detection System (IDS) [1] is a network security monitoring system. Network traffic is one of the main network states. When network intrusions occur, network traffic anomalies usually occur. Therefore, network traffic anomaly detection is the current network Research focus of Network Intrusion Detection System (NIDS).

However, the continuous change of network attack patterns has increased the difficulty of network traffic anomaly detection [2]. Based on the empowerment effect of artificial intelligence, cyberspace security is facing new risks, including network attacks becoming more and more intelligent, and large-scale attacks becoming more and more difficult. Network attacks are becoming more and more frequent, the concealment of network attacks is getting higher and higher, the game-fighting nature of network attacks is becoming stronger and stronger, and important data is becoming easier to steal, etc. [3]. Maintaining network security is a process of attack and defense games. Network traffic Anomaly detection, as a prerequisite for ensuring network security, has received more and more attention because it can identify unknown network attacks.

The representational capacity is constrained and the false alarm rate is high [4]. It is challenging for classical machine learning to accomplish the goal of analysis and prediction due to the increase in huge data on the network, the improvement of network capacity, the complexity of data, and the diversity of features [5]. Large-scale network traffic data can be processed successfully using the deep learning approach. Deep learning offers better representation performance when compared to conventional machine learning techniques, which can significantly increase the effectiveness and precision of network traffic anomaly identification. The identification of network traffic anomalies is a powerful tool for thwarting contemporary network attacks. The network traffic anomaly detection model is the main topic of this study, which also suggests a multi-scale memory residual network-based network traffic anomaly detection model.

1.2 MSMRNet based IDS Model

Since standard recurrent neural networks have an issue with gradient disappearance, the long-short-term memory neural network (LSTM) has been presented as a solution (RNN).Its basic unit is a structure containing multiple groups of neurons, called a cell (cell), as shown in Figure 1.

Combining the idea of residual network and long-term short-term memory network, this paper proposes a network traffic anomaly detection model based on MSMRNet,

There are non-numeric data such as protocol type and service type in the network traffic data, and the machine learning model cannot handle non- numeric data, so the network traffic data needs to be processed numerically. At the same time, the network traffic data is different, and the characteristic attributes There is a large difference in magnitude between [5], so it is necessary to carry out dimensionless processing on the network traffic

data. The initial network traffic data $X0 = \{x1, x2, \cdots, xn\}$, where $f = |X0|$ represents the characteristic dimension of the initial traffic data, and $n = |X|$ represents the characteristic dimension of the network traffic data after data preprocessing.

MSMRNet for deep feature extraction, that is, the initial input of MSMRNet $X1 = X$. MSMRNet is formed by stacking several multi-scale memory residual modules, and its l multi-scale memory residual the difference module takes Xl as input and generates output Xl+1, where the input Xl and output Xl+1 have the same dimension. The multi-dimensional output $Y0$ is one-

dimensionalized by the Flatten layer to obtain the

Input the preprocessed network traffic data X to MSMRNet for deep feature extraction, that is, the initial input of MSMRNet $X1 = X$. MSMRNet is formed by stacking several multi-scale memory residual modules, and its l multi-scale memory residual the difference module takes Xl as input and generates output Xl+1, where the input Xl and output Xl+1 have the same dimension. The multi-dimensional output $Y0$ is one-dimensionalized by the Flatten layer to obtain the output $Z0$. The local features are comprehensively processed through the fully connected layer [21] Obtain the output Z. Use the softmax function as the classifier to realize the network traffic classification, and obtain the network traffic classification result Y. Each element in Y represents the probability of each network traffic category, and the maximum probability category is the classification result. The calculation formula as shown in formula (10), Wd and bd represent the weight matrix and bias item respectively.

$Y = softmax(Z) = softmax(WTZ0 + bd)$ … … (10)

The implementation method of the network traffic anomaly detection model based on MSMRNet is shown in Algorithm 1.

Input the preprocessed network traffic data X to one-hot encoding are shown in Figure 2 As shown in (a), it can be seen that the normal flow data points overlap with the abnormal flow data points in a large area. The PCA two-dimensional visualization results of the

output $Z0$. The local features are comprehensively processed through the fully connected layer [21] Obtain the output Z. Use the softmax function as the classifier to realize the network traffic classification, and obtain the network traffic classification result Y. Each element in Y represents the probability of each network traffic category, and the maximum probability category is the classification result. The calculation formula as shown in formula (10), Wd and bd represent the weight matrix and bias item respectively.

$Y = softmax(Z) = softmax(WTZ0 + bd)$ … … (10)

The implementation method of the network traffic anomaly detection model based on MSMRNet is shown in Algorithm 1.

1.3 Experiment

In order to obtain an effective data preprocessing method, this experiment uses the PCA two-dimensional visualization method to analyze the feature space distribution of the experimental data set after data preprocessing. The PCA two-dimensional visualization results of the experimental data set after

experimental data set after one-hot encoding and standardization processing are shown in Fig. 2(b), which can be It can be seen that the normal flow data points and the abnormal flow data points have been partially

separated, but there are still some overlapping areas. The PCA two-dimensional visualization results of the experimental data set after one-hot encoding and normalization processing are shown in Figure 2(c) , it can be seen that compared with the results after one-hot encoding and normalization, normal flow data points and abnormal flow data points have been effectively separated. Therefore, this experiment uses one-hot encoding and deal with.

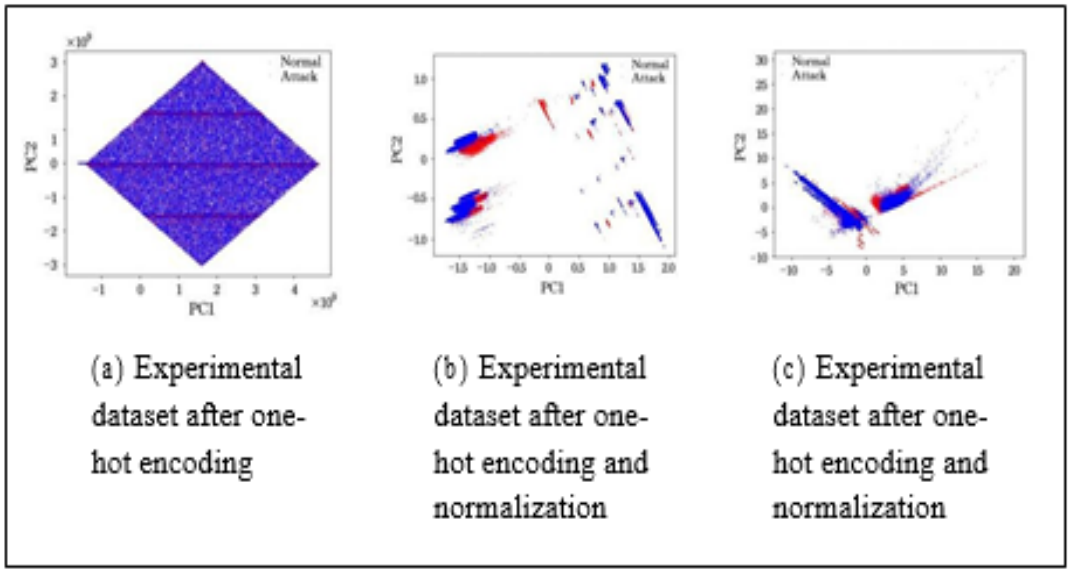

Figure 2 Visualization of Data Set after Preprocessing using PCA

1.4.4 Validity Verification Experiment

In order to verify the effectiveness of MSMRNet in solving the problem of network degradation, this paper constructs a multi-scale memory network (Multi-Scale Memory Network-work, MSMNet) of different depths and compares it with MSMRNet. The experimental model is as follows.

MSMNet-5: It is stacked by 5 multi-scale memory modules, including 20 training parameter layers, 10 non-training parameter layers and 1 fully connected layer.

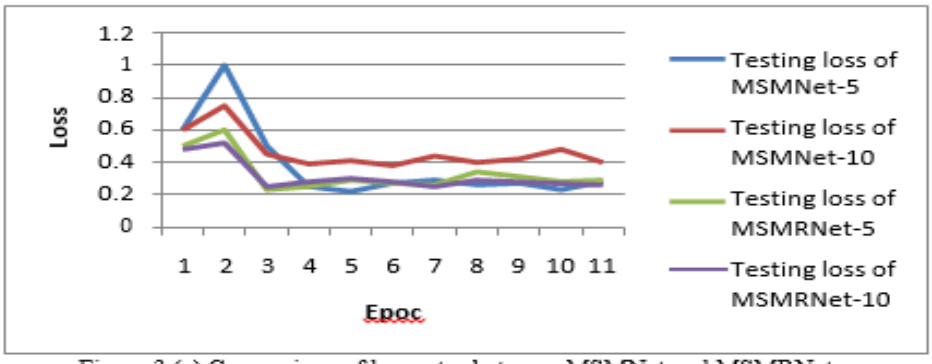

Figure 3 (a) Comparison of loss rates between MSMNet and MSMRNet

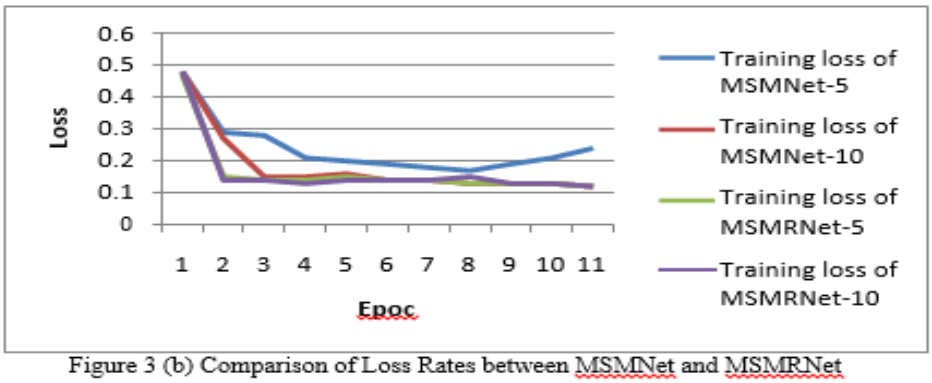

Figure 3 (b) Comparison of Loss Rates between MSMNet and MSMRNet

MSMRNet-5: It is stacked by 5 multi-scale memory residual modules, including 20 training parameter layers, 10 non-training parameter layers and 1 fully connected layer.

MSMNet-10: It is stacked by 10 multi-scale memory modules, including 40 training parameter layers, 20 non-training parameter layers and 1 fully connected layer.

MSMRNet-10: It is stacked by 10 multi-scale memory residual modules, including 40 training parameter layers, 20 non-training parameter layers and 1 fully connected layer.

Figure 3 (a) and (b) show the comparison of the loss rate between MSMNet and MSMRNet during training and testing.

1.4 Conclusion

This work proposed a network traffic anomaly detection model based on multi-scale memory residual network to address the issues of poor environmental adaptation, restricted representation ability, and weak generalization ability of the network traffic anomaly detection model based on deep learning. This essay is based on credible The effectiveness of the network traffic data preprocessing method is demonstrated by the analysis of the three-dimensional feature space distribution; the multi-scale one- dimensional convolution is combined with the long short-term memory network, and the model representation ability is enhanced through the deep learning algorithm; based on the idea of the residual network, the realization of in-depth feature extraction, while preventing gradient disappearance, gradient explosion, and over fitting. The results of data preprocessing visualization demonstrate that following one-hot encoding, the results of validity verification experiments and performance evaluation experiments show that adding identity mapping can accelerate model convergence, improve network traffic anomaly detection performance, and effectively solve the problem of network degradation; comparative experimental results show that normalization processing can effectively separate normal traffic and abnormal traffic data. Performance metrics have improved.

Abstract – **: Among the many network data mining tasks, link prediction is crucial. Due to the in-depth development of graph neural network research, related models can learn essential features of the network more effectively and have achieved good prediction results in tasks such as link prediction. However, unlike the CNN model in deep learning, the existing graph neural network model only aggregates the first-order neighbor information of nodes and does not fully consider the topological structure characteristics between neighbor nodes. On this basis, a motif-based graph neural network link prediction model is proposed. The model adopts the self-encoder structure. In the encoding process, the adjacency matrix of the node is constructed through the motif, and then the motif neighborhood of the node is obtained. Next, the neighbor information is aggregated according to the neighborhood of each type of motif, and the node is obtained through nonlinear transformation. Finally, concatenate the representations of nodes under each type of motif. However, since different motif structures have other importance in the network, the attention network gives the attention weights expressing different motifs. The vector representation of nodes is provided by connecting the attention network. During decoding, the network is reconstructed by computing the similarity between nodes. Investigational results on several citation collaborator networks show that the proposed method surpasses most baseline algorithms on two metrics, effectively improving the accuracy of network link prediction.**

I. INTRODUCTION

A network is an abstract representation of real-world objects and their interactions, where nodes stand for entities and links for the one-to-one or two- to-two relationships between them. These networks contain rich node attribute information, structural information and network evolution information. During the evolution of the network, some links may appear or disappear, and it is necessary to complete the missing data and make predictions about links that could be added or removed in the near or distant future. At the same time, as an important division in the field of data mining, link prediction has very important practical significance. For example, in biological network analysis [1-3], link prediction can mine and complete biological data. In scientific collaborators [4-6] and friend recommendations [7-10], link prediction can recommend relevant new friends and scientific collaborators. As a classic problem in the field of data mining, the link prediction problem has many related models and methods. Most of the current link prediction methods are based on the similarity assumption of node representations, that is, the more similar the representations of node pairs, the greater the possibility of generating links, so the problem boils down to finding high-quality node representations so that the representations of nodes retain The topological features of the original network, that is, the nodes connected by edges in the original network, are relatively similar in the representation of nodes.

Recent advances in graph-structured network embedding approaches and graph neural networks have helped the model become even better at representing network nodes[11-13].

This research offers a motif-based graph neural network link prediction model to enhance node representation capability while also accounting for computational economy..

1.2 PRELIMINARY KNOWLEDGE

1.2.1 Basic Definition

Let G = (V; E) represent a graph network, V represents a node set, E represents an edge set, if two nodes vi and vj are connected by an edge, then (vi, vj) ∈ E [14-17]. A recurring theme An instance of the sub-graph M of a graph G, where just a few of the network's nodes are present, is well-defined as follows:

Definition 1 (motif) [18] Let M be a connected sub-graph of graph G = (V; E), and satisfy any (vi, vj) ∈ EM ,(vi, vj) ∈ E, then M is called G , where EM represents the edge set of sub-graph M.

Different third-order motifs and fourth-order motifs are shown in Figure 1 (expressed as $M3$, $M4$, the first

subscript i of each motif Mij represents the number of nodes, and the second subscript j is the specified sorting), in the research cooperation network, the motif $M31$ represents that two authors have cooperated with one other author, but they have not cooperated with each other. Often this happens in collaborations between ordinary researchers and scientific celebrities. $M32$ represents the cooperation of researchers who are close to the same level, and the three authors have cooperated with each other.

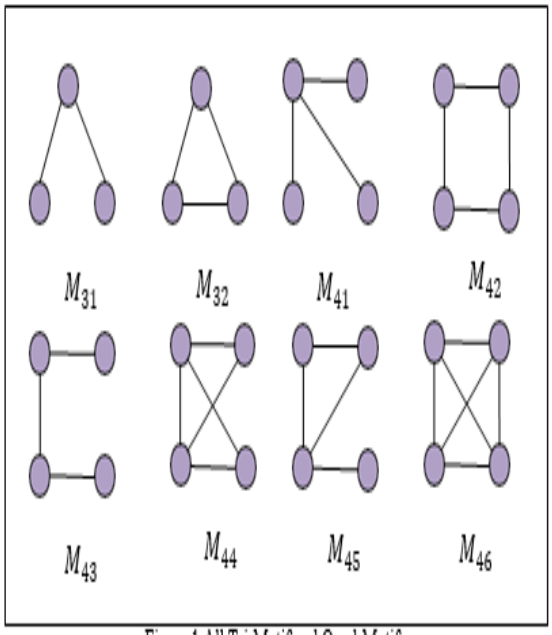

Figure 1 All Tri-Motif and Quad-Motifs

Indicates that two authors have collaborated with one other, but they have not collaborated with each other. Often this happens in collaborations between ordinary researchers and scientific celebrities. M32represents the cooperation of researchers who are close to the same level, and the three authors have cooperated with each other.

Definition 2 (Instances of Motifs) [18] Let Su = (VS, ES) be the containing node u instance of motif S, if Su is a subgraph of graph G, and there are VS ∈ V, ES ∈ E such that For any x, y ∈ VS, (x, y) ∈ ES there exists a bijection ψ: S → M such that (x, y) ∈ ES iff(ψS(x), ψS(y)) ∈ EM . Definition 3 (motif neighbors) for a specified motif type M, among the first-order neighbors of node vi, the nodes located in the same type of motif as vi are called the neighbors of node vi based on motif M.

The two motifs (v, v1, v2) and (v, v3, v4) in Figure 2 are two instances of motif M32, and v1, v2, v3, v4 are also motif neighbors of v. In different networks, there are different eigenmotifs belonging to the network, which occur much more frequently than that sub-graph in random graphs. In the calculation process, in order to excerpt the motif features of the network, it is necessary to search all the motifs that are isomorphic to different types of motifs from the network, and the calculation cost of this process is relatively high. In order to reduce the computational complexity, this paper only considers the third-order and fourth-order motifs. First, the software mfinder[19] is used to find out how many of each theme type are spread throughout the network, and the distribution of motifs in each network is given.

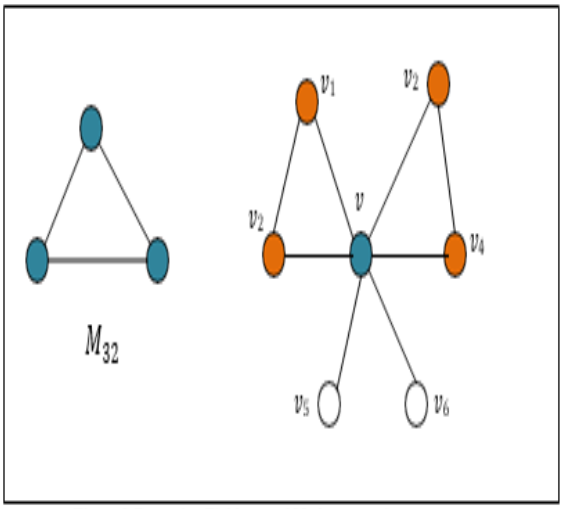

Figure 2 Receptive Field around Node v contains v_1, v_2, v_3, v_4

1.3 Link Prediction Model Based on Motif Graph Neural Network

This paper introduces a motif-based spatial convolution operation to extract features of nodes [18]. Given the motif M and the target node vi, the input node is a 1-dimensional vector, and the dimension of the mapped node is F = 1. Define the weight matrix $w0$ of node vi and the weight wj of its neighbor node vj , then the convolution at node v can be defined as the weighted sum of the neighbors of the motif M based on the motif M of node vi , namely:

$$h^M(v_i) = \sigma\left(x_i w_0 + \sum_{j=1}^{N} A^M_{ij} x_j w_j\right) \ldots\ldots\ldots (4)$$

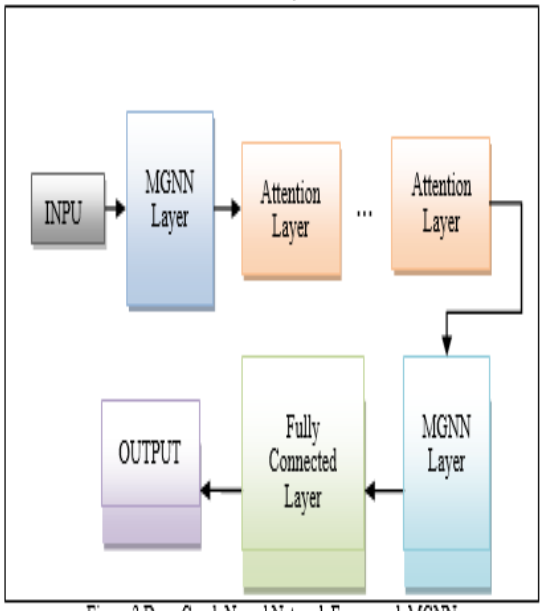

Figure 3 Deep Graph Neural Network Framework MGNN

Fig 3 Among them, xi, xj represent the attribute vectors of nodes vi, vj. hM (vi) represents the convolution output of node vi, σ(·) represents the activation function, such as ReLU(·) or Softmax(·), the weight sharing process is to give the same weight to the motif neighbors of node vi. Furthermore, the situation of the above formula can be extended to the general situation: the attribute matrix X of the node is a matrix of N × D dimensions, and the output dimension is F, then:

HM = σ(XWM + (DM)−1)AM XWM … … . (5)

Since the feature information of a single type of motif cannot fully represent a node in the process of representing each node, it is necessary to synthesize the information of multiple types of motifs. However, in the process of aggregation, different types of motifs have different importance to each node. In order to reflect the different influences of various motifs on node representation in the convolution process, this paper adds the attention mechanism of motifs [18].

$$h(vi) = \sum_{i=1}^{U} \alpha k,i\, hk(vi) \qquad (6)$$

α $= softmax(e$

$) = \exp(ek,i) \ldots\ldots\ldots (7)$

k,i

k,i

U

j =1

(ej,i)

In the formula, U is the number of motifs, αk,i = αk,i (hk(vi)) = W. hk(vi)

is a one-dimensional convolution about hk(vi), and the attention coefficient αk,i reflects the The importance of volume Mk to node vi, hk(vi) is the convolution output of node vi under Mk. In this paper, the motif graph neural network model is referred to as MGNN (motif-based graph neural network), and its network architecture is shown in Figure 3. After the aggregation of convolutions of different types of motifs, the attention network is connected in the activation layer. These two parts form a basic neural network unit, and then iterate layer by layer. Finally, after aggregating the convolutional output of various motifs in the convolutional layer, the final node's output is obtained through a fully connected network express.

1.4 Experiment and Results

This research offers a homogeneous network-based MGNN link prediction model, and demonstrates the efficiency of the method on different real network datasets. During training, some links (positive class edges) of the dataset have been eliminated, although all node properties remain unaltered. The justification and test sets are constructed with the detached edges and the equal number of randomly picked unconnected node pairs (negative class edges) (negative class edges).

The Cora dataset comprises a total of 2708 sample points, each sample point being a scientific publication, and individually document is signified by a 1433-dimensional word vector. After stemming and deleting stop words, only 3703 words are left. The PubMed dataset includes 19,717 research publications on diabetes from the PubMed database. There are 44,338 citation linkages in

the network. A word vector from the dataset's lexicon of 500 distinct terms, weighted by their frequency in the document's TF and IDF values, describes each publication[29-30]. Use the mfinder software to give the motif distribution of each network (as shown in Table 1). (as shown in Table 1). In order to further improve the computational efficiency, the motifs including 3 nodes and 4 nodes in the network are picked.

Data Set	M_{3_1}	M_{3_2}	M_{4_1}	M_{4_2}	M_{4_3}	M_{4_4}	M_{4_5}	M_{4_6}
Cora	76.70	3.30	15.10	80.40	0.10	4.10	0.20	0.10
CiteSeer	95.30	4.70	30.70	61.50	6.20	0.61	0.07	0.92
PubMed	98.25	1.75	46.10	49.10	0.60	3.90	0.28	0.02

1.4.1 Experiment Description and Summary

Table 2 displays the findings from the experiments. After combining the high-order structural information on the two data sets, the method in this paper can obtain a better representation of network nodes on most networks, and the link prediction results are improved by 1%~ compared with traditional methods. 4%. At the same time, the prediction result on the PubMed data set is slightly lower than that of VGAE. Due to the consideration of the motif construction data of the node, the number of motifs may not obey the normal distribution, so the experimental results of the auto-encoder will be lower than that of the variable in some cases the result corresponding to the self-encoder.

Method	Cora		CiteSeer		PubMed	
	AUC	AP	AUC	AP	AUC	AP
VGAE	91.4	92.6	90.8	92.0	96.4	96.5
LINE	76.0	75.5	73.1	75.2	72.2	72.0
MGNN(*)	91.9	92.1	90.7	91.6	67.2	76.2
VMGNN(*)	91.6	91.4	92.0	91.0	62.3	74.0
MGNN	92.1	91.4	93.3	93.7	92.4	91.8
VMGNN		93.5	94.6	95.1	95.9	94.4

1.4.2 Ablation Experiment

This section compares the method in this paper with VGAE and MGNN+MLP (fully connected network). VGAE combines the graph convolutional network GCN and autoencoder to achieve good results in link prediction tasks. MGNN+MLP is a fully connected network MLP linked after the MGNN network to illustrate the efficiency of the model MGNN+Attention in this article. The result is shown in Figure 4 (a) and (b).

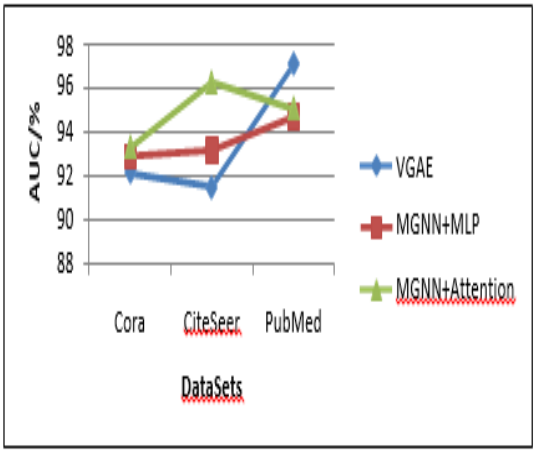

Figure 4 (a) Comparison Results

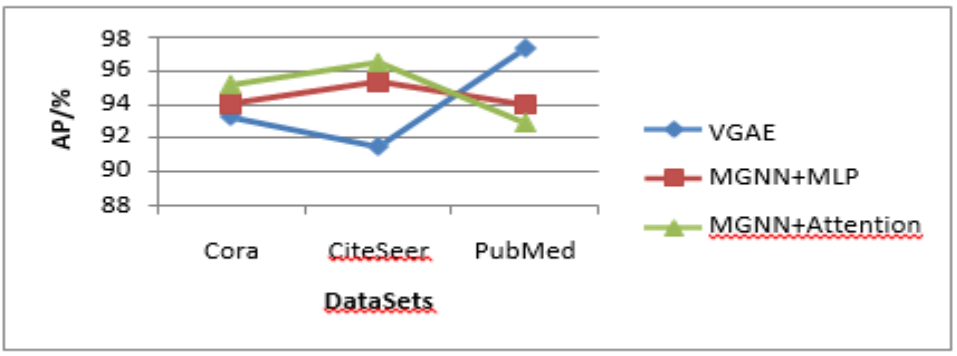

Figure 4 (b) Comparison Results

The experimental outcomes demonstrate that, in most situations, the model presented in this work outperforms the other two types of models, which further demonstrates that incorporating the motif structure into the model can effectively improve the predictive ability of the neural network. At the same time, the comparison between MGNN+MLP and MGNN+Attention also verified the effectiveness of the link attention network in the MGNN network, indicating that the importance of different motifs needs to be considered in the process of node representation.

1.4.3 Experimental Efficiency Comparison

This section gives a comparison of the running time of each model on the link prediction task on the network Cora and CiteSeer. Figure 5 gives a comparison chart of the operating efficiency of the six corresponding algorithms.

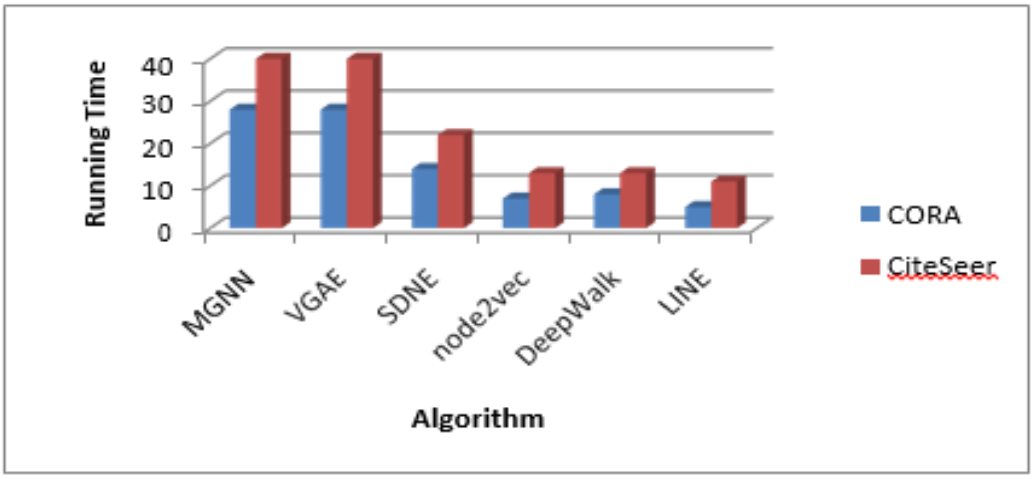

Figure 5 Comparison of Algorithm on Different Datasets

As shown in Figure 5, the shallow network model based on graph representation learning is more efficient, but it is difficult for such a model to learn the complex structural information of the nodes in the network. The method in this paper combines multi-layer neural network structure and high- order motif information. Although the computational cost is high, it has achieved a significant improvement in link prediction indicators compared with graph representation learning methods. At the same time, because the model adopts the auto-encoder framework, the running time is close to that of models such as graph auto-encoder (VGAE).

1.5 Conclusion

In this study, we offer a homogenous network-based model for predicting links in neural networks, using motifs from graphs as inspiration. Using a graph convolutional neural network, the network's high-order structure-motif information are combined, and each motif structure is given. The representation of the nodes is obtained, and the attention weights of various motifs for the nodes are further considered, and finally the network is reconstructed by using the representations of the nodes. The effectiveness of the algorithm is verified on link prediction tasks of several conventional citation datasets. Computational efficiency and accuracy need to be further improved in large-scale networks. When the model is being trained, MGNN uses the high-order motif information of the nodes, and the computational cost of the model increases to a certain extent.

Leaf Life – A Study On Plant Disease Predictor

Kaif Qureshi, Urmil Pawar,, Prabhat Pankaj, Anam Khan
Thakur College of Engineering and Technology
Mumbai,India

Abstract— **: Identification of plant diseases is the first step in mitigating decreases in agricultural output productivity and quantity. Examining patterns on plants that are visible to the unaided eye is a common practice in studies on plant diseases. For agriculture to be sustainable, disease detection and plant health monitoring are crucial. Plant disease tracking manually is exceedingly difficult. It requires a lot of labour, expertise in plant diseases, and protracted processing durations. Hence, image processing is used to detect plant diseases. The steps involved in the disease detection process include image acquisition, image pre-processing, picture segmentation, feature extraction, and classification.**

I. INTRODUCTION

: The Plant Disease Predictor is a computer system designed to assist farmers, growers, and agricultural researchers in identifying plant diseases and predicting their potential spread. The purpose of the system is to help prevent the loss of crops due to disease and to assist in making informed decisions about disease management strategies.
The importance of predicting plant diseases is to help protect crops and reduce the impact of diseases on agricultural productivity and food security. Accurately predicting disease outbreaks allows farmers and growers to take proactive measures to prevent the spread of diseases, reduce losses, and protect their crops.
User Interface Design: Discuss the design of the user interface, including the layout, color scheme, typography, and overall visual style. Highlight the considerations and principles used to design the interface to ensure ease of use and user-friendliness.

1. Given that our target users are farmers, who may not have the latest smartphones or high-speed internet connections, it's essential to design a user interface that is lightweight and responsive, minimizing the use of graphics and images that could slow down the app's performance.
2. In designing the user interface for the Plant Disease Predictor app, we need

3. to prioritize ease of use and intuitive navigation, making it simple and straightforward for users to input data, view results, and get the information they need to identify and manage plant diseases.

4. A clear, consistent visual hierarchy is critical in designing the user interface, using typography, color, and layout to create a well-structured and visually appealing interface that guides the user's attention to the most critical elements on each screen.

5. We need to ensure that the user interface design of the app is accessible and user-friendly for all users, regardless of their level of technical expertise or physical abilities, using design principles like contrast, simplicity, and consistency to make the app usable for a wide range of people.

6. An intuitive interaction design is critical for the success of the app, enabling users to easily input and view information, and providing feedback that guides them through the process of identifying and managing plant diseases.
7. The user interface design should prioritize function over form, focusing on the essential features and functionalities that users need, and avoiding unnecessary bells and whistles that could slow down the app or distract users from their primary goals.
8. To ensure that the user interface is effective, we will conduct user testing and evaluation, using feedback from users to refine the design and improve its usability, accessibility, and overall effectiveness.
Here is the AI generated idea for ui/ux design for 'Plant Disease Predictor' app. This is close to what our end product will look like:

Figure 1 : Fronted End Design (a)

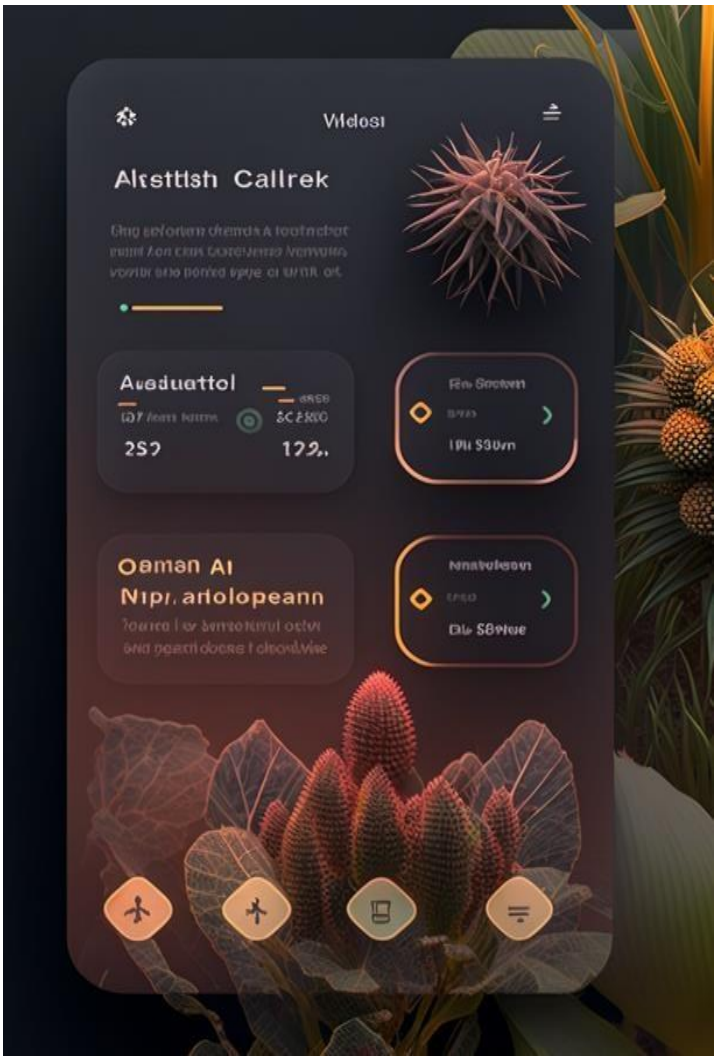

Figure 2 : Fronted End Design (b)

Overview of our Design:The front-end part of the Plant Disease Predictor system typically consists of a user-friendly interface that allows users to input information about the symptoms of a disease, the type of plant affected, and other relevant information. The system then analyzes this information and provides a list of potential diseases, along with information about the symptoms, causes, and management strategies.

Functionalities of the front-end part of the system include image recognition and upload, symptom analysis, disease prediction, and management recommendations. The system may also provide information about disease prevention and control measures, including the use of resistant varieties, crop rotation, and fungicide applications. By providing quick and accurate information about plant diseases, the Plant Disease Predictor can help farmers and growers make informed decisions about disease management and protect their crops from the impact of diseases.

I. Interaction Design: Describe how the app allows the user to interact with the system, including the navigation, input and output components, and the feedback mechanisms provided to guide the user.

II. Information Architecture: Explain how the front-end organizes the information and functionalities of the app, including the use of hierarchy, grouping, and labeling to create a clear and intuitive structure.

III. Accessibility and Usability: Discuss how the front-end design ensures accessibility and usability for a wide range of users, including those with disabilities, limited technical skills, and different cultural backgrounds.

IV. Design Evaluation: Describe the methods used to evaluate the design of the front-end, including user testing, heuristic evaluation, and expert review. Present the results of the evaluation and discuss the improvements made based on the feedback received.

V. Accessibility and Usability: Discuss how the front-end design ensures accessibility and usability for a wide range of users, including those with disabilities, limited technical skills, and different cultural backgrounds.

VI. Design Evaluation: Describe the methods used to evaluate the design of the front-end, including user testing, heuristic evaluation, and expert review. Present the results of the evaluation and discuss the
improvements made based on the feedback received.

Model Building using Deep Learning

Deep learning is a subset of machine learning, which is essentially a neural network with three or more layers. These neural networks attempt to simulate the behavior of the human brain—albeit far from matching its ability—allowing it to “learn” from large amounts of data.Presented a technique of deep learning for detection of disease in plants that could cause damage in crops and agriculture resulting in loss of crop yield. The current deep learning methods expansion found their plant disease detection application, thereby contributing the robust tool having higher results on accuracy.It is the most promising one for fine grained classification of disease similarity as this scheme evades the labor- intensive feature extraction and the segmentation.

Following is the flowchart representing basic methodology for model building.

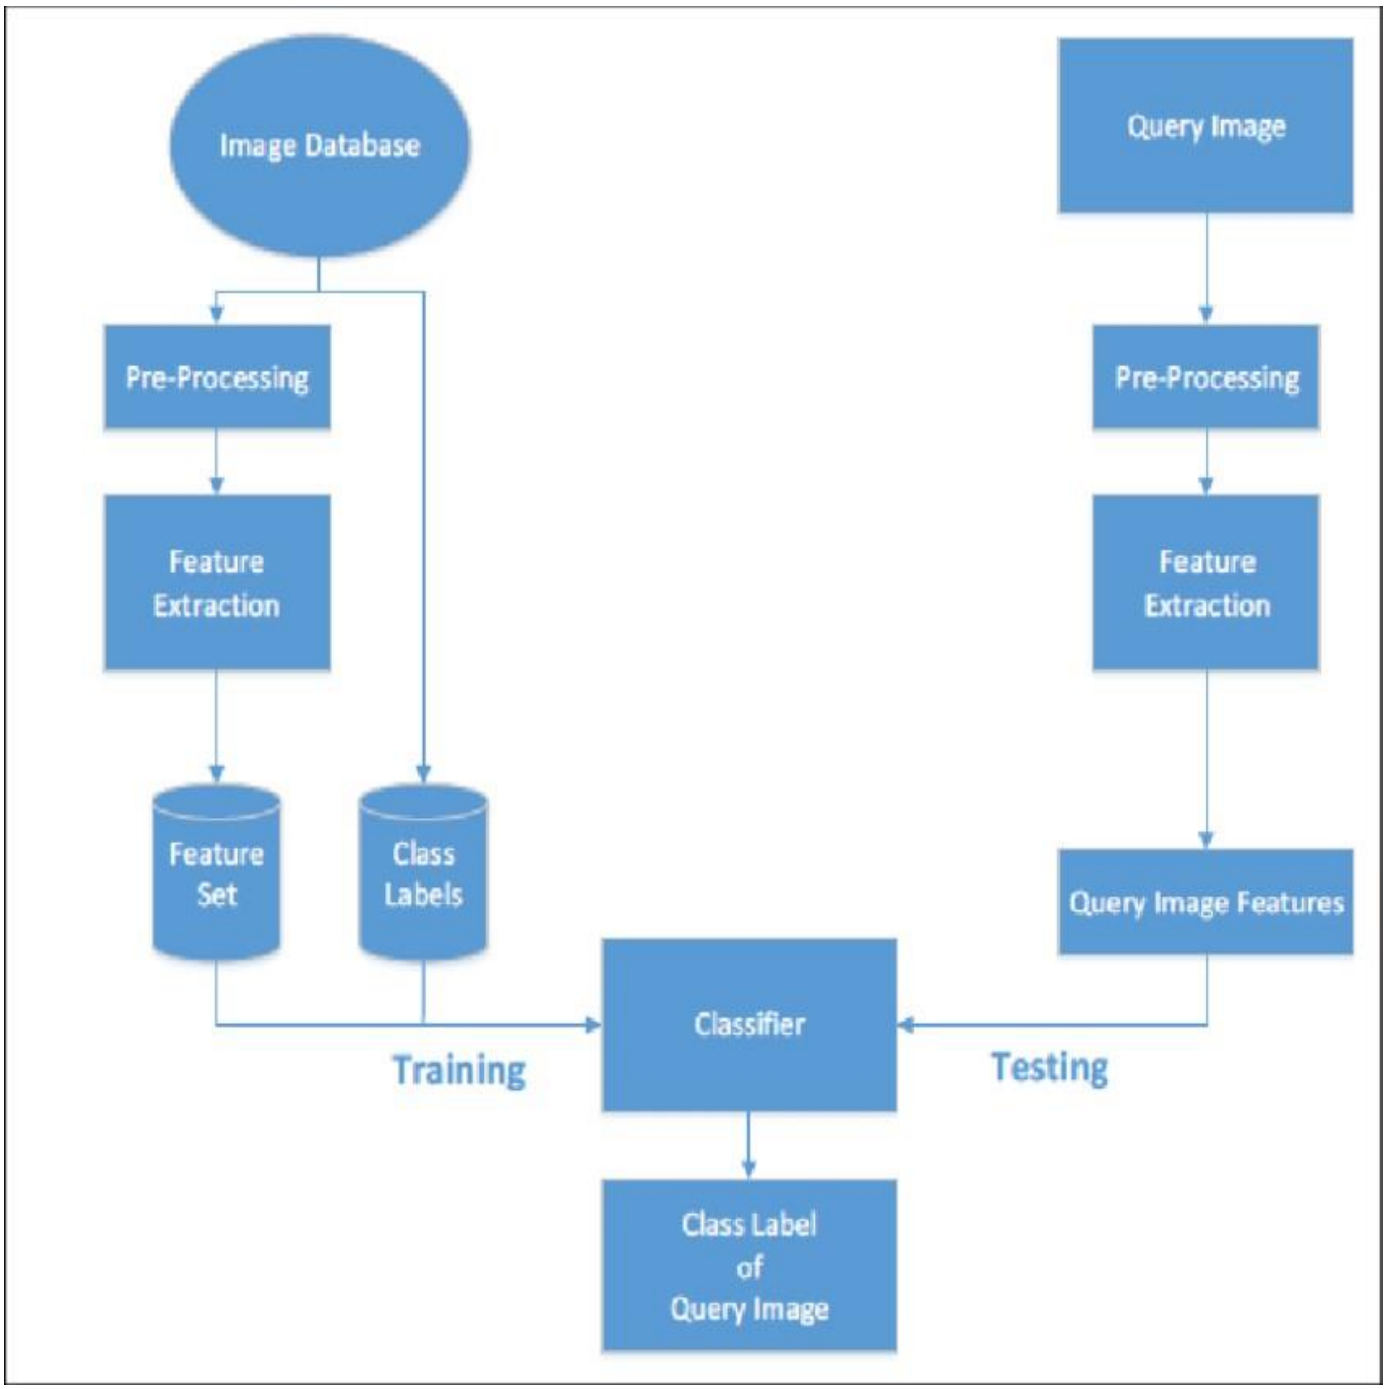

Figure 3 : Basic Methodology for model building

Data Collection

The image dataset was collected from Kaggle using the following link- https://www.kaggle.com/datasets/saroz014/pla nt-disease The dataset is of 2 GB containing images of plant leaves belonging to 38 different categories. It consists of 2 folders-train and test with 38 directories in each. It altogether consists of 54,305 images of which 43456 are used for training and 10849 are used for validation. It is collaborated by Saroj Raj Sharma on Kaggle.

PREPROCESSING

The model is built in Google collab in which the zip file of the dataset is imported. After importing two batches of tensor image data are generated for training and testing with real time data-augmentation with ImageDataGenerator() and flow_from_ directory().After preprocessing a 3D array of image dataset and 2D array of label dataset is generated.

The visualization of some images after preprocessing is as follows:

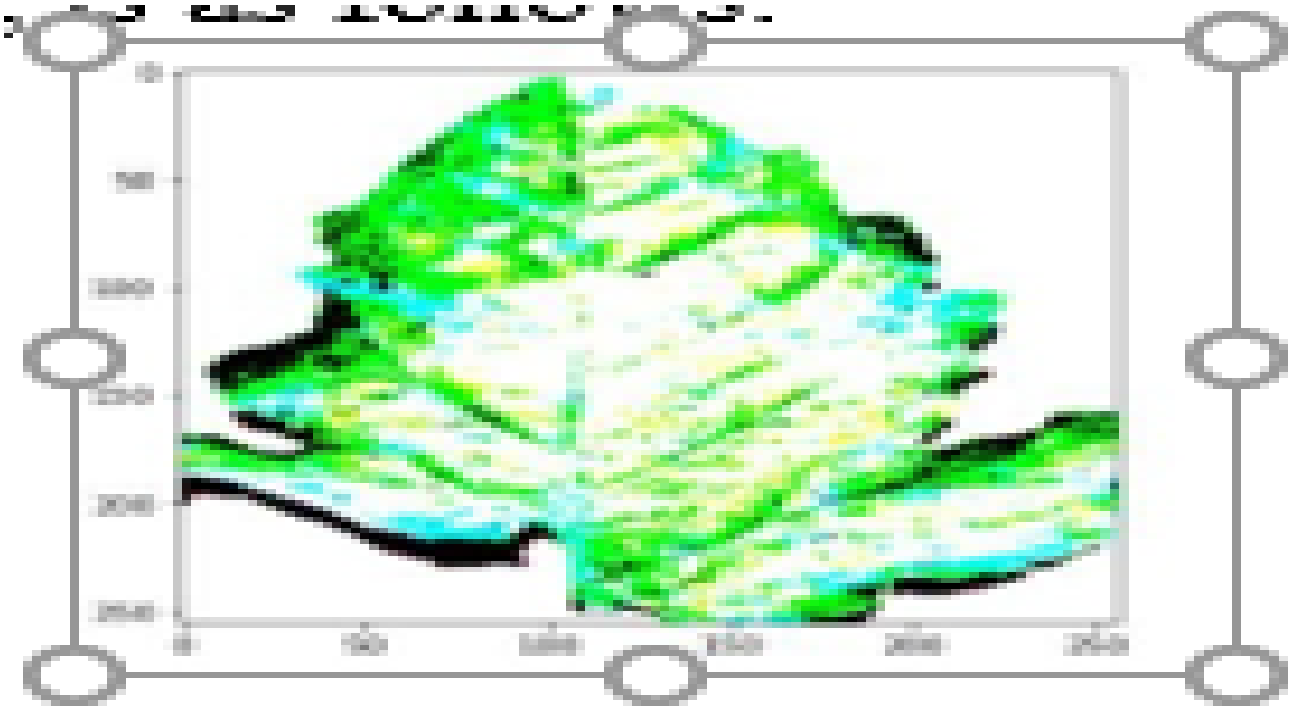

Figure 4 : Visualizations of Leaves

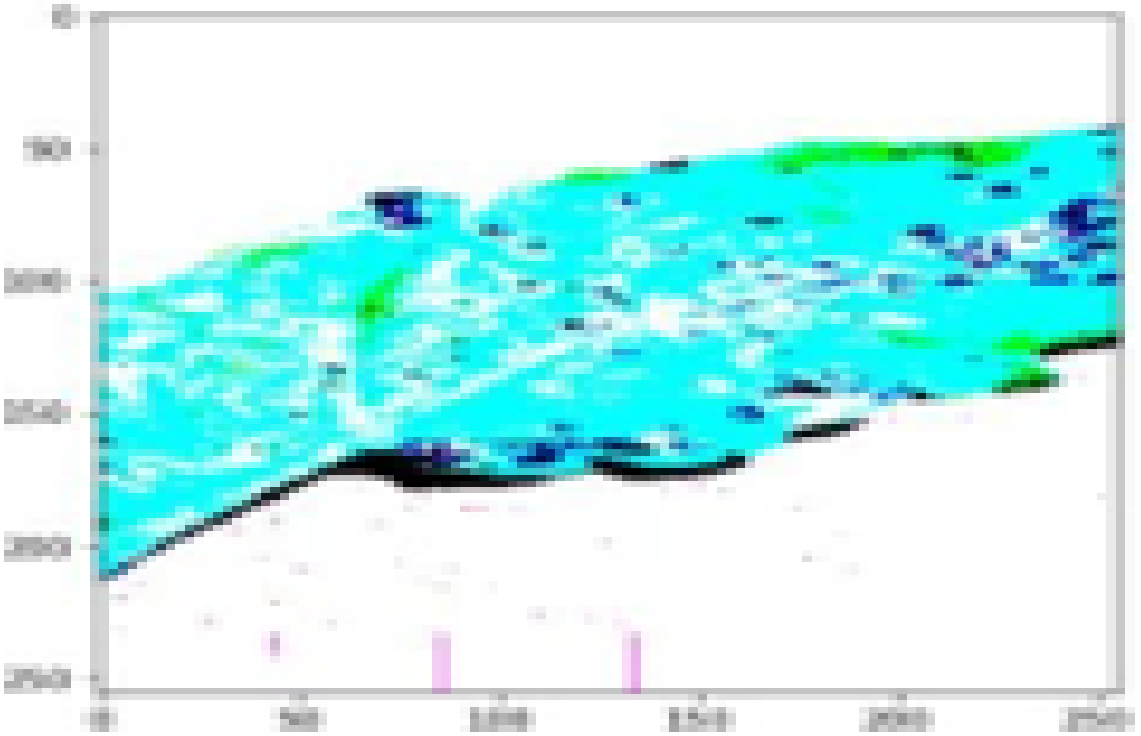

Model Building

For model building a prebuilt model for image classification 'VGG-19' is used. VGG is known as the "visual geometry group" and was introduced by the oxford university which made this type of deep CNN model for the "Image Net Large scale recognition of visual challenge" (ILSVRC) held in 2014. This structure comprises of best function up to date on comparing the other deep neural networks. Though several kinds of parameters exist, this structure only focuses on the padding convolution layer, fully connected layer, and max pool having the outcome of softmax layer. The model is thus not built from scratch. Following is the summary of the model in which it's top layer is replaced by a Dense layer of 38 units with the activation function 'softmax'.

The optimizer which is used for compiling the model is 'adam' with loss-function 'categorical_crossentropy'. ModelCheckpoint callback is used in conjunction with training using model. fit() to save a model or weights (in a checkpoint file) model.h5 for best model only in terms of validation accuracy. Early Stopping technique is used for deep neural network so that model can stop training when validation accuracy no longer begin to yield improves on a validation set .

Result 1 : Summary Of the Diagnosis

Layer (type)	Output Shape	Param #
input_1 (InputLayer)	[(None, 256, 256, 3)]	0

flatten (Flatten)	(None, 32768)	0
dense (Dense)	(None, 38)	1245222

Total params: 21,269,606
Trainable params: 1,245,222
Non-trainable params: 20,024,384

Evaluation

Training and testing data is passed through the model.The model is build for 50 epochs.The model trained and improved uptill the accuracy is reached upto 82.74% .So the accuracy of our Plant disease predictor is 82.74%.

The model is saved as best_model.h5 using ModelCheckpoint().For Prediction following images are passed into the model after preprocessing

Observation:

Prediction

loss=5.653777599334717
Accuracy is 82.74495601654053

Lable-Apple healthy

Lable-Peach__Bacterial__spot

These images were passed to a function that converts them into an array and then preprocesses thembefore Following were the results which were obtained from the predictor-For 1st image

```
1/1 [==============================] - 0s 17ms/step
Apple___healthy
```

Result 2 : Apple Leaf Image

For 2nd image

```
1/1 [==============================] - 0s 19ms/step
Peach___Bacterial_spot
```

Result 3 : Peach Leaf Image

Conclusion : Food security is seriously threatened by crop diseases, yet due to a lack of the essential infrastructure in many places throughout the world, it is still difficult to identify them quickly. Smartphone-assisted disease detection is now achievable thanks to growing smartphone adoption worldwide and recent developments in computer vision made possible by deep learning. The trained model's accuracy on a held-out test set is 82.74%, passing them for prediction.
A directory containing the label-names as values having their label-index as keys was maintainedwhich was used by the function to map the generated output with the appropriate name.

proving the viability of this method. Overall, a clearroad for smartphone-assisted crop disease diagnosis on a gigantic worldwide scale is presented by the method of training deep learning models on progressively larger and publicly available image datasets.

Maximum Convergence Accuracy forHybrid Indoor Positioning System

Kavita Thakur, Dr. Vinit Dongre
Electronics & Telecomm. Department
Thakur Polytechnic, Thakur College of Engineering
Mumbai, India

Abstract-**For tracking people or object's Location in the indoor environments, a network device is suggested known as IPS.. This technology mainly used because of supervising the health, position, guidance in different sectors like Universities, museums, airports, hospitals and warehouses the main advantages of IPS with distinct feature like reduction of material and energy cost over time that has huge impact compared to other technology which are more costly.**

Among various technology like (UWB) Wireless Fidelity (Wi-Fi) Bluetooth Low Energy (BLE). (Wi-Fi)Technology is an outstanding approach for indoor navigation and positioning due to already available Wi-Fi Infrastructure Wireless IPS has categorized into two approaches :geometrical –calculation based and Scene – Analysis based former relies on measurement of geometrical parameter of Distance and angles by physical characteristics of Signal. RSS is the performance parameter used for achieving robustness and accuracy which is most concerned factor for current scenario

Most Recent Research has solved the problem of inconsistency on Received Signal Strength (RSS) using fingerprint method. But the RSSI that received may contain some noise. This paper mainly proposed a method to estimate or tracking the real position of dynamic user. With RSSI value as input to be processed and the result of it will be a location (x, y) value, then repeat the process to create an estimate coordinate map of route taken. Our proposed method is based on fingerprinting with weighted sum of four nearest reference access point to estimate the position of dynamic user then using Extended Kalman Filter as a tracking algorithm. In this paper we try new ways to collect the data of RSS by dynamically collecting the data in many routes to see whether the proposed algorithm could estimate the position better. We achieve an average mean of error around 2cm using Weighted Sum using Kalman Filter tested on dynamic data.

Key words: Indoor Positioning System, Dynamic User Localization, Fingerprinting Method, Weighted Sum Model, Extended Kalman Filter

1. INTRODUCTION

Location detection has been popular implemented in outdoor environments by the introduction of GPS technology. GPS has made many changes on our daily activities; the usefulness to navigate to other places has been a very important factor of the success of GPS. Different from outdoor positioning, GPS technology can't be used for indoor positioning. GPS technology had limited access to indoor positioning because of many factors such as lack of line of sight and in indoor the signal of the GPS will be attenuated as they cross through walls [4].Building structure and in other case the indoor positioning system would behave differently. Also, in Indoor positioning there is many obstacle that need to be included as an obstruction. This cause the GPS could not applied into IPS

Various indoor positioning technologies has been proposed based on the literature review such as Infrared, Ultrasound, WLAN/Wi-Fi, BLE and RFID to estimate the position of user in indoor position environment. Among them, Wi-Fi and BLE used similar bandwidth of 2.4 GHz radio wave frequency but based on [14,12] BLE has more advantage than Wi-Fi because of lower material cost and high availability of BLE because of shorter channel width and 3 dedicated advertisement channel also supported by most modern smartphones which made BLE more advantageous than Wi-Fi technology.

BLE is introduced as a new form of wireless communication that is designed for short range communication [05-12]. BLE act as a replacement for cable to transmit the data into another device. Most of the time BLE stays in sleep mode constantly except when connection is initiated [14]. In the previous research most of the experiments on other literature are based on static user, where positions of users are estimated while users are immobile. The dynamic user with fingerprinting algorithm and implement tracking element on the position by Kalman Filter to see the difference.

In the Fingerprinting method we can get the object's location based on the signal strength that are channeled from the BLE, it consists of 2 main phase that are Offline and Online phase. Offline phase used to store the experimental condition of radio wave on a grid based possible location with signal strength received from each transmitter as the reading value, meanwhile online step is the phase where positioning be done where measurement of signal strength from each transmitter will be used to match the condition stored from previous step

Fingerprinting in indoor positioning systems was also known as scene analysis method which was used to measure the condition of radio frequency signal on the test field. The measurement of radio frequency was taken not only to determine position on the online phase but also to avoid wrong measurement because of obstacle material, human cause, etc. Much research has been focused on removing the noise caused by other factors, but there are no exact methods to remove it.

There are two main proposed methods in this paper to solve our problem. First one, this paper intended to implement a tracking algorithm based on RSSI value of Bluetooth but with the extended version because of the non-linearity of RSS measurement. We proposed this tracking algorithm because of the change from static user data collection to dynamic user data collection. Also, we proposed this filtering algorithm because in [13] we see an improved accuracy around 93% by using various filtering algorithm. The proposed method

expected to improve the current accuracy by tracking the estimated position based on measured noise covariance, process noise covariance, and Kalman gain. We proposed to capture the data dynamically by walking in a route that we had created with some constraint and see whether the algorithm proposed could measure the distance or not.

2. RELATED WORKS

Indoor Positioning System using BLE technology has been experimented on many known techniques from Wi-Fi technology [7,8] like trilateration is a method of position estimation using the distance between mobile target and the receiver with the received RSSI as the measuring unit. The position of an object can be measured with a minimum of 3 estimated distances which is why this method was called trilateration. The disadvantages of this method is the simplicity of the measurement only based on the placement of BLE or Wi-Fi access point location and current RSS information which can change depending on environmental change also due to multiple interference on other radio signal that will cause the distance estimated contain some noises.

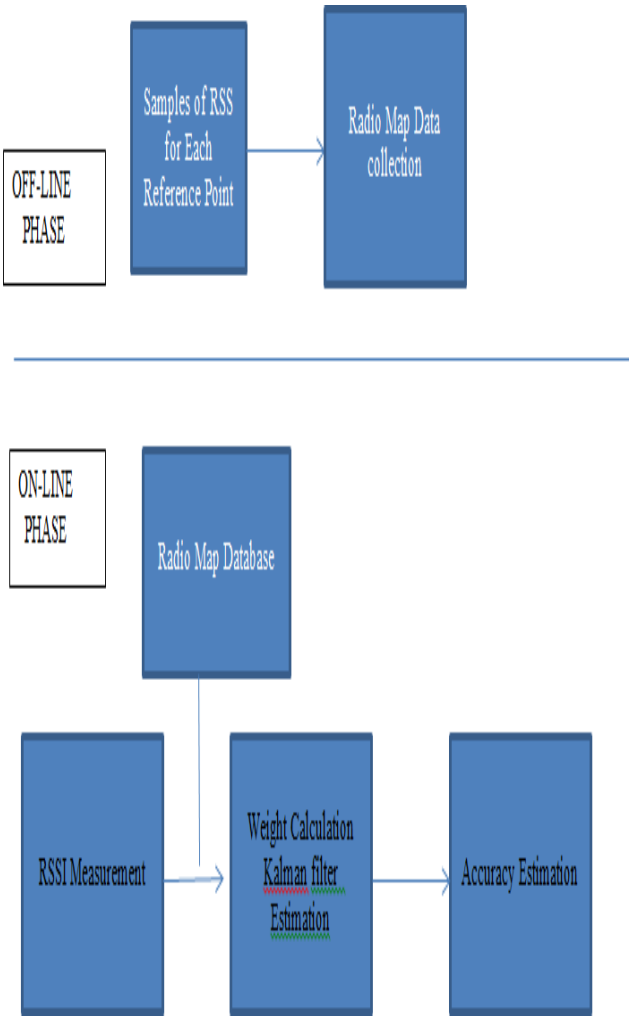

Figure 1: Outlines for online and offline Phase of with RSSI values for IPS using Hybrid Wi-fi system

Figure 2: Screenshot for Moving Blue dot denoted as outline room location with RSSI value at each Wi-Fi denoted as Red spot at each Edge Corner

1. PROPOSED METHODS

1.1 Scene Analysis Based

In this paper we proposed an Indoor Positioning System by using BLE with fingerprinting approach exploits available infrastructure to evaluate the user's location with different RSSI observed at the "radio map" is the setup imposed at different Aps and estimates its position by positioning algorithm method. There are two main phases of fingerprinting method proposed in this paper shown in Figure 1 Outlines for online and offline Phase of with RSSI values for IPS using Hybrid Wi-fi system ,offline phase is designed for learning the RSS at each reference point (Figure 2). This method simply creates Radio Map Database by gathering on each of the reference points and started receiving RSS from all BLE beacon then send the representative data to database. One row of data on the radio map database consisting 2d coordinate value (x, y) where the Reference point (gathered point) are and each BLE beacon RSS received. Then Euclidean distance is regularly applied to calculate

minimum distance between Aps the The main task of this phase is to collect fingerprint data to build a model [5].

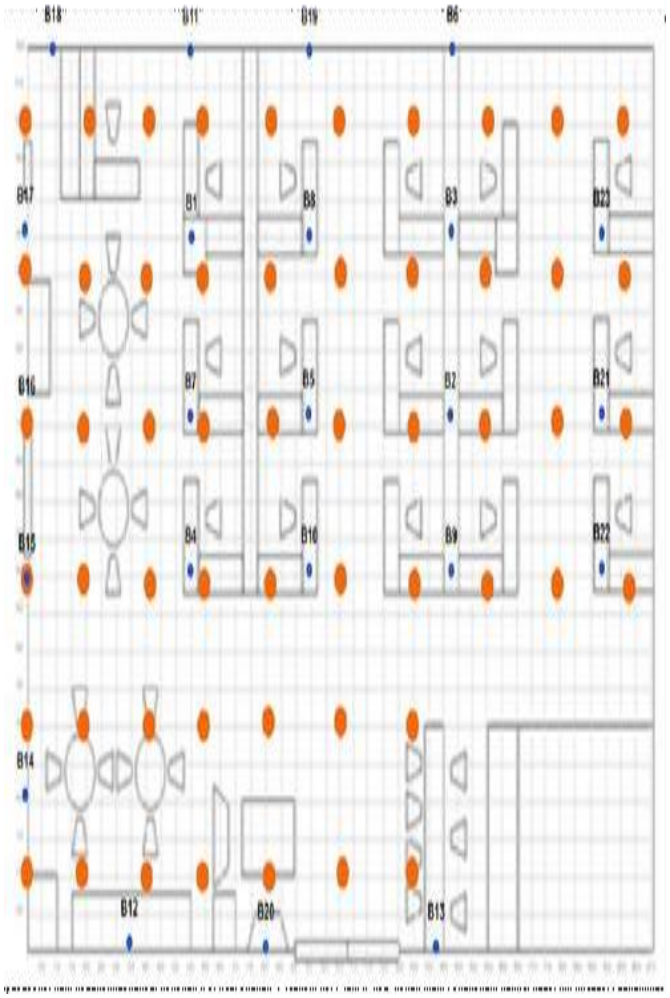

Figure 3: Phase of Location of XYZ Campus room

The deterministic positioning algorithm is based on the measured signal strength on radio map creation phase to match the real-time measured signal strength to determine the position of receiver While deterministic positioning algorithm is based on signal that matches the corresponding fingerprint data to determine receiver position, probabilistic positioning algorithm approaches this by calculating the probability distribution of radio wave signal strength during a certain time and stored in fingerprint database to be used on online phase also during the online phase of positioning, the more static a user are on the position, the more accurate the result of position estimation will be which is why probabilistic positioning algorithms cannot be used to determine the position on a dynamic device.

2.1 Kalman Filter

The potential technique for Wi-fi and Bluetooth signal in practical environment with updating current location is essential to meet user requirement the state transition function is as shown

$$Xk = FXk\text{-}1 + Gdk + vk \quad (1$$

)With measurement Z that is :

$$Zk = HXk + Wk \quad (2)$$

Where F,G indicates identity matrices ; vk, wk is the process and measurement noise at the time step k, respectively. These parameter are required to be independent and have cumulative distribution function .

$$Vk = N(0, Q) \quad (3)$$

$$Wk = N(0, R) \quad (4)$$

Where Q, R is the process noise variance and measurement noise covariance matrix, respectively.

The Kalman Filter is the solution for linear problem with assumption of Gaussian noises .The algorithm consists of two phases ;prediction and observation phase [9]. Estimation of wifi location error can be given as (5),(6) receiver and TDOA is the measurement taken by examining the difference of time between each radio signal interval. The most accurate usage of TOA/TDOA has been proposed by [10] where radio wave propagation was modeled as probabilistic model and determination of position will be based on time-delay estimation algorithms and this method has proven to solve the fading effect of radio wave propagation.

To solve the problem of multipath radio wave phenomenon and more accurate measurement on positions, fingerprinting technique was developed. Fingerprinting on IPS uses Wi-Fi Access Point ID or BLE ID and RSSI where an experimental site with transmitter scattered then divides the space into small grids and collects the RSSI value on each grid to be saved into a database is called a radio map [1, 11]. From here, there are

two approaches that have been known so far to determine the position of receiver deterministic positioning

$$R = [0\ 2] \quad (5)$$

algorithm and probabilistic positioning algorithm.
The test field is built on the 6th floor of the XYZ campus as a specimen and the device used for Bluetooth receiver

$$Q = [0.1 \quad 0\ ] \quad (6)\ 0 \quad 0.1$$

In the application for moving object a movement is

changes unpredictably. Therefore the Kalman Filter will be updated based on step detection. Regularly in two phase ,the prediction phase relies on estimation of Wi-fi results.

4 EXPERIMENTAL DESIGN

4.1 Experimental Setup

researcher [7, 8, 10] has proposed a new idea to include other parameters that can be taken as measurement such as Time of Arrival (TOA) and Time Difference of Arrival (TDOA). TOA is the time measured for a radio wave from

Figure 3: BLE beacons

Test field used in this experimental design is an office room with size 10 m x 12 m shown at Figure 5. Reference point are placed with 2 meters gap each shown in Figure 4

First, we configured Wi-Fi module as Access point Bluetooth beacon from HC-05 shown in Figure 3 with transmit power of 20 dBm and transmit interval of 100 milliseconds. Then the RSSI value will be deployed in this research as shown in Figure 2 represented by the blue dots as beacon deployed where on the site will be placed at 5m apart each other height from the floor

Due to the simplicity on basic idea of trilateration, many

transmitter to reach

and total reference point are used in the radio map. On each reference point 100 samples were taken by smartphone device specified on Table 1 to log the RSS received while standing on the point around 3 minutes for the entire sample of a point to be taken .along with user id and password for authentication success status.

Figure 2 Log in with Authenticated user-id

The test field is built on the 6th floor of the xyz location campus as a specimen and the device used for Bluetooth receiver is a smartphone device with specifications of "one plus 6T" shown on Table 2.

RSSI VALUEIN DB	WIFI-1	WIFI-2	WIFI-3	WIFI-4	δ(DB)
RSSI 1	**-30**	**-56**	**-48**	-100	10.2
RSSI 2	**-28**	**-58**	**-48**	-100	4.1
RSSI 3	**-27**	**-60**	**-47**	-100	3.6
RSSI 4	**-29**	**-59**	**-48**	-100	15.6
RSSI 5	**-21**	**-63**	**-48**	-99	23.8
RSSI 6	**-25**	**-55**	**-47**	-100	31.3

RSSI 7	**-21**	**-59**	**-48**	-98	35.3
RSSI 8	**-22**	**-60**	**-46**	-98	7.2

Table 1 Sampling Point from Wi-fi Module

4.1 Experimental Evaluation

Our framework uses two metrics for assessment are; Exactness :use the RMS of the determined location and position

Error i= $\sqrt{(x - \hat{x})2 + (y - \hat{y})2}$ ·· (7)

Where (x,y) represents for the true physical position and $(\hat{x},\hat{y})$represents the estimated position.

4.3.1 Test Point 1: Evaluation of RSSI value for Scene based Approach

The screenshot illustrates our room used for training points of the project in 10mx12m room with 4 Wi-Fi modules with samples of data Spatially with estimation of error using Kalman Filter to reduce the fluctuation of the signal strength model baed on strongest access points.

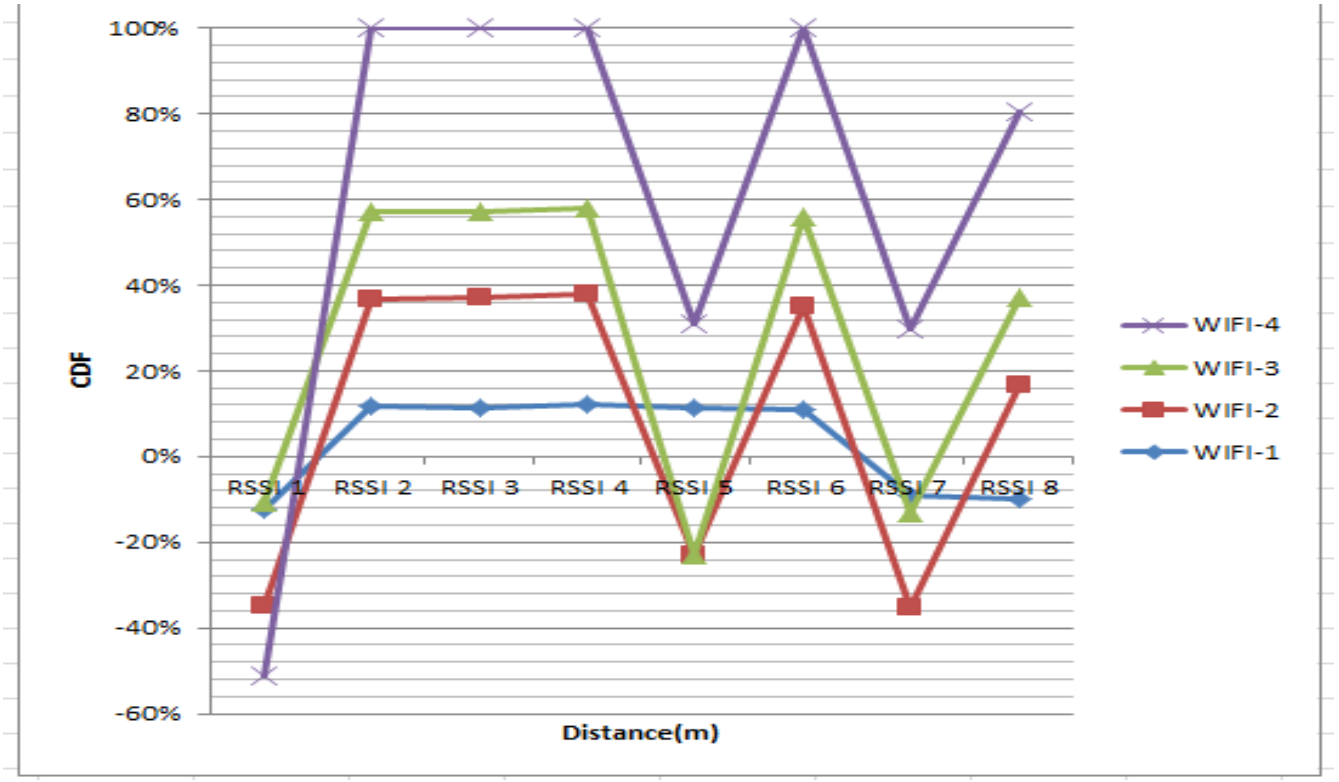
Figure 3: Screenshot of Estimation for accuracy level of different access point along with RSSI value

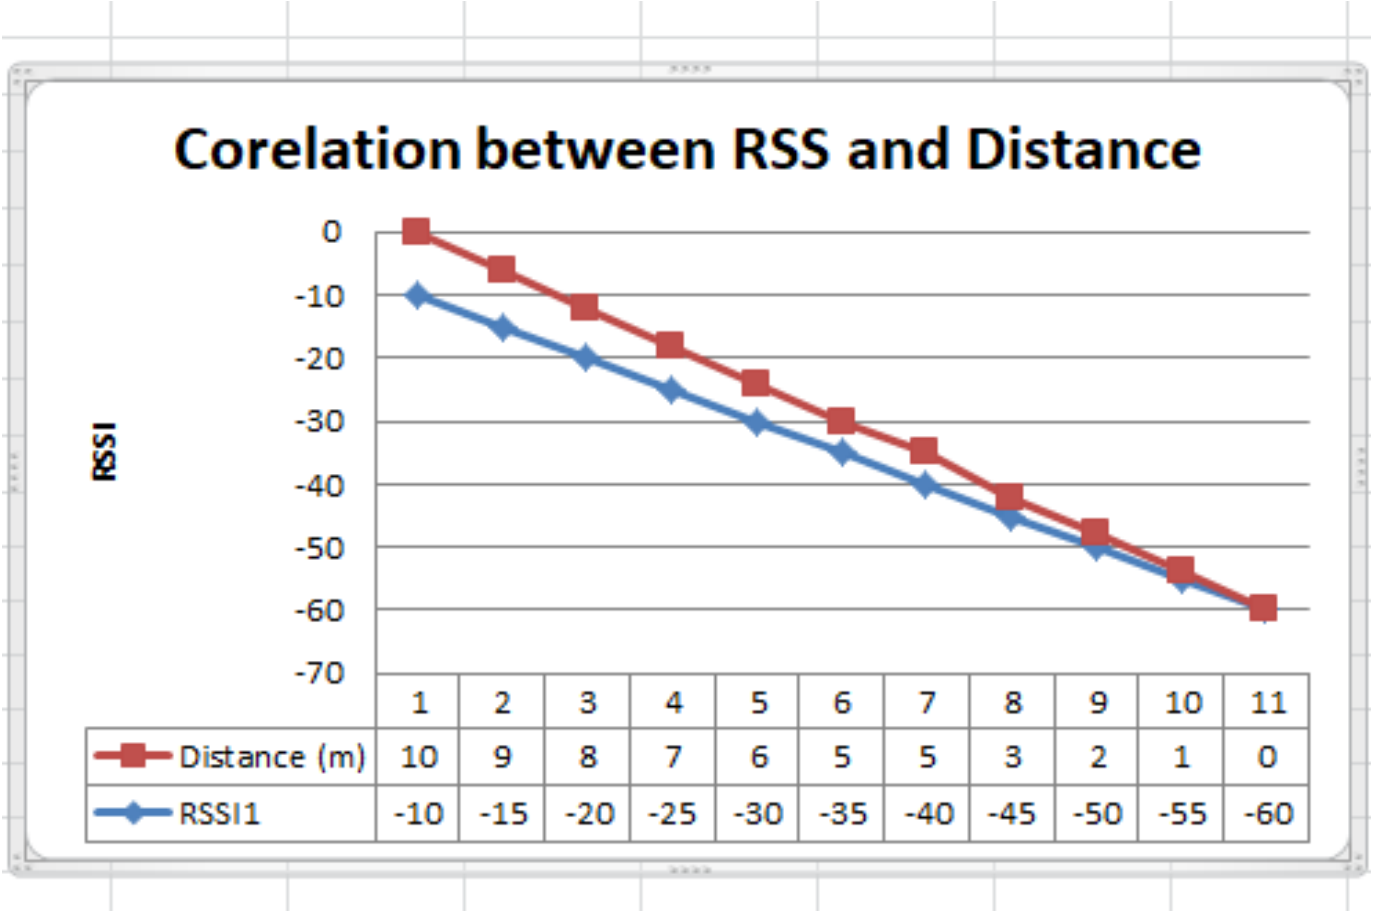
4.3.1 Test Point 2: Evaluation of Hybrid Method depicting correlation between RSS and Distance

As per the tabular form of the received signal strength we can determine the estimation of error and the accuracy factor showing the correlation between the accuracy and RSS values.The Wi-Fi fingerprinting average positioning exactness of the hybrid framework can be 45% to 74% respectively

Aver = $1/n \sum n \ \ error\ i$ (8)

Where n is the number of the test point of Wi-fi nodes
Precision : It is defined as consistency of the system in order to determine the robustness of the position techniques with CDF (Cumulative Distribution Function of the distance)is applied .





CONCLUSION

In this paper we provided a review of the state-of-art in hybrid indoor positioning system based on Wi-Fi and Bluetooth with estimation of different access points for acquiring accuracy. The test results shown that introduces effective and consistent improvised provision for estimation of accuracy a a level of half meter .Major importance is relying in flexibility adaptivity for scalability in future development can be integrated with other approaches of IPS. Future work will be critical analysis for the performance estimation in various investigations in RSSI observation from Aps in different time.

LensPatrol: Detecting Anomalous Event

Mr. Shubham Zope,Mr. Venkatesh Rallapalli,Mr. Nihar Kenny, Mr.
Rakshit Deshmukh, and Dr. Sujata Khedkar
Department of Computer Engineering
Vivekanand Education Society's Institute of Technology (VESIT)
Mumbai, India

Abstract. **The advent of technology and subsequent waves of technological modernization have had a massive impact on society today. Along with the development, there has been an increase in activities that can only be categorized as abnormalities or anomalies. Due to these anomalies, security has received the greatest importance in recent times. Setting up CCTVs to constantly monitor people and how they interact is a very common practice in most organizations. It is nearly impossible for the authorities to continuously review these surveillance films to determine whether the occurrences are suspicious or not because it takes continual attention from their staff. This is the issue being addressed here. The Proposed System uses the CCTV feed to detect abnormalities like Weapons, Theft, Fire, Masks, etc., and upon detection, the respective authorities can be notified immediately. The surveillance footage is further analyzed to identify the busiest counter, person count, and queue analysis which is then summarized in a report for the management. Detection algorithms like CNN,**
ConvLSTM, Resnet, YoloV3, and YoloV5 have been trained and YoloV5 showed a mean Average Precision (mAP) of 53.6 with a loss of 0.012.

Keywords. **Video Analytics, Event Detection, Deep learning, Object Detection, Anomaly Detection**

1. INTRODUCTION

The Banking Industry has seen modifications in banking rules and their exchanges due to rapid advancements in technology. Banks are looking for intelligent solutions to monitor their premises, and detect and raise an alarm for any suspicious activities. These solutions need to be highly accurate so that the system can rely on them even after working hours. The core value or principle on which any bank works is trust. They strive to achieve customers' trust in their bank and their employees. And this can only be done by providing them with a sense of security. For this reason, they employ a workforce to constantly monitor their premises either physically or via CCTV or a combination of both. Although watching multiple areas via several CCTV feeds is quite efficient, there is a possibility that certain mishaps may go unnoticed by the human eye or it might be too late before they get noticed by the security personnel. This causes a delay in taking swift action against criminal activities which may cause a loss of life or property. To prevent this, an intelligent CCTV proctoring system titled "Lenspatrol" is developed. This Proposed System has considered possible nefarious activities that can happen on the bank's premises and developed detection models for the same. LensPatrol can broadly be classified into three modules, i.e., security, analysis, and predictive modules. The proposed system uses the YOLOv5 algorithm and OpenCV library for detection and identification purposes and generates an accurate analysis report for the banks.

2. LITERATURE SURVEY

An enormous amount of research carried out in the last decade has led to several new technologies, applications, and even algorithms to detect abnormal events. Some of these papers have been reviewed to get a better understanding of this field of study and aid in the implementation of LensPatrol.

MM. Salehin et al. [1] present a system to summarize videos by extracting the most valuable videos from a long, continuous video stream.. The proposed method contains the following steps- (i) Foreground object extraction, (ii) Motion information estimation, (iii) Visual saliency difference calculation, and (iv) Key frame selection through SVM. The above-proposed method performs better than the state-of-the-art methods, according to comprehensive experiments. Another system by S. Saravanan [2] focuses on putting in place a smart camera that watches operations in banks and can spot any kind of unusual conduct, allowing robbers to be traced using movement and time-based facial recognition. V.Singh et al. [3] present a method for identifying deviations from the norm in actual CCTV footage. It might not be possible to identify anomalies in these recordings using only the standard data. As a result, both normal and irregular movies are taken into account to handle the intricacy of these genuine anomalies, which maximises the model's accuracy. S. Gupta et al. [4] proposes a new framework for video summarization – perceptual video summarization where choosing the right frames for the synopsis requires summarization that is in line with the characteristics of human understanding.

The paper by C. Kumar et al. [5] focuses on the early detection of fire accidents. Fires are identified in picture or video sequences using a classification

model that incorporates deep learning with transfer learning. The ResNet-50-SVM pair was chosen as the implementation model out of many deep learning and classification models since it provided the best measurement figures (Accuracy, Precision, and Recall values for this arrangement were 97.8%, 97.46%, and 97.66% respectively).

For the weapon detection module, works like S.Narejo et al. [6] through IP cameras study, the cutting-edge YOLO V3 object detection model was adopted and trained over the available dataset for firearms identification. The goal of this project was to create an integrated framework for reconnaissance security that gradually distinguishes the weapons and, if the identification is positively true, it will caution/brief the guards to control the predicament by coming at the place of the incident.

It has been observed from experimental results of [6], in comparison to other approaches like AlexNet + SVM, Faster RCNN, and CNN VGG - 16, which produced accuracies of 95%, 95.4%, and 93.1% correspondingly for various kinds of data, YOLOv3 produces the highest accurate results (98.89%) for the amassed picture dataset.

The work by H.Jain et al. [7] presents an automatic gun (or) weapon detection system using a convolution neural network (CNN) based SSD and Faster RCNN algorithms. It is discovered that the SSD method provides faster performance with 0.736 s/frame compared to Faster RCNN's 1.606 s/frame. Faster RCNN provides superior accuracy, with a score of 84.6%, whereas SSD provides a score of 73.8%. Both SSD and Faster RCNN algorithms are simulated for prelabeled and self-created image datasets for weapon (gun) detection. Works like M.T.Bhatti et al. [8] adopt the deep learning methodology, particularly Convolutional Neural Networks. The outcomes of using deep neural networks for object identification were assessed in terms of accuracy, speed, and the common F1 score measure. Modern deep learning-based YOLOv3, FasterRCNN-InceptionResnetv2, SSDMobileNetv1, and YOLOv4 models were trained and put to the test. The research by S. Boudoir et al. [9] questions the focus on only the analysis of trajectories for anomaly detection. Instead, it presents a method for the detection and localization of abnormal events in scenes, based only on a

training dataset of normal situations.

The most lucrative targets for fraudsters are banks, insurance companies, and other financial institutions. In the financial year 2022, the Reserve Bank of India (RBI) reported bank frauds amounting to 604 billion Indian rupees. Fraud Detection plays an important role in minimizing these losses as proposed by D.Sarma et al. [10]. Video and surveillance feeds can be analyzed for several aspects such as weapons, fire, ATM Fraud, and snatching that constitute abnormalities in banks and other public places. Roy et al. [11], by training a sizable UAM that includes qualities from all activities, suggest a method for using the similarities between snatch steals and regular actions. This led to the creation of a framework whose learning is independent of labelled snatch steal cases, which are notoriously hard to gather due to their rarity and limited quantity.

1.1 Existing Systems and their drawbacks

Existing surveillance systems are generally single-feed classification-type systems that do not perform analysis to gain insights from the captured activities. Also, various IOT-based analytics and detection systems use external hardware like sensors attached to the machine which increases the cost of the system. When it comes to monitoring, public spaces like banks that have CCTV and computerised systems need a staff and regular attention to determine whether the recorded behaviours are unusual or suspicious. This is often hard or even impossible for a human being to accurately classify. Many of these systems are single-domain detection systems that are used to track a specific kind of anomaly like Theft or Fire, Long Queues, etc.

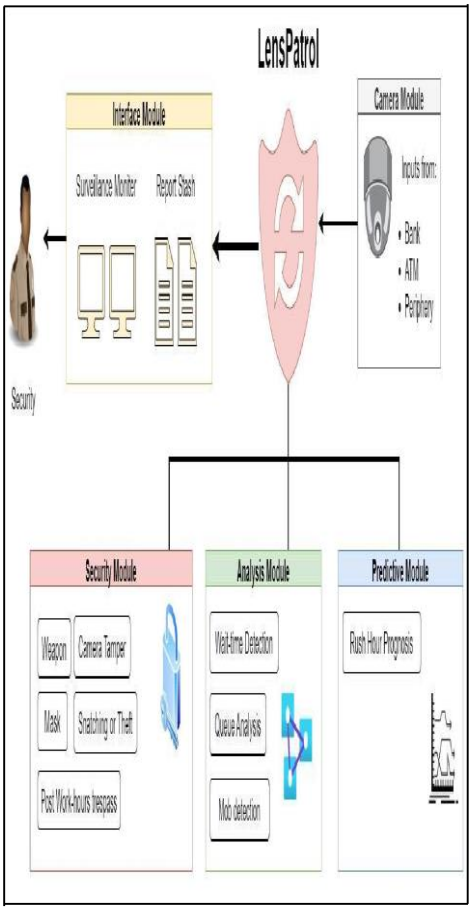
3. METHODOLOGY

The suggested application basically is a bank surveillance and analytics system. This proposed system can broadly be divided into three modules viz., Security Module, Analysis Module, and Prediction Module. *A. Security Module:*

In this, the proposed system is going to identify four events through the closed-circuit television (CCTV) system. The four events are as follows:

- Snatching
- Weapon
- Robber Mask
- Fire
- Camera Tampering
- Post- work hour detection

To train a model that can identify the above-mentioned events, the proposed system needed a large dataset. Since this sensitive dataset was not available anywhere easily, youtube videos were downloaded regarding that event. Around 120 videos were downloaded and converted into frames. Amongst the collected frames, many were blurry and of poor quality; hence, such frames could not be used for training purposes. After this various Deep Learning models were trained on the dataset and evaluated based on their accuracy. CNN, Resnet, Vgg16, LSTM, ConvLstm, YOLOv3, YOLOv4, and YOLOv5 were trained and results were checked for each model. YOLO gave better results than other models so YOLO was chosen for training the dataset. For the training of YOLO, various steps were followed like downloading a labelling software named Labellmg to map image frames to their classes. In this, around 26k images were annotated to their respective classes. After mapping all the images to their respective classes, they were trained for 4-5 hrs and results were computed on some test videos.



(Figure 2 - Modular)

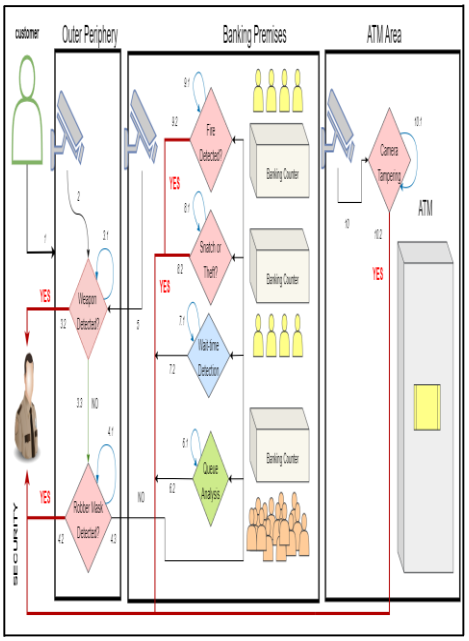
B. Analysis Module:

The whole motive for this module is to utilize the entire footage captured by CCTV cameras and analyze it to provide infographics to the bank. Analysis was conducted through CCTV for the following:

- Count number of people
- After working hours intruder detection
- Dwell time detection
- Person tracking
- Mob detection
- Camera Tampering

Persons were detected using the OpenCV library and then assigned a unique Id to every person in the person and also kept the count of people in the frame and the overall count. After that using that unique Id dwell time was also calculated for each person in the frame. Also, a program was created for camera tampering in OpenCV, in which if the screen gets darker or blurry then it triggers an alert. This analysis might help the bank to improve its security and reduce the manual work done by people by automating this concept. *C. Prediction Module:*

The data collected by the analysis module can be then analyzed and inferences can be drawn from it. Its aim is to provide accurate predictions for the busiest counter at a particular time of the day and also perform rush hour prognosis. LSTM model can be used to generate an accurate prediction of the time-series type data collected in the analysis module. This module's maximum potential will be unleashed when LensPatrol gets integrated with an actual bank. Only then real-time data can be used by the model to get precise predictions.



(Figure 3 - Block Diagram)

For the purpose of this system, the entire premises is divided into three areas, hereby referred as sectors, with each sector having separate camera modules:

1) Outer Perimeter

The customer visits the premises through the outer periphery, where initially, the camera continuously screens for any weapon present on the individuals, along with sustained lookout for individuals seen wearing robber masks. If one or both modules reports back positive identification on their respective fields, the security personnel are alerted and a report for the event is generated and stored in the database.

2) Banking Premises

Once the individual enters the actual banking area, they are persistently monitored by the cameras for the aforementioned criteria. Besides these, the camera modules also carry an incessant stake-out for the rest of the activities like a snatching or theft event, attempts at tampering the cameras at any point of time and detecting whether it's a trespasser present post working hours. Actions taken on a positive hit on any event are similar to that of the previous sector. Furthermore, the cameras also scrutinize the entire populace present to analyse the crowd and its wait-time at the counters, as well as carrying out a prognosis of the number of people standing in queues across the various counters. Reports are generated for analytics purposes, which include infographic depiction of the collected data.

3) ATM Area

Every bank is usually accompanied by its very own ATM adjacent to the main banking premises. The camera module in this sector stays alert for any kind of camera tampering attempts, accompanied by the rest of the security measures like firearms or robber masks.

4. PROPOSED ALGORITHMS

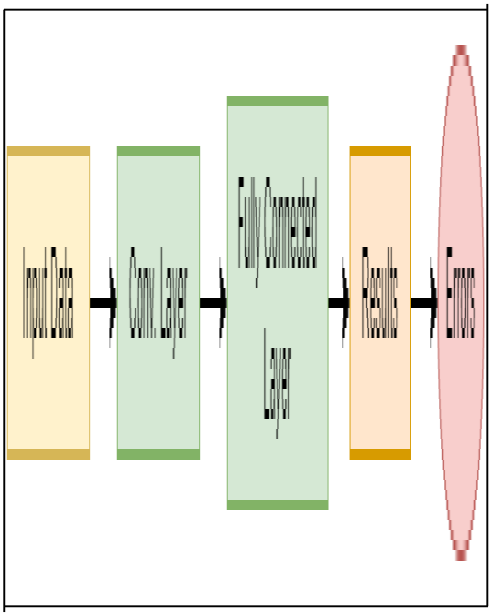
- CNN:

A neural network type called a convolutional neural network, or CNN or ConvNet, is particularly adept at processing input with a grid-like architecture, like an image. The training process of a neural network generally involves two steps:

1. Forward Propagation: Input Data is received, processed, and output is generated.
2. Backward Propagation: Error is calculated and network parameters are updated.

Convolutional Networks can be broken down into two parts:

1. The Convolution layers: Responsible for extracting features from input data
2. Fully Connected (Dense) layers: Responsible for generating the output using data from the convolution layer.



(Figure 4 - CNN Architecture)

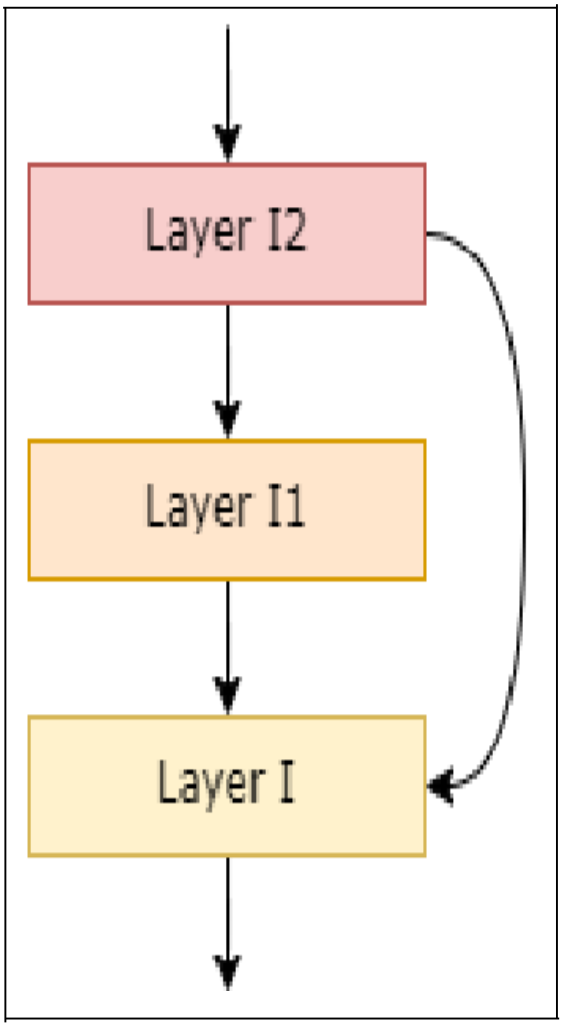
- ConvLSTM:

ConvLSTM is a kind of recurrent neural network used for spatiotemporal prediction that incorporates convolutional structures in both the input-to-state and state-to-state transitions.

The ideal method for working with photos is a CNN (Convolutional Neural Network) architecture. Convolutional layers, which the image passes through to extract significant information, are used. The output is joined to a fully-connected Dense network after going through a few convolutional layers sequentially. ConvLSTM, a recurrent layer similar to LSTM with the sole exception that internal matrix multiplications are swapped out for convolutional operations, can be applied in the situation of sequential images. As a result, rather than being a 1D vector containing features, the ConvLSTM cell keeps the input dimension of the data that flows through it (2D or 3D).

- Resnet:

It is a CNN architecture model. ResNet, short for Residual Networks, is a classic neural network used as a backbone for many computer vision tasks.

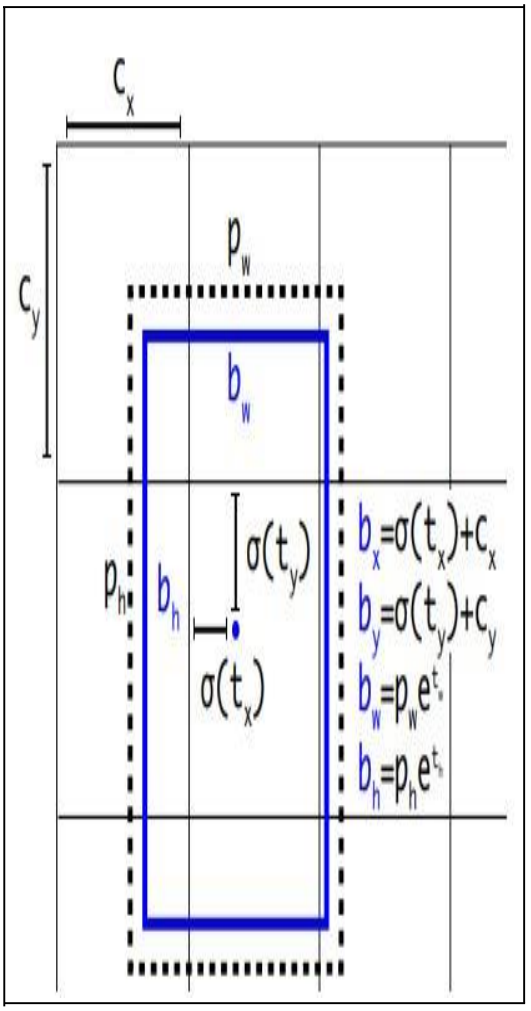


(Figure 5 - Canonical Form of Resnet. Layer L-1 is skipped from L-2 to L)

- YOLOv3:

A real-time object detection system called YOLOv3 (You Only Look Once, Version 3) recognises particular things in films, live feeds, or still photos. To find an item, the YOLO machine learning system leverages features that a deep convolutional neural network has learned.

The approach in prior detection systems was to repurpose the classifiers for detection. The model was applied to an image at multiple locations and scales and the regions of the image which produced high scores were considered as detections. Yolov3, however, applies a single neural network to the entire image. The image is then divided into areas and bounding boxes by this network, and probabilities are forecast for each region. The bounding boxes are weighted using the predicted probabilities.

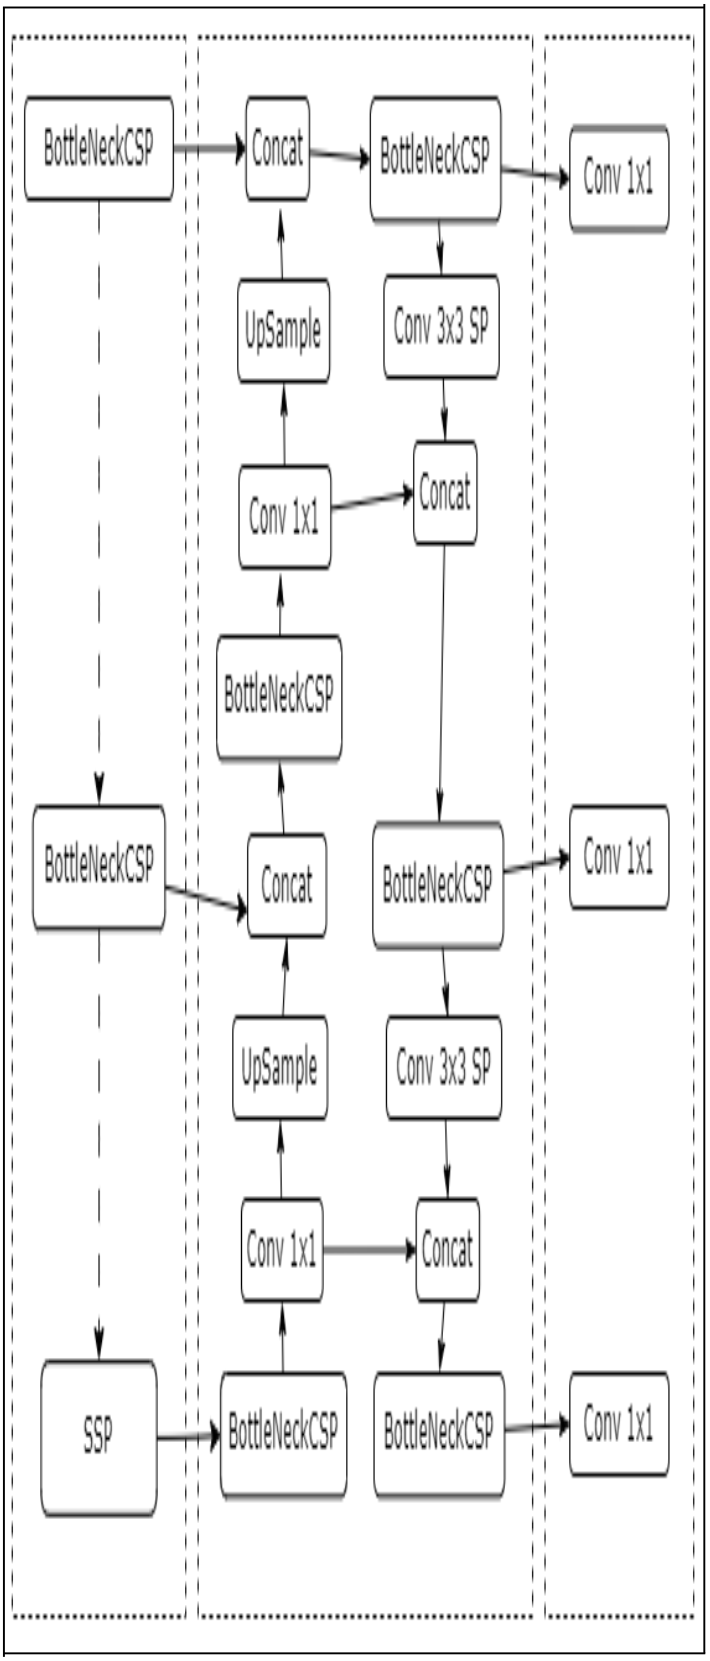


(Figure 6 - Bounding Boxes with dimension priors and location prediction - from paper [12]) The advantage of YOLO over other classifier systems can be listed as follows:

1. Predictions are based on global context as it looks at the entire image at testing time.
2. Makes the predictions using single network evaluation, unlike CNN-based systems.
3. Faster, lightweight, and improved training and testing performance.

- YOLOv5:

The YOLOv5 collection of object identification frameworks and models, which was developed by Ultralytics as part of their open-source R&D AI techniques, incorporates best practices that have been developed through thousands of hours of study and development.. It was released in 2021 with newly added features like support for panoptic segmentation and object tracking further improving the model's performance.



(Figure 7 - YOLOv5 Architecture)

Model	***Accuracy / mAP***	***Loss***
CNN	96.32%	0.112
ResNet	90.65%	0.20
YOLOv3	82.91%	0.60
YOLOv5	53.6 (mAP)	0.012

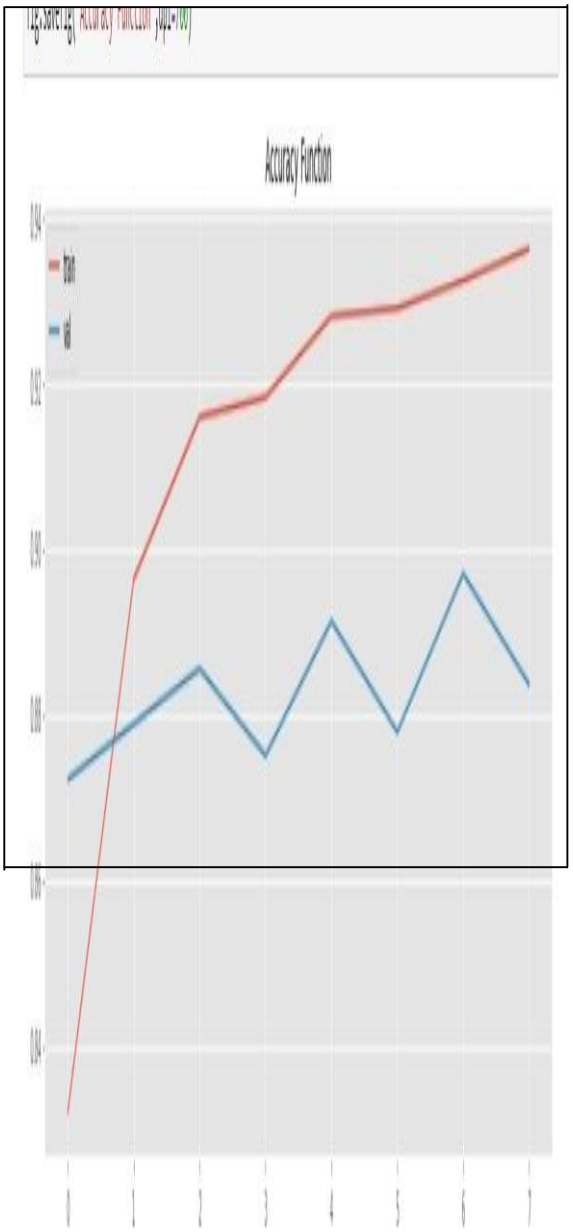
5. RESULTS AND DISCUSSION

By adjusting various parameters and modifying the dataset, four models were trained. The goal was to detect and classify frames into 4 categories, Snatch, Weapon, Fire, and Mask. Following were the validation results for each model:

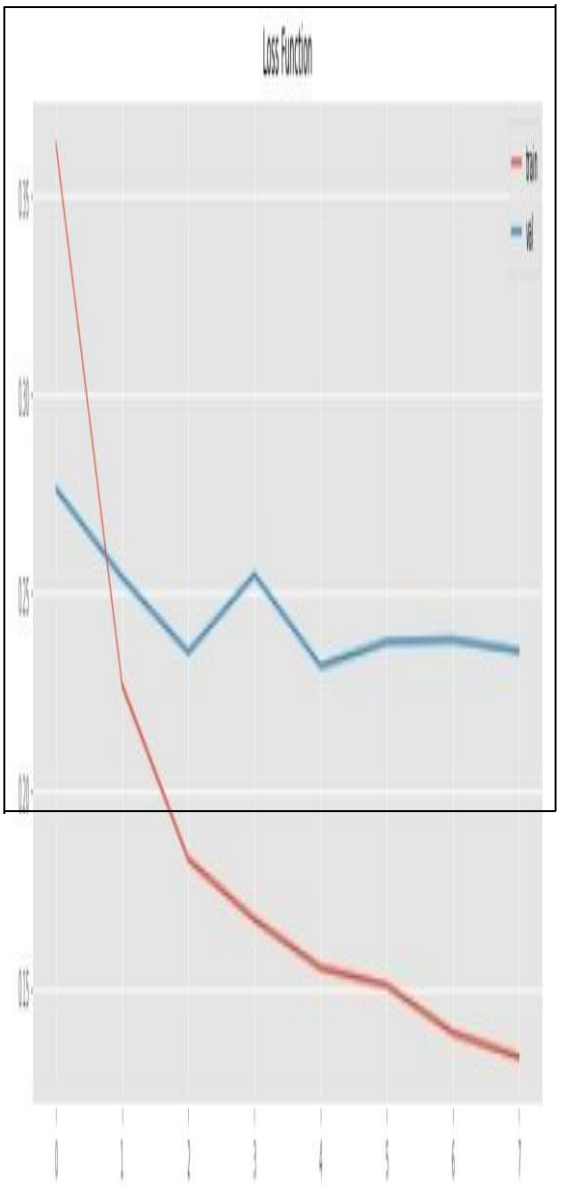
TABLE I. RESULTS OBTAINED FROM THE TRAINED ALGORITHMS

Though the accuracy shown by the CNN algorithm is the highest, it is overfitted to the data on which it is trained and hence performs poorly on new data.

For ResNet the accuracy and loss functions showed the following trend:



(Figure 8 - Accuracy Plot for ResNet)



(Figure 9 - Loss Plot for ResNet)

From Figure 8 and Figure 9, in the case of ResNet, the training loss decreases over several iterations and accuracy increases. The validation accuracy fluctuates a lot and validation loss sees a sudden spike but then approximately becomes constant.

In comparison to CNN and ResNet, YOLOv3 gave more accurate results, with lesser false positives on videos independent of the training dataset. A training loss of 0.36 was observed in the case of YOLOv3.

YOLOv5 performed far better as compared to the other 3 models. A very low training loss of 0.1 was observed in the case of YOLOv5. As it was able to detect faster and provide more accurate results,

All four classes were integrated into one model in YOLOv5.

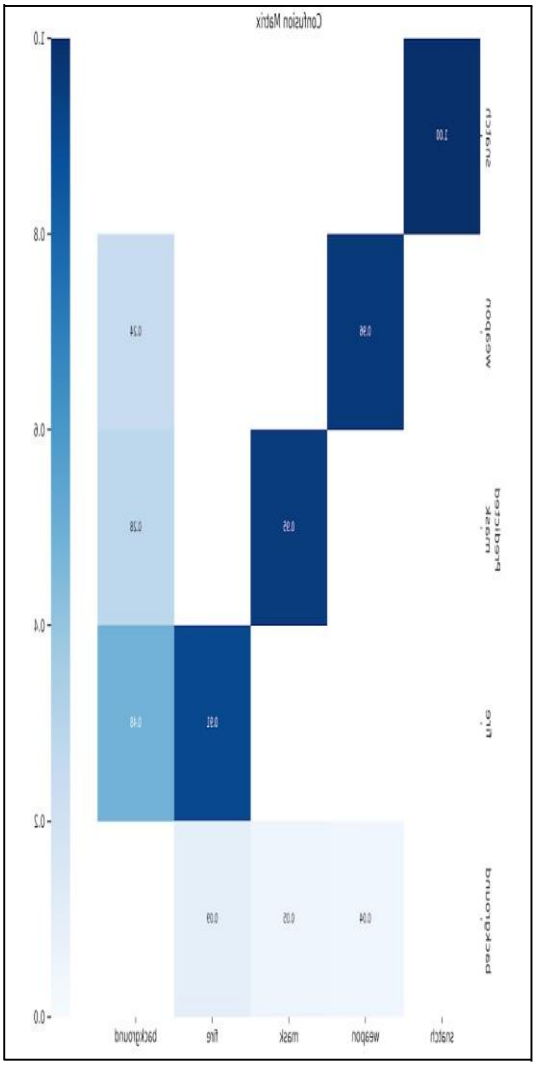


Figure 10) Confusion Matrix for YOLOv5

6. Conclusion And Further Work

An effective and robust event detection, and analysis system has been proposed and implemented. Various suspicious events like Snatch/Theft, Fire, Weapons, and Camera Tampering are detected using LensPatrol, and respective authorities are immediately informed in case of mishaps. Also, the CCTV footage that is being captured when such nefarious activities are not happening can be analyzed to understand various aspects of the banking process. Algorithms like YOLO and ResNet have been used to perform the classification of detected events and train models to predict outliers accurately. The future work focuses on adding more components to the analysis module which would help financial institutions to improve their day-to-day banking operations and provide infographics to them for better analysis and convenience.

Internet of Things (IOT): Future Application and research

Anuradha Tonge, Vijay.M.Rakhde[2], Lawlesh.N.Yadav
Computer Science & Engineering
Shri Sai College of Engineering & Technology, Bhadrawati, India

Abstract—**With the Internet of Things (IoT) gradually it evolves as the subsequent phase of the evolution of Internet, it becomes crucial for recognizing the various potential domains and also for application of the Internet of things, and the challenges of the research that are associated with these applications. Ranging from smart cities, to health care, agriculture, logistics and retail, to even smart living and smart environments Inter of things is expected to infiltrate into virtually all aspects of daily life. Even though the current Internet of things it enables the technologies which have greatly improved in the present years, there are still many more problems which require attention. Since the Internet of things concept ensues from heterogeneous technologies, many research challenges are therefor bound to arise. The fact that Internet of things is so expansive that affects practically all areas of our lives, makes it a significant research topic for studies in various related fields as information technology and computer science. Thus, Internet of things is paving the way for new dimensions of research that should be carried out. This paper presents the recent development of IoT technologies and future applications and challenges.**

Keywords—**Internet of Things; applications; smart:cities , environment , agriculture, living ,challenges** .

1. INTRODUCTION

The IOT can be described as the network of communication which connects to the individual information whereas the internet of things is interconnected system distinctively address able physical items with various degree of processing and actuation capabilities that share the capability to communicate through the Internet as their joint platform . the main objective of the Internet of Things is to make possible for objects which is been connected with other objects, individuals, at any time and also anywhere using any network or service. The Internet of Things (is gradually being regard as the subsequent phase in the Internet evolution. Internet of things will make possible for ordinary devices be linked to the internet in order for achieve minimum goals. Currently, an estimated number of only 0.6% devices that can be part of Internet of things has been connected so far . However, by the year of 2023, it is likely to say that over 90 billion devices will having internet connection an internet connection.

As the internet continues to evolve in the system and environment, it has become more than a simple network of computers, but also network of various devices, while Internet of thing serves as a network of various “connected” devices a network of networks as shown in Fig. 1. Nowadays we can see that, devices like smart phones, vehicles, industrial systems, cameras, toys, buildings, home appliances, others can all share information over the Internet. Regardless of sizes and functions, these devices can

accomplish smart reorganizations, tracing, positioning, and process control. In the earlier years, there has been an important of Internet capable devices. Even its most significant commercial effect has been observed in the consumer electronics field, . particularly the revolution of smartphones and the interest in wearable devices (watches , bluetooth etc.), connecting people has become merely a fragment of a bigger movement towards the association of the digital worlds. With all this, the Internet of Things (IoT) is expected to continue expanding, which it can run. This is the evident from ambiguity in the expression of

"Things" which makes difficult to outline the ever-growing limits of the Internet of things. While in commercial success it continues to materialize, the Internet of things constantly it offers a virtually limitless supply of opportunities, not only just in businesses but also in researches

2. Potential Domains for IOT

Potential applications of IOT are not only numerous they are also quite diverse as they permeate into virtually all aspects of daily life of individuals, society. The applications of Internet of things cover broad areas which include manufacturing and also industrial sector, health sector, agriculture, smart cities, security and emergencies among with many others.

A. Smart Cities

The Internet of things plays a role in improving the smartness of cities and also enhancing general infrastructure. As some of the Internet of things application areas in creating smart cities which include intelligent transportation , smart building, traffic, waste management , smart light, smart parking, urban maps,That may include different

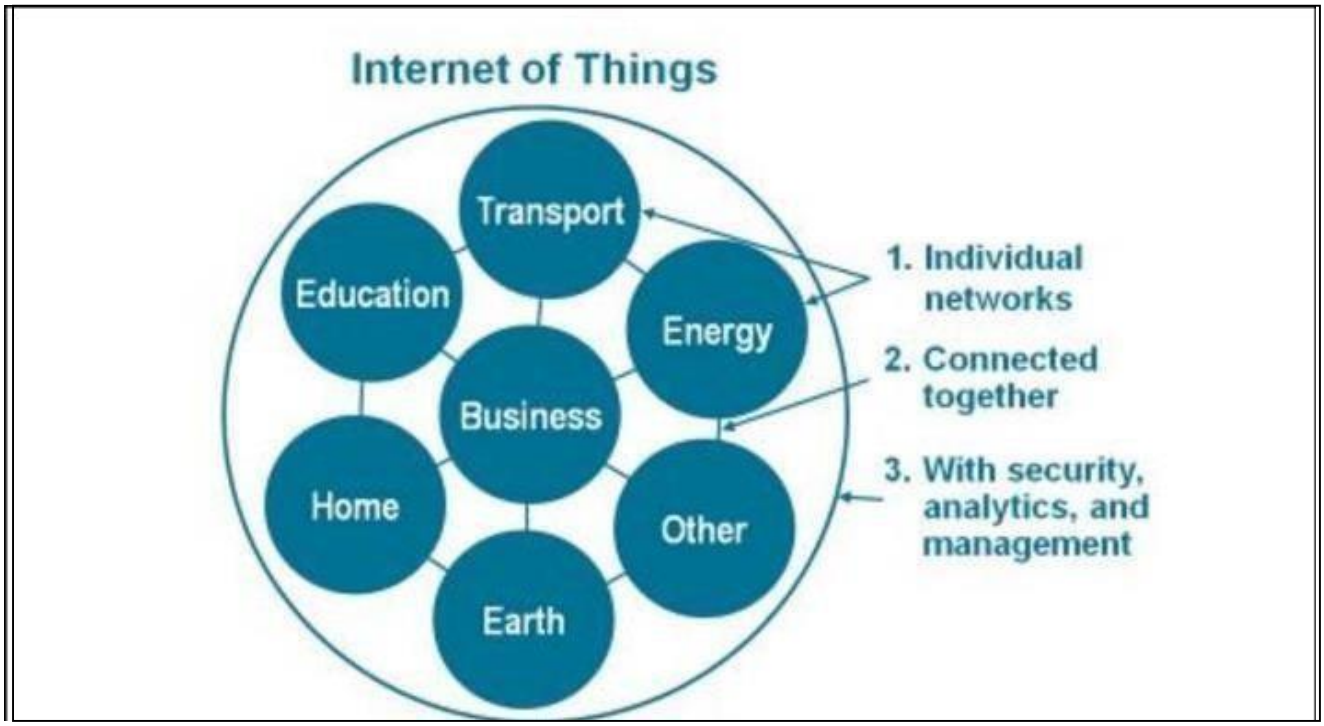

Fig :1 IOT can viewed as network of networks

functionalities as; monitoring parking spaces within the city, monitoring vibrations and material conditions of bridges and buildings, putting in place sound devices monotering in sensitive parts of cities, as well as monitoring the levels of vehicles. Artificial Intelligence enabled internet of things can be utilized to monitor, control and reduce traffic congestions in Smart Cities . Moreover, Internet of things allows the installation of intelligent and adaptive street lighting and detection waste and also the waste containers by keeping tabs of trash collection . Intelligent highways can provide warning messages and information which are important, such as access to diversions depending on the climate conditions and it may be unexpected occurrences like traffic jams and accidents. Application of Internet of things to achieve smart cities would require using radio frequency identification , sensors. Some of them which are already developed applications in this area are the Aware home and the Smart Santander functionality. In the US, some major cities like Boston have plans , how to implement the Internet of Things in most of their systems ranging from their parking meters, sprinkler systems, and sewage grates are been scheduled to be interlinked and connected to the internet. Those applications will offer significant break throughs in terms of saving money and energy.

B. Healthcare

Most of the healthcare systems in many countries are inefficient, slow and prone to error. This can be easily changed since the healthcare sector relies on the numerous activities and devices which can be automated and enhanced through technology.

Additional technology that can facilitate numerous operations like sharing of report to multiple individuals and locations, kipping of the record and dispensing medications would go long way in changing the healthcare sector. A lot of benefits that Internet of things application offers in the healthcare sector that are more categorized into tracking of patients, staff, identifying, as well as authenticating, individuals, and the automatic gathering of data. Hospital workflow can be improved once patients flow is tracked. The additional authentication and identification reduce incident which may be harmful to patient, maintains record and cases of fever mismatching infants. In addition, automatic data collection and transmission is vital process automation, reduction of form processing timelines, automated procedure auditing and medical inventory management. The Sensor devices allows functions centered on patients, particularly, in diagnostic, conditions and gathering real-time information about patients' health indicators . utility domain names in this area consist of; being able to reveal a affected person's compliance with prescriptions, telemedicine answers, and indicators for patients' well-being. Thereby, sensors may be applied to outpatient and inpatient sufferers, dental Bluetooth gadgets and toothbrushes which could deliver facts after they may be used and patient's surveillance. other factors of IoT in this capability include; RFID, Bluetooth, and c084d04ddacadd4b971ae3d98fecfb2a among others. those will substantially enhance dimension and tracking techniques of crucial features like blood pressure, temperature, heart charge, blood glucose, levels of cholesterol, and many others. The packages of net of factors (IoT) and net of everything (IoE) are

further being prolonged via the materialization of the net of Nano-matters (IoNT) . The notion of

IoNT, because the call implies, is being engineered by using integrating Nano-sensors in numerous gadgets (things) using Nano networks. scientific software, as shown in fig is one of the predominant focuses of IoNT implementations. utility of IoNT in human frame, for treatment purposes, facilitates get right of entry to to facts from in situ elements of the body which were hitherto in reachable to experience from or by using the use of the ones scientific instruments incorporated with bulky sensor size. for this reason, IoNT will permit new clinical records to be accumulated, main to new discoveries and better diagnostics.

C. Smart Agriculture and Water Management

The IoT has the capability to strengthen and decorate the agriculture region thru inspecting soil moisture and in the case of vineyards, tracking the trunk diameter. IoT would permit to manipulate and maintain the quantity of vitamins discovered in agricultural merchandise, and regulate microclimate situations so that it will make the maximum of the production of veggies and fruits and their nice. furthermore, reading climate conditions allows forecasting of ice statistics, drought, wind changes, rain or snow, for this reason controlling temperature and humidity tiers to prevent fungus in addition to different microbial contaminants. with regards to farm animals, IoT can help in figuring out animals that graze in open places, detecting damaging gases from the animal excrements in the farms, and also controlling boom conditions in offspring to enhance chances of fitness and survival and so forth. furthermore, via IoT software in agriculture, a number of wastage and spoilage may be averted thru right tracking strategies and management of the complete agriculture field. It additionally results in better electricity and water manage.

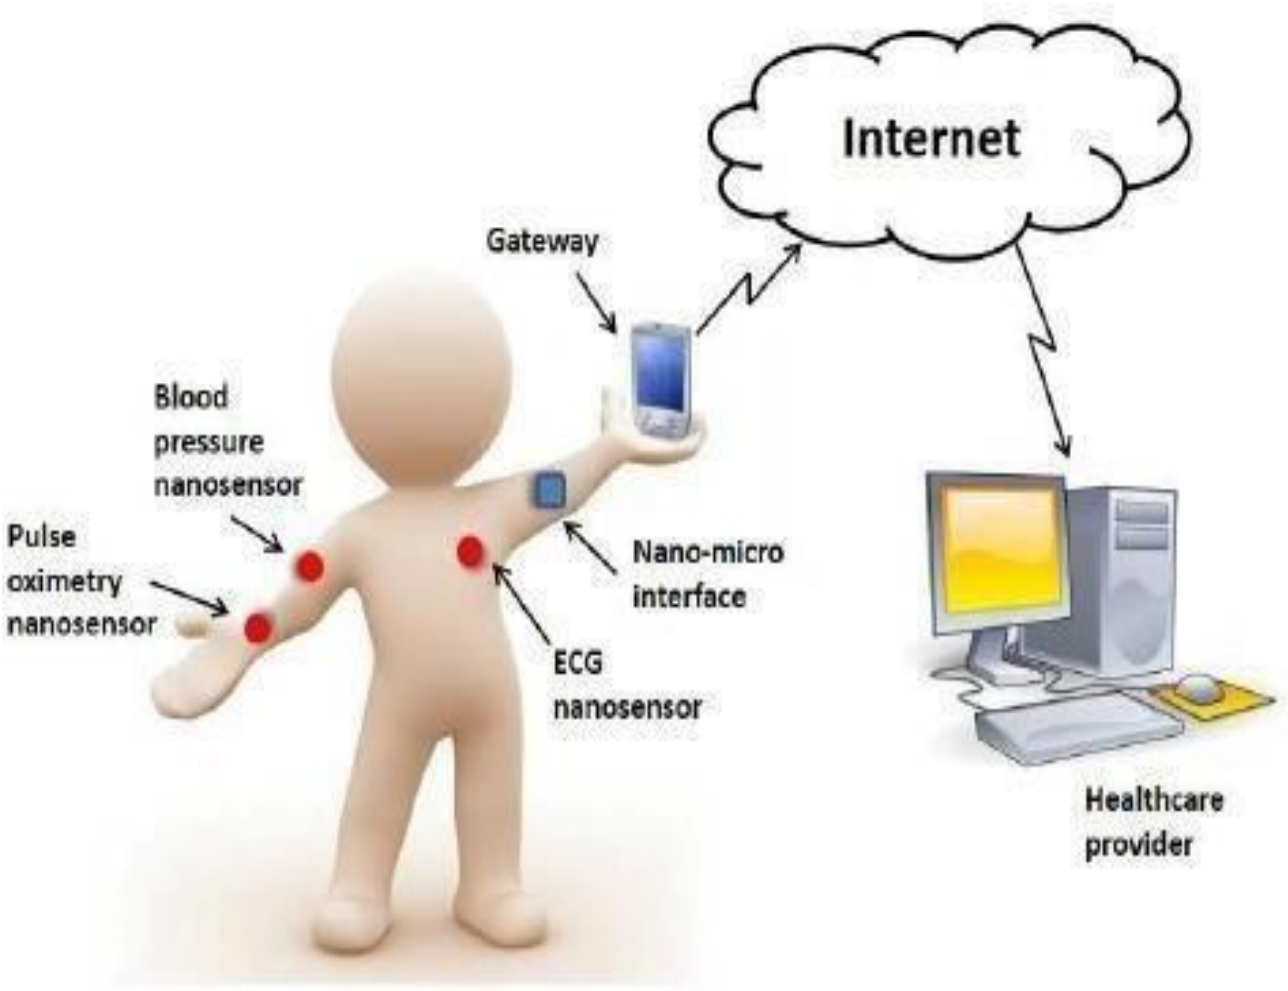

Fig :2 Internet of Nano Things

D. Smart Living

In this area, IoT can be carried out in far flung manage gadgets wherein you possibly can remotely transfer home equipment on and off for this reason stopping injuries in addition to saving power . other smart home appliances encompass refrigerators equipped with liquid crystal display (Liquid Crystal show) displays, allowing one to understand what is available interior, what has over stayed and is nearly expiring as well as what desires to be restocked. This statistics also can be related to a smartphone application allowing one to access it while outdoor

the residence and therefore purchase what is wanted. moreover, washing machines can permit one to remotely screen laundry. in addition, a huge range of kitchen devices can be interfaced through a telephone, consequently making it possible to adjust temperature, like in the case of an oven. a few ovens which have a self-cleaning characteristic can be without difficulty monitored as well. In terms of protection in the home, IoT may be implemented thru alarm systems and cameras can be set up to screen and locate window or door openings as a result stopping intruders.

E. Smart Environment

The environment has a important position within all factors of lifestyles, from humans, to animals, birds and additionally flora, are all affected via an unhealthy surroundings in one way or another. There have been severa efforts to create a wholesome surroundings in phrases of removing pollutants and lowering wastage of resources, but the lifestyles of industries, as well as transportations wastes coupled with reckless and dangerous human actions are commonplace location elements which always damage the surroundings. therefore, the environment calls for smart and revolutionary ways to assist in monitoring and coping with waste, which offer a giant amount of data that forces governments to install place systems with a purpose to guard the environment. clever environment techniques integration with IoT generation should be created for sensing, tracking and evaluation of gadgets of the environment that provide potential benefits in achieving a sustainable lifestyles and a green international. The IoT era lets in watching and handling of air fine through records collection from faraway sensors throughout cities and presenting round the clock geographic insurance to accomplish better methods of coping with traffic jams in principal cities. additionally, IoT generation may be applied in measuring pollution tiers in water and consequently enlighten selections on water usage. In waste control, which includes various sorts of waste, like chemical substances and pollutants being detrimental to the environment and to humans, animals, and plants as nicely, IoT also can be implemented. this could be finished by using environmental protection by using controlling industrial pollutants through instantaneous tracking and control systems mixed with supervision similarly to selection making networks. This serves to lessen waste .

3. Research Challenges

For all of the above capacity packages of IoT, there has to be right feasibility into the extraordinary domain names to examine the achievement of a few programs and their functionality. As with another form of generation or innovation, IoT has its challenges and implications that ought to be looked after out to allow mass adoption. despite the fact that the contemporary IoT allowing technology have substantially improved in the latest years, there are nevertheless numerous problems that require interest, as a result paving the manner for brand new dimensions of research to be carried out. for the reason that IoT idea ensues from heterogeneous technologies which can be used in sensing, collecting, movement, processing, inferring, transmitting, notifying, dealing with, and storing of records, a variety of studies challenges are sure to arise. these studies challenges that require attention have consequently spanned one-of-a-kind research regions .

A. Privacy and Security

Thanks to the fact that IoT has emerge as a vital element as regards the destiny of the net with its elevated usage, it necessitates a want to correctly address protection and accept as true with features. Researchers are aware about the weaknesses which presently exist in lots of IoT devices. furthermore, the basis of IoT is laid on the existing wireless sensor networks (WSN), IoT as a consequence architecturally inherits the same privacy and protection troubles WSN possesses . diverse assaults and weaknesses on IoT systems prove that there's certainly a want for extensive ranging security designs so that you can protect data and systems from stop to give up. Many assaults commonly make the most weaknesses in precise gadgets thereby gaining get admission to into their structures and therefore making comfy devices inclined . This safety hole similarly motivates complete protection answers that encompass research that is efficient in applied cryptography for facts and machine protection, non-cryptographic safety strategies as well as frameworks that help developers to come up with secure systems on devices which can be heterogeneous. there's a want for more studies to be performed on cryptographic protection offerings that have the capability to operate on useful resource constrained IoT devices. this would allow specific skilled users to securely use and installation IoT structures no matter the inadequate consumer interfaces that are available with nearly all IoT gadgets. similarly to the safety and safety factors of the IoT, extra regions like confidentiality in conversation, trustworthiness, and authenticity of verbal exchange parties, and message integrity, and supplementary protection necessities ought to also be integrated. those may include features like being capable of save you verbal exchange of diverse events. as an instance, in commercial enterprise transactions, smart objects should be prevented from facilitating competitors' get entry to to exclusive statistics in the gadgets and for this reason the usage of this records maliciously.

B. Processing, Analysis and Management of Data

The process for processing, analysis and facts management is quite difficult due to the heterogeneous nature of IoT, and the huge scale of facts amassed, specially in this period of large data . presently, most structures make use of centralized structures in offloading facts and carrying out computationally intensive tasks on an international cloud platform. though, there may be a regular challenge about traditional cloud architectures now not being effective in terms of moving the large volumes of information which can be produced and fed on by IoT enabled devices and to have the ability similarly help the accompanying computational load and simultaneously meet timing constraints . maximum systems are therefore relying on modern-day answers such as cellular cloud computing and fog computing that are both based totally on edge processing, to mitigate this project.

C. Monitoring and Sensing

Although technology concerned with monitoring and sensing have made extraordinary development, they're continuously evolving specially focusing on the electricity performance and shape element. Sensors and tags are usually anticipated to be energetic constantly as a way to achieve on the spot statistics, this thing makes it essential for power efficiency especially in lifetime extension. concurrently, new advances in nanotechnology/biotechnology and miniaturization

have allowed the improvement of actuators and sensors on the Nanoscale.

Conclusion

The IoT can great be defined as a CAS (complex Adaptive gadget) so as to keep to adapt hence requiring new and progressive forms of software engineering, structures engineering, project control, in addition to severa other disciplines to expand it further and manage it the coming years. The application regions of IoT are quite numerous to allow it to serve one of a kind customers, who in turn have distinctive needs. The generation serves three categories of customers, individuals, the society or groups and institutions. As mentioned in the application section of the research paper, the Internet of things has without a doubt a large functionality to be a exceedingly transformative force, a good way to, and to a degree does already, undoubtedly effect hundreds of thousands of lives international. according to, this has become even extra obtrusive, as unique governments around the arena have shown an hobby in the IoT concept through presenting more investment inside the subject that is supposed to facilitate similarly research. a terrific example is the chinese government.

Acknowledgement

I would like to expand gratitude to project guide **Prof. Vijay.M.Rakahde** who guided by providing the valuable suggestion in numerous way on this project which gave us the inspiration to improve our self independency. Secondly I would like to express my gratitude toward the project mentor **Prof. Lawlesh.N.Yadav** who help in finalizing the work done within the limited time period, I would also like to express heartfelt thanks to Head Of Department **Lawlesh.N.Yadav** who has given us a platform where we can work on developing the projects and demonstrate the practical applications.

Abstract – **In persistent kidney disease (CKD) is the various great contributor to morbidity and mortality from non-communicable illnesses which can affected 10–15% of the worldwide populace.**

CKD to detect chronic kidney disease patient's information regarding various clinical parameters the data is collected from UCI Machine learning Repository. The main objective of paper is to deal mainly with different classification algorithms and compare accuracy. PCA is applied and binary classification algorithms starting off with KNN, Logistic Regressor, Support Vector Machine Regressor with RBF- kernel and Decision Tree. A plot of roc-auc and log-loss has observed for each training and cross-validation data and best hyper-parameters were selected for each of the model and performed building ensembles with Random Forest classifier and Stacking Classifier and they seem to perform pretty good than the other models. After training the model performed testing using test data and results were pretty good. The effects from the experiments indicated that RF primarily based on recursive function removal with go validation has higher performance than SVM and DT. In the end created a web-application to make it easy to use and test. In the backend we had our pipeline which performed attribute transformation followed by prediction by our best models.

Keywords: Support Vector Machines ,EHR, K-nearest Neighbor, CKD Binary Classification, Logistic Regressor, Random Forest, Decision Tree, RBF-kernel, Stacked Classifier, SVM, DT, KNN

I. INTRODUCTION

Chronic Kidney Disease is a typical and significant illness that is prominently found in India and even globally. Kidney illness needs explicit clinical treatment dependent on an interminable state of patients from initial stage to final stage. The techniques will shift dependent on the reason. The treatment generally comprises of actions to regulate signs and indications, decrease inconveniences, and moderate movement of the illness [1]. In diagnosing it specialists direct a few trials of a patient in the research facility for example blood, urine, and so on. The creatinine is an ordinary left-over resulting from the muscle breakdown. Quantification of the level to which the kidneys are sifting the blood for the evacuation of creatinine can be done using a simple blood test. The presence of protein in the urine can be tested using a simple urine test. Protein specifically (albumin) is a part of the blood that doesn't ordinarily go through the kidney channels into those tests. The specialists generally decide the condition and treatment of patients and this information will be recorded in Electronic Health Record (EHR) as clinical information of patient.[2]

The causes of chronic kidney disease are diabetes and high blood pressure, which are responsible for up to two-thirds of the cases. Diabetes happens when your blood sugar is too high, causing damage to many organs in your body, including the kidneys, as well as blood vessels, nerves and eyes. High blood pressure, or hypertension, occurs when the pressure of your blood against the walls of your blood vessels increases. If uncontrolled, or poorly controlled, high blood pressure can be a leading cause of heart attacks, strokes and chronic kidney disease. Also, chronic kidney disease can cause high blood pressure chronic kidney disease, also called chronic kidney failure, describes the gradual loss of kidney function. The kidneys filter wastes and excess fluids from the blood, which are then excreted in form of urine number of inhabitants in Indian individuals that experience the ill effects of the kidney diseases has multiplied over the time and the circumstance has taken a terrible shape. Significant number of the grown-up individuals experiences the ill effects of a portion of different types of kidney maladies. Chronic Kidney Disease (CKD) incorporates several types of diminished capacity of kidneys like a weakened kidney or kidneys that are in danger because of mellow, moderate and extreme constant kidney disappointment [3].

The individuals having age in late sixties or early seventies around the world 20 % men and 25% of ladies have CKD. Infectious sicknesses namely impact intestinal sickness or AIDS are supplanted by non-infectious illnesses. These include kidney ailment, diabetes or coronary illness as the aggregate wellsprings of untimely impermanence around the globe. Majority of these passing's happen in nations with center or low-salary bunch individuals, while 25 percent of this weight happens to individuals with underneath 60 years old [4].

850 million people throughout the world are likely to have

Kidney disease from different factors [21]. Evaluation of classifiers such as K-NN, RF and ANN on a dataset of 400. Wrapper feature selection were implemented and five features were selected for model construction in the study. The highest classification accuracy is 98% by RF and a RMSE of 0.11. S. Tekale et al. [10] worked on "Prediction of Chronic Kidney Disease Using Machine Learning Algorithm" with a dataset consists of 400 instances and 14 features. They have used decision tree and support vector machine. The dataset has been preprocessed and the number of features has been reduced from 25 to 14. SVM is stated as a better model with an 96.75

II. ITERATURE REVIEW

C.Sathish Kumar and P.Thangaraju [1] has proposed a three pre-processing techniques namely missing value replacement, normalization and discretization were used to filter the data set. After every filteration three classifiers namely Naive Bayes, Multilayer Perceptron and Support Vector Machine were applied to the pre-processed data set. Results displayed that after pre- processing, Support Vector Machine outperforms all the other classifiers in terms of accuracy. The time taken to build the model by using above algorithms is not accurate so many more algorithms need to be performed and compared.

Mubarik et. al. [2] has projected a framework that will aid specialists in treating their patients with kidney disease. Support Vector Machine (SVM) technique was used for the creation of this framework. The study mainly is divided as classification modeling and framework development. Guidelines and model for the classification of kidney disease was discovered from the classification modeling. The Decision Support System created by this diagnosis has some principal highlights like reading file, Classifying entities, tolerable error limit and diagnosis. The precision of this framework is 92.34 %. This framework has relied upon SVM to help specialist in more accurately choosing the patient with chronic kidney disease.

Yedilkhan et. al. [3] have considered kidney diseases and proposed new automatic classification algorithm. It can be used to find dependent on physical assessments, research facility tests and clinical history having qualities like non-meddling, modest and spare. The exhibition proportions of SVM classifier with linear kernels were being assessed so as to locate the best scores for affectability, particularity, and exactness measurements utilizing SVM with linear kernel.

Vijayarani and Dhayanand [4] have concluded that Support Vector Machine performs superior to Naive Bayes by improved precision to anticipate kidney diseases.

Chatterjee et. al. [5] present Modified Cuckoo Search (MCS) trained Neural Network (NN) to efficiently detect CKD at an earlier stage. MCS model has been proposed to conquer the issue of utilizing nearby pursuit-based learning algorithms to prepare the NNs. The NN weight vector is upgraded by applying MCS for NN preparing. The local search-based learning algorithms might be caught in neighborhood optima and issue has been defeated utilizing MCS to prepare the Neural Network and it really attempts to limit the Root Mean Squared Error (RMSE) included during the preparation procedure of the NN.

Zhang and Rothenbacher [6] proposed the comparison to detect CKD. The middle predominance of CKD was 7.2% in people matured 30 years or more seasoned. In people matured 64 years or more established pervasiveness of CKD fluctuated from 23.4% to 35.8%. It is a worldwide medical issue with an expanding commonness, and greater expense.

Krishnan and Sumit [7] present the exploration study that 10% of individuals in the overall is experiencing CKD.

Ahmed and Aljaaf [8] proposed propelled phase of CKD can be seen by certain side effects, for example, tiredness, swollen lower legs. There are banters on the reasons for such ailment. A few causes for the most part rely upon certain circumstances squeezing the kidneys. Be that as it may, National Institute of Diabetes, Digestive and Kidney Diseases announced that primary driver of CKD are hypertension and diabetes. Notwithstanding these reasons, National Health Service (NHS) declared that CKD can be influenced because of elevated cholesterol, kidney infection, polycystic kidney illness, blockages in the progression of pee, long haul, normal utilization of specific drugs.

Gunarathne W.H.S.D et. al. [9] have concluded that machine learning algorithm has forecasted through data analytics for CKD by using classification algorithms such as Multiclass Logistic Regression, Multiclass Decision Forest, and Multiclass Neural Network. The primary centre was to distinguish another CKD patient's wellbeing condition by centering increasingly highlighted regions which will assist with having a superior thought regarding patient's condition and stages utilized were business understanding, information understanding, information arrangement, demonstrating, assessment, sending. The Microsoft Azure machine learning can be utilized to apply all the four classifiers to the dataset. By utilizing this studio, it anticipated the precision of result Decision Forest predicted 99.1%, Multiclass Decision predicted 96.6%, Logistic Regression predicted 95.0% and Neural Network predicted the accuracy 97.5%. Advantage is that expectation procedure is less tedious and it will assist the specialists with starting the medicines ahead of schedule. Furthermore, it can also be used to diagnose additional patients with lesser amount of time.

Sirage Zeynu and Shruti patil [10] presented survey prediction of CKD using data mining. The main objective is to observe the application of data mining, classification algorithm and feature selection methods to analyse and predict different disease. Chronic kidney disease and other diseases can be very well analyzed and predict by data mining and feature selection methods. Survey was done to find out hidden pattern of relationship which is related to CKD. In this paper technique used are k-nearest Neighbour (KNN), Artificial Neural Network (ANN) and decision tree. Methods have been used to identify and predict for chronic kidney to improve the performance accuracy of the algorithms.

Tommaso Di Noia et. al. [11] proposed Automatic tool has been created and made accessible for both online web applications and android versatile application for checking interminable kidney disease is available or not. In this paper it portrayed a choice emotionally supportive network abusing a troupe of ANNs to anticipate end stage

of kidney disease (ESKD). The model has been worked via preparing a lot of neural systems by means of a dataset

of Bari. The framework has been executed as a Restful help and both an Android customer and a Web customer are at present accessible to get to.

Almasoud and Ward [22] aimed in their work to test the ability of machine learning algorithms for the prediction of chronic kidney disease using subset of features. They used Pearson correlation, ANOVA, and Cramer's V test to select predictive features. They have done modeling using LR, SVM, RF, and GB machine learning algorithms. Finally, they concluded that Gradient Boosting has the highest accuracy with an F-measure of 99.1

III. EXISTING SYSTEM

The data source for this study is St. Paulo's Hospital. It is the second-largest public hospital in Ethiopia which admits large number of patients with chronic diseases. There are dialysis treatment and kidney transplant center in the hospital. The dataset for this study is patients' records of chronic kidney disease from patients admitted to the renal ward during 2018 to 2019. Some of them were obtained from the same patient history data at different times of different stages. Chronic Kidney Disease firstly in this system the data is collected from UCI Machine learning Repository. Dataset is used to pursue for precision using three classification algorithms i.e. Naive Bayes, Support Vector Machine and Multilayer Perceptron. Firstly, three pre-processing techniques discretization, missing worth replacement and normalization used which find out all missing values. While performing pre- processing state it has found that 24 properties have some degree of misplaced characteristics. The most misplaced data found is Red Blood Cells has 38% missing data for example around containing patient's data gathered over a time of thirty-eight years (1972–2010) at Renal Unit of the University

152 events from 400 models are misplaced and furthermore White Blood Cell check has found 27% misplaced data for example around 106 events from which 400 cases are absent. Moreover, rbcc (Red Blood Cell count) found 131 events of the hard and fast 400 cases which are misplaced. It contains up to 33% missing data. This misplaced data can basically influence the finishes from available information can be analysed. This misplaced data is filled by displacing missing characteristics and the number of shuffling mode or mean. For every single misplaced data mean substitution strategy is used to override the data and also mean assessment of each and every attribute is used to setup the misplaced data event for the proportionate characteristic. Ensuing to recover misplaced characteristics entire data can be normalized to give best impetus and each incentive to be 1 also base motivator for each credit to be 0.

Here are the following steps of algorithm [1][2]. Step 1: Load the CKD data set.

Step 2: Complete the classification process on the CKD data set utilizing three classifiers in particular SVM, MLP, Naive Bayes.

Step 3: Find and break down the exactness of over three classifiers.

Step 4: Reload the CKD data set again from vault.

Step 5: Apply three pre-processing methods, for example, Discretization, Missing Value Replacement and Normalization individually in a specific order to the CKD data set.

Step 6: After each channel, order the data set utilizing Naive Bayes, MLP, SVM classifiers and Discretization.

Step 7: Determine and investigate the classifiers precision in the wake of pre-processing methods.

Step 8: Relate the exactness of the classifiers when using the pre-preparing methods

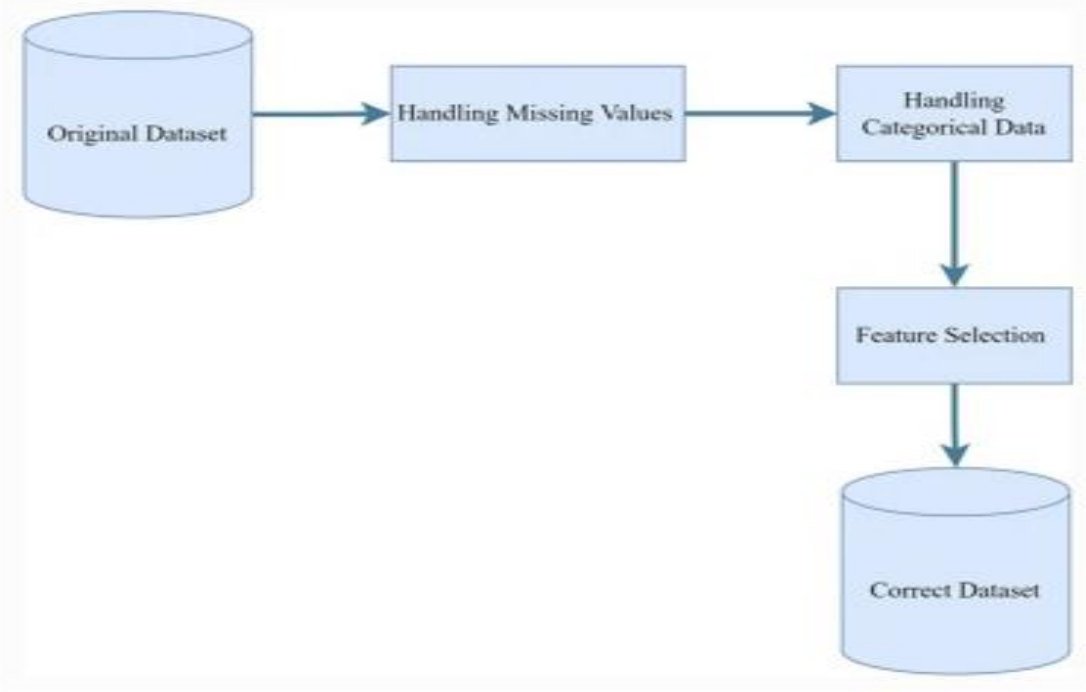

Figure 1. Chronic kidney disease dataset preprocessing steps

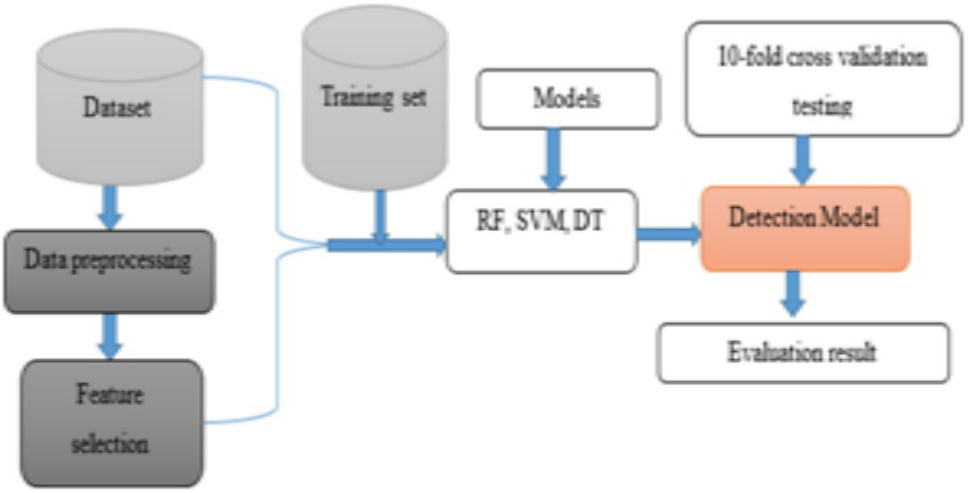

Figure 2.Existing Model building flow diagram

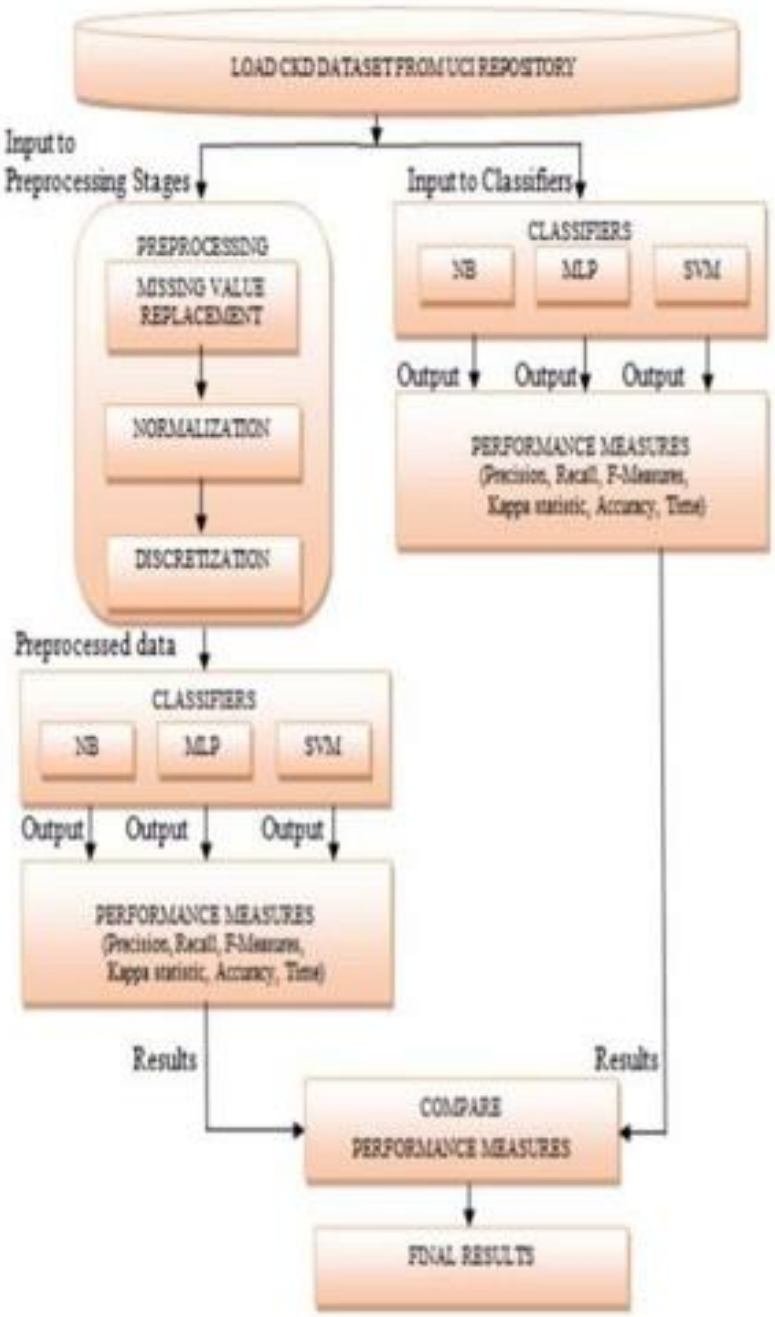

Figure 3. Block diagram of Existing system

Classifier	Accuracy
NB before pre-processing	90.00%
NB after replacing missing values, Normalization and Discretization	92.25%
MLP before pre-processing	91.75%
MLP after replacing missing values, Normalization and Discretization	91.00%
SVM before pre-processing	97.75%
SVM after replacing missing values, Normalization and Discretization	98.75%

TABLE I. Classifier Accuracy before and after applying pre-processing technique

After comparison of all algorithms result will be compared based on accuracy received and final output will be calculated based on the above result. Hence while comparing the result after filteration all the output was completely different and difficult to identify CKD present or not.[1][3][4][7][11]

Performance evaluation is the critical step of developing an accurate machine-learning model. Prediction model shall to be evaluated to ensure that the model fits the dataset and work well on unseen data. The aim of the performance evaluation is to estimate the generalization accuracy of a model on unseen/out-of-sample data. Cross-Validation (CV) is one of the performance evaluation methods for evaluating and comparing models by dividing data into partitions. The original dataset was partitioned into k equal size subsamples called folds: nine used to train a model and one used to test or validate the model. This process repeated k times and the average performance will be taken. Tenfold cross-validation have been used in this study. Different performance evaluation metrics including accuracy, precision, recall, f1-score, sensitivity, specificity have been computed.

True positive (TP): are the condition when both actual value and predicted value are positive.

True negative (TN): are the condition when both the actual value of the data point and the predicted are negative.

False positive (FP): These are the cases when the actual value of the data point was negative and the predicted is positive.

False negative (FN): are the cases when the actual value of the data point is positive and the predicted is negative.

Recursive Feature Elimination with Cross-Validation (RFECV): An optimization algorithm to develop a trained machine-learning model with relevant and selected features by repeatedly eliminating irrelevant features. It repetitively creates the model, keeps aside the worst performing feature at each iteration, and builds the next model with the remaining features until the features are completed to select best subset of features [25]. It eliminates the redundant and weak feature whose deletion least affects the training and keeps the independent and strong feature to improve the generalization performance of the model [26]. This method uses the iterative procedure for feature ranking and to find out the features that have been evaluated as most important. Because this technique work interacting with a machine learning model, it first builds the model on the entire set of features and ranked the feature according to its importance.

IV. PROPOSED SYSTEM

Firstly, the CKD dataset is taken and tested for accuracy by doing Exploratory Data Analysis, Null value Imputation based on mean, median, group by, Feature Engineering binarzing, log transformation and after modelling Predictions in terms of probability is compared with stacking classifier against as shown. In chronic disease information guide of this framework is acknowledged by three sections: Train Dataset, Modelling and Stacking as appeared in Figure 4. The development of the Dataset is available on Kaggle tool and contains several parameters like age, blood-pressure, specific gravity, albumin, red blood cell count, pus cells, pus cell clumps, bacteria, blood glucose random, blood urea, serum creatinine and so on. It contains a total of 25 parameters. The data was collected over a period of two - month period in India contains about 600 rows and two class labels = 'ckd' (chronic kidney disease) and 'nckd' as shown in

S.No.	Attributes	Attribute Category	Attribute Description	Attribute Values
1	age	Numerical	Age	Years
2	bp	Numerical	Blood Pressure	mm/Hg
3	sg	Nominal	Specific Gravity	1.005, 1.010, 1.015, 1.020, 1.025
4	al	Nominal	Albumin	0, 1, 2, 3, 4, 5
5	su	Nominal	Sugar	0, 1, 2, 3, 4, 5
6	rbc	Nominal	Red Blood Cells	Normal, Abnormal
7	pc	Nominal	Pus Cell	Normal, Abnormal
8	pcc	Nominal	Pus Cell Clumps	Present, Not_Present
9	ba	Nominal	Bacteria	Present, Not_Present
10	bgr	Numerical	Blood Glucose Random	mgs/dl
11	bu	Numerical	Blood Urea	mgs/dl
12	sc	Numerical	Serum Creatinine	mgs/dl
13	sod	Numerical	Sodium	mEq/L
14	pot	Numerical	Potassium	mEq/L
15	hemo	Numerical	Haemoglobin	gms
16	pcv	Numerical	Packed Cell Volume	0, 1, 2...
17	wbcc	Numerical	White Blood Cell Count	cells/cumm
18	rbcc	Numerical	Red Blood Cell Count	millions/cumm
19	htn	Nominal	Hypertension	Yes, No
20	dm	Nominal	Diabetes Mellitus	Yes, No
21	cad	Nominal	Coronary Artery Disease	Yes, No
22	appet	Nominal	Appetite	Good, Poor
23	pe	Nominal	Pedal Edema	Yes, No
24	ane	Nominal	Anemia	Yes, No
25	class	Nominal	CKD, Not_CKD	CKD, Not_CKD

TABLE II. Dataset that contains attribute, attribute description and values

Figure 2 and Table 2. optimize the above problem for the following classification metrics log-loss, ROC-AUC score, precision, recall, and F1-score. Approach to solve this problem was the same as that to solve any binary classification problem.

As shown in Figure 2 It has train dataset to prepare a model, to train it and the test dataset is new data where the output values are withheld from the algorithm [12]. It performs predictions from the trained model on the inputs from the test dataset and compare them to the withheld output values of the test set working on Exploratory Data Analysis and looked at what the data contains the following which is implemented upon null value imputation for the missing attributes.

Figure 3. Train dataset of ckd or notckd classification.

Once that is done, it should follow to continue with EDA (Exploratory data analysis) univariate analysis as well as multivariate analysis deciding upon attributes which are important in solving the problem. Binarizing the features or applying some kind of group-by aggregation is some of the strategies that were followed to build new features and working on log transformations to the features which followed skewed distributions or performed reflection along with log transformation to obtain Gaussian distribution for the feature. Validation of the newly obtained feature will help to do statistical analysis like correlation check with target variable and analysis of variance in certain cases. All the above exploration will apply on train data. Distribution of target variable for both positive and negative class is almost same. A pipeline going to transform the attributes in cross-validation into required features. Instead of it going to just perform single fold cross-validation and checked for log-loss and roc-auc score for both training and cross- validation data [13].

On the modelling part while doing research work PCA was done to know the distribution of features and the kind of variance explained by each of them. It was observed that data might be linearly separable after seeing the scatter plot of two features which explained maximum variance. Then decided to build binary classifiers starting off with KNN, Logistic Regression, Support Vector Machine Regression with RBF-kernel and Decision Trees. After that we decided to implement testing using test data and results was very good. In the end web-app application is implemented to make it easy to use and test. In the backend pipeline is used to performed attribute transformation followed by prediction by our best models.

Let us describe the following points in given Figure 3 step by step follow as:

Step1: Load the CKD data set.

Step2: perform data Pre-Processing i.e. Impute attribute plus cells, replacing null values of packed cell volume, Imputing null values in white blood cell count.

Step3: Perform feature selection modelling.

Step4: Apply Principal Component Analysis on developed feature set to visualize if there is any separation in data points that can observe in lower dimension. PCA is applied on standardized data. So first convert the above feature frame into standardized data frame and apply PCA to see how it can observe variance in data.

Step5: Building a simple Logistic Regression model and after each set Transforming the Input data to build the feature set for testing and cross validation and Building a Decision Tree with no hyper-parameter tuning.

Step6: Heat maps to compare AUC and Log loss for train and Cross Validation data.

Step7: Perform Decision Tree Classifier with hyper-parameter tuning and compare it with all algorithms i.e. Support Vector Machine, Logistic Classifier, Random Forest, Decision Tree, K- nearest Neighbor, and Stacked Classifier.

Step8: Apply Stacking classifier used to test data by checking precision recall, F1-score, log-loss and roc-auc.

Classifier	AUC_Score	Log_Loss
Logistic Regression (1_ratio=1.0, max_iter=1000)	1.000000	0.063457
KNeighbors Classifier(n_neighbors=3)	0.980769	0.868558
Decision Tree Classifier (max_depth=3)	0.980769	0.863489
(DecisionTree Classifier (max_ features= auto)	1.000000	0.052073
Stacking Classifier(estimators=[('logCif',\n)	1.000000	0.065721

TABLE III. Classifier Accuracy and log loss after applying pre-processing techniques

As shown in Table2 the classification algorithm display accuracy score and log loss after applying pre-processing techniques and all the missing data on particular field is calculated as zero

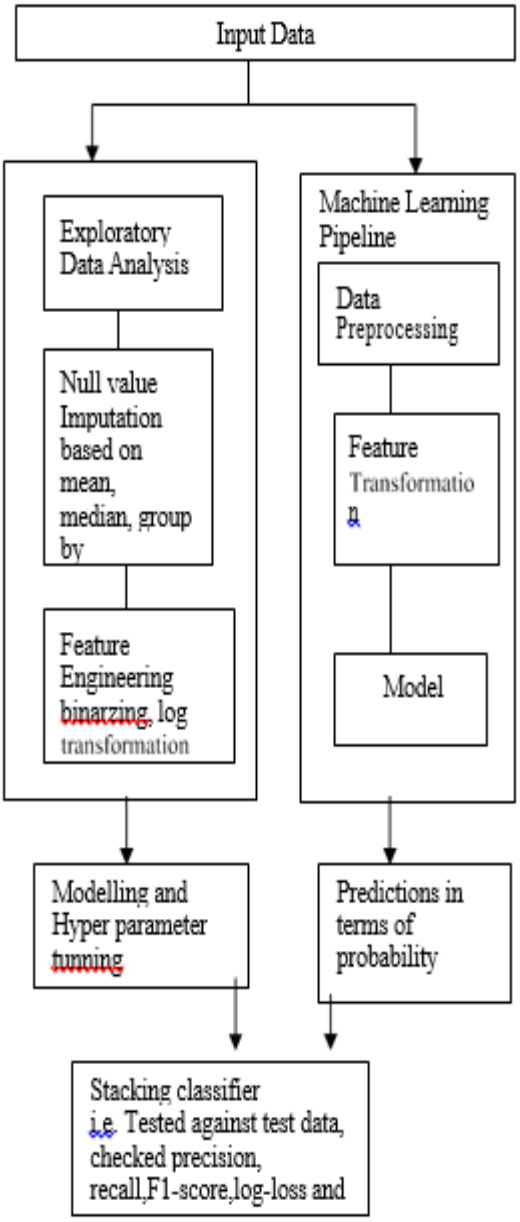

Figure 4. Block Diagram of proposed system.

V. RESULT

In output section figure 4 to figure 7 contains 11 attributes

i.e. patient's age, blood pressure, albumin, sugar, blood glucose random, blood urea, serum creatinine, sodium, hemoglobin, red blood cell count, white blood count and five classifier algorithms is been applied which showed the values in 0's and 1's. 0 represents ckd is not detected and 1 represents ckd is detected

Attributes contains numeric, nominal values. 1.Age(numerical) age in years

2.Blood Pressure(numerical) bp in mm/Hg 3.Albumin(nominal) al - (0,1,2,3,4,5)

4.Sugar(nominal) su - (0,1,2,3,4,5)

5.Blood Glucose Random(numerical) bgr in mgs/dl 6.Blood Urea(numerical) bu in mgs/dl

7. Serum Creatinine(numerical) sc in mgs/dl

8. White Blood Cell Count(numerical) wc in cells/cumm 9.Class (nominal)class - (ckd, notckd)

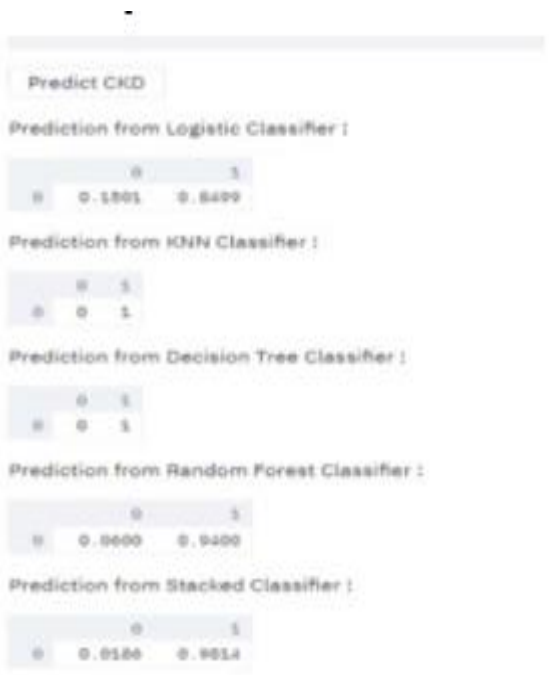

Figure 6: Values with CKD not present.

Figure 4 and 5 shows the value enter in web-based application predicted chronic kidney disease is not present.

Figure 5. Values with different features.

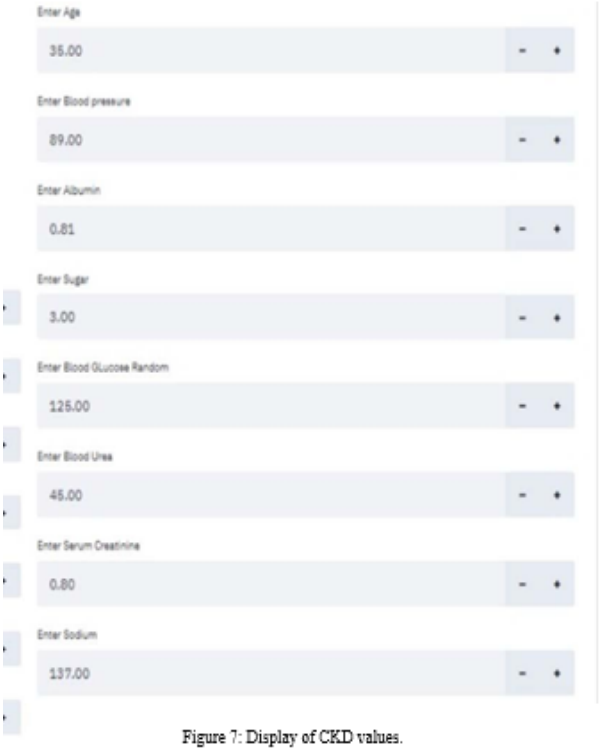

Figure 7: Display of CKD values.

Figure 6 and 7 shows the value enter in web-based application predicted chronic kidney disease is present.

In Figure 7 Algorithm which has the higher accuracy with the minimum execution time has chosen best algorithm. In this Classification each classifier shows different accuracy rate. Stacking Classifier has the maximum classification accuracy and it is considered best classification algorithm.

Figure 8: Values with CKD present.

VI. CONCLUSION

To prevent the progress of persistent kidney disorder to kidney failure. on this look at 3 system-getting to know models RF, SV, DT, and two function choice strategies RFECV and united states were used to build proposed models. the existing system pre- processing techniques like normalization and substitution of missing value has been applied in dataset to check and improve the accuracy but it showed result by using only three algorithms

i.e. Naive Bayes, Multilayer Perceptron and Support Vector Machine classification but results were compared and no proper filtrations of missing value took place. So, in this paper come up with a binary classification solution and also existing algorithms implemented helped to get new accurate value by combination of all new algorithm in proposed system to solve the above problem of pre-processed data using missing value and to train data performed exploratory data analysis, null value imputation based on mean, median and group by and also feature engineering, binarizing, log-transformation is been decided to use to train data. Modelling section has been implemented using PCA by performing different classifier i.e. Support Vector Machine, Logistic Classifier, Random Forest, Decision Tree and K-nearest Neighbor are used to perform roc-auc, log-loss for performance metric measurement. Stacking classifier is used to test data by checking precision recall, F1-score, log-loss and roc- auc

Specifically, pipeline is used to transform the attributes in cross-validation into required features. In the backend used pipeline which is performing attribute transformation followed by prediction by best models to perform single fold cross-

validation and checked for log-loss and roc-auc score for both training and cross-validation data and plot of roc-auc and log- loss was observed for each training and cross-validation data and best hyper-parameters were selected for each of the model. In the end after modelling created a web-app to make it easy to use and test by entering data of patient in attributes like age, blood pressure, albumin, sugar, blood glucose random, blood urea, serum creatinine, sodium, haemoglobin, red blood cell count, white blood cell count by entering all the field it will predict ckd by comparing all the algorithms whether it is present or not in form of 0 & 1. 0 represents ckd is not detected and 1 represents ckd is detected.

VII. FUTURE SCOPE

This work will be considered as research for the healthcare system for Chronic kidney disease patient. Extension to this work is that implementation of deep learning since deep learning provides high-quality performance than machine learning algorithms.

ACKNOWLEDGEMENT

We are thankful to all those who helped us make this paper, for the valuable information provided by them in their respective fields. We are grateful for their co-operation during the writing of the paper.

Build near real time social media intelligence using web scraping and visualization

Mr. Bhavesh Pandekar, Dr. Savita Sangam
Big Data and Analytics, Department of Computer Engineering
KPMG India, School of Engineering and Applied Sciences, University of Mumbai, Kalyan - 421301

Abstract—**social media has become a powerful tool for marketers and advertisers to reach their target audience. With the help of platforms like Facebook, Twitter, Instagram, and YouTube, businesses are able to create campaigns that are more engaging and effective than ever before. In addition to providing valuable insights into customer behavior, social media also allows businesses to share content with a wider audience in real time. By leveraging the power of social media, marketers and advertisers can create more effective strategies that have the potential to generate substantial results. Brands are always looking for ways to increase their market share and grow their customer base. One way to do this is by understanding the consumers better. Retailers often use market research to figure out who their target audience is, what they want, and how they behave. With the combination of web scraping and data visualization to build a near real time platform to analyze incremental data it is the best way to help researchers to understand the audience.**

Keywords—**Web Scraping, Social Media, Data Mining**

I. Introduction

The term social media refers to a computer-based technology that facilitates the sharing of ideas,thoughts, and information through virtual networks and communities. Social media is internet-based and gives users quick electronic communication of content, such as personal information,documents, videos, and photos. Users engage with social media via a computer, tablet, or smartphone via web-based software or applications.

Social media originated as a way to interact with friends and family but was later adopted by businesses that wanted to take advantage of a popular new communication method to reach out to customers. The power of social media is the ability to connect and share information with anyone on Earth or with many people simultaneously.There are many social media platforms worldwide but the biggest social media platform is listed as below.

YouTube is an increasingly popular platform for social media marketers due to its broad reach and potential for creative content. With YouTube, businesses can create engaging videos that effectively convey their message to a wide audience. Additionally, YouTube's advanced targeting capabilities make it easier than ever to target specific demographics and increase the likelihood of reaching the right people with your message. This makes YouTube an essential tool for any serious social media marketer looking to get the most out of their campaigns.

Social media YouTube data analysis is the process of analyzing user data collected from YouTube to gain insights into user behavior and preferences. This data analysis can be used to inform marketing decisions, optimize content, and more. With the increasing popularity of YouTube videos, it is essential to understand how users interact with this platform so that businesses can make informed decisions about their video content strategy.

Web scraping is the process of extracting data from a website. It is a method for gathering information without having to enter the site manually and extract it. Web scraping can be done by using a programming language or by using an online service. Web scraping is used in market research because it provides access to data that would not be available otherwise, as well as being able to quickly gather large amounts of data with little effort. It is used in order to get a

more complete understanding of what is happening in the market and in an industry, as well as being able to track changes to produce better analysis.

II. Related Work

Social Media Analytics is concern with developing and evaluating informatics tools and frameworks to gather, monitor, analyze, summarize, and visualize social media data, usually driven by specific requirements from a target application.is an interdisciplinary research area that's concerned with developing, adapting and increasing informatics tools, frameworks and methods to trace, collect and analyze an outsized amount of structured, semi structured and unstructured social media data to extract useful patterns and data. Graphic theory is probably the goal strategy for analyzing social media platforms in the first period of such a platform [1].

The operating system says used in social media data with certain conclusions the goal of determining the key components of the system,

for example, harps and communications (e.g. Facilitators and volunteers). They are not influenced by this, the community is respected as the customers they have physical movement or sensation of different clients, the

method of tracking or impact on the choices made by different clients in the system. This hypothesis has kept it extremely powerful on the scale of the story data

[2]. This is because it is equipped beyond the actual physical representation function of information to be used in information structures. Centrality measure was used to investigate power.

Clients in the same social system group always decide things and manage each one others consider experience in things or installed features. This is known as the recommender framework.

Considering the similarities between hubs in the field of communication hubs CF method known as cofiltering can be used which forms one of the three phases of a recommendation framework (RS) , can be used for

study relationships between customers. Items can be placed in a client considering the measurement of their common organization [10]. Where the main failure of CF is the minimum of information, based on content (other RS technique) investigate information structures to submit suggestions. Be that as it may, the cross types of methods often suggest suggestions by joining CF and data-based recommendations [11].

III. SYSTEM ARCHITECTURE

Building a social media intelligence platform is about developing and evaluating informatics tools and frameworks for collecting, monitoring, analyzing, summarizing, and visualizing communication data, often driven by specific needs from a targeted application.

Social media and statistical analysis provides a rich source of educational research challenges for social scientists, computer scientists. For building this platform we follow the architecture which is cost effective and most of the technology are open source technology.

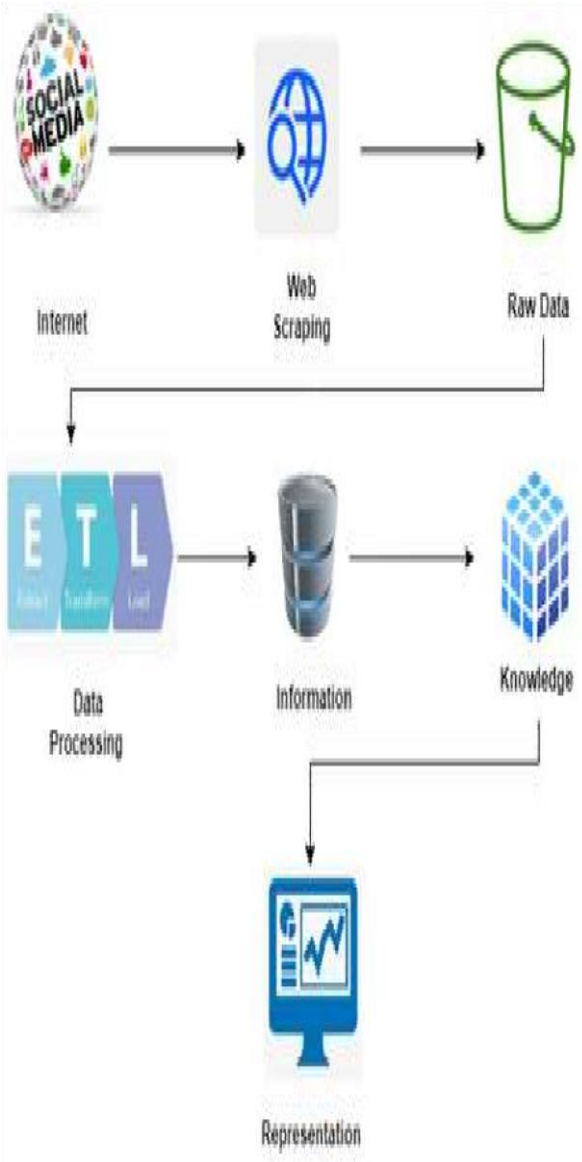

Fig 1. Near Real Time Social Media Intelligence Architecture.

A. Internet

The internet has revolutionized the way businesses market their products and services. With the ability to reach customers around the world, marketing on the internet has become a powerful tool for businesses of all sizes. From SEO to pay-per-click campaigns, digital marketing tactics can be used to reach target audiences and increase visibility for brands. As such, it is no surprise that more businesses are turning to online marketing as a way to maximize their success in today's digital world.

The internet is an ever-growing platform for communication, collaboration, and entertainment. It has become the most powerful tool for businesses to reach their target audience through branding. Branding is the process of

creating a unique identity for a product or service in order to differentiate it from competitors and be more memorable to customers. Through branding, businesses can create a strong online presence and build trust with their customers.

B. Web Scraping

Although social media data is accessible through APIs, due to the amount of data marketing, many major sources such as Facebook and Google make it very difficult for students to gain full access to their 'raw' data; There are very few social data sources that provide affordable data donations to academics and researchers. News services such as Thomson Reuters and Bloomberg often charge a premium for access to their data. In contrast, Twitter recently announced a Twitter Data Grants program, in which researchers could request access to Twitter social media tweets and historical data for information on its large data set (Twitter has over 500 million tweets per day). We can build web scraping applications using programming language, API and open source technology.

- Selenium
- Python Beautiful soup
- Graph API : Facebook , Instagram etc.

C. Data Processing & Information

Once the data comes into the raw bucket, cleaning up random text data (e.g., standard text), especially real-time data streamed at high frequency, introduces many research problems and challenges.

D. Knowledge

Comprehensive analysis of the field of data mining for ideas the process of segmenting, viewing and understanding data on a website is called segmentation. Large data blocks are cut into smaller sections and the process is repeated until the correct level of detail is reached for better analysis. Cutting and dialing therefore presents data in new and different ways and provides a closer look at it for analysis.

E. Representation

Visual representation of data in which information is summarized in a particular system for the purpose of conveying information clearly and effectively in graphic ways. Given the size of the data involved, visibility will grow significantly. For visualization we can use multiple tools or libraries but in our project we used which is mentioned below:

- Matplotlib
- Seaborn

1. IV. DESIGN REQUIREMENTS

A use case diagram is a simplest representation of a user's interaction with the system that shows the relationship between the user and the different components of the system in which the user is involved. A use case diagram can identify the different types of the users of a system and the different

use cases and will often be accomplished by other types of the diagrams as well

2. Use Case Diagram.

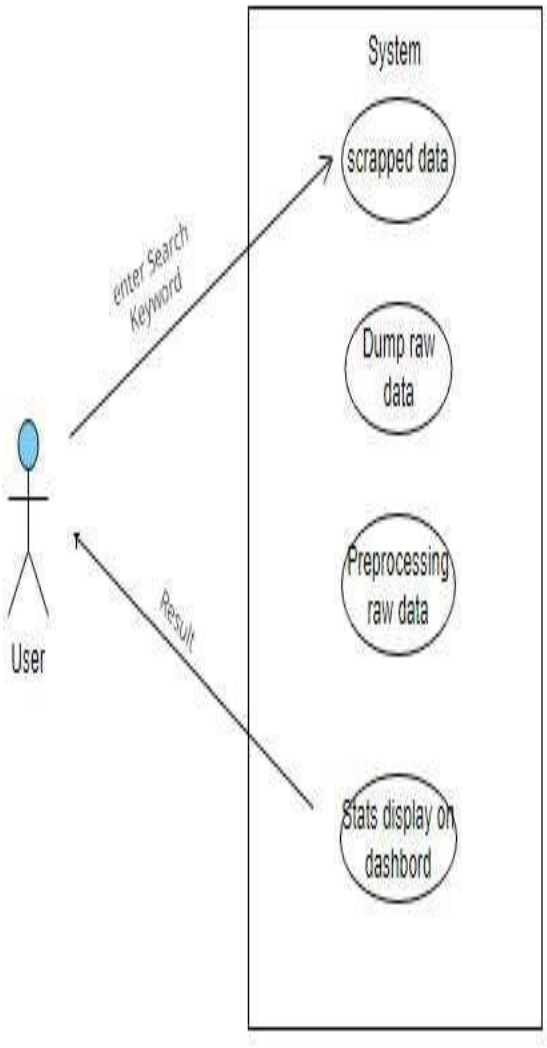

Fig 2. Design Requirements

3. DATA FLOW DESIGN

A DFD(Data Flow Diagram) is a graphical representation of the 'flow' of data through an information system,modeling its process aspect.A DFD is often used as a preliminary step to create an overview of the system,which can later be evaluated. DFD can also be used for the visualization of data processing.

A DFD shows what kind of information will be an input to a system and its respected output,where the data will come from and go and where the data will be stored.It does not show the hidden information like time taken by process how the process completed internally etc.

4.

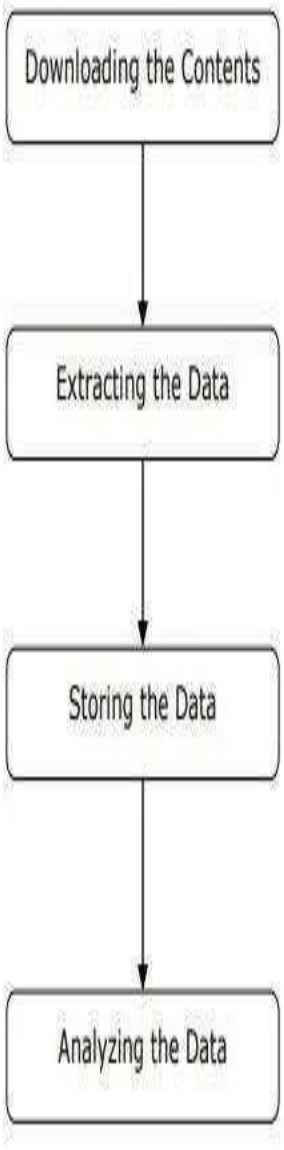

Fig 3. Data Flow Diagram

5. V. REQUIREMENTS

The hardware and software requirements of our project is as follow

F. Hardware Requirements

1. Processor- Intel core i3 and above
2. RAM- 4GB or above
3. Hard Disk- 4GB or above

G. Software Requirements

1. Windows 8 or above
2. Python 3.6.7
3. Selenium 4.7
4. PIP and NumPy 1.13.1, pandas, matplotlib, seaborn
5. Jupyter Notebook

6. VI. RESULT AND ANALYSIS

Social media YouTube data analysis is the process of analyzing user data collected from YouTube to gain insights into user behavior and preferences. This data analysis can be used to inform marketing decisions, optimize content, and more. With the increasing popularity of YouTube videos, it is essential to understand how users interact with this platform so that businesses can make informed decisions about their video content strategy.

H. Keyword Searching Using Selenium WebDriver

Once we run the code system automatically go to the YouTube site and append the specified data into created DataFrame.

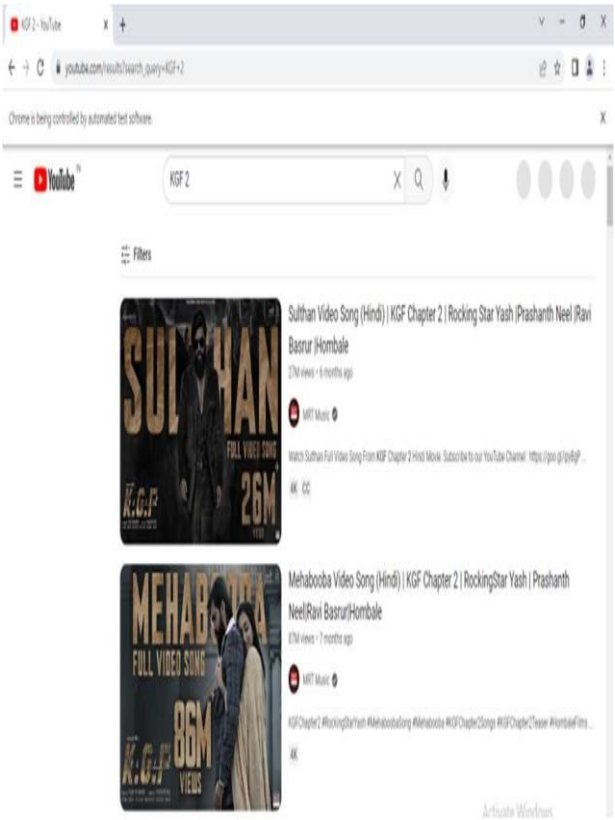

fig 4. Search Keyword on YouTube

Once Data come into Dataframe its looks like below with Title , Meta Data (Description) , URL from HTML Page.

Fig 6. Data After ETL process

A real-world data generally contains noises, missing values, and maybe in an unusable format which cannot be directly used for analysis. Data preprocessing is required for cleaning the data and making it suitable for the system which increases the efficiency of the system. After cleaning data it look like clean and now it is easy to use for analysis purpose.

I. Extract Comments and Cleaning the Comments

YouTube Comments Scraping is a process of extracting comments from YouTube videos. It has become an essential tool for marketers and researchers looking to gain insights into the opinions of their target audience. By scraping YouTube comments, businesses can monitor customer sentiment in real-time, track competitor performance, and identify trends in public opinion. This data can be used to inform marketing strategies, product development decisions, and customer service initiatives.

Fig 8. Extract all comment from YouTube

Regular Expressions (Regex) is an essential tool for text analytics. It is powerful in searching and manipulating text strings. Compared to the traditional approach for processing strings with a combination of loops and conditionals, one line of regex can replace many lines of code. Regex expression used to preprocess the author comment means remove garbage values from received sentences like special character, numerical value which is not making any sense for analysis.

Fig 13. Tree Plot of search keyword

VII. CONCLUSION AND FUTURE SCOPE

The project concludes by highlighting the Web Scraping technique along with sentimental analysis. This chapter gives an indication of the direction in which the future work should be carried out. The chapter is organized into two sections as follows:

- Conclusion
- Future Work

A. Conclusion

The main goal of this project was to explain how to use web scraping techniques to gather data from the web and display it in a meaningful way. We were able to accomplish this goal by using data from different social media platform to create a meaningful inside for business use. It will save a great deal of loading time. In fact, you would save yourself time and financial loss in a very nice way using this social media intelligence system.

B. Future Scope

Some limitations of this study are the unstructured, irrelevant ,missing attribute values. To build a sentimental model of received data with many null and irrelevant values may lead to some issues in analysis. Testing these models with large valid datasets with minimal or no missing attribute values reveals more insights and better analysis.

Using Motion Capturing Technology for Visualization Requirements

Priyanka Bolinjkar, Pranjali Sankhe
Department of Computer Engineering
Thakur College of Engineering and Technology, Mumbai, India
Priyanka.bolinjkar@tcetmumbai.in , Pranjali.sankhe@tcetmumbai.in

Abstract: **In this paper, we describe a development of the Motion Visualization System which make us understand intuitively a series of action of an actor by coordinate's information obtained from motion capture system (MC System). "Motion capture technology" was initially applied in a very narrow field, mainly in the field of animation films. With the maturity of motion capture technology, its application fields are becoming more and more extensive, such as motion analysis and sports training. A complete motion capture system usually includes multiple parts such as signal acquisition equipment, data processing, data transmission, and sensors. At present, motion capture systems mainly include optical motion capture systems, electromagnetic motion capture systems, and mechanical motion capture systems. What we call motion capture today usually refers to the use of sensors and software to transcribe the movements of real actors into the movements of digital models in 3D games or animations. The interaction follows the paradigm of moving from mimicking kinetic material into a self-reflection teaching approach. The interactive avatar is the reflection of the performer, but on the same time the avatar depicts a character, a dance partner which can inspire the user who moves to explore different ways of moving.**

Keywords**: Motion Capture, Motion Visualization, 3D models.**

1. INTRODUCTION

Many types of motion capture system (MC System) is used for not only entertainment fields of movies and computer graphics animations but also any fields like sports, action analysis and so on. The motion data acquired from MC System include various information and the volume of data grows very large. For showing the motion, special software is used and the transform the data sequence into animation of acting body is generally used method. And for showing some characteristics of the motion, many methods are proposed like curve graph for angle and/or speed, overlaying picture and so on. The curve graphic representation is suitable for long time motion with repetition. However, from the representation we have no way to get some characteristics of the motion except our eyes. Trough motion capture technology, various real actions of people in three-dimensional space can be collected, and the collected data information can be entered into the virtual model, thereby generating a series of motion data records. Mechanical motion capture relies on mechanical devices to track and measure motion trajectories. A typical system consists of multiple joints and rigid links, and angle sensors are installed in the rotatable joints, which can measure the changes in the rotation angle of the joints. When the device moves, according to the angle change measured by the angle sensor and the length of the connecting rod, the position and movement trajectory of the endpoint of the rod in space can be obtained. The angle sensor measures and records the rotation angles of the joints. According to these angles and the mechanical dimensions of the model, the pose of the model can be calculated, and these pose data are transmitted to the animation software so that the character model in it can also make the same pose. This is an early motion capture device, but there is still a certain market until now. Foreign countries have given this device a very vivid name: "Monkey." An application form of mechanical motion capture is to connect the moving object to be captured with the mechanical structure, and the motion of the object drives the mechanical device, which is recorded by the sensor in real time.

2. MOTIVATIONS

The idea of the method proposed in this paper is based on principle of slit camera. The slit camera is used for judgments of horse racing and track sports, the media art and so on. On another our research, principle of the slit camera is applied to video scene display compactly and to extract features of video scene. The best feature of the slit camera is to be able to display the local domain of the space of long time scene compactly and to extract characteristics of the scene by wellknown image processing techniques on displayed images without original scene. So we need no programs for extraction of some kind of characteristics other than using package software like Photoshop. To show and extract the characteristics of motion, we transform position and/or angle data given by sensors at a moment to a colour line which correspond to one slit of the slit camera, and place the lines in a row every moment. Now, we describe how to visualize motion of four limbs as a example of our method. Four limbs (Right arm, left arm, right leg and left leg) are corresponding to sensor number 7-9, 8-9, 3-9, and 4-9 respectively.

3. Related Work

Recent research papers describe relevant experiments of adopting mo-cap technologies and interactive interfaces in screen, augmented and virtual reality settings. In the following section we describe related work relevant to dance education which use different technologies of motion capture, such suits with optical mo-cap, and Kinect. A prototype dance training support system (Just Follow Me) with motion capture and mixed reality technologies. The system uses an intuitive "ghost" metaphor and a firstperson viewpoint for effective motion training. Using the ghost metaphor (GM), it visualizes the motion of the trainer in real time as a ghost (initially superimposed on the trainee) that emerges from one's own body. The trainee who observes the motion from the first-person viewpoint "follows" the ghostly master as closely as possible to learn the motion. "YouMove" a system for learning full body movements with

a direct application in dance education. It allows users to record and learn physical movement sequences through a simple recording system that allows anyone to create and share training content. The training system uses recorded data to train the user using a largescale augmented reality mirror. The system trains the user through a series of stages that gradually reduce the user's reliance on guidance and feedback. YouMove is comprised of a Kinect-based recording system, and a corresponding training system. Introduces a motion analysis and comparison framework that is based on Laban Movement Analysis (LMA), used also in the context of teaching folk dances, and a prototype virtual reality simulator in which users can preview segments of folk dance performed by a 3D avatar and repeat them. Describe a prototype system that automatically evaluates dance performances against a dance professional performance and provides visual feedback to the performer in a 3D virtual environment. The system acquires the motion of a performer via Kinectbased human skeleton tracking, making the approach viable for a wide range of users, including home enthusiasts. Kinect-based system that combines the functionality of studio mirrors and prescriptive images to provide the user with instructional feedback in real-time. The results of its usability evaluation with ballet students [16], show a potential for its use in ballet education but improvements of Super Mirror are needed to comply with the standardized subject matter expert's criteria.
